ABSTRACT BOOK

VIRTUAL

23RD INTERNATIONAL AIDS CONFERENCE

6 - 10 JULY 2020

AIDS2020

Scientific Programme Committee

Co-Chairs

Annette Sohn, Thailand International - Co-Chair
Beatriz Grinsztejn, Brazil IAS – Co-Chair
Steffanie Strathdee, United States - Local/Regional Co-Chair

Members

Track A: Basic and Translational Research
Denise Hsu, Thailand
Melanie Ott, United States

Track B: Clinical Research
François Venter, South Africa
Roy Gulick, United States

Track C: Epidemiology and Prevention Research
Andrew Grulich, Australia
Jared Baeten, United States

Track D: Social and Political Research, Law, Policy and Human Rights
Kenneth Ngure, Kenya
Nabila El-Bassel, United States

Track E: Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors
Khuat Thi Hai Oanh, Vietnam
Stefan Baral, Canada

Track F: Political Research, Law, Policy and Human Rights
Tshepo Ricki Kgositau, South Africa
Eric Goosby, United States

Scientific Programme Track Committees

Track A: Basic and Translational Research

Track Leads
Denise Hsu, Thailand
Melanie Ott, United States

Committee Members:
Asier Saez-Cirion, France
Galit Alter, United States
Katherine Luzuriaga, United States
Lindi Masson, South Africa
Roger Paredes, Spain
Susana Valente, United States
Thumbi Ndung'u, South Africa

Track B: Clinical Research

Track Leads
François Venter, South Africa
Roy Gulick, United States

Committee Members:
James McMahon, Australia
Laura Waters, United Kingdom
Meg Doherty, World Health Organization
Michelle Moorhuse, South Africa
Sandra Wagner Cardoso, Brazil
Thanyawee Puthanakit, Thailand
Turner Overton, United States

Track C: Epidemiology and Prevention Research

Track Leads:
Andrew Grulich, Australia
Jared Baeten, United States

Committee Members:
Albert Liu, United States
Ayden Scheim, United States
Elizabeth Irungu, Kenya
Gregg Gonsalves, United States
Mukta Sharma, World Health Organization
Peter Godfrey-Fausset, Switzerland
Rachel Baggaley, World Health Organization
Valdilea Veloso, Brazil

Track D: Social and Behavioral Research

Track Leads:
Kenneth Ngure, Kenya
Nabila El-Bassel, United States

Committee Members:
Ariane van der Straten, United States
Innocent Modisaotsile, United Nations Populations Fund
Kawango Agot, Kenya
Geoffrey Setswe, South Africa
Renee Heffron, United States
Sonia Lee, United States
Weiming Tang, China

Track E: Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors

Track Lead:
Khuat Thi Hai Oanh, Vietnam
Stefan Baral, Canada

Committee Members:
Azizbek Boltaev, Uzbekistan
Elvin Geng, United States
Irene Mukul, Kenya
Nitttaya Phanuphak, Thailand
Paula Mendes Luz, Brazil
Rose Craigue, World Food Programme
Sharmistha Mishra, Canada

Track F: Political Research, Law, Policy and Human Rights

Track Lead
Tshepo Ricki Kgositau, South Africa
Eric Goosby, United States

Committee Members:
Allan Maleche, Kenya
Eszter Kismödi, Switzerland
Ilya Zhukov, United Nations Population Fund
Lucy Stackpool-Moore, Switzerland
Marijke Wijnroks, Switzerland
Matthew Kavanagh, United States
Sofia Gruskin, United States

Abstract submission

Over 6,200 abstracts were submitted to the 23rd International AIDS Conference *(AIDS 2020: Virtual)*.

The Scientific Programme Committee (SPC) is very thankful for all the abstract submissions received. While the SPC found many very high-quality abstracts among the *AIDS 2020: Virtual* submissions, due to limitations in the conference programme, more abstracts were rejected than accepted – with an overall acceptance rate of 39%.

All abstracts went through a blind peer-review process done by over 1000 abstract reviewers. These reviewers are international experts in the field of HIV, including members of SPC and track members. Each abstract was reviewed by three to four reviewers. The abstracts were reviewed for the quality and originality of the work. Late-breaking abstract reviews included an additional assessment of the late-breaking nature of the research.

All reviewers were instructed to abstain from scoring any abstract on which they were an author or co-author, had a financial or personal conflict of interest, or did not have the appropriate expertise to evaluate. Each abstract was scored numerically against five pre-determined criteria, which were equally weighted to get a final score. The final score ranged from one (the lowest) to six (the highest). Any abstracts that received less than three reviews or where there was a scoring discrepancy between reviewers were additionally reviewed by the SPC.

Statistics for Abstracts

Regular abstracts submitted	6239
Regular abstracts accepted	2314
Oral abstracts	202
Poster discussion abstracts	127
Poster exhibition abstracts	1985
Late-breaking abstracts submitted	324
Late-breaking abstracts accepted	90
Late-breaking oral abstracts	29
Late-breaking poster abstracts	61
Total abstracts submitted	6563
Total abstract accepted	2404

Region and gender breakdown of presenting authors of all accepted abstracts:

Gender

Female:	55%
Male:	43%
Transgender female:	0.05%
Transgender male:	0.5%
Non-binary or gender non-conforming:	1%

Region

Africa:	32%
Asia & the Pacific Islands:	15%
Europe:	12%
Latin America & Caribbean:	7%
USA & Canada:	34%

Abstract Mentor Programme

The Abstract Mentor Programme (AMP) was introduced at the 15th International AIDS Conference (AIDS 2004), with the objective to help young or less experienced researchers improve their abstracts before submitting them, in order to increase the chance of their work being presented at conferences. Over the years, the AMP has proven to increase the motivation of early career researchers, as well as the number of abstract submissions received from resource-limited countries.

This year, 161 mentors reviewed 225 draft abstracts submitted by 163 researchers. 210 out of 225 AMP mentees submitted an abstract to the conference and 69 got accepted (33 %).

We would like to thank all volunteer abstract mentors, listed below, who supported early-career HIV researchers improve the quality of their abstracts.

International Abstract Review Committee

The 23rd International AIDS Conference, and the first virtual edition of the International AIDS Conference (AIDS 2020: Virtual) received more than 6,200 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientific programme.

More than 1,000 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientific quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference:

Table of Contents

Oral Abstract Sessions

OAA01	Controlling HIV: lessons from controllers	1
OAA02	Cutting edge HIV therapeutics	3
OAA03	HIV vaccine development: How to forge ahead	6
OAA04	New insights into the HIV reservoir	9
OAB01	Adolescents and young people	11
OAB02	ARV, cure and testing strategies	14
OAB03	Antiretrovirals session 1	16
OAB04	Antiretrovirals session 2	18
OAB05	TB	20
OAB06	Weight and metabolic changes & ART	24
OAB07	Youth and children/pediatrics/women	26
OAC01	Adolescent girls and young women: evaluations including DREAMS evaluation	29
OAC02	Can we achieve UTT? What can UTT achieve?	31
OAC03	Harm reduction: Are we making progress?	34
OAC04	I Test, You Test, We All Test: Multiple Roads to the First 90	36
OAC05	Next steps in PrEP	39
OAC06	Pleasure, prevention, or fear: Far reaching effects of online messaging and mHealth interventions	42
OAC07	PMTCT 2020: Successes in mothers and children	45
OAC08	PrEP at Scale	47
OAD01	Breaking the silence of stigma: Innovative approaches	50
OAD02	Gender dynamics and HIV transmission	53
OAD03	HIV & Society: Community and structural approaches for HIV prevention, treatment and care	55
OAD04	Panoramic view of drug use and HIV	58
OAD05	Powering HIV testing: Towards the target	60
OAD06	PrEP 360: PrEP around the world	63
OAD07	The whole person: Addressing all aspects of health of people living with HIV	65
OAD08	TikTok: Time's running out for adolescent and young people's health	68
OAD09	Young @ heart: Ageing and HIV	70
OAE01	Across the cascade: Research methods in implementation science	73
OAE02	Breaking the cycle: from aid to sustainable development	75
OAE03	Health for all: UHC and social protection	77
OAE04	Innovation in initiation, treatment and care: Differentiated Service Delivery	80
OAE05	It's raining men: How to effectively engage men into care	82
OAE06	Money makes the world go around: Domestic financing for an effective HIV response	85
OAE07	PrEP-ing for success: Adaptations for improving PrEP uptake	87
OAE08	Take the wheel: Communities in the driving seat of HIV service delivery	89
OAF01	Demystifying data: Methodologies and monitoring for evidence-based approaches	92
OAF02	Equal before the law: effective strategies to protect human rights	94
OAF03	Living in the shadow: Stigma, social justice and sexual violence	96
OAF04	The defense shall not rest: Rights, rhetoric and reality	99

Poster Discussion Sessions

PDA01	HIV, co-infection and co-morbidities	102
PDA02	Kill or be killed: HIV vs host immune responses	104
PDB01	Achieving virologic suppression	107
PDB02	Neurocognitive and mental health	109
PDB03	Opportunistic infections	112
PDB04	Resistance	114
PDC01	Emerging success stories in PrEP in MSM and TGW in Asia	117
PDC02	Gaps in our response: Who are we missing?	120
PDC03	Mortality and tuberculosis: What are we doing to prevent them?	123
PDC04	Untangling the web of sexual reproductive health and sex differences in prevention	126
PDD01	From within: Effective strategies for community mobilization and demand creation	129
PDD02	Harnessing the power of technology and innovative methodology	132
PDD03	Sexual concurrency and sexual networks	135
PDD04	Still a long way to go: HIV care for mothers and children	138
PDD05	The Big Cs: Circumcision, condoms and contraception	141
PDE01	Communities at the forefront: Integrating communities in HIV programming	144
PDE02	Different methods, better results: Differentiated service delivery in HIV testing and prevention	146
PDE03	From faith to MTV: Expanding the reach of HIV services	149
PDE04	How data is leading innovation: Evidence informed programmes	152
PDE05	Money doesn't grow on trees: Affordability and cost-effectiveness in the HIV response	154
PDF01	Queer Eye: A focus on gender dimensions in HIV programming	158
PDF02	Rights are Right: Ensuring rights based approaches	160

Poster Exhibition

Track A – Basic and translational research

PEA0001-0009	Viral origins, evolution and diversity	163
PEA0010-0013	HIV biology (entry, replicative cycle, transcriptional expression and regulation)	167
PEA0014-0018	Viral fitness, persistence and resistance	169
PEA0019-0020	HIV controllers (including post-treatment controllers) and long-term non-progressors	172
PEA0021-0023	Innate immunity	173
PEA0024	Humoral immunity (including broadly neutralizing antibodies)	174
PEA0025-0028	Cellular immunity	175
PEA0029-0032	Mucosal immunity	177
PEA0033-0038	HIV transmission and dissemination	178
PEA0039-0046	Systemic immune activation and inflammation	181
PEA0047-0048	T cell depletion and reconstitution, and immune ageing	184
PEA0049-0050	Microbiomes and microbial translocation	185
PEA0051-0053	Correlates of HIV susceptibility and disease progression (biomarkers and genetics)	186
PEA0054-0056	Viral mechanisms of HIV/SIV persistence and latency	187
PEA0057-0060	Identification and characterization of HIV reservoirs	189
PEA0061	Eliminating/silencing latency	191
PEA0062	Gene therapy	191
PEA0063-0064	ARVs, small molecules and immunomudulating agents	192
PEA0065	Novel antivirals and formulations	193
PEA0066	Nucleic acid-based HIV therapies	193
PEA0067-0072	HIV and co-morbidities	194
PEA0073-0077	HIV and co-infections (TB, viral hepatitis, other)	197
PEA0078	Novel assays of immune responses	199
PEA0079-0082	Novel approaches to assess viral load and ARV resistance/tropism	199
PEA0083-0087	ARV pharmacodynamics and pharmacokinetics	201
PEA0088	Neuropathogenesis	204

Track B – Clinical research

PEB0088-0089	Acute and early infection	205
PEB0090	Impact of co-factors (e.g., viral clade, tropism, genetic factors) on disease progression	206
PEB009-0098	Morbidity, mortality and life expectancy in clinical research	206
PEB0099-0110	HIV testing and retesting (e.g., point-of-care diagnostics)	211
PEB0111-0115	Viral load and CD4 monitoring	216
PEB0116-0122	Resistance to ART	219
PEB0123-0125	Diagnostics of co-infections and co-morbidities	223
PEB0126-0127	Biomarkers for the prediction of morbidity and mortality	225
PEB0128-0143	Tuberculosis: Prevention, diagnosis, treatment	226
PEB0144-0147	Opportunistic infections (excluding TB): Bacterial, non-TB mycobacterial, viral and parasitic infections	234
PEB0148-0153	Viral hepatitis C	236
PEB0154-0157	Other viral hepatitis (e.g., A, B, D, E)	239
PEB0158-0169	STIs (including HPV)	241
PEB0170-0173	Neurologic disorders	246
PEB0174-0175	Depression and other psychiatric manifestations	248
PEB0176-0178	Malignancies (AIDS and non-AIDS)	249
PEB0179-0187	Cardiovascular disease	251
PEB0188-0190	Bone disease	256
PEB0191-0192	Renal disease	257
PEB0193	Metabolic, lipid and endocrine complications (including lipodystrophy)	258
PEB0194-0203	Weight gain	258
PEB0204-0207	Hepatic complications (e.g., NASH)	264
PEB020-0210	Mental health and HIV	266
PEB0211-0216	Ageing with HIV (including polypharmacy and frailty)	267
PEB0217-0223	Other ART complications and adverse reactions	270
PEB0224-0227	Other non-communicable diseases	274
PEB0228	Co-morbidities and ART complications in key populations	275
PEB0229-0233	ART in acute, first- and second-line therapies	276
PEB0234	ART in highly treatment-experienced persons	278
PEB0235-0359	Regimen simplification and switch studies	279
PEB0242-0247	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring	282
PEB0248-0249	Drug interactions	286
PEB0250-0259	Antiretroviral drug resistance	287
PEB0260-0265	Long-acting agents and other drug delivery systems (e.g., injectables, implants, microneedle patches)	292
PEB0266-0270	Adherence	295
PEB0271	Ethical issues in clinical trials and treatment strategies	297
PEB0272	Cure interventions	298
PEB0273	Nutrition	298
PEB0274-0275	Sex-specific issues of ART efficacy, adverse reactions and complications	299
PEB0276-0282	Pregnancy (clinical management issues and pharmacokinetics)	300
PEB0283-0286	Contraception	303
PEB0287-0290	Diagnosis of HIV disease in paediatric and adolescent populations	305
PEB0291	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring in paediatric and adolescent populations	307
PEB0292	Drug formulations for infants and children	307
PEB0293-0294	Clinical trials in paediatric and adolescent populations	308
PEB0295-0301	ARV management strategies in paediatric and adolescent populations	309
PEB0302-0310	Adherence in paediatric and adolescent populations	312
PEB0311-0358	TB/HIV co-infection in paediatric and adolescent populations (including treatment and prevention)	317
PEB0312-0315	HIV complications and co-morbidities in paediatric and adolescent populations	317
PEB0316-0319	HIV-associated co-infections and malignancies in paediatric and adolescent populations	319
PEB0320-0321	Behavioural health outcomes in paediatric and adolescent populations	322
PEB0322-0329	Mental health and neurocognition in paediatric and adolescent populations	323
PEB0330-0335	HIV-exposed uninfected children	327

PEB0336-0340	Transition of adolescents into adult care	330
PEB0341-0344	Clinical issues in men who have sex with men	333
PEB0346	Clinical issues in transgender people	334
PEB0347-0352	Clinical issues in people who use drugs	335
PEB0353-B0357	Clinical issues in other vulnerable populations, including unstable settings (migrants) and incarcerated settings	338

Track C – Epidemiology and prevention research

PEC0358	Natural history, morbidity patterns and survival	342
PEC0359-0365	Epidemiology of HIV in the general population	342
PEC0366-0380	Epidemiology of HIV in men who have sex with men	345
PEC0381-0385	Epidemiology of HIV in infants and children	352
PEC0386-0391	Epidemiology of HIV in adolescents	354
PEC0392-0395	Epidemiology of HIV in women	357
PEC0396-0419	Epidemiology of HIV in other key vulnerable populations (e.g., people who inject drugs, women, transgender women, sex workers, prison populations, older groups)	359
PEC0420-0756	Risk factors for acquisition, infectivity and transmission of HIV	369
PEC0436-0440	Epidemiology of AIDS events (e.g., AIDS-related opportunistic infections and cancers)	377
PEC0441-0448	Epidemiology of non-AIDS infections and communicable diseases (e.g., viral hepatitis, STIs)	379
PEC0449-0454	Epidemiology of non-AIDS non-communicable diseases (e.g., non-AIDS cancers, CVD)	383
PEC0455-0458	Describing the spread of HIV through molecular epidemiology	386
PEC0459-0473	Surveillance in key population groups	388
PEC0474-0477	Determining the incidence of HIV	395
PEC0478-0480	Novel methods/algorithms for detecting acute and recent HIV infections	397
PEC0481-0483	Monitoring acute HIV infections	398
PEC0484-0487	Measuring the epidemic through population-based surveys (including the undiagnosed fraction)	400
PEC0488-0493	Measuring the population impact of prevention and treatment interventions	402
PEC0494	Measuring the population-level impact of policy-level HIV interventions	404
PEC0495-0499	Monitoring and evaluation of health systems along the HIV cascade	405
PEC0500-0502	Surveillance of drug resistance	407
PEC0503-0504	Describing the spread of HIV through geographical information systems	409
PEC0505-0515	Advances in public health surveillance and new approaches	410
PEC0516-0520	Measuring and evaluating quality of service provision and health outcomes through public health surveillance	415
PEC0521-0529	Modelling the potential impact of prevention strategies on the HIV epidemic	418
PEC0530-0535	The role of social and sexual networks in the spread of HIV	422
PEC0536-0538	The role of syndemics	425
PEC0539	Understanding the spread of HIV through behavioural studies	427
PEC0540-0541	Modelling future healthcare needs	427
PEC0542-0544	Identifying optimal service models	428
PEC0545-0564	Reaching and recruiting key populations for HIV services (online, offline, online-to-offline)	429
PEC0565-0594	Innovative HIV testing strategies (peer-led testing, peer-mediated testing, self-testing with and without online/offline support, use of fourth-generation and recency assays)	438
PEC0595-0605	Demonstration and pilot projects for PrEP, PEP, male circumcision	451
PEC0606-0649	Scale up of PrEP	457
PEC0650-0656	Scale up of PEP and male circumcision	477
PEC0657-0661	Integrating STI, sexual and reproductive health and HBV and HCV services in HIV prevention programmes	481
PEC0662-0686	Developing tailored and comprehensive services for specific key and vulnerable populations	483
PEC0687-0694	Sexuality, gender and prevention technologies (including condoms, treatment as prevention, male circumcision, pre-exposure prophylaxis)	495
PEC0695-0700	Access to harm reduction interventions	499
PEC0701-0706	Optimizing vertical transmission prevention programmes	501
PEC0707-0708	Combination prevention strategies	504
PEC0709-0711	Innovative behavioural interventions	505
PEC0712-0713	Structural interventions	507
PEC0714-0719	Other new prevention tools	508
PEC0720-0757	Measuring and enhancing retention and adherence in HIV prevention programmes	511
PEC0740-C0745	Key population-led prevention programmes (from reach, recruit, test, treat, prevent and retain)	520
PEC0746	Public-private partnerships	523
PEC0747-C0751	Community involvement and good participatory practice in epidemiological and prevention research	523
PEC0752-0753	Harnessing big data for epidemiological research/digital epidemiology	526
PEC0754	Harnessing new technology for understanding epidemic dynamics	527
PEC0755	Ethical and human rights issues in research and development	527

Track D – Social and behavioural research

PED0755-0756	Community engagement in research and research dissemination	528
PED0757-0760	Knowledge translation and dissemination of research and programme outcomes	529
PED0761-0762	Mixed methods, integrated approaches and synergies in HIV research and intervention	531
PED0763-0764	Qualitative and ethnographic methods in HIV research	532
PED0765	Role of social and behavioural science in biomedical responses	532
PED0766-0770	Social and behavioural concepts and theories	533
PED0771	Host cellular factors and latency	535
PED0772-0773	Strengthening social and behavioural data collection and analysis	536
PED0774-0779	Adaptation to living with HIV for individuals, families and communities	537
PED0780-0792	Ageing with HIV: Evolving and additional needs and responses	540
PED0793-0805	Confronting stigma: Lessons learned	545

PED0806-0809	Experiences and impacts of antiretroviral therapy	551
PED0810-0828	Growing up with HIV: Specific needs and interventions for children and adolescents	553
PED0829-0831	HIV and the workplace: Policies, responding to stigma and/or discrimination, unemployment, return to work and rehabilitation	562
PED0832-0838	Living with HIV and co-infections and/or co-morbidities	563
PED0839-0840	Pain management and palliative care	566
PED0841-0848	Peer support: Lessons learned, access to services and health outcomes	567
PED0849-0863	Positive health, dignity, psychological well-being and mental health	570
PED0864-0868	Prevention interventions and their effects on the lives and relationships of people living with HIV	577
PED0869-0877	Sexual and reproductive health, fertility, family planning, pregnancy and abortion	580
PED0878-0899	Conceptualizing social and structural factors and their impacts	583
PED0900-0904	Dynamics of social status and power: Sex, gender, age, race/ethnicity, sexual orientation and disability	593
PED0905-0906	Economic transitions and social and cultural changes affecting HIV and the HIV response	595
PED0907-0913	Humanitarian crises and HIV	596
PED0914-0917	Intergenerational and/or transactional sex	600
PED0918-0919	Media, cultural and religious representations of HIV and of key populations	602
PED0920-0922	Migration and HIV	602
PED0923-0926	Political and structural factors	604
PED0927-0929	Prisons and other closed settings	606
PED0930-0935	Sexual- and/or gender-based violence and exploitation (including in conflict settings)	607
PED0936-0954	Societal stigma towards people living with HIV and key populations	610
PED0955-0956	Socioeconomic differences: Poverty, wealth and income inequalities	618
PED0957-0959	Violence and conflict: Political, social, structural, interpersonal and family-based	619
PED0960-1012	Gay, bisexual and other men who have sex with men	620
PED101-1021	Intersectional identities and multiple vulnerabilities to HIV and co-infections	643
PED1022-1323	Other populations vulnerable in specific contexts	648
PED1032-1056	People who use drugs (including by injection)	653
PED1057-1325	Sex workers	664
PED1086-1118	Transgender people	677
PED1119-1140	Young key populations	691

OAA01 CONTROLLING HIV: LESSONS FROM CONTROLLERS

OAA0102

LOW LEVELS OF INTACT PROVIRAL DNA IN HIV ELITE CONTROLLERS ASSOCIATE WITH CELL-ASSOCIATED HIV RNA AND PROTECTIVE HLA ALLELES

M. Peluso[1], N. Iyer[1], S. Kumar[1], S. Munter[1], L. Torres[1], R. Hoh[1], S. Deeks[1], W. Trypsteen[2], T. Henrich[1]
[1]University of California, San Francisco, United States, [2]Ghent University, Ghent, Belgium

BACKGROUND: The levels of intact and defective HIV provirus and their biological correlates in large cohorts of individuals who control HIV the absence of therapy ("elite controllers") are unknown.
METHODS: We used the intact proviral DNA assay (IPDA) to estimate the levels of intact and defective HIV provirus in cryopreserved PBMCs from 74 highly curated HIV elite controllers. We evaluated associations with clinical parameters, cell-associated unspliced HIV RNA measured using quantitative PCR, and the presence of protective HLA alleles (B*27, *57, and *58). Many individuals had no detectable intact proviruses. As DNA shearing is a known limitation of the IPDA, and as corrections traditionally require having detectable levels of intact HIV DNA, we applied the shearing index correction based on the lowest observed non-intact concentration.
RESULTS: Of the 74 controllers, 41 (55.4%) had undetectable levels of intact provirus. This is a greater proportion compared with a cohort of ART-suppressed individuals that we have previously reported (7/81, 8.6%; p<0.001). Detectable levels of intact provirus ranged from 10.5 to 3429.5 copies/10^6 cells. The median level of 3' defective provirus was 80.9 (IQR 0-210), 5' defective provirus was 38.5 (IQR 0-137.1), and combined defective provirus was 137.4 (IQR 89.0-391.0) copies/10^6 cells. The median ratio of intact/defective provirus was 0.17 (0-0.5), which is comparable to what we previously reported among those on ART (0.15, 0.05-0.33). Across all controllers, both the estimated intact provirus and combined defective provirus level directly correlated with higher levels of cell-associated RNA (r=0.41, p=0.0014; r=0.50, p<0.001, respectively). Furthermore, individuals without detectable provirus were more likely to have at least one protective HLA allele (69% vs 40%, p=0.014). When the analysis was performed using the traditional shearing correction methods, individuals without detectable provirus had higher CD4/CD8 ratios (1.14 vs 0.90, p=0.021).
CONCLUSIONS: Elite controllers have low levels of intact provirus, but the level of transcriptional activity is directly correlated with the frequency of intact virions. Protective alleles are associated with no detectable levels of intact HIV, arguing that potent and stringent T cell mediated control of the reservoir is possible.

OAA0103

IN-DEPTH CHARACTERIZATION OF FULL-LENGTH ARCHIVED HIV GENOMES IN LONG-TERM POST-TREATMENT AND NATURAL HIV CONTROLLERS (ANRS CODEX/IVISCONTI COHORT)

P. Trémeaux[1], F. Lemoine[2], M. Gousset[1], A. Mélard[1], F. Boufassa[3], O. Gascuel[2], O. Lambotte[4], L. Hocqueloux[5], A. Saez-Cirion[2], C. Rouzioux[6], V. Avettand-Fenoel[1], ANRS CODEX/iVISCONTI Cohort Study Group
[1]University of Paris/Cochin Institute, Paris, France, [2]Pasteur Institute, Paris, France, [3]Université Paris Sud/INSERM CESP U1018, Paris, France, [4]Université Paris Sud/INSERM UMR 1184, Paris, France, [5]Orléans Hospital, Orléans, France, [6]University of Paris, Paris, France

BACKGROUND: Post-treatment controllers (PTCs) and natural HIV controllers (HICs) are models of HIV remission but their mechanisms of control are different. We characterized HIV blood reservoir to better understand this control.
METHODS: The reverse transcriptase (RT) gene viral diversity and the near-full-length proviral landscape of 9 PTCs were compared to those of 13 HICs (6 aviremic-HICs and 7 blipper-HICs) and of individuals under efficient antiretroviral therapy initiated either at the primary infection (PHI, n=6) or during the chronic phase (CHI, n=6), by single genome amplification and deep-sequencing. Bioinformatic tools were developed to identify genetic defects.
RESULTS: Overall, more than 25000 RT sequences and 510 full-length genomes were studied. The proviral diversity was lower in the PTC, PHI and aviremic-HIC groups than in the blipper-HIC and CHI groups. The proportion of intact genomes was lower in the CHI (median [IQR]: 2 [0-8]%) than the PHI (23 [13-34]%) group but similar among others, despite a high inter-individual variability (HICs: 0 [0-28]%, PTCs: 4 [0-14]% 9.2 years [7.4-12.5] after treatment interruption). No difference was observed in the amounts of intact proviruses between groups. A subsequent sample taken four to six years later for three PTCs revealed no evolution of the proviral quasispecies and defects. The higher total HIV-DNA loads in CHI were due to higher amounts of defective proviruses. HICs harbored lower proportions of hypermutated proviruses than the other three groups, suggesting that APOBEC3G/3F does not play a prominent role in them. A deletion in the *nef* gene was observed in every proviral sequence of two HICs, suggesting a role of these attenuated strains in the viral control in these HICs.
CONCLUSIONS: For the first time, we show the presence of intact proviruses and a stable and low viral diversity in PTCs after treatment interruption, reflecting a low residual replication over years. The absence of difference in the proviral landscape between PHIs and PTCs after treatment interruption suggests that post-treatment control is mainly linked to non-viral factors, contrary to some cases of natural control. The difference of defective (but not intact) proviruses amounts between groups suggests a role of these forms in the pathogenesis of HIV infection.

OAA0104

SUPPRESSION OF HIV-1 LINKED LONG NON-CODING RNAS IN VIREMIC HIV-1 POSITIVE INDIVIDUALS IS ASSOCIATED WITH ONGOING VIRAL REPLICATION

C. Van Hecke[1], S. Kinloch-de Loes[2], T. Schynkel[1], E. Malatinkova[1], K. Vervisch[1], Y. Noppe[1], S.L. Rutseart[1], L. Vandekerckhove[1], W. Trypsteen[1]
[1]Ghent University, Department of Internal Medicine and Pediatrics, HIV Cure Research Center, Gent, Belgium, [2]Royal Free Hospital and University College London, Division of Infection and Immunity, London, United Kingdom

BACKGROUND: Long non-coding RNAs (lncRNAs) are recently established as a new layer in the HIV-host response with the identification of several lncRNAs directly affecting HIV infection in vitro. However, their impact on HIV-1 infection and replication in vivo remains largely unexplored and proves a necessity to further understand their clinical importance. Therefore, this cross-sectional study has assessed expression levels of HIV-1 linked lncRNAs in cohorts of infected individuals with different levels of virological control to determine their association with the HIV-1 reservoir and host restriction factors.

METHODS: The expression levels of five established HIV-linked lncRNAs (MALAT1, NEAT1, NRON, GAS5 and linc01426) were evaluated by qPCR in peripheral blood mononuclear cells from 14 healthy individuals and 104 HIV-1 positive individuals subdivided into five pre-defined cohorts: recent seroconverters (n=19), ART-naïve progressors (n=12), ART-naïve long term non-progressors (n=17), early (n=24) and late ART-treated HIV-1 positive individuals (n=32). The levels of HIV-1 markers were assessed via digital PCR assays for cell-associated HIV RNA, total HIV-1 DNA and 2LTR circles, together with qPCR profiling of host markers: IFIT and MX1. Next, lncRNA expression changes in these cohorts were determined via pairwise multiple comparisons testing (Kruskal-Wallis with Nemenyi test) and associations with HIV-1 reservoir markers or host factors were explored via spearman correlation analysis.

RESULTS: The expression of all five lncRNAs was significantly downregulated in ART-naïve progressors with high HIV-1 viral load (all $p<0.0003$) and their expression levels were negatively correlated with viral load and total HIV-1 DNA (all $p<0.01$), indicating that the depletion of these lncRNAs is associated with ongoing viral replication and larger reservoir size. Only one lncRNA, GAS5, showed a negative correlation with HIV-1 usRNA ($p=0.009$), suggesting that individuals with lower levels of GAS5 have more ongoing viral transcription. Furthermore, one lncRNA NRON demonstrated a negative correlation with MX1 levels ($p=0.001$), suggesting that interferon-induction after infection is a possible driving factor for this lncRNA.

CONCLUSIONS: The present data characterized lncRNA expression in-depth for the first time across HIV-1 cohorts to address their link with the HIV-1 reservoir and gained further evidence on their importance in HIV-1 infection with possible implications for clinical follow-up or future therapeutic strategies.

OAA0105

ASSESSING THE T CELL COMPARTMENT OF THE EXTREMELY RARE PHENOTYPE OF ELITE CONTROL IN CHILDREN

V. Vieira[1], E. Adland[1], D. Malone[1], J. Millar[1], M. Muenchhoff[2], C. Fortuny Guash[3], C. Brander[4], A. Prendergast[5], G. Tudor-Williams[6], P. Goulder[1]
[1]University of Oxford, Department of Paediatrics, Oxford, United Kingdom, [2]Max von Pettenkofer-Institute, Department of Virology, Munich, Germany, [3]Hospital Sant Joan de Déu, Universitat de Barcelona, Servicio de Pediatria, Barcelona, Spain, [4]IrsiCaixa - AIDS Research Institute, Badalona, Spain, [5]Queen Mary University of London, Centre for Genomics and Child Health, London, United Kingdom, [6]Imperial College, Department of Paediatrics, London, United Kingdom

BACKGROUND: Although important progress on prevention of mother-to-child transmission has been achieved, the incidence of HIV-infected children is still a burden in low-income countries. An intervention that leads to remission can be an important instrument in the epidemic control. However, due to the unique features of the immune system in children, strategies tailored in adults might not be applicable to this age group. Adults who spontaneously control viraemia (elite controllers) have been extensively investigated as a natural model of remission. This phenotype has not been studied in children, since paediatric elite controllers (PEC) are extremely rare, approximately 10-fold lower than in adults.

METHODS: In this study, we investigated the T cell compartment and the HIV-specific response of four PEC, 13 non-progressors, 10 progressors and 8 HIV-exposed uninfected (EU) individuals matched by age. Peripheral mononuclear cells samples were analysed by flow cytometry.

RESULTS: The CD4 T cell immunophenotype in PEC, non-progressors and EU is similar, with a high naïve cells percentage and low expression of HLA-DR, CD38, PD-1 and CCR5. Clustering analysis shows a clear pattern of PEC grouping together with EU for activation markers on total, central memory and effector memory cells. The CD8 T cell compartment in PEC, however, shows increased frequency of more differentiated subsets and higher activation, but lower PD-1 expression. Upon stimulation with HIV peptides pools Gag-specific CD8+ and CD4+ T cells were more polyfunctional in PEC than in the non-progressors and progressors. Unexpectedly, across all the groups studied, IFN-γ expression on CD4 T cells negatively correlated with viral load.

CONCLUSIONS: Viraemic control in the paediatric population is only achieved after years of infection, compared to weeks in adults. Very low levels of immune activation in PEC and non-progressors are important to maintain normal-for-age CD4 counts and preserve CD4 T-cell function until antiviral immune activity has developed sufficiently to reduce viraemia. Although robust HIV-specific CD8+ T cell responses are present among PECs, unlike adult EC these children are not enriched with the well-described protective HLAs. Other mechanisms yet to be determined are also likely contributing to viraemic control among PECs.

OAA0106

VIROLOGICAL AND IMMUNOLOGICAL EVALUATION OF INDIVIDUALS WITH SPONTANEOUS PERSISTENT VIRAL CONTROL WITHOUT ART

M. Khan[1], J. Tosswill[2], J. Haddow[1], K. Pollock[1], T. Elliott[1], P. Patel[2], A. Menezes[2], T. Mbisa[2], C. Brown[2], D. Bradshaw[2], G.P. Taylor[1], S.J. Fidler[1]
[1]Imperial College London, Department of Medicine, Section of Virology, London, United Kingdom, [2]Public Health England, Infectious Diseases, London, United Kingdom

BACKGROUND: HIV elite controllers (EC) maintain undetectable viral loads (<20 HIV RNA copies/ml) and normal CD4/CD8 counts without ART. Despite WHO guidelines recommending ART irrespective of CD4 count and viral load, there remains a lack of consensus on best EC management. We have applied molecular and immunological assays to better understand mechanisms of natural viral control and possible negative immunological consequences.

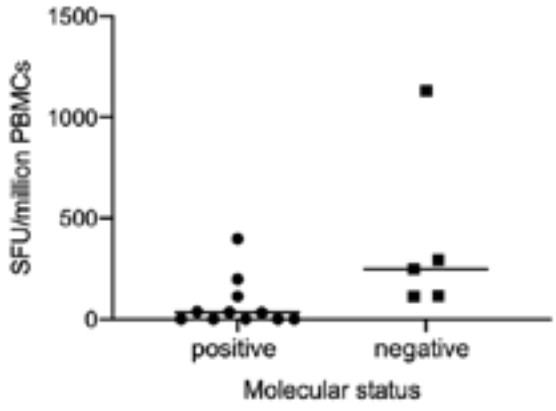
METHODS: A prospective study of 17 ECs attending a tertiary referral clinic (2017-2019) in London, measuring the following:

NRTIs plasma concentrations by LC-MS; nucleic acids by single copy assays RNA /ml and DNA/105 PBMCs, targeting gag, pol and int genes; CD4, CD8, CD25 and HLA-DR by flow cytometry; HIV specific CD8 T-cell responses using a pool of gag, env, nef and vif peptides in IFN-γ ELISPOT; plasma cytokines (IL-2,IL-6, TNF-α, MIP-1β, CRP) by mesoscale Vplex.

RESULTS: EC had a median age 42y (IQR=37-54), 10 were female and NRTIs were not detected.

HIV nucleic acid was not detected in 5 (molecular-negative) but detected in 12 (molecular-positive); HIV RNA in 9/12 (median 5cpm, range=2-17), HIV DNA in 7/12.

	CD4 cells/uL	CD8 cells/uL	CD4:8 ratio	T-cell activation
Molecular Positive Median (IQR)	1015 (751-1369)	553 (372 -817)	1.9 (1.3-2.5)	CD4+CD25+% 23 (18-32) CD8+CD25+% 8.5 (6.7-11) CD4+HLA-DR+% 7 (5.7-10) CD8+HLA-DR+% 19 (15-31)
Molecular Negative EC Median (IQR)	785 (658-1138)	779 (436 -911)	1.5 (0.8-2.5)	CD4+CD25+% 22 (11-24) CD8+CD25+% 6 (4.5-11) CD4+HLA-DR+% 8 (5-8) CD8+HLA-DR+% 16 (10-24)



[Figure. HIV specific CD8 T cell responses]

All had CD4 and CD8 counts within normal range and 16 had CD4:CD8 ratio >1. Neither T-cell activation markers nor plasma cytokine concentrations differed significantly between groups.

The frequency of CD8 responses was significantly higher (p=0.01) in molecular-negative (median=248 SFU/106 PBMCs, IQR= 115-293) than molecular-positive EC (median = 33 SFU/106 PBMCs, IQR=0-75).

CONCLUSIONS: EC can be sub-classified as molecular-positive and molecular-negative. Higher frequency of HIV-specific CD8 responses in molecular-negative suggests this may be important in the level of control. In this cohort, irrespective of detection of nucleic acids, there is no evidence of increased T-cell activation or inflammation. Further studies are essential to determine the role of lifelong ART in such EC.

BACKGROUND: "Kick-and-kill" HIV cure strategies involve latency reversal followed by immune-mediated clearance of infected cells. Our prior work demonstrated strong latency reversal of SIV by AZD5582, a SMAC mimetic targeting the non-canonical NF-kB pathway. Here, we combined AZD5582 with bispecific HIVxCD3 DART molecules to reduce viral reservoirs in SHIV-infected, ART-suppressed rhesus macaques (RMs).

METHODS: 13 RMs were infected with SHIV.C.CH505.375H.dCT. Triple ART (TDF+FTC+DTG) was initiated at 16 weeks. After 42 weeks, 8 ART-suppressed RMs received a cocktail of 3 HIVxCD3 DART molecules with rhesusized Fc domains having A32, 7B2 or PGT145 anti-HIV-1 envelope specificities. For 10 weeks, DART molecules were administered weekly (1 mg/kg each) followed 2 days later by AZD5582 (0.1 mg/kg). Five RMs served as controls. Reservoir size was measured by cell-associated SHIV-DNA and -RNA and quantitative virus outgrowth.

RESULTS: Peak viremia (106-107 copies/mL) occurred 2 weeks after infection; 2 weeks of ART suppressed viral loads to below detection (<60 copies/mL). Three RMs showed transient control of viremia <60 copies/mL before ART. DART molecule serum levels declined after 3-5 doses coincident with development of anti-drug antibodies, but Cmax levels >100 ng/mL (sufficient for near-maximal redirected killing of infected CD4+ cells in vitro) were maintained for

8-9 doses. AZD5582 did not increase on-ART viremia or cell-associated SHIV-RNA in blood or lymph node CD4+ T cells. SHIV-DNA levels in blood or lymph node CD4+ T cells did not decline after treatment. Similarly, no differences were observed between experimental and control groups for SHIV-DNA in GI tract or spleen CD4+ T cells, or replication-competent virus in lymph node or spleen CD4+ T cells.

CONCLUSIONS: DART molecules did not reduce reservoir size in animals on ART, likely due to inadequate latency reversal. Lack of latency reversal in this system may be related to low pre-ART viral loads (<105 copies/mL) and low pre-LRA reservoir size (<102 SHIV-DNA copies/million blood CD4+ T cells), which we have found to predict AZD5582-induced on-ART viremia in SIV-infected, ART-suppressed RMs. Future studies to assess efficacy of Env-targeting DART molecules to reduce viral reservoirs may be more suited to settings with greater viral burden.

OAA0203

INFECTION OUTCOME IN RT-SHIV INFECTED MACAQUES TREATED EARLY WITH ANTIRETROVIRAL THERAPY ALONE OR IN COMBINATION WITH THE TLR7 AGONIST VESATOLIMOD

M. Daly[1], S. Ruone[1], D. Rudolph[1], C. Dinh[1], A. Holder[1], J. Mitchell[1], M. Sterling[1], K. Nishiura[1], G. Khalil[1], C. Tansey[2], J. Weed[2], K. Curtis[3,1], V.V. Van Eygen[4], W. Spreen[5], W. Heneine[1], J.G. García-Lerma[1]
[1]Centers for Disease Control and Prevention, Division of HIV and AIDS Prevention, Atlanta, United States, [2]Centers for Disease Control and Prevention, Division of Scientific Resources, Atlanta, United States, [3]Centers for Disease Control and Prevention, National Center for HIV/AIDS Prevention, Atlanta, United States, [4]Janssen Research & Development, Clinical Microbiology and Immunology, Beerse, Belgium, [5]ViiV Healthcare, Medicine Development, Research Triangle Park, United States

BACKGROUND: Early antiretroviral therapy (eART) preserves immune function and limits virus diversification but is not curative in people due to rapid viral reservoir establishment. We modeled in macaques the effect of a potent eART regimen [emtricitabine/tenofovir alafenamide (FTC/TAF) and long-acting cabotegravir/rilpivirine (CAB-LA/RPV-LA)] with or without the TLR7 agonist vesatolimod (VES).

METHODS: Eight rhesus macaques infected intrarectally with RT-SHIV initiated treatment with human-equivalent doses of oral FTC/TAF (20 and 1.5 mg/kg daily) and intramuscular CAB-LA/RPV-LA (50 and 200 mg/kg monthly) at 6 [range=5-8] days post-infection (dpi). Group I (n=4) was treated for 12 months. Group II (n=4) was treated for 4 months and also received weekly VES (0.15 mg/kg). Two untreated animals were used as controls. Plasma viremia was monitored by RT-PCR (limit of quantification=50 copies). Antibody responses to p66, gp130, gp41, nef, gp36, gp140, and p27 were measured using an SIV/HIV Bio-Plex assay. The wilcoxon rank sum test was used to compare medians.

RESULTS: Peak viremia in the eART-only and eART+VES groups were similar (3.4 [range=2.7-4.3] and 4.2 [3.7-4.4] log10 RNA copies/ml, p=0.111) and lower than the untreated controls (6.8-7.0 log10RNA copies/ml). Virus replication from treatment initiation until virus suppression was similar in the eART-only and eART+VES animals (AUC=42.6 [31.6-59.7] and 45.0 [38.4-51.07] RNA copies/ml/day, p=0.886), although eART+VES suppressed replication earlier (18 [14-22] vs. 13 [11-13] dpi, p=0.029). All macaques from the eART-only group had undetectable viremia during treatment and remain aviremic 10 months after treatment interruption. Serologic responses in untreated controls were observed for the full panel tested. In contrast, responses in the eART and eART+VES groups were limited to gp140, albeit they developed at different rates (14 [14-17] vs. 36.5 [33-40] days post-infection, respectively, p=0.029). The eART-VES animals are currently undergoing treatment interruption.

CONCLUSIONS: Using a relevant macaque model of mucosal RT-SHIV infection we show that potent early ART leads to prolonged viral control after treatment interruption. Serologic responses, limited to gp140, were consistent with efficient virus control. The combination of eART and VES quickly suppressed viremia and delayed serologic responses. Further characterization of immune function and virus dynamics will shed light on the immunomodulatory effect of VES during acute infection.

TYROSINE KINASE INHIBITORS PROMOTE ANTIVIRAL RESISTANCE IN CD4+ T CELLS AGAINST HIV-1 INFECTION EVEN AFTER TREATMENT WITHDRAWAL

L. Vigón[1], S. Rodríguez-Mora[1], V. García[2], A. Luna[2], G. Bautista[3], M. Galán[1], J. Alcamí[1], J.L. Steegmann[4], A. Spivak[5], V. Planelles[5], M.R. López-Huertas[1], M. Coiras[1]
[1]Institute of Health Carlos III, AIDS Immunopathology, Majadahonda, Spain, [2]Hospital Universitario Ramón y Cajal, Hematology, Madrid, Spain, [3]Hospital Universitario Puerta de Hierro, Hematology, Majadahonda, Spain, [4]Hospital Universitario La Princesa, Hematology, Madrid, Spain, [5]University of Utah School of Medicine, Division of Microbiology and Immunology, Department of Pathology, Salt Lake City, United States

BACKGROUND: Our group described previously that tyrosine kinase inhibitors (TKIs) used against chronic myeloid leukemia (CML) show antiviral effect against HIV-1 by interfering with SAMHD1 phosphorylation, HIV-1 proviral integration and transcription and also decreasing viremia and reservoir size in NSG mice engrafted with human CD34+ cells. By blocking T-cell proliferation induced with homeostatic cytokines, TKIs might also impede reservoir replenishment, delaying viral rebound after controlled treatment interruption. Finally, TKIs showed immunomodulatory properties that may be preserved after treatment interruption (TI) due to deep molecular response (DMR) against cancerous cells.
Objective: To evaluate whether PBMCs from CML patients on TI are still resistant to HIV-1 infection.

METHODS: PBMCs from patients with CML on TI (Off-TKI) (n=17) and healthy donors (n=30) were analyzed by flow cytometry. Proviral integration was analyzed by Alu-qPCR and viral protein synthesis was quantified by chemiluminescence. Ex-vivo infection was performed with NL4-3_renilla strain.

RESULTS: 1) Off-TKI patients were 57% male, 43% female; mean age of CML diagnosis 61±5.5 years; mean lymphocyte count 2.4±0.3x103/ml; previously treated with imatinib, nilotinib and/or dasatinib for 5.3±0.4 years; mean time off treatment 13.7±3.5 months. 2) CD4+T cells from Off-TKI patients showed 2.1-fold reduced levels of phosphorylated (p)SAMHD1 in non-activated conditions, and CD4+CD25+CD69+ decreased 2.6-fold, regarding healthy controls. After activation with PHA/IL-2, CD4+pSAMHD1+ and CD4+CD25+CD69+ populations were similar in Off-TKI and controls. 3) Ex-vivo HIV-1 infection of PBMCs from Off-TKI decreased 12.4- and 5.2-fold proviral integration and viral proteins synthesis, respectively. 4) Expression of Natural Killer (NK) ac-

tivation marker CD56 increased 5-fold in CML patients off treatment. Populations of cytotoxic cells CD56+CD16+CD107a+ and CD8±TCRgd+ increased 5- and 3-fold in Off-TKI, respectively.

CONCLUSIONS: CD4+ T cells from CML patients on TI showed response to activating stimuli, with normal levels of pSAMHD1 and activation markers. However, these cells were resistant to HIV-1 infection, even though patients withdrew treatment with TKIs more than 1 year ago. Cytotoxic cell populations with antiviral effect were detected in these patients. These results suggest that TKIs could be used temporarily as cART adjuvants in HIV-infected patients to modulate the immune response in order to interfere with reservoir replenishment and reactivation.

OAA0205

COMBINING A CONDITIONAL SUICIDE GENE WITH CCR5 KNOCKOUT FOR ANTI-HIV GENE THERAPY

R. Yeh[1], T. Mehmetoglu-Gurbuz[2], A. Joshi[2], H. Garg[2]
[1]Paul L. Foster School of Medicine, El Paso, United States, [2]Texas Tech University Health Sciences Center El Paso, Department of Molecular and Translational Medicine, El Paso, United States

BACKGROUND: The recent success of the Berlin and London patients has attracted the attention of the scientific community worldwide to achieve an HIV cure for a wider group of patients. However, mathematic modeling has suggested that strategies targeting CCR5 alone will fail unless combined with a suicide gene. Hence, we developed a combined suicide gene therapy approach to target viral entry along with a conditional cytotoxic gene to specifically eliminate HIV-infected cells.

METHODS: We developed a 2-step gene therapy approach involving the delivery of TKSR39 gene via vector 1 (integrating lentivirus) and CCR5 knock-out combined with tat expression via vector 2 (non-integrating vector). Vector 1 incorporated an internal ribosomal entry site (IRES) followed by the GFP sequence to allow for sorting of the transduced cells. This TZM-TKSR39 CCR5 KO cell line was thoroughly characterized for resistance to HIV infection and specific killing of HIV-infected cells in the presence of ganciclovir.

RESULTS: TZM-TKSR39 cells developed in the lab previously were transduced with CCR5 sgRNA packaged lentiviral particles. Through sorting, enrichment of the CCR5 KO population was achieved and potential CCR5 KO candidates were obtained by single cell cloning. HIV infection of TZM-TKSR39 CCR5 KO cells resulted in negligent infection with R5 tropic HIV while still allowing infection with X4 tropic HIV. CCR5 deletion was further confirmed via a T7 endonuclease PCR. Moreover, the cells were susceptible to ganciclovir mediated cell killing after an X4 tropic virus infection.

CONCLUSIONS: Our study provides proof of principle for an HIV gene therapy to modify stem cells from an HIV infected patient to achieve a cure. Our combined gene therapy approach prevents viral entry via CCR5 knockout. However, in the event of X4 virus emergence, specific cell killing of infected cells can be achieved via ganciclovir. This approach is highly regulated and capable of targeting both X4 and R5 variants and has the potential to create an HIV proof immune system.

GENE THERAPY WITH AN ANTI-*TAT* GENE CAN STRONGLY BLOCK HIV-1 TRANSCRIPTION AND VIRUS REPLICATION IN MOUSE MODELS OF INFECTION

D. Harrich[1], H. Jin[1], L. Rustanti[2]
[1]QIMR Berghofer Medical Research Institute, Cell and Molecular Biology, Brisbane, Australia, [2]Australian Red Cross, Blood Research, Brisbane, Australia

BACKGROUND: Nullbasic (NB) is a mutant protein of the HIV-1 transcriptional activator protein, Tat. Our research has demonstrated that NB is a nontoxic, first-in-class antiviral agent that inhibits HIV production and viral spread in human T cells by independent mechanisms: 1) it inhibits the transcriptional activation function of Tat, 2) it disrupts HIV mRNA trafficking by interfering with the viral Rev regulatory protein, 3) it inhibits HIV reverse transcription. We have shown that with stable expression in cells, NB inhibits HIV replication in human cells and it also inhibits HIV reactivation from latently infected cells.

METHODS: We used retroviral gene therapy vectors to deliver a Nullbasic-ZsGreen1 fusion protein or ZsGreen1 to human CD4+ T cells, which were purified and transplanted into NOD-SCID or BALB/c-Rag2-/-γc-/- (RAG2) mice. The mice were infected with HIV-1 and virus replication was followed for up to 8 week. As an adjunct method, we also trialled layered double hydroxide nanoparticles (LDH NPs) to deliver NB protein to primary human CD4+ T cells.

RESULTS: Both mouse models showed that Nullbasic inhibited virus replication. In Rag2 mice, Nullbasic-ZsGreen1 delayed replication and lowered viral titres by ~10-15 fold. Increased virus replication inversely correlated with Nullbasic-ZsGreen1 expression in CD4+ T cells. Interestingly, NOD-SCID mice had CD4+ T cells that showed robust expression of Nullbasic-ZsGreen1 and up to 7,000-fold inhibition of HIV-1. We observed that 100% of CD4+ T cells can be treated with NB-LDH NPs. NB was detected in treated cells for three days.

CONCLUSIONS: Interest in strategies leading to a functional cure for HIV-1 infection by long-term or permanent viral suppression is growing. Here, we show that a mutant form of the HIV-1 Tat protein, referred to as Nullbasic, inhibits HIV-1 transcription in infected CD4+ cells *in vivo*. Analysis shows that stable expression of Nullbasic in CD4+ cells could lead to durable anti-HIV-1 activity. Nullbasic, as a gene therapy candidate, could be a part of a functional-cure strategy to suppress HIV-1 transcription and replication.

OAA03 HIV VACCINE DEVELOPMENT: HOW TO FORGE AHEAD

MULTIVARIANT HIV-1 INFECTION IN INFANTS WITH BROADLY NEUTRALIZING PLASMA ANTIBODIES: IMPLICATION FOR POLYVALENT VACCINES

N. Mishra[1], S. Sharma[1], A. Dobhal[1], M. Makhdoomi[1], S. Kumar[1], R. Singh[2], B. Das[2], R. Lodha[3], S. Kabra[3], K. Luthra[1]
[1]All India Institute of Medical Sciences, Biochemistry, New Delhi, India, [2]All India Institute of Medical Sciences, Microbiology, New Delhi, India, [3]All India Institute of Medical Sciences, Pediatrics, New Delhi, India

BACKGROUND: An effective HIV-1 vaccine that can curtail the AIDS pandemic is the need of the hour. Several second-generation broad and potent neutralizing antibodies (bnAbs), mostly targeting distinct conserved regions of the viral envelope glycoprotein (env), have been isolated and shown to have a protective effect. Due to the extensive antigenic diversity of HIV-1, bnAbs develop in a subset of infected individuals over 2-3 years of infection. Interestingly, infected infants have been shown to develop plasma bnAbs frequently and as early as one-year post-infection, with features atypical than adult bnAbs, suggesting the factors governing bnAb induction in infants are different than those in adults. Understanding the antigenic features in infants with early bnAb responses will provide key information on the antigenic triggers driving B cell maturation pathways towards the induction of bnAbs.

METHODS: Plasma neutralization activity and bnAb susceptibility profiles were assessed by TZM-bl based neutralization assays. HIV-1 RNA was isolated from plasma samples of infants, and full-length envelope genes were amplified, sequenced and cloned for the generation of pseudoviruses. Viral diversity, recombination, and phylogeny analysis were performed using MEGAX, RAPR, HIV AnalyzeAlign and SimPlot. Antigenic characterization of candidate vaccine strains was done using surface binding assays, ELISAs and on-cell sDC4 triggering assay.

RESULTS: Herein, we evaluated the presence of plasma bnAbs in 51 infants of Indian origin perinatally infected with HIV-1 clade C and identified the viral factors associated with early bnAb responses. A strong association of multivariant infection in infant elite neutralizers with development of plasma nAbs targeting diverse autologous viruses was observed. We observed the plasma nAbs in infants with multivariant infection to target both variants, suggesting env specific antibodies generated in context of two distinct viral variants can target epitopes on both envelopes. In addition, several viral strains capable of serving as potential vaccine candidates were identified from infant elite neutralizers.

CONCLUSIONS: Our data provides information supportive of polyvalent vaccination approaches for pediatric HIV-1 vaccination.

INTRADERMAL MVA VACCINATIONS PROVIDE SUPERIOR PROTECTION COMPARED TO INTRAMUSCULAR MVA VACCINATIONS AGAINST A HOMOLOGOUS TIER 2 SHIV CHALLENGE

V.S. Bollimpelli[1], P.B.J. Reddy[1], S. Gangadhara[1], T. Charles[2], S. Burton[2], C. Labranche[3], G. Tharp[2], T.M. Styles[1], T. Legere[1], S.P. Kasturi[2], D. Montefiori[3], G. Shaw[4], J. Moore[5], S. Bosinger[2], P. Kozlowski[6], B. Pulendran[7], C. Derdeyn[2], E. Hunter[2], R.R. Amara[1]
[1]Emory University, Microbiology and Immunology, Atlanta, United States, [2]Emory University, Pathology, Atlanta, United States, [3]Duke University, Department of Surgery, Durham, United States, [4]University of Pennsylvania, Philadelphia, United States, [5]Weill Medical College of Cornell University, New York, United States, [6]Louisiana State University Health Sciences Center, New Orleans, United States, [7]Stanford University, Stanford, United States

BACKGROUND: The composition of antigen presenting cells is different in different compartments and thus the route of immunization can markedly influence the magnitude and quality of evoked immune response and thereby vaccine efficacy. Here, we tested the influence of intradermal (ID) and intramuscular (IM) routes of MVA immunization on HIV vaccine efficacy.

METHODS: We immunized two groups of rhesus macaques (n=10/group) with DNA/MVA/Protein vaccine regimen. DNA and MVA vaccines expressed SIV Gag and membrane anchored trimeric HIV BG505 envelope (Env). Soluble BG505-SOSIP.664 trimer protein plus 3M-052 adjuvant encapsulated in nanoparticles was used as a protein boost. While both groups received DNA immunizations intradermally and protein immunizations subcutaneously, they differed only in the route of MVA immunization where one group received MVA via ID and the other via IM route.

RESULTS: Both groups (ID and IM) showed strong binding antibody response to BG505-SOSIP.664 gp140 in serum/vaginal secretions, and some animals generated autologous neutralizing antibody response against BG505.664 Env but these were comparable between the groups. IFNg+ SHIV-specific CD8 T cell responses were marginally higher (not significant) in the IM group. However, the MVA-ID vaccination induced significantly higher proliferating CD4 T cells in blood consisting of effector memory (CD45RA-CCR7-), circulating Tfh (CXCR5+), and non-Th1 (CXCR3-) cells compared to MVA-IM. Similarly, the GC-Tfh and GC-B cells in the LNs were higher in the MVA-ID group. Following 10 weekly BG505-SHIV intravaginal challenges, protection was evident only in the MVA-ID group (vaccine efficacy of 73% per exposure, p=0.006 with 40% of the animals completely protected), but not in the MVA-IM group. Analysis of DC and monocyte activation in blood after MVA immunization revealed markedly higher activation of non-classical (CD16+ CD14-) monocytes and CD11c+ DCs in the MVA-IM group not in the MVA-ID group. Analysis of RNA transcriptome in blood after MVA immunization revealed marked induction of inflammasome pathway in the MVA-IM group but not in MVA-ID group.

CONCLUSIONS: These results demonstrate that MVA-ID vaccination is superior to MVA-IM vaccination for protection against HIV and the route of MVA vaccination markedly influences the quality of T helper response and innate activation that are associated with difference in protection outcome.

OAA0304

PRIMING WITH DNA EXPRESSING TRIMERIC V1V2A244 ALTERS THE IMMUNE HIERARCHY AND FAVORS THE DEVELOPMENT OF V2-SPECIFIC HIV ANTIBODIES IN RHESUS MACAQUES

S. Devasundaram[1], M. Rosati[1], H.V. Trinh[2], M. Rao[2], X.-P. Kong[3], A. Valentin[1], S. Zolla-Pazner[3], G.N. Pavlakis[1], B.K. Felber[1]
[1]National Cancer Institute at Frederick, Frederick, United States, [2]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [3]NYU School of Medicine, New York, United States

BACKGROUND: The RV144 clinical vaccine trial showed that reduced risk of HIV infection is correlated with non-neutralizing antibody (Ab) responses targeting the V1V2 region of the HIV gp120 Env, making this region an important vaccine target. To induce V2-specific Abs, we tested the immunogenicity of a vaccine regimen that includes priming with DNA expressing the trimeric epitope-scaffold V1V2A244 immunogen.

METHODS: The vaccine regimen included 2 DNA primes followed by 3 DNA + protein co-immunization boosts. The "V1V2 group" (N=4) was primed with V1V2A244-2J9C DNA (Jiang, J Virol 2016; Zolla-Pazner, J Virol 2016) and the "gp145 group" " (N=4) was primed with gp145 DNA expressing membrane-bound trimeric Env and soluble gp120. The booster vaccine in both groups consisted of gp145 DNA and GLA-SE-adjuvanted gp120. The V1V2 group also received V1V2A244 DNA in the boost. Antibodies were monitored after the prime and the boost.

RESULTS: The V1V2 group developed robust Ab responses recognizing heterologous trimeric V1V2-scaffold proteins and cyclic V2 from different clades (B,C,E), whereas only low levels of V2 Abs were induced by the gp145 DNA vaccine. The V1V2 DNA-induced Abs also potently recognized gp120 by ELISA and trimeric clade A/ECM244 and clade CCH505 Env anchored on the cell surface of stably transduced HEK293 cells detected by flow cytometry. Peptide mapping showed greater Ab breadth within the V2 region in the V1V2 group, with Abs specific for the V2 peptide RDKKQKVHALFYKLDIVPIE (HXB2 AA166-185), a critical target identified in RV144, which was only found by immunization with the V1V2A244 DNA. Importantly, Ab responses to a V2 peptide with the K169V mutation were drastically reduced, mimicking the specificity of monoclonal and polyclonal Abs induced in RV144 (Liao, Immunity 2016; Zolla-Pazner, PLoS One 2013). The magnititude and breadth of the V2-specific responses were higher in V1V2 group with lower V3 responses.

CONCLUSIONS: Our results demonstrate that priming with DNA expressing trimeric V1V2 focuses the Ab response on the V1V2 region of gp120, inducing cross-clade reactive Abs. This regimen alters the hierarchy of immunodominant Env epitopes, providing a selective advantage for induction the V1V2 Abs associated with protection from SHIV and HIV.

OAA0305

SEQUENCE AND STRUCTURE GUIDED HIV-1 CLADE C TRIMERIC IMMUNOGEN DESIGN TO INDUCE NEUTRALIZING AND V1V2 DIRECTED ANTIBODY RESPONSES

A. Sahoo[1], C. LaBranche[2], S. Shen[2], T.M. Styles[1], V. Velu[1], S. Gangadhara[1], D. Montefiori[2], G.D. Tomaras[2], R.R. Amara[1]
[1]Emory Vaccine Center, Yerkes National Primate Research Center, Emory University, Atlanta, United States, [2]Duke Human Vaccine institute, Duke University School of Medicine, Duke University, Durham, United States

BACKGROUND: About 50% of global HIV-1 infections are due to clade C viruses and there is a great need for the development of stabilized natively-like trimeric clade C gp140 protein immunogen for inducing neutralizing antibodies by vaccination. The C.1086 based gp140 trimer would be of interest as the monomeric gp120 version of this protein is currently being used in a Phase 2a/b clinical study (HVTN702). The unstabilized C.1086 K160N (to improve binding to bnAb PG9) gp140 protein does not induce autologous neutralizing antibodies.

METHODS: Structure and sequence guided screening of 1086.C mutants and characterization by size-exclusion chromatography, NE-EM, improved antibody binding profile, immunogenicity in rabbits, characterization of the serum.

RESULTS: To develop a stable trimer, we adopted recent structure guided strategies to design SOSIP, NFL (Native Flexible Linker) and UFO (Uncleaved Full-Length Optimized) forms of the protein. The NFL and UFO versions yielded higher trimeric fractions than the SOSIP counterpart which predominantly formed aggregates. UFO design was further selected based on improved binding to V1V2 specific bnAb PG16 than C.1086_NFL. Sequence guided mutational analysis of the V2 hotspot region (V2HS,165-181) highlighted K166R to markedly improve binding to the V1V2 trimer-specific bnAb PGT145. Additional structure guided modifications were adopted to improve the stability of the envelope. Variants at V2HS showed significant enhancement in binding to multiple V1V2 directed bnAbs. Alterations of residues at position 173 of the V2HS region was found to influence the immune responses. Following immunization in rabbits, one of the variants at 173 position improved Tier-2 neutralization titres, recognition of membrane anchored envelopes and influenced V1V2 (displayed on gp70 scaffold) from envelopes across diverse clades. One of the neutralizers was able to induce antibodies targeting the V1V2 region which competed with known trimer specific V2 directed bnAbs. We are currently analyzing the neutralization specificity of the serum. Encouragingly, one of the immunogens elicited strong autologous neutralization titer (100-800) in macaques.

CONCLUSIONS: The stabilized C.1086 K160N UFO trimer protein can induce tier-2 neutralizing antibodies and enhance binding antibodies specific to gp70-V1V2 and membrane anchored trimeric Env. We are currently understanding mechanisms by which changes at position 173 would influence the immune responses.

PROTECTIVE EFFICACY OF A VACCINE INDUCING GAG/VIF-SPECIFIC CD8+ T BUT NOT CD4+ T CELLS AGAINST REPEATED INTRARECTAL LOW-DOSE SIVMAC239 CHALLENGES

H. Ishii[1], K. Terahara[2], T. Nomura[1], T. Tokusumi[3], T. Shu[3], H. Suzuki[4], D. Fujiwara[4], H. Sakawaki[5], T. Miura[5], T. Matano[1,6,7]
[1]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, [2]National Institute of Infectious Diseases, Department of Immunology, Tokyo, Japan, [3]ID Pharma Co., Ltd., Ibaraki, Japan, [4]Kirin Holdings Co., Ltd., Yokohama, Japan, [5]Kyoto University, Institute for Frontier Life and Medical Sciences, Kyoto, Japan, [6]University of Tokyo, Institute of Medical Science, Tokyo, Japan, [7]Kumamoto University, Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan

BACKGROUND: Virus-specific CD4+ T-cell responses are crucial for induction of effective CD8+ T-cell responses against virus infection. Vaccine-induced CD4+ T cells, however, can be preferential targets for HIV/SIV infection. Recent studies have indicated the detrimental effect of vaccine–induced CD4+ T cells on HIV vaccine efficacy (J Virol 88:14232, 2014; Sci Transl Med 11:eaav1800, 2019), supporting a rationale for vaccine design inducing HIV-specific CD8+ T-cell responses without HIV-specific CD4+ T-cell induction but with non-HIV antigen-specific CD4+ T-cell help. Based on this concept, we have developed a novel immunogen, CaV11, consisting of tandemly-connected overlapping 11-mer peptides spanning viral Gag capsid (CA) and Vif. This CaV11 immunogen is expected to selectively elicit Gag/Vif-specific CD8+ T cells with inefficient Gag/Vif-specific CD4+ T-cell induction, because the ideal length of CD4+ T-cell epitopes is longer than 11 mers, whereas CD8+ T-cell epitopes are 8-11 mers. In the present study, we evaluated the protective efficacy of a CaV11-expressing vaccine against repeated intrarectal low-dose SIV challenges in rhesus macaques.

METHODS: Twelve rhesus macaques received four times of intramuscular CaV11-expressing DNA vaccination at weeks 0, 1, 3 and 4 and four times of intranasal and intramuscular CaV11-expressing Sendai virus vectors (SeV-CaV11) at weeks 6, 7, 12 and 18. These twelve vaccinated and seven unvaccinated macaques were intrarectally challenged with low-dose (200 $TCID_{50}$) SIVmac239 repeatedly every 2 weeks starting from 6 weeks after the last vaccination.

RESULTS: All the vaccinated animals efficiently induced Gag/Vif-specific CD8+ T-cell responses with inefficient Gag/Vif-specific CD4+ T-cell responses after SeV-CaV11 vaccination. After eight times of SIV challenge, six of the seven unvaccinated macaques were infected, whereas eight of the twelve vaccinated were protected from SIV infection. Kaplan-Meier analysis indicated a significant difference between unvaccinated and vaccinated (P = 0.0341 by Log-rank test).

CONCLUSIONS: The present study for the first time indicates the potential of canonical CD8+ T cells induced by Env-independent vaccination to protect HIV acquisition, suggesting that CD8+ T-cell induction by using this immunogen design is a promising HIV vaccine strategy.

OAA0307

CO-IMMUNIZATION OF DNA AND PROTEIN IN THE SAME ANATOMICAL SITES INDUCES SUPERIOR PROTECTIVE IMMUNE RESPONSES AGAINST SHIV CHALLENGE

B.K. Felber[1], Z. Lu[1], X. Hu[1], A. Valentin[1], M. Rosati[1], J.A. Weiner[2], X. Shen[3], C.C. LaBranche[3], D.C. Montefiori[3], W.B. Williams[3], K.O. Saunders[3], H.V. Trinh[4], M. Rao[4], M.S. BACKGROUND: We compared immunogenicity and protective efficacy of an HIV vaccine comprised of DNA (env and gag) and Env proteins by co-administration of DNA and Protein in the same muscle or by separate administration of the DNA and Protein components in contralateral sites.

METHODS: Female rhesus macaques (20 animals/group) were immunized with a 6-valent vaccine including DNA plasmids expressing membrane-anchored gp145 Env sequentially isolated from a HIV-1 infected individual (CH505). The DNA was delivered by IM injection followed by in vivo electroporation. The vaccine also included a gp120 Env protein component matching the sequences encoded by the plasmid DNA and adjuvanted in GLA-SE. The DNA and protein vaccine components were administered in the same anatomical sites ('Co-administration') or in contralateral sites ('Separate Administration') After 6 vaccinations in 4-month intervals, the macaques were challenged by weekly intravaginal exposures with low dose T/F tier-2 SHIV CH505 stock.

RESULTS: Only macaques in the co-administration vaccine group were protected against SHIV CH505 acquisition, with a 67% risk reduction per exposure after 15 weekly IVAG challenges. Macaques in the co-administration group developed higher Env-specific humoral and cellular immune responses. Non-neutralizing Env antibodies, ADCC and antibodies binding to Fc-gamma Receptor IIIa were associated with decreased transmission risk. These data suggest that simultaneous recognition, processing and presentation of DNA + Env protein in the same draining lymph node play a critical role in the development of protective immunity.

CONCLUSIONS: Co-immunization of DNA+Protein in the same muscle is superior for inducing protective immune responses against repeated tier-2 SHIV challenge. The advantage of co-immunization vaccine regimens targeting immunogens to the same draining LN could also be beneficial to other vaccine modalities and other pathogens.

OAA04 NEW INSIGHTS INTO THE HIV RESERVOIR

OAA0402

CONTRIBUTION OF MONOCYTES AND CD4 T CELL SUBSETS IN MAINTAINING VIRAL RESERVOIRS IN SIV-INFECTED MACAQUES TREATED EARLY AFTER INFECTION WITH ANTIRETROVIRAL DRUGS

H. Rabezanahary[1], J. Clain[1], G. Racine[1], G. Andreani[1], G. Benmadid-Laktout[1], O. Zghidi-Abouzid[1], G. Silvestri[2], J. Estaquier[1,3]
[1]Centre de Recherche du CHU de Québec, Université Laval, Québec, Canada, [2]Yerkes National Primate Research Center, Emory University, Atlanta, United States, [3]INSERM U1124, Université Paris Descartes, Paris, France

BACKGROUND: Although early antiretroviral therapy (ART) suppresses viral replication, ART discontinuation results in viral rebound, indicating early viral seeding and absence of full eradication. Therefore, identified the nature of infected cells and sanctuaries that contribute to viral rebound are crucial for HIV cure.
METHODS: Rhesus macaques (RMs) were infected intravenously with SIVmac251 (20 AID50). Some of them were treated with ART at day 4 post infection. RMs were sacrificed at different time point post-infection during natural infection (no ART), under ART (ART) and after ART interruption (ATi). Lymphoid tissues, including spleen, mesenteric and axillary/inguinal LNs, and intestine (colon, ileum, and jejunum parts) were recovered immediately after euthanasia. By flow cytometry, CD4 and monocyte cell subsets were sorted. Viral load and cell-associated viral DNA and RNA were quantified by RT-PCR as well as productive infectious viruses.
RESULTS: We demonstrated that, in the absence of ART, monocyte cell subsets harbor viral DNA and RNA, and viruses produced after stimulation are infectious. We also demonstrated that TEM and TFH cells are the main preferential SIV target cells producing infectious SIV after T cell activation. We provided evidence that early ART, administrated at day 4 post-infection, efficiently prevents viral dissemination. Furthermore, our results highlighted that early ART prevents infection of monocyte cell subsets in different tissues whereas ART did not prevent the establishment of viral reservoirs in TEM and TFH cells from visceral tissues including spleen and mesenteric LNs. We also observed that early ART drastically reduced inflammation. Consistent with previous reports, ART interruption is associated with viral rebound in less than 2 weeks, leading to viral dissemination and targeting both monocyte and T cell subsets.
CONCLUSIONS: Altogether, our results demonstrated that early ART prevents viral infection of monocytes but is unable to prevent infection of two major CD4 T cell subsets. Given the rapid dynamics of viral rebound after ATi, our results in RMs suggests that ART is actively suppressing viral production in infected cells, but once interrupted, these cells refill the pool of cells which are the main targets for SIV.

CELL PROLIFERATION CONTRIBUTES TO THE INCREASE OF GENETICALLY INTACT HIV OVER TIME

B. Horsburgh[1], B. Hiener[1], K. Fisher[1], J.-S. Eden[1], E. Lee[1], S. von Stockenstrom[2], L. Odevall[2], J. Milush[3], T. Liegler[3], R. Hoh[3], R. Fromentin[4], N. Chomont[4], S. Deeks[3], F. Hecht[3], S. Palmer[1]
[1]The Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, [2]Karolinska Institutet, Department of Microbiology, Tumor and Cell Biology, Stockholm, Sweden, [3]University of California, Department of Medicine, San Francisco, United States, [4]Université de Montréal, Centre de Recherche du CHUM and Department of Microbiology, Infectiology and Immunology, Montreal, Canada

BACKGROUND: Effective HIV eradication strategies require an understanding of the mechanisms maintaining persistent HIV during therapy. Therefore, we examined the role of memory cell proliferation in maintaining genetically-intact proviruses over 4 years of effective therapy.
METHODS: Naïve (N), central (CM), transitional (TM) and effector (EM) memory CD4+ T-cells were sorted from the peripheral blood of two participants on long-term ART. Additional sequences from naïve, CM HLA-DR+/DR-, TM HLA-DR+/DR- and EM HLA-DR+/DR- T cells were obtained 4 years later. Full-length individual proviral sequencing was used to characterise proviruses as intact or defective. Clusters of ≥2 100% genetically identical proviral sequences - indicative of host cell proliferation – were identified.
RESULTS: A total of 287 and 448 sequences were isolated from the first and second time-points, and 34 (12%) and 90 (20%) were considered intact. At both times the frequency of intact genomes differed between cell subsets, EM>TM>CM/N. In each subset, HLA-DR+ memory T-cells contained more intact provirus than HLA-DR- memory T-cells. The proportion of identical sequences was significantly higher in intact proviruses compared to defective at the second time-point (85% vs 41%, p=0.03), but not the first. However, when the cell of origin was taken into account there was no significant difference in the proportion of 100% identical intact and defective genomes (p=0.133). There was a significant correlation at the second time-point between the proportion of identical sequences overall and the proportion of intact proviruses (R2=0.58-67, p=0.02-0.04). The majority (44/51, 86%) of sequences observed at both time-points (over four years) were found in cells of the same memory phenotype.
CONCLUSIONS: Genetically intact proviruses were found most frequently in the more differentiated EM cells. However, the frequency of intact proviruses was increased in each memory cell subset when the cell expressed HLA-DR, highlighting the role of cellular activation in maintaining the reservoir. Moreover, the correlation between cellular proliferation and intact provirus highlights the importance of host cell proliferation in maintaining HIV over time. These findings demonstrate the importance of limiting cellular activation, differentiation and proliferation in strategies aimed at reducing the reservoir.

OAA0404

MULTIPLE SANCTUARY SITES FOR INTACT AND "DEFECTIVE" HIV-1 IN POST-MORTEM TISSUES IN INDIVIDUALS WITH SUPPRESSED HIV-1 REPLICATION: IMPLICATIONS FOR HIV-1 CURE STRATEGIES

H. Imamichi[1], V. Natarajan[2], F. Scrimieri[2], M. Smith[1], Y. Badralmaa[2], M. Bosche[2], J. Hensien[1], T. Buerkert[1], W. Chang[2], B. Sherman[2], K. Singh[1], H.C. Lane[1]
[1]NIAID, NIH, CMRS, LIR, Bethesda, United States, [2]Frederick National Laboratory for Cancer Research, Frederick, United States

BACKGROUND: The rapid viral rebound observed following treatment interruption, despite prolonged time on ART with plasma HIV-RNA levels <40 copies/ml, suggests persistent HIV-1 reservoirs outside of blood. The purpose of the present study was to characterize post-mortem tissues for HIV-1 DNA and RNA in an effort to identify potential sanctuary sites in the body.

METHODS: Autopsy specimens were collected from 8 donors with suppressed HIV-1 replication at the time of death (blood HIV-RNA levels <5 copies/1 µg host-genomic RNA). In addition to blood, tissue specimens were collected from lymph nodes, spleen, GI-tract, CNS, lung, heart, kidney, liver pancreas and testes. Levels of HIV-DNA and HIV-RNA were determined using quantitative PCR. HIV-1 proviruses were analyzed by 5'LTR-to-3'LTR PCR single-genome amplification of near full-length HIV-1 and direct amplicon sequencing.

RESULTS: HIV-DNA and HIV-RNA species were detected in all 8 donors and ranged from <5 to 943 copies/2 µg gDNA and <5 to 102 copies/1 µg gRNA. While HIV-1 provirus and cell-associated HIV-RNA could be found in all donors, no universal tissue hotspots were found across the donors. A total of 1,329 HIV-1 provirus sequences were obtained (average 222, range 50-745, per donor). Intact proviruses represented 5.1% (range 0-22.5%) of provirus in the blood and tissues. Lymph nodes had the greatest number of intact proviruses. "Defective" proviruses containing lethal genetic alterations or large internal deletions showed wide-spread tissue distributions. The relative abundance varied by donor and much of the proviral DNA was associated with clonal expansions. Expanded provirus clones represented 43% (range 22-67.4%) of all HIV-1 proviruses detected. Of note, similar findings were found in 3 donors with active HIV-1 replication (blood HIV-RNA levels ≥5 copies/1 µg gRNA, range: 15-3,550) at the time of death.

CONCLUSIONS: We have demonstrated wide-spread tissue distributions of HIV-1 proviruses and viral RNA in an autopsy study of individuals with suppressed HIV-1 replication. There were no universal hot spots with concentrations of HIV-1 proviruses and/or viral RNA in tissues. These data demonstrate persistent HIV-1 transcription at the tissue level, absence of common tissue sanctuary sites, and thus highlight the difficulties in designing effective HIV-1 cure strategies.

OAA0405

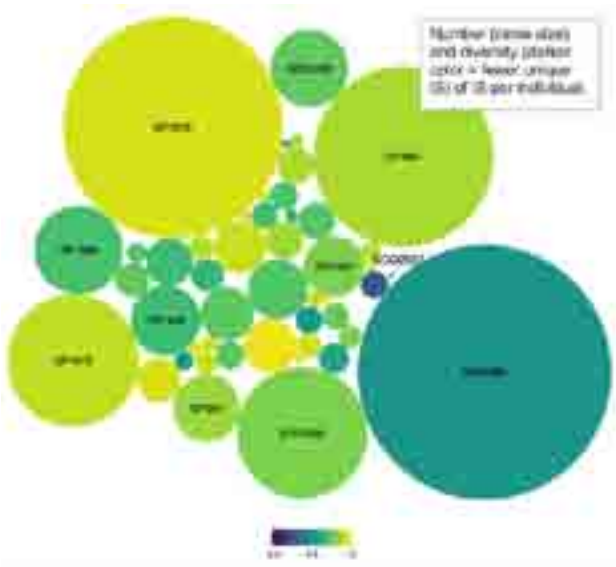
HIGH-THROUGHPUT CHARACTERIZATION OF HIV LATENT RESERVOIR DEMONSTRATES INTEGRATION INTO GENES ASSOCIATED WITH INFLAMMATION, CELL CYCLE, AND NUCLEAR ENVELOPE ASSEMBLY, ENRICHMENT IN ACCESSIBLE CHROMATIN, AND LARGE AMOUNTS OF DEFECTIVE PROVIRUS

P. Roychoudhury[1,2], K. Haworth[2], H. Zhu[1], C. Levy[1,2], M.-L. Huang[1], C. Thanh[3], T. Henrich[3], R. Hoh[3], S. Deeks[3], F. Hladik[2,1], H.-P. Kiem[2,1], K. Jerome[1,2], S. Lee[3]
[1]University of Washington, Seattle, United States, [2]Fred Hutchinson Cancer Research Center, Seattle, United States, [3]University of California, San Francisco, United States

BACKGROUND: HIV integration is a key step in the viral replication cycle. Prior *in vivo* studies have demonstrated that integration in specific genes may impact reservoir size and dynamics.

METHODS: HIV integration sites (IS) were identified from bulk CD4-enriched cryopreserved PBMCs from HIV+ ART-suppressed individuals. Publicly available chromatin accessibility data (ATAC-seq, DNase-seq) and gene sets (MSigDB) were analyzed in relation to IS data. Intact HIV DNA was estimated using a ddPCR assay detecting 5 regions of the HIV genome.

RESULTS: Participants in this cross-sectional study were mostly male (96%, n = 50) with median age 45y, nadir CD4+ T cell count 364 cells/mm^3, pre-ART HIV RNA 4.7 $\log_{10}$copies/mL, 4.7y on ART, and 1.4 years to ART initiation. We identified 38,214 unique IS with 80% in genes, and over-representation of gene sets associated with chromatin accessibility, inflammation, and nuclear envelope assembly. Although only 5% of IS (SD = 1.9%) were in known open chromatin regions, this exceeds the average amount of accessible chromatin in the genome. Most IS were seen 1-2 times; 26 individuals had clone sizes >3. The largest expanded clone was found in a participant (SCO2557) with low CD4 nadir and poor immune recovery (CD4<200); the associated IS was in the *PIR* gene involved in NF-kB signaling. The only female participant (SCO2568) had expanded clones in *RBM6* and *CUL9*, encoding tumor suppressor proteins, and low CD4 nadir, but subsequent immune recovery. Across participants, the majority of proviral DNA was found to be defective.



CONCLUSIONS: In the largest *in vivo* HIV integration study to date, we observed enrichment of IS in open chromatin, genes regulating cell cycle, inflammation, and nuclear envelope assembly. We showed that the majority of HIV DNA is defective viral sequences and highlight two unique clinical cases warranting further longitudinal studies in participants with poor immunologic recovery and in female participants.

OAA0406

THE SIZE OF HIV RESERVOIR IS ASSOCIATED WITH TELOMERE SHORTENING AND IMMUNOSENESCENCE IN EARLY ART-TREATED HIV-INFECTED CHILDREN

A. De Rossi[1], A. Dalzini[1], G. Ballin[1], S. Dominguez-Rodriguez[2], P. Rojo Conejo[2], C. Foster[3], P. Palma[4], L. Sessa[4], E. Nastouli[5], S. Pahwa[6], P. Rossi[4], C. Giaquinto[1], EPIICAL Consortium
[1]University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy, [2]Hospital Universitario 12 de Octubre, Madrid, Spain, [3]Imperial College Healthcare NHS Trust, London, United Kingdom, [4]Bambino Gesù Children's Hospital, Rome, Italy, [5]UCL Great Ormond Street Institute of Child Health, London, United Kingdom, [6]University of Miami, Miami, United States

BACKGROUND: HIV infection is linked to premature senescence, with increased risk of aging-associated illnesses. Early ART has been associated with a reduced HIV reservoir in HIV-perinatally infected children (PHIV), but its impact on the senescence process is an open question. Telomeres are critical for cellular replicative potential and their shortening is a marker of cellular senescence and aging process. We investigated the relationship between immunosenescence and HIV reservoir in PHIV enrolled in a multicenter cross-sectional study (CARMA, EPIICAL consortium).
METHODS: 37 PHIV, who started ART <2 years of age and had undetectable viremia for at least 5 years, were enrolled in this study. HIV-DNA copies on CD4 cells and relative telomere length and levels of T-cell receptor rearrangement excision circle (TREC, marker of thymic output) on CD4 and CD8 cells were quantified by qPCR. Senescent and activated CD4 and CD8 cells were estimated by flow cytometry. To explore the associations between cellular parameters, HIV reservoir and age at ART initiation, data were analyzed using a multivariable Poisson regression (adjusted for baseline % CD4, plasmaviremia, age at reservoir measurement, and age at ART initiation as interaction term).
RESULTS: HIV reservoir was significantly (p<0.001) associated with immunosenescence (1.23[1.21-1.26]) and telomere shortening (0.15[0.13-0.17]) in CD4 cells, and immune activation (3.67[3.49-3.85]) and TREC levels (1.08[1.06-1.11]) in CD8 cells. These associations decreased by 1%, 10%, 6% and 6%, respectively, for each month ART was delayed. Early treated PHIV (ART initiation ≤6 months of age) displayed significantly lower HIV-DNA level (89[56-365] *vs* 552[303-1001] copies/10^6 cells) and % CD4 senescent cells (1.0[0.5-2.7] *vs* 2.9[2.0-6.3]) than late treated ones (see Figure).
CONCLUSIONS: This is the first demonstration that HIV reservoir is directly associated with telomere shortening and immunosenescence on CD4 cells. Early ART initiation restricts the size of viral reservoir and the premature immunosenescence in PHIV.

OAB01 ADOLESCENTS AND YOUNG PEOPLE

OAB0102

NEUROCOGNITIVE CORRELATES OF ALCOHOL AND CANNABIS USE PROBLEMS AMONG ADOLESCENTS AND EMERGING ADULTS LIVING WITH HIV: ATN 129

B. Millar[1], V. Dinaj-Koci[2], H. Budhwani[3], S. Naar[4], S. Nichols[5], Adolescent Medicine Trials Network for HIV/AIDS Interventions (ATN)
[1]Hunter College, City University of New York (CUNY), PRIDE Health Research Consortium, New York, United States, [2]Wayne State University, Department of Family Medicine and Public Health Sciences, Detroit, Michigan, United States, [3]University of Alabama at Birmingham, School of Public Health, Department of Health Care Organization and Policy, Birmingham, Alabama, United States, [4]Florida State University, Center for Translational Behavioral Science, Tallahassee, Florida, United States, [5]University of California, San Diego, School of Medicine, Department of Neurosciences, La Jolla, United States

BACKGROUND: Substance use represents an important health issue for youth living with HIV (YLWH). Accordingly, identifying neurocognitive factors influencing substance use among YLWH is vital. We tested associations between three often-tested neurocognitive factors -- inhibitory control (Flanker task), risk-taking (Balloon Analogue Risk Task, BART), and delay discounting (Money Choice Questionnaire, MCQ) -- and alcohol and cannabis use among YLWH aged 17-24. We adjusted for working memory, processing speed, and episodic memory, areas commonly affected by HIV disease.
METHODS: Participants enrolling for a U.S.-based comparative effectiveness trial for alcohol-using YLWH from 2014-2017 reported on demographics and completed computerized neurocognitive tasks: Flanker Task (NIH Toolbox), MCQ, BART, as well as Working Memory (NIH Toolbox List Sorting), Processing Speed (Visual Patterns; NIH Toolbox), and immediate recall on the Hopkins Verbal Learning Test-Revised. Alcohol and cannabis use frequency and associated problems were summarized using the ASSIST's substance use involvement score (log-transformed).
RESULTS: Of the 179 participants (mean age, 21.4), 18 reported perinatal HIV infection. Most identified as Black (82%), and gay or bisexual males (72%). Overall, comparatively lower processing speed and immediate recall, though not working memory, were observed in this sample relative to age-matched norms. Linear models, adjusting for age, gender, and recent cannabis use, showed

greater alcohol substance involvement was associated with lower Flanker (b=-.01, p=.03) and BART (b=-.01, p=.05), but not MCQ. Adding HIV-related covariates (working memory, processing speed, immediate recall, and whether perinatally-infected), only Flanker remained significant (b=-.01, p=.03). Among the 151 cannabis-using participants, models adjusting for age and gender showed greater cannabis substance involvement was associated only with lower Flanker scores (b=-.00, p=.03).

Adding in the above HIV-related covariates, Flanker remained significant (b=-.00, p<.05). Scoring one standard deviation lower on Flanker was associated with a 1.23 point and 1.15 point increase on substance involvement scores (range: 0-39) for alcohol and cannabis, respectively.

CONCLUSIONS: Greater alcohol and cannabis involvement was consistently associated with lower ability to inhibit attention to irrelevant stimuli, but not with risk-taking (adjusted for HIV-related covariates) or delay discounting. This highlights the importance of inhibitory control and executive functioning more generally for substance use prevention among YLWH.

OAB0103

CONSTRUCT VALIDITY SUPPORTS USE OF A NOVEL, TABLET-BASED NEUROCOGNITIVE ASSESSMENT FOR ADOLESCENTS AND YOUNG ADULTS AFFECTED BY PERINATAL HIV FROM VULNERABLE COMMUNITIES IN THE UNITED STATES

R.N. Robbins[1], J. Liu[2], A.F. Santoro[1], N. Nguyen[1], J. Raymond[1], E. Siegel[1], S. Espinel[1], C. Dolezal[1], A. Wiznia[3], E. Abrams[4], C.A. Mellins[1]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, New York, United States, [2]New York State Psychiatric Institute, Psychiatry, New York, United States, [3]Albert Einstein College of Medicine and Jacobi Medical Center, Department of Pediatrics, Bronx, United States, [4]ICAP at Columbia University, Mailman School of Public Health, New York, United States

BACKGROUND: Neurocognitive impairment is common among adolescents and young adults (AYA) living with perinatally-acquired HIV (PHIV) and perinatal HIV-exposure without HIV-infection (PHEU). However, current assessment methods are time-consuming, require specialized forms, equipment and highly trained personnel to administer and score which precludes their use in many contexts. NeuroScreen is a novel, highly automated, relatively brief (25 minutes), easy-to-use by any staff, tablet-based neurocognitive assessment tool that provides real-time results, with potential to make neurocognitive assessments more available. This study examined how well (i.e., construct validity) the NeuroScreen app measures the neurocognitive domains of processing speed, working memory and executive functioning in AYA with PHIV and PHEU based on established gold-standard, paper-and-pencil tests of those domains.

METHODS: Participants came from an ongoing longitudinal study (CASAH) of AYA with PHIV and PHEU from vulnerable communities in New York City. To assess validity, at their last follow up, 62 AYA (33 PHIV, 29 PHEU) completed eight NeuroScreen tests of processing speed, working memory, executive functioning, as well as the gold-standard Trail Making Tests A and B (TMT A [processing speed] and B [executive functioning]), and WAIS-IV Digit Span Forwards and Backwards [working memory]) . Pearson correlation coefficients were computed between the paper-and-pencil and NeuroScreen tests.

RESULTS: Median age of participants was 24 years (IQR 22-26); 64% were male, 46% Latinx, and 44% African-American. The paper-and-pencil and NeuroScreen tests of processing speed, working memory, and executive functioning were all significantly correlated with each other, respectively (Table 1).

Gold-Standard Tests → NeuroScreen Tests ↓	TMT A[a] Correlation Coefficient	Digit Span Forwards[b] Correlation Coefficient	Digit Span Backwards[b] Correlation Coefficient	TMT B[c] Correlation Coefficient
Trail Making 1[a]	0.28*	-0.21	-0.33**	0.26*

*Note: *p<0.05, **<0.01, ***p<0.001;*
test of: [a]processing speed, [b]working memory [c]executive functioning

[Table 1. Pearson Correlation Coefficients between Gold-standard (paper-and-pencil) and NeuroScreen tests]

CONCLUSIONS: Results provide support for use of NeuroScreen with this population. Given its significant associations with gold-standard tests, as well as ease-of-use, automation, and real-time results, NeuroScreen has great potential as a scalable assessment tool for clinical and research practice – providing access to much needed neurocognitive assessments for AYA at risk for neurocognitive deficits from HIV and other vulnerabilities.

OAB0104

HIGH LEVELS OF MENTAL HEALTH RESILIENCE AMONG ADOLESCENTS LIVING WITH HIV IN THAILAND AND CAMBODIA

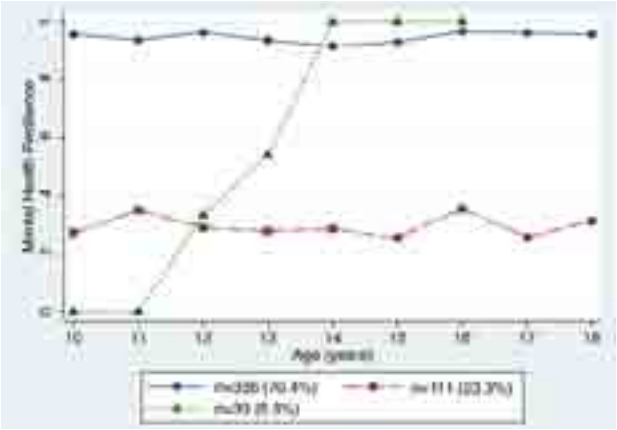
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, New York, United States, [2]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Science, Chicago, United States, [3]National Center for HIV/AIDS Dermatology and STDs, Phnom Penh, Cambodia, [4]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [5]Faculty of Medicine, Khon Kaen University, Department of Pediatrics, Khon Kaen, Thailand, [6]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [7]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [8]Nakornping Hospital, Chiang Mai, Thailand, [9]Prapokklao Hospital, Chanthaburi, Thailand, [10]Faculty of Humanities, Chiang Mai University, Department of Psychology, Chiang Mai, Thailand, [11]Missouri Institute of Mental Health/University of Missouri-St. Louis, Missouri, St. Louis, United States, [12]The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [13]Faculty of Medicine, Chulalongkorn University, Department of Pediatrics, Bangkok, Thailand

BACKGROUND: Adolescents affected by HIV (i.e., perinatally acquired HIV [PHIV] and HIV-exposed but uninfected [HEU]) are at risk for mental health (MH) problems; many, however, do not have MH problems. We used group-based trajectory modeling to identify resilient MH trajectories and their predictors.

METHODS: PHIV, HEU and HIV-unexposed, -uninfected (HUU) Thai and Cambodian adolescents from the RESILIENCE Study underwent four yearly MH assessments. Resilient MH was defined as no MH problem at any study visit on the Child Behaviour Checklist, Children's Depression Inventory (<18 years) or Center for Epidemiological Studies-Depression Scale (≥18 years). Resilience trajectory assignment was made through maximum likelihood estimation and Bayesian Information Criterion. Multinomial logistic regression examined baseline predictors of trajectories.

RESULTS: 477 adolescents (201 PHIV, 131 HEU and 145 HUU; females 56%), median age 13 years (IQR 11-15) at enrollment, were evaluated over a median of 3 (IQR 2-4) visits. Analyses revealed a 3-trajectory classification (Figure 1). Group 1 (n=336) had consistently high resilience (91-97% of visits with no MH problems). Group 2 (n=111) had consistently low resilience (25-35% of visits with no MH problems). Group 3 (n=30) had increasing resilience from ages <11 to 15. Adolescents in Group 2 were more likely to: be PHIV than HUU (relative risk ratio [RRR] 1.46 (95%CI 1.00 – 2.12)), have lost any parent (RRR 1.74 (95%CI 1.25 – 2.43), and live with someone with MH problems (RRR 1.92 (95%CI 0.80 – 4.65)) than adolescents in Group1. Household income and sex were not associated with group membership.



[Figure 1. Group based trajectories of mental health resilience (blue circle = Group 1; red square = Group 2; green triangle = Group 3)]

CONCLUSIONS: Most adolescents in the RESILIENCE Study exhibited MH resilience, including those with PHIV. The strongest predictors of low MH resilience were PHIV, losing any parent, and living with a person with MH problems. MH interventions for AYA experiencing parental loss and other adverse family events may increase the likelihood of resilient MH outcomes as youth age.

OAB0105

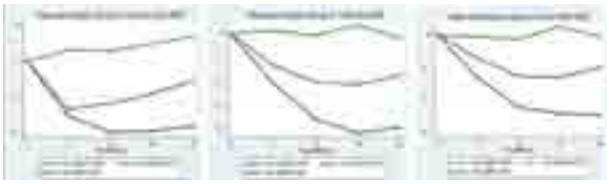
DEPO-PROVERA WORSENS BONE LOSS WITH TDF-CONTAINING ART INITIATION IN YOUNG WOMEN

F.K. Matovu[1,2,3], J.A. Babirye[1], M. Nabwana[1], P. Musoke[4,1], M. Beksinska[5], J.M. Pettifor[6], M.G. Fowler[7], T.T. Brown[8], for the BONE:CARE Study Team
[1]Makerere University-Johns Hopkins University Research Collaboration, Kampala, Uganda, [2]Makerere University College of Health Scienced, School of Public Health, Kampala, Uganda, [3]Consortium for Advanced Research and Training in Africa/ University of Witwatersrand, Johannesburg, South Africa, [4]Makerere University College of Health Sciences, Department of Pediatrics and Child Health, Kampala, Uganda, [5]Maternal Adolescent & Child Health (MatCH) Research, Johannesburg, South Africa, [6]University of the Witwatersrand, Department of Paediatrics, Johannesburg, South Africa, [7]Johns Hopkins University School of Medicine, Department of Pathology, Baltimore, United States, [8]Johns Hopkins University, Division of Endocrinology, Diabetes, and Metabolism, Baltimore, United States

BACKGROUND: Antiretroviral therapy (ART) initiation with tenofovir disoproxil fumarate (TDF) is associated with bone mineral density (BMD) loss. Among women of reproductive age, depot medroxyprogesterone acetate (DMPA, Depo Provera) also negatively impacts BMD. Our goal was to determine the combined BMD effects of DMPA and TDF initiation in young women over two years, compared to a matched HIV-uninfected group.

METHODS: Women were recruited from 11 HIV care centers and general health facilities around Kampala, Uganda and classified based on their combination of HIV status, TDF use and DMPA use. We compared 3 groups: women initiating TDF-containing ART with (HIV+/DMPA+/TDF+) and without DMPA (HIV+/DMPA-/TDF+) and an HIV-uninfected control group not taking DMPA (HIV-/-DMPA-/TDF)-. All HIV+ women were ART-naïve at baseline. BMD assessments of lumbar spine(LS), total hip(TH) and femoral neck(FN) were done using dual energy x-ray absorptiometry at 6-monthly intervals. We used repeated measures analyses to compare rate of change, calculated as percent (%) change in BMD/ year.

RESULTS: Between March 2015 and October 2017, we enrolled 265 HIV-infected women initiating TDF-containing ART (159 DMPA users, 106 non-hormonal users), and 69 uninfected. Median age was 26 years. Baseline BMD was not significantly different from that of HIV-uninfected controls. Annualized rates of BMD loss were higher in HIV-infected women with greatest loss occurring in DMPA users compared to HIV-infected non-hormonal users, or uninfected controls at all sites: 4.0%(-4.4, -3.6) vs. -1.8%(-2.2, -1.4) vs. 0.8%(0.4, 1.1) at LS, -2.1%(-2.3, -1.9) vs. -0.9%(-1.1, -0.6) vs. –0.0%(-0.4, 0.3) TH, and -2.5%(-2.8, -2.2) vs. -1.0%(-1.3,-0.7) vs. 0.1%(-0.3, 0.5) FN respectively. These changes were significantly different between the three groups, all p-values <0.05 (figure).



[Figure: Mean percent change in BMD among HIV infected DMPA, and no-hormonal users initiating TDF based ART compared to uninfected controls]

CONCLUSIONS: Concomitant DMPA use was associated with a doubling of BMD loss in young women initiating TDF-containing ART. Newer treatment bone sparing regimens like tenofovir alafenamide-based ART may mitigate BMD loss and early aging among HIV-infected women.

OAB0106

OPTIMIZATION TO DOLUTEGRAVIR-BASED ART IN A COHORT OF VIRALLY SUPPRESSED ADOLESCENTS IS ASSOCIATED WITH AN INCREASE IN THE RATE OF BMI CHANGE AND ODDS OF BECOMING OVERWEIGHT

N. Thivalapill[1], N. Mthethwa[2], S. Dlamini[2], J. Petrus[2,3], T. Simelane[2], X. Katembo[2], M. Abadie[2,3], F. Anabwani[2], S. Perry[2,3], N. Mthethwa[4], H.L. Kirchner[3,5], A. Mandalakas[3], B. Lukhele[2], A. Kay[2,3]
[1]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [2]Baylor Children's Foundation-Eswatini, Mbabane, Eswatini, [3]Baylor College of Medicine, Pediatrics, Houston, United States, [4]Eswatini National AIDS Program, Mbabane, Eswatini, [5]Geisinger Health System, Department of Population Health Sciences, Geisinger, United States

BACKGROUND: Antiretroviral therapy (ART) regimens that contain Dolutegravir (DTG) have been reported to be associated with increases in body mass index (BMI). However, this relationship has been poorly elucidated in adolescents, especially those in Sub-Saharan Africa.

METHODS: BMI measurements in a retrospective observational cohort of 605 virally suppressed (< 200 copies/ml[3]) adolescents living with HIV and enrolled in care at a clinical site in Eswatini, were analyzed between 1 year prior to DTG initiation and up to 1 year after DTG initiation. 295 females and 310 males had an average of 6.4 visits and a total of 4,040 visits within the study period. Two random-effects linear spline models, with knots at DTG initiation, were used to model the rate of change in BMI and the odds of becoming obese or overweight, as defined by WHO BMI-for-age cutoffs, while adjusting for sex, DTG companion drugs, previous ART regimens, and age at DTG initiation.

RESULTS: In the first model, the rate of change in BMI was 0.316 kg/m^2 per year prior to DTG initiation while the rate of change after DTG initiation was 0.941 kg/m^2 per year ($p < 0.0001$). The second model reported no change in the odds of becoming overweight or obese prior to DTG initiation (OR = 0.998, p = 0.136). After DTG initiation, the odds of becoming overweight or obese increased by approximately 1% every day (OR = 1.010, p = 0.015). Patients on TDF-3TC-DTG compared with ABC-3TC-DTG had higher BMIs on average, as did females compared with males. BMI did not vary significantly by previous ART regimens (nevirapine or efavirenz).

CONCLUSIONS: The results suggest that DTG initiation is associated with an increase in the rate of BMI change and an increase in the odds of becoming either overweight or obese in adolescents living with HIV. Further investigation is required to assess how DTG impacts BMI in adolescents following a longer duration of treatment. Future work in a larger sample of this cohort is planned to estimate a predictive tool to identify adolescents who are most likely to become overweight or obese after being optimized to DTG.

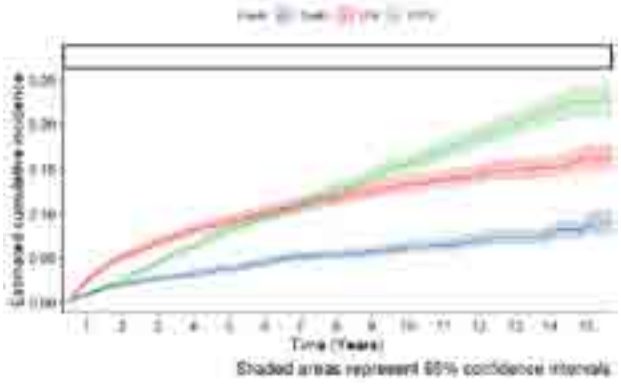
LATE-ONSET OPPORTUNISTIC INFECTIONS WHILE ON ART IN LATIN AMERICA

I. Núñez-Saavedra[1], B. Crabtree-Ramirez[1], B.E. Shepherd[2], T.R. Sterling[2], P. Cahn[3], B. Grinsztejn[4], C.P. Cortes[5], D. Padgett[6], J. Sierra-Madero[1], C. McGowan[2], A.K. Person[2], Y. Caro-Vega[1], Caribbean, Central and South America network for HIV epidemiology (CCASAnet) study group
[1]Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico, [2]Vanderbilt University, Nashville, United States, [3]Fundación Huésped, Buenos Aires, Argentina, [4]Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [5]Fundación Arriarán, Santiago, Chile, [6]Hospital Escuela Universitario, Tegucigalpa, Honduras

BACKGROUND: Incidence of late-onset (occurring after 6 months of antiretroviral therapy [ART] start) AIDS-defining opportunistic infections (LOIs) and factors associated to them are largely unknown in resource-limited settings. The aim of this study was to describe the incidence and risk factors of LOIs in 5 sites from Latin America as part of the Caribbean, Central and South America network for HIV epidemiology (CCASAnet).

METHODS: We included all adults ART-naive patients enrolled at CCASAnet sites in Argentina, Brazil, Chile, Honduras, and Mexico from 2001-2015 who remained in care after 6 months of ART. We excluded patients with unavailable prior AIDS status. Among those who developed a clinical outcome, we report median time to LOI, death and LTFU. Using a Fine and Gray competing risk model (treating death and LTFU as competing events) we estimated the cumulative incidence of each outcome over time and calculated sub-distribution hazard ratios.

RESULTS: 5966 patients were elegible. Median follow-up was 5.5(IQR 3.01-9.06) years. 1837(31%) patients had a clinical outcome (701[38%] were LOIs). Estimated cumulative incidence at 5 years was of 9% for LOIs, 8% for LTFU, and 4% for death (fig1). Commonest LOIs were tuberculosis (27%), esophageal candidiasis (13%), and P. jirovecii pneumonia (12%). Median time to event was 2.5 years for LOIs, 3.4 for death, and 4.5 for LTFU. Having an AIDS defining-event during the first 6 months of treatment (HR:1.97[1.57-2.46]) , lower CD4 count at ART start (HR:1.33[1.33-1.33] for CD4:100vsCD4:300), and starting ART earlier years (HR:1.35[1.33-1.37] for 2005vs2015) were significantly associated with a higher risk of LOI.



[Figure 1: Cumulative incidence estimates for LOI, Death and LTFU]

CONCLUSIONS: In our cohort, LOIs continued to occur late during follow up. Risk factors were similar to those usually associated with early opportunistic infections. Closer long term follow up may be

warranted in patients with lower CD4 at ART start and those initiating during the earlier years of the cohort.

BACKGROUND: Immune checkpoint inhibitors (ICPi) are a major advance in cancer treatment. Whether they can act as a latency reversal agent towards an HIV cure is yet unknown, with still sparse immune-virological data.
METHODS: OncoVIRIM is a biological sub-study of the ongoing ANRS CO-24 OncoVIHAC prospective multicenter cohort including virally suppressed PLHIV treated with anti-PD1 for cancer. Blood samples were obtained at baseline and before different cycles (cycles 2, 3/4, 9, 15/18, 27/36, 51). Were evaluated by flow cytometry: T cell counts (CD3, CD4, CD8), T cell differentiation and activation markers (CD45RA, CCR7, CD27 and CD69, CD27, CD38, Ki67, HLA-DR), ICP expression, and HIV-specific T cells measured by intracellular cytokine staining (ICS) ; by PCR: ultrasensitive plasma HIV-RNA and total cell associated HIV-DNA.
RESULTS:

	Median baseline (range)	Median delta (D) or median fold change (FC) from C2 to D0 (n=)	Median delta (D) or median fold change (FC) from last point to D0 (n=)	p between C2 and D0 (Wilcoxon signed-rank test)	p between last point and D0 (Wilcoxon signed-rank test)
CD4 HLA-DR+	3,48% (0,52-6,17)	2,91 (D, n=10)	-0,26 (D, n=12)	0,0039	0,5693
CD8 PD1+	28,8% (20-42)	-24,1 (D, n=10)	-23,335 (D, n=11)	0,0195	0,001
CD8 CTLA4+	0,05% (0.01-0.25)	-0,015 (D, n=10)	0,0005 (D, n=12)	0,625	0,6621
CD8 TIM3+	5,66% (2-17)	-0,27 (D, n=10)	1,115 (D, n=12)	0,7695	0,2734
HIV-specific-CD8+	1,42% (0,1-6,52)	0,0025 (D, n=5)	0,0003 (D, n=6)	0,8125	0,8468
HIV-RNA	20 cp/mL (1-47)	1 (FC, n=6)	1 (FC, n=7)	0,75	0,8539
HIV-DNA	218 cp/10^6 cells (40-620)	0,486 (FC, n=6)	0,501 (FC, n=7)	0,625	0,4375

Fourteen patients had been enrolled (median age 61 years), from January 2018 to June 2019. The median follow-up was 6 months (range 1-18), 4 patients stopped treatment and 6 died. The median baseline CD4 cell count value was 373/mm3 (range 90-888), CD4/CD8 ratio was 0.8 (range 0.1-2.1). At C2 and at last time point, there was no significant change in CD4 and CD8 cell counts or in T cell subsets distribution. However, proportions of HLA-DR+ CD4 T cells increased by 85% at C2 without change in other activation markers. PD1 expression dramatically decreased by 95% at C2 without change in CTLA4 and TIM3 expression overtime. Frequencies of HIV-specific-CD8 T cells remained stable overtime, but with higher PD1 expression on IFN-γ+ HIV-specific-CD8 T cells compared to non-HIV-specific-CD8 T cells at baseline (70% vs 38%, p=0.0012). HIV-RNA and DNA remained stable overtime (final median values: 10.5 cp/mL and 80 cp /10^6 cells).
CONCLUSIONS: In a context of HIV infection and cancer, these preliminary data on a limited number of patients suggest that ICPi used in monotherapy do not significantly impact the clinical biology of HIV infection.

OAB0204

A NEW TOOL FOR ACHIEVING THE FIRST GOAL OF UNAIDS 90-90-90 TARGETS - HIV SELF-TESTING WITH URINE

J. Ma[1], Y. Wang[2], T. Zhang[3], Y. Wang[1], Y. Lv[1], C. Jin[1], J. Wang[2], Y. Jiang[1]
[1]National Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Department of AIDS/STD Control and Prevention, Dehong Prefecture Center for Disease Control and Prevention, Yunnan, China, [3]Center for Infectious Diseases, Beijing You'an Hospital, Capital Medical University, Beijing, China

BACKGROUND: In view of insufficient HIV diagnosis in China, there is an urgent need of self-testing. In August 2019, the first HIV self-testing kit (colloidal gold) using urine specimen was approved by CFDA, which largely promoted the progress of HIV self-testing in China. To provide scientific evidence for large scale application, the performance of HIV self-testing with urine was evaluated in multicenter studies.
METHODS: To evaluate the concordance of urine and blood colloidal gold kit, paired blood and urine specimen were collected from all 827 newly diagnosed HIV infected individuals and 214 healthy individuals in Dehong prefecture in 2018. To evaluate the performance of HIV self-testing with urine in untrained individuals, 1066 individuals participated in a multicenter study of HIV self-testing with questionnaire and testing in Beijing, Kunming and Zhenzhou including 92 from HIV positive people, 423 from key populations, and 551 from general population.
RESULTS: The HIV antibody detection concordance of colloidal gold kit with urine and blood was 98.07% (811/827) in HIV positive individuals and 100% (214/214) in healthy people. In the survey, 98.2% of untrained participants thought that they could complete HIV self-testing with urine independently, and 97.84% thought that the experience of HIV self-testing with urine was good. Overall, the antibody detection concordance between self-testing by untrained individuals and professional testing was 99%. And the detection error rate was 0.66%, 6.86%, and 2.16% in strong positive samples, weakly positive samples, and negative samples, respectively. The main causes of testing error included inaccurate volume of sample and inaccurate reacting time. The erroneous result was related with education level while it was unrelated to age, gender and location.
CONCLUSIONS: Our multicenter studies indicated that the innovative HIV self-testing product using urine is acceptable, easy to use, and has good detection concordance with professional testing using blood. As a new testing strategy in China, HIV self-testing with urine provides an acceptable, convenient, and safe tool for people pursuing personal testing with better privacy, which will make important contribution to achieve the first goal of the UNAIDS 90-90-90 targets.

VESATOLIMOD, A TOLL-LIKE RECEPTOR 7 (TLR7) AGONIST, INDUCES DOSE-DEPENDENT IMMUNE RESPONSES IN HIV CONTROLLERS

J. Wallin[1], J. Boice[1], L. Zhang[1], C. McDonald[1], O. Podlaha[1], P. Shweh[1], M. Ramgopal[2], C. Brinson[3], E. DeJesus[4], A. Mills[5], P. Shalit[6], S.G. Deeks[7], J. Milush[7], A. Ferre[8], B. Shacklett[8], D.M. Brainard[1], D. SenGupta[1]
[1]Gilead Sciences Inc., Foster City, United States, [2]Midway Research Center, Fort Pierce, United States, [3]Central Texas Clinical Research, Austin, United States, [4]Orlando Immunology Center, Orlando, United States, [5]Southern California Men's Medical Group, Los Angeles, United States, [6]Peter Shalit MD, Seattle, United States, [7]University of California, San Francisco (UCSF), San Francisco, United States, [8]University of California, Davis, United States

BACKGROUND: An inadequate antiviral immune response occurs in People with HIV (PWH), requiring lifelong antiretroviral therapy (ART). Therefore, therapeutics designed to promote immune-mediated ART-free remission are under clinical evaluation. Vesatolimod (VES) is an oral, selective, small molecule TLR7 agonist shown to be safe and well tolerated in PWH. Dose-dependent inductions of circulating serum cytokines and immune cell activation have been observed with VES treatment in HIV-negative volunteers and PWH on ART. In addition, VES was associated with a modest delay in viral rebound and decrease in viral set-point in HIV controllers in a placebo-controlled Phase 1b trial. We further investigated the immune mechanisms of this effect.

METHODS: We enrolled 25 HIV controllers (pre-ART viral load 50-5000 c/mL) on ART. Seventeen participants were administered bi-weekly VES 4-8 mg (dose escalated within-individual) for 10 doses, and eight participants received placebo. Participants were evaluated during an analytic treatment interruption (ATI) phase for up to 24 weeks to analyze the treatment effect on viral rebound. Peripheral blood mononuclear cells (PBMCs) and plasma were collected at baseline and on-treatment (prior to ATI) for pharmacodynamic (PD) measurements and evaluation of HIV-specific immune responses.

RESULTS: Compared to placebo, VES induced a dose-dependent increase of interferon stimulated mRNAs (ISGs: ISG15, MX1, and OAS1) and cytokines/chemokines (ITAC, IP-10, IL1ra and IFN-a), peaking 24 hours post-dose and returning to baseline by 7 days post-dose. The ISG inductions plateaued at 6 mg with mean increase from baseline of 19-, 8- and 6-fold for ISG15, MX1, and OAS1, respectively. The minimal dose of VES where consistent and detectable cytokine/chemokines occurred was at 6 mg, with mean concentrations of 49, 368, 1834, and 0.6 pg/ml for ITAC, IP-10, IL1ra, and IFN-a, respectively. HIV-specific T cell responses as assessed by intracellular cytokine staining (ICS) increased from baseline in some VES-treated participants.

CONCLUSIONS: The PD and mechanistic activity of VES in PWH may play an important role in HIV cure innovations that include other agents such as CD8+ T-cell-inducing vaccines and monoclonal antibodies.

ANALYSIS OF PROTOCOL DEFINED VIROLOGIC FAILURE THROUGH WEEK 48 FROM A PHASE 2 TRIAL (P011) OF ISLATRAVIR AND DORAVIRINE IN TREATMENT-NAÏVE ADULTS WITH HIV-1 INFECTION

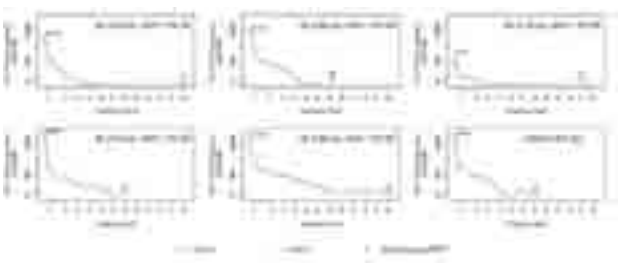
C. Orkin[1], J.-M. Molina[2], Y. Yazdanpanah[3], C. Chahlin Anania[4], E. DeJesus[5], J. Eron[6], S. Klopfer[7], A. Grandhi[7], K. Eves[7], D. Rudd[7], M. Robertson[7], P. Sklar[7], C. Hwang[7], G. Hanna[7], T. Correll[7]
[1]Queen Mary Univeristy of London, London, United Kingdom, [2]St. Louis Hospital and University, Paris, France, [3]Bichat Hospital, Paris, France, [4]Hospital Hernan Henriaquez Aravena of Temuco, Temuco, Chile, [5]Orlando Immunology Center, Orlando, United States, [6]University of North Carolina, Chapel Hill, United States, [7]Merck & Co., Inc., Kenilworth, United States

BACKGROUND: Islatravir (ISL,MK-8591) is the first nucleoside reverse transcriptase translocation inhibitor (NRTTI) in development for treatment and prevention of HIV-1 infection. The objective of this analysis is to show detailed data of participants who discontinued with protocol-defined virologic failure (PDVF) from the phase-2 trial of islatravir (ISL) and doravirine (DOR).

METHODS: Randomized, double-blind, dose-ranging trial participants initially received ISL(0.25, 0.75, or 2.25 mg) with DOR(100 mg) and lamivudine(3TC, 300 mg) or fixed-dose combination of DOR, 3TC, and tenofovir disoproxil fumarate(DOR/3TC/TDF) daily. Participants receiving ISL achieving HIV-1 RNA<50 copies/mL at week-20 or later stopped 3TC at next visit. PDVF was conservatively defined as rebound with confirmed HIV-1 RNA≥50 copies/mL after suppression any time during the trial or non-response with failure to achieve HIV-1 RNA<50 copies/mL by week-48. Participants with PDVF were required to discontinue from the trial.

RESULTS: 121 participants received study drug and were included in analyses. At week-48, 89.7% (26/29), 90.0% (27/30), 77.4% (24/31) of randomized participants achieved HIV-1 RNA<50 copies/mL in the 0.25, 0.75, and 2.25mg ISL groups, respectively, compared to 83.9%(26/31) with DOR/3TC/TDF. Six participants had PDVF; 2 rebounders each in the 0.25 and 0.75 mg ISL groups, 1 non-responder in the 2.25mg ISL group and 1 rebounder in the DOR/3TC/TDF group. All confirmatory HIV-1 RNA Levels were <80copies/mL (Figure1); none met criteria for resistance testing. Despite changing to new regimens, three of six participants (1 each from the 0.25 and 0.75 mg ISL groups and 1 from the DOR/3TC/TDF group) continued to have low-level viremia during 42-day post-discontinuation assessment.

CONCLUSIONS: Rates of PDVF were low and all participants who discontinued due to PDVF had HIV-1 RNA levels below the clinically significant level of 200 copies/mL. The observed low-level viremia was comparable to levels detected in other treatment-naïve studies.



OAB0303

ADHERENCE AND FACTORS ASSOCIATED WITH VIROLOGIC SUCCESS IN HIV-1 INFECTED ADULTS WITH TUBERCULOSIS RECEIVING RALTEGRAVIR OR EFAVIRENZ IN THE ANRS 12300 REFLATE TB2 TRIAL

O. Marcy[1], N. De Castro[2], C. Chazallon[1], E. Messou[3], S. Eholié[4], N. Bhatt[5], C. Khosa[5], D. Laureillard[6], G. Do Chau[7], V. Veloso[8], C. Delaugerre[2], X. Anglaret[1], B. Grinsztejn[8], J.-M. Molina[2], ANRS 12300 Reflate TB2 Study Group
[1]University of Bordeaux, Bordeaux Population Health - Centre Inserm U1219, Bordeaux, France, [2]Hôpital Saint Louis - APHP, Paris, France, [3]CEPREF, Abidjan, Cote D'Ivoire, [4]CHU de Treichville, SMIT, Abidjan, Cote D'Ivoire, [5]Instituto Nacional de Saude, Maputo, Mozambique, [6]CHU de Nimes, Nimes, France, [7]Pham Ngoc Thach Hospital, Ho Chi Minh City, Vietnam, [8]Fiocruz, IPEC, Rio de Janeiro, Brazil

BACKGROUND: Few studies have explored the use of integrase strand transfer inhibitors in HIV-1 infected adults with tuberculosis. The Reflate TB2 trial failed to show non-inferiority of raltegravir 400mg BID compared to efavirenz 600mg QD at week 48. We aimed to identify factors associated with virologic success, including adherence.

METHODS: ANRS 12300 Reflate TB2 was an open-label randomized trial conducted in Brazil, Côte d'Ivoire, France, Mozambique and Vietnam. ART-naïve HIV1-infected adults on tuberculosis treatment were randomized (1:1) to receive raltegravir 400mg BID or efavirenz 600mg QD with TDF 300mg QD and 3TC 300mg QD. We assessed adherence using pill counts. Poor adherence was defined as pill count ratio <95%. We assessed determinants of virologic success (HIV-1 RNA ≤50cp/ml at 48 weeks) using logistic regression.

RESULTS: 460 patients were enrolled (Brazil 43, Côte d'Ivoire 172, France 4, Mozambique 130, Vietnam 111; 230 in each trial arm): median age 35 (IQR 29-43) years, 40% female, median CD4 103 (IQR 38-239) cells/µL, median plasma HIV-1 RNA 5.5 log/mL (IQR 5.0–5.8) with 340 (74%) patients having HIV-1 RNA >100,000c/mL. Median pill count ratios over the study duration were 96.9% (IQR 89.4 - 100.0) and 100.0% (IQR 94.3 - 104.5) in the raltegravir and efavirenz arms, respectively, and poor adherence was seen in 96 (43%) and 60 (27%) patients, in the raltegravir and efavirenz arms, respectively (p-value <0.001 for both). Overall, virologic success was achieved in 289/453 (64%) patients (excluding French), including 139/228 (61%) from raltegravir arm and 150/225 (67%) from efavirenz arm. In univariate analysis, gender, HIV-1 RNA, and adherence were associated with virologic success. In a multivariate model forcing country and study arm, female gender (OR: 1.77; 95CI 1.16-2.72), HIV-1 RNA <100,000c/mL (OR 2.29; 95%CI 1.33-3.96) and [100,000c/mL – 500,000c/mL (OR 1.62; 95%CI 1.02-2.57) versus >500,000c/mL, and pill count ratio ≥95% (OR 2.38; 95%CI 1.56-3.52) were independently associated with virologic success.

CONCLUSIONS: In the Reflate TB2 trial, higher adherence, lower baseline HIV-1 RNA levels and female gender, but not treatment arm, were associated with virologic success. Lower treatment adherence to the raltegravir BID regimen might explain the failure to show non-inferiority to the efavirenz regimen.

OAB0304

REDUCING ART TO LESS THAN 3-ARV REGIMEN LINKED TO INCREASED SYSTEMIC INFLAMMATION

S. Serrano-Villar[1], M.R. López-Huertas[2], F. Gutiérrez[3], M. Beltrán[4], M. Pons[5], P. Viciana[6], J. Portilla[7], F. García[8], S. Moreno[5], CoRIS
[1]University Hospital Ramón y Cajal, Infectious Diseases, Madrid, Spain, [2]Carlos III Health Research Institute, Madrid, Spain, [3]University Hospital of Elche, Elche, Spain, [4]Carlos III Health Institute, Madrid, Spain, [5]University Hospital Ramón y Cajal, Madrid, Spain, [6]University Hospital Virgen del Rocío, Sevilla, Spain, [7]University Hospital of Alicante, Alicante, Spain, [8]University Hospital San Cecilio, Granada, Spain

BACKGROUND: We assessed the long-term consequences of changing triple therapy (3DR) to 2-drug regimens (2DR) or PI-based monotherapy (1DR) on virological failures, clinical events, and systemic inflammation.

METHODS: We selected ART-naive patients initiating triple ART from 2004 to 2018 in the Spanish AIDS Research Network (CoRIS) who achieved virologic suppression (VS) in the first 48 weeks of ART and either remained on 3DR or were switched to 2DR (3TC+bPI; 3TC+DTG; DTG+RPV, CAB+RPV) or 1DR (bDRV or bLPV). We calculated cause-specific cumulative incidence curves and used multivariate Cox proportional hazards models adjusted for potential confounders to estimate hazard ratios for the endpoints: 1) severe non-AIDS events (NAE), 2) AIDS or AIDS-related death, 3) all-cause death, 4) virological failure, 5) composite endpoint of virological failure/serious NAE/death. In a nested study, we compared IL-6, CRP, D-dimers and IFABP trajectories during VS using multivariate mixed models and linear splines.

RESULTS: From 14458 patients, 8416 met the inclusion criteria; 7665 remained on 3DR, 424 switched to 2DR and 327 to 1DR. The median time from enrolment to censoring was 4.9, 6.9 and 8.4 years in the 3DR, 2DR and 1DR groups, respectively (P<0.001).

No between-group differences in the risk of endpoints 1-3 were detected. ART reduction after 24 months of therapy was associated with greater risk of virological failure (P=0.003) and greater risk of the composite endpoint (p=0.005), both driven by higher risk with 1DR but not with 2DR.

We analyzed 710 samples from 174 subjects (3DR, N=90; 2DR, N=61; 1DR, N=23). Compared to 3DR, 2DR was associated with increases of IL-6 (p=0.01), CRP (p=0.003) and D-dimers (p=0.001) after year 3 from VS. A similar pattern was observed for the comparison between 3DR and 1DR, (only significant for D-dimers trajectories, p=0.002).

CONCLUSIONS: In this large cohort of virally suppressed individuals, 1DR was associated with a greater risk of virological failure, with no significant differences between 2DR and 3DR. However, maintaining 3DR was associated with a more favorable long-term anti-inflammatory profile than switching to 2DR or 1DR. The potential clinical implications of these findings on the development of non-AIDS events deserve further investigation.

BACKGROUND: Islatravir (ISL, MK-8591) is the first nucleoside reverse transcriptase translocation inhibitor (NRTTI) in development for treatment of HIV-1 infection. We previously showed that ISL-based regimens had similar efficacy to DOR/3TC/TDF in a phase 2 trial in treatment naïve adults. Here we present a detailed safety analysis of the week 48 results.

METHODS: In this randomized, double-blind, dose-ranging trial, participants were initially assigned to receive ISL (0.25, 0.75, or 2.25 mg) with doravirine (DOR, 100 mg) and lamivudine (3TC, 300 mg) or a fixed-dose combination of DOR, 3TC, and tenofovir disoproxil fumarate (DOR/3TC/TDF) once daily. Participants receiving ISL with HIV-1 RNA<50 copies/mL at Week 20 or later stopped taking 3TC at their next visit and continued DOR+ISL at initial dosage; most participants stopped 3TC at Week 24. For the current analysis, we conducted a detailed review of adverse events (AE) examining the initial 24-weeks, the 24-week period after 3TC removal, and the cumulative 0 through 48-week study period.

RESULTS: 121 participants received drug and were included in the analyses. Similar AE rates between treatment arms were observed across all arms of the trial for each time period. No dose-dependent difference in the safety profile of ISL was observed. AEs were more frequent in the first 24 weeks of the trial as compared to the second 24-week period for all treatment arms (Table1).

	Weeks 0-24		24 weeks after 3TC removal for ISL Groups		Weeks 0-48	
	Combined ISL	DOR/3TC/ TDF QD	Combined ISL	DOR/3TC/ TDF QD	Combined ISL	DOR/3TC/ TDF QD
Number of Participants, N	90	31	86	28	90	31
≥ AE, n (%)	60 (66.7)	20 (64.5)	51 (59.3)	16 (57.1)	66 (73.3)	24 (77.4)
Drug-related AE, n (%)	5 (5.6)	6 (19.4)	3 (3.5)	1 (3.6)	7 (7.8)	6 (19.4)
Serious AE, n (%)	2 (2.2)	1 (3.2)	2 (2.3)	1 (3.6)	3 (3.3)	2 (6.5)
Discontinued due to AE, n (%)	0	0	2 (2.3)	1 (3.6)	2 (2.2)	1 (3.2)
AEs of Moderate or Severe Intensity, n (%)	21 (23.3)	11 (35.5)	21 (24.4)	10 (35.7)	32 (35.6)	15 (48.4)

Overall, diarrhea (most mild and transient) was more frequently reported for DOR/3TC/TDF (16.1%) as compared to ISL groups (combined 6.7%) while headache (most mild and transient) was more common in ISL groups (combined 11.1%) as compared to the DOR/3TC/TDF group (6.5%).

CONCLUSIONS: ISL was well tolerated regardless of dose through 48 weeks of treatment. Most AEs were mild and transient and did not result in study discontinuation.

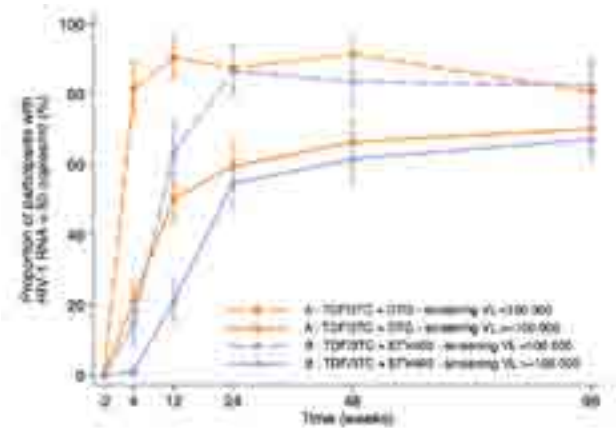
[1]Faculty of Medicine and Pharmaceutical Sciences University of Dschang, Yaoundé, Cameroon, [2]Central Hospital of Yaoundé, Yaoundé, Cameroon, [3]Site ANRS, Yaoudé, Cameroon, [4]TransVIHMI, Université Montpellier, IRD, INSERM, Montpellier, France, [5]Military Hospital of Yaoundé, Yaoundé, Cameroon, [6]Cité Verte Hospital, Yaoundé, Cameroon, [7]CREMER, Yaoundé, Cameroon, [8]Service de Vigilance des Recherches Cliniques ANRS Inserm, Paris, France, [9]University Hospital Center of Montpellier, Montpellier, France, [10]Geneva University Hospitals, Geneva, Switzerland

BACKGROUND: The updated WHO 2019 guidelines for ARV treatment recommend a Dolutegravir (DTG)-based regimen as the preferred first-line regimen and low-dose Efavirenz (EFV400) as an alternative option. The non-inferior efficacy of DTG compared with EFV400 was prevoiously reported at W48. We report here the W96 data.

METHODS: NAMSAL is a phase 3 randomized, open label, multicentre trial conducted in Yaoundé. HIV-1 infected ARV-naive adults with HIV-RNA viral load (VL)>1000 copies/mL were randomized (1:1) to DTG 50 mg or EFV 400 mg once daily, both with tenofovir disoproxil fumarate (TDF)/lamivudine (3TC). Randomization was stratified by screening VL and by site. The primary endpoint was the proportion of patients with VL<50 copies/mL at W48 and extended at W96 (10% non-inferiority margin).

RESULTS: 613 participants (DTG arm: 310; EFV400 arm: 303) received at least one dose of study medication. In the ITT analysis at W96, the proportion of patients with HIV RNA <50 copies/mL was 73.9% (229/310) and 72.3% (219/303) respectively (difference, 1.3%; 95% CI, -5.8 to 8.3; p-value <0,001).



[Figure 1:]

Figure 1 shows the viral suppression according to Baseline VL. The per-protocol analysis showed similar results. Virological failure (WHO definition) was observed in 27 participants (DTG: 8; EFV400: 19), 3 were switched from DTG to EFV600 (May 2018 WHO signal). No resistance mutations to DTG was observed, unlike the EFV400 with 18 resistances (NNRTI+/-NRTI) in the 19 confirmed failure

cases. Weight gain was greater in DTG arm (median weight gain: 5.0/3.0 Kg; incidence of obesity 12.3%/5.4%). 18 AE were observed (DTG: 8; EFV400: 10); one single participant in DTG arm had missing data.

CONCLUSIONS: W96 results confirm the non-inferior efficacy of the DTG-based regimen and the no emergence of resistance to DTG. Virological success rate remains lower in patients with a high initial VL in both arms. We observed a continuous weight gain in the DTG arm.

POOLED ANALYSIS OF 4 INTERNATIONAL TRIALS OF BICTEGRAVIR/EMTRICITABINE/TENOFOVIR ALAFENAMIDE (B/F/TAF) IN ADULTS AGED >65 OR OLDER DEMONSTRATING SAFETY AND EFFICACY: WEEK 48 RESULTS

M. Ramgopal[1], F. Maggiolo[2], D. Ward[3], B. Lebouche[4], G. Rizzardini[5], J.-M. Molina[6], C. Brinson[7], H. Wang[8], J. Gallant[8], S. Collins[8], I. McNicholl[8], H. Martin[8]

[1]Midway Research, Fort Pierce, United States, [2]Division of Infectious Diseases, ASST Papa Giovanni XXIII, Bergamo, Italy, [3]Dupont Circle Physicians Group, Washington, D.C., United States, [4]Research Institute, McGill University Health Centre, Montreal, Canada, [5]Division of Infectious Diseases, Luigi Sacco Hospital, ASST Fatebenefratelli Sacco, Milan, Italy, [6]Department of Infectious Diseases, Saint Louis Hospital, University Paris Diderot, Paris, France, [7]Central Texas Clinical Research, Austin, United States, [8]Gilead Sciences, Foster City, United States

BACKGROUND: As life expectancy for people with HIV increases, optimizing antiretroviral therapy to fit the needs of older adults, including those with co-morbidities and multiple medications, is paramount. B/F/TAF is a small single-tablet regimen with few drug-drug interactions, a high barrier to resistance and may provide a beneficial option for older patients.

METHODS: In this pooled analysis of 4 international trials (Studies 1844, 1878, 4030 and 4449) of virologically suppressed (HIV-1 RNA<50 copies/mL), treatment-experienced adults, we evaluated the efficacy and safety of switching to B/F/TAF for participants ≥65 years. Primary endpoint was HIV-1 RNA<50 copies/mL at Week 48 as defined by the FDA Snapshot algorithm.

RESULTS: 140 participants were age ≥ 65 years at study enrollment. Median age (Q1, Q3) was 68 years (66, 72), 14% were female, and 88% were White. Medical history at baseline was significant for diabetes 22%, hypertension 55%, cardiovascular disease 24% and dyslipidemia 59%.

At W48, the proportion with HIV RNA<50 copies/mL was 92% (129/140); 11 (8%) had no virologic data in window (5 discontinued study drug due to AE but had last available HIV-1 RNA<50 copies/mL; 6 had missing data but were still on study drug). No participant had virologic failure. Most common adverse events (AEs) were nasopharyngitis and arthralgia (7% each). Eleven participants (8%) had a study drug related AE, all were either Grade 1 or Grade 2.

There were no Grade 3-4 study drug-related AEs. Four participants had AEs that led to premature study drug discontinuation: abdominal discomfort, drug withdrawal syndrome, device related infection, and alcohol withdrawal syndrome. Median changes from baseline in fasting lipids were: total fasting cholesterol (-7mg/dL), LDL (-2mg/dL), HDL (0mg/dL), triglycerides (-15mg/dL) and total cholesterol:HDL (-0.1). Median weight change was 1.0 kg (IQR -0.9, 3.0). Ten percent (14/140) of participants had Grade 3 or 4 laboratory abnormalities.

CONCLUSIONS: Switching to B/F/TAF in older adults was well tolerated and safe while maintaining high rates of virologic suppression through 48 weeks. These data support the use of B/F/TAF for treatment of adults ≥65 years who could benefit from a small tablet with few drug-drug interactions and an established safety profile.

BACKGROUND: ACTG A5288 was a strategy trial in resource-limited settings (RLS) enrolling PLWH failing 2nd line PI-based ART. Participants with resistance to LPV and/or all NRTIs were assigned to 3 different cohorts (B,C,D) according to resistance profiles (Figure) and started 3rd line regimens that included raltegravir (RAL), darunavir/ritonavir (DRV/r) and/or etravirine (ETR). At 48 weeks, 87% of participants in these cohorts achieved HIV-1 RNA≤200. At sites where RAL, DRV/r or ETR were not available outside the study, the drugs were provided via the study for 96 additional weeks. We report here long-term outcomes over 144+ weeks, including all available follow-up (FU) of participants in Cohorts B, C and D.

METHODS: All participants were initially followed until 48 weeks after the last participant was enrolled. During the additional long-term FU, HIV-1 RNA was done every 48 weeks and CD4 count at 96 weeks; HIV-1 RNA≤200 copies/mL was imputed if necessary if both preceding and succeeding HIV-1 RNA≤200; CD4 count changes were estimated using loess regression.

RESULTS: Of 257 participants, 38% were female. At study entry, median age 42y; CD4 count 179 cells/uL; HIV-1 RNA: 4.6 log10 copies/mL. Median FU, 168 weeks (IQR: 156-204); 15 (6%) were lost to FU and 9 (4%) died. 27/246 (11%), 26/246 (11%) and 13/92 (14%) of PLWH who started RAL, DRV/r and ETR, respectively, discontinued these drugs, three due to adverse events. Estimated proportions with HIV-1 RNA≤200 copies/mL were 87%, 86%, 83% and 80% at weeks 48, 96, 144 and 168 (95% CI at week 168: 74-85%). Estimated mean increases in CD4 count were 150, 201, 245 and 265 cells/uL, respectively (95% CI at week 168: 247-283).

CONCLUSIONS: Third-line regimens containing RAL, DRV/r, and/or ETR were very well tolerated and provided a high rate of durable virologic suppression among people living with HIV in RLS.

SUB-OPTIMAL OUTCOMES WITH SWITCHING TO ZIDOVUDINE VS. RECYCLING TENOFOVIR IN SECOND-LINE TREATMENT IN HAITI

S. Pierre[1], C. Nguyen[2], B. Iryna[2], F. Homeus[1], V. Guillaume[1], C.P.J. Pierre[1], G. Sainvil[1], A. Julien[1], G. Julmiste[1], Y. Macius[1], G.P.-L. Florestal[1], V. Rouzier[1], P. Severe[1], P. Cremieux[2], M.M. Deschamps[1], B. Liautaud[1], S. Koenig[3], J.W. Pape[1]
[1]GHESKIO Centers, Research, Port-au-Prince, Haiti, [2]Analysis Group, Boston, United States, [3]Brigham Women Hospital, Boston, United States

BACKGROUND: World Health Organization (WHO) guidelines recommend an optimized nucleoside reverse transcriptase inhibitor (NTRI) backbone for second-line ART, including switching from tenofovir (TDF) to zidovudine (AZT), with presumed low-level AZT resistance. However, many providers in resource-poor countries recycle TDF in second-line treatment due to concerns for toxicity and twice-daily dosing of AZT and due to demonstrated efficacy of NRTIs (in spite of genotypic resistance found in several recent studies).

METHODS: Using electronic medical records from GHESKIO (Port-au-Prince, Haiti), we identified adult patients who failed first-line Efavirenz (EFV)/TDF/3TC and were switched to a second-line regimen that included ritonavir-boosted protease inhibitor (bPI), in combination with either TDF/3TC or AZT/3TC. Retention, adherence, and viral suppression outcomes were evaluated at 12 month after initiation of second-line regimen. Adherence was approximated using pharmacy refill data. Multivariable logistic regression was used to determine predictors of virologic suppression.

RESULTS: From 2012 to 2018, 1,017 patients met study criteria and were analyzed. Of these, 509/1017 (50.0%) were women. Median patient age was 40.7 years. 733/1017 (72.1%) patients continued on TDF/3TC on second-line, while 284/1017 (27.9%) were switched to AZT/3TC. Retention was similar in both groups with 612/733 (83.5%) in the TDF/3TC and 236/284 (83.1%) in the AZT/3TC group remaining in care. Of the patients with viral load at 12 months, 253/480 (52.7%) had VL<200 copies/mL in TDF/3TC vs 72/200 (36.0%) in the AZT/3TC group (p<0.001). Viral suppression in patients with ≥90% adherence was also better in the TDF/3TC group with 166/230 (72.2%) compared to 43/75 (57.3%) in the AZT/3TC group (p<0.016). Predictors of viral suppression included recycled TDF/3TC (odds ratio [OR]: 2.08; 95% CI: 1.46, 2.97), secondary or higher education level (OR: 1.53; 95% CI: 1.10, 2.14) and being married/living together (OR 1.51; 95% CI: 1.00, 2.27).

CONCLUSIONS: The WHO-recommended optimized NTRI backbone for second-line ART, which includes switching from TDF to AZT, was associated with lower rates of viral suppression than recycled TDF in Haiti. This may potentially be due to twice-daily dosing and poor tolerability of AZT. ART adherence was found to be poor regardless of NRTI backbone, therefore additional interventions are needed to improve adherence in this population.

OAB0502

EFFICACY AND SAFETY OUTCOMES (HIV SUBGROUP ANALYSIS) IN THE NIX-TB TRIAL - BEDAQUILINE, PRETOMANID AND LINEZOLID FOR TREATMENT OF EXTENSIVELY RESISTANT, INTOLERANT OR NON-RESPONSIVE PULMONARY MULTIDRUG-RESISTANT TUBERCULOSIS

M. Olugbosi[1], D. Everitt[2], F. Conradie[3], A. Crook[4], G. Wills[4], E. Sun[2]
[1]TB Alliance, Clinical Development, Pretoria, South Africa, [2]TB Alliance, New York, United States, [3]University of the Witwatersrand, Clinical HIV Research Unit, Johannesburg, South Africa, [4]University College London, London, United Kingdom

BACKGROUND: Nix-TB achieved 92% treatment success among 109 XDR and treatment-intolerant or non-responsive (TI/NR) MDR TB patients in South Africa, with a 3-drug, all-oral, 6-month regimen of Bedaquiline, Pretomanid and Linezolid (BPaL). Half of the study population (51%) were HIV+.

METHODS: Nix-TB is an open label single arm study of extensively drug-resistant (XDR) or treatment-intolerant or non-responsive (TI/NR) multidrug-resistant (MDR)-TB patients, with primary endpoint of relapse-free microbiologic and clinical cure 6 months after end of therapy. Safety data analysis was descriptive with no inferential tests carried out. HIV+ patients were required to have CD4+ > 50 cells/μL and be able to receive allowed ARV regimens (NVP-, LPV/r-, or RAL-based with NRTIs). Here we present a HIV subgroup analysis of the efficacy and safety data from the study.

RESULTS: 56 HIV+ patients (of 109 total) were on ARV therapy prior to enrolment. 39 patients (69.6%) switched pre-enrolment ARV to allowed regimens and these were all changes from EFV- regimens to either LPV/r- or NVP- regimens. CD4 count was available for 51 participants with mean, median and range of 394, 343, 55 – 1023 cells/uL respectively.

Success at the primary endpoint was 91% (95% CI, 80-97) in HIV+ and 92% (95% CI, 81-98) in HIV- patients. Results from a cox regression model showed that HIV status did not affect time to negative culture conversion status [hazard ratio 0.78 (95% CI, 0.50, 1.19); p= 0.249].

Among HIV+ and HIV- patients, grade 3 or 4 TEAEs were reported in 62.5% and 50.9%, hepatic TEAEs in 46.4% and 30.2%, peripheral neuropathy in 78.6% and 83%, hematopoietic cytopenias in 53.6% and 41.5%, and serious TEAEs in 16.1% and 17.0%, respectively. Of the 8 reported deaths (7.3% of total study population), 5 (8.9%) and 3 (5.7%) were in the HIV+ and HIV- population respectively.

All surviving patients (irrespective of HIV status) were able to complete the full 26 weeks of therapy.

CONCLUSIONS: Results of this simplified, shortened all oral regimen for highly drug-resistant TB show sustained high efficacy and manageable safety irrespective of HIV status.

Swindells[11], for the Acquired Immunodeficiency Syndrome (AIDS) Clinical Trials Group (ACTG) 5300/International Maternal Pediatric Adolescent AIDS Trials (IMPAACT) I2003 Protecting Households on Exposure to Newly Diagnosed Index Multidrug-resistant Tuberculosis Patients (PHOENIx) Feasibility Study Team

[1]Johns Hopkins University, Medicine, Baltimore, United States, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Social & Scientific Systems, Silver Spring, United States, [4]University of Cape Town, Cape Town, South Africa, [5]Byramji Jeejeebhoy Government Medical College, Pune, India, [6]Asociación Civil Impacta Salud y Educación, Lima, Peru, [7]Division of AIDS, National Institute of Allergy and Infectious Diseases, NIAID, NIH, Bethesda, United States, [8]Emory Rollins School of Public Health, Atlanta, United States, [9]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [10]Aurum Institute, Parktown, South Africa, [11]University of Nebraska Medical Center, Medicine, Infectious Diseases, Omaha, United States

BACKGROUND: To prepare for a clinical trial testing a novel TB preventive therapy (TPT) in high RR/MDR-TB burden settings, we sought to quantify the incidence proportion of TB infection (TBI) and disease (TBD) among household contacts (HHCs) of RR/MDR-TB cases.

METHODS: RR/MDR-TB HHCs in 8 high burden countries were enrolled in a cross-sectional study and then reassessed 1 year later. TBI was assessed at baseline by tuberculin skin test (TST) and interferon gamma release assay (IGRA), QuantiFERON Gold/Gold In-Tube; if IGRA-negative or indeterminate at baseline, HHCs age >=5 years had repeat IGRA at 1 year. TBD screening was performed using symptom screen, chest radiography, and mycobacteriology at baseline and follow-up. High-risk groups were defined as children <5 years, HIV-infected, or TBI. Generalized Estimating Equations approach to fit logistic models was used to account for within household correlation.

RESULTS: Of 1007 HHCs of 284 RR/MDR-TB cases, baseline prevalence of TBI was 55.0% by TST, 65.6% by IGRA, and prevalent TBD was 12%. At median of 51.4 weeks later, 850 (81.5%) HHCs from 247 households were traced; 6 HHCs (0.6%) had died (2 with TB). 253 (30%) HHCs were eligible for IGRA testing and 243 had it performed; 52 (21%) converted to IGRA-positive and 1 was indeterminate. 1-year cumulative TBI incidence among HHCs age <5 years was 21.6%; 10.9% among 5-14 years; and 25.5% among >=15 years, p=0.007. There was no difference in IGRA conversion by HIV status (22.1% in HIV+ and 21.5% in HIV-/unknown, p=0.95). 1-year cumulative TBD incidence was 2.3% (n=16); 15 (93.7%) were within high-risk groups. Cumulative TBD incidence was 2.7% in high-risk groups compared to 0.5% in those not in high-risk group (p=0.006); higher in <15 years than >=15 years (4.9% vs 1.3%, p=0.023); higher but non-significantly in HIV+ compared to HIV-/unknown (6.6% vs 1.9%, p=0.21). Only 26 (5%) of 553 high risk HHCs received TPT; mostly isoniazid monotherapy.

CONCLUSIONS: By one year of follow-up, most HHCs exposed to RR/MDR-TB had TBI. All but one new TBD event occurred in a high-risk group. Few received TPT, illustrating the enormous need for novel therapies and TPT scale up among this very high-risk population.

OAB0504

ASSESSMENT OF THE TUBERCULOSIS CLINICAL CASCADE AMONG CHILDREN LIVING WITH HIV ON ANTIRETROVIRAL THERAPY, 16 SUB-SAHARAN PEPFAR-SUPPORTED PROGRAMS, OCTOBER 1, 2018 TO MARCH 31, 2019

M.R. Patel[1], M. Itoh[1], K. Battey[1], H. Kirking[1], E. Click[1], R. Golin[2], T. Al-Samarrai[3], H.T. Wolf[3], P. Agaba[4], E. Rivadeneira[1], S. Modi[1]

[1]US Centers for Disease Control and Prevention, Atlanta, United States, [2]US Agency for International Development, Washington, United States, [3]US Office of the Global AIDS Coordinator, Washington, United States, [4]US Military HIV Research Program, Bethesda, United States

BACKGROUND: Tuberculosis (TB) is underreported and contributes to substantial morbidity and mortality in children, particularly children living with HIV (CLHIV). We examined The US President's Emergency Plan for AIDS Relief (PEPFAR) data to identify opportunities to reduce TB burden among CLHIV.

METHODS: We analyzed PEPFAR data for CLHIV (<15 years) on antiretroviral treatment (ART) from October 1, 2018 to March 31, 2019. Of 21 PEPFAR-supported countries in sub-Saharan Africa, 5 were excluded due to non-reporting of age-disaggregated TB data. The remaining 16 were categorized by region, high pediatric TB incidence (≥25,000 per 100,000), and high CLHIV burden (≥60,000). We analyzed these TB cascade indices: TB symptom screening coverage (percentage screened at least once), screening positivity (percentage with positive screen), proxy TB treatment initiation rate (percentage with positive screen initiating TB treatment), proxy TB preventive therapy (TPT) initiation rate (percentage with negative screen initiating TPT), and TPT completion (percentage initiating and completing TPT).

RESULTS: In total, 555,851 CLHIV were included, representing 86% of CLHIV on ART across PEPFAR-supported programs. Of these, most were screened for TB (median 93%, interquartile range [IQR]: 86%-100%); however, few (median 3%, IQR:2%-6%]) screened positive. Of those screening positive, median TB treatment initiation rate was 19% (IQR:15%-29%). A median 8% [IQR:4%-11%]) of those screening negative initiated TPT. Of those initiating TPT, median completion was 72% (IQR:47%-79%). TB cascade indices were similar by TB incidence and CLHIV burden; TPT completion was lower in Western/Central Africa (62%), despite higher TPT initiation (24%) (Figure).

[Figure: Median tuberculosis clinical cascade indices among children living with HIV on antiretroviral therapy by pediatric TB incidence, CLHIV burden, and region, 16 sub-Saharan PEPFAR-supported programs, October 1, 2016 to March 31, 2019 (n=555,651)]

CONCLUSIONS: TB screening coverage was high, but screening positivity was lower than expected, suggesting poor screening quality. Low TPT initiation and completion underscores that national TPT plans should address pediatric-specific clinical guidance, supply chain, and routine monitoring. Age-disaggregated TB diagnosis data are needed, as proxies likely underestimate TB treatment initiation and overestimate TPT initiation rates.

RISK FACTORS FOR HEPATOTOXICITY IN HIV-INFECTED WOMEN RECEIVING ISONIAZID PREVENTIVE THERAPY IN PREGNANCY AND POSTPARTUM

A. Gupta[1], L. Aaron[2], G. Theron[3], K. McCarthy[4], S. Bradford[4], T. Chipato[5], T. Vhembo[5], L. Stranix-Chibanda[5], C. Onyango-Makumbi[6], G. Masheto[7], N. Chakhtoura[8], P. Jean Phillippe[9], R. Browning[9], T. Sterling[10], A. Weinberg[11], G. Montipiedra[2], for the IMPAACT P1078 TB APPRISE Study Team
[1]Johns Hopkins University, Medicine, Baltimore, United States, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Stellenbosch University, Obstetrics and Gynecology, Cape Town, South Africa, [4]Family Health International FHI360, Durham, United States, [5]University of Zimbabwe College of Health Sciences Clinical Trials Research Centre, Harare, Zimbabwe, [6]Makerere University–Johns Hopkins University Research Collaboration, Kampala, Uganda, [7]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [8]Eunice Kennedy Shriver National Institute of Child Health and Human Development, NIH, Bethesda, United States, [9]Division of AIDS, National Institute of Allergy and Infectious Diseases, NIAID, NIH, Bethesda, United States, [10]Vanderbilt University Medical Center, Nashville, United States, [11]University of Colorado Denver Anschutz Medical Campus, Aurora, United States

BACKGROUND: IMPAACT P1078, a Phase IV randomized, double-blind, placebo-controlled non-inferiority multi-country trial assessing the safety of 28 weeks of isoniazid (INH) preventive therapy (IPT) initiated during pregnancy (immediate IPT) versus deferring to week 12 postpartum (deferred IPT) in HIV-infected women on ART, showed higher than expected hepatotoxicity. We investigated hepatotoxicity risk factors.

METHODS: We examined all-cause hepatotoxicity defined as Grade ≥3 alanine transaminase (ALT) with or without symptoms or bilirubin > 2x upper limit of normal. We performed Poisson regression on study arm, country of enrollment, age, pharmacogenetics of INH and efavirenz (EFV) metabolism, timing of cotrimoxazole initiation, and baseline status of the following: ARV regimen, Hepatitis B and C, CD4, HIV VL, BMI, mid-upper arm circumference. Adjusted models included study arm and covariates with p<0.25 in unadjusted model. Study arm effect modification by ARV regimen was also evaluated.

RESULTS: Of 945 women with follow-up ALT measurements, 63 (6%) experienced ≥1 hepatotoxicity event; 29 (6%) in immediate and 34 (7%) in deferred arm; 5 (8%) occurred in pregnancy, 5 (8%) within 1 week after delivery, and 53 (84%) in postpartum >1 week. ARV regimen and cotrimoxazole use ranged widely by country (66%-100% taking EFV regimen; 0%-31% taking NVP regimen, and 5%-95% taking cotrimoxazole) as did slow metabolizing status (20%-70% for INH NAT2 genotype and 8%-30% for EFV CYP2B6 genotype). There was a study arm, ARV interaction; higher hepatotoxicity was observed with nevirapine (NVP) in immediate arm, and with EFV in deferred arm. Hepatotoxicity was also associated with cotrimoxazole initiation and marginally with Hepatitis C (Table). There was significantly higher risk of hepatotoxicity among slow EFV metabolizers. All other participant characteristics analyzed were not associated with hepatotoxicity.

Participant Characteristics	Group	Estimated Risk Ratio	95% Confidence Interval	P-value
INH/ARV regimen interaction EFV: Immediate vs Deferred (ref) NVP: Immediate vs Deferred (ref)		 0.73 8.67	 (0.41, 1.27) (1.06, 70.81)	0.028
Hepatitis C serology		3.60	(0.87, 14.88)	0.077
Mid upper arm circumference (ref obesity)	Malnutrition <23 Normal 23-31	0.37 0.77	(0.05, 2.77) (0.45, 1.32)	0.420
Initiated cotrimoxazole after week 12 postpartum (vs never initiated before week 12 postpartum)		4.57	(1.80, 11.47)	0.001
CYP2B6 genotype (ref slow)	Fast Intermediate	0.37 0.44	(0.16, 0.84) (0.23, 0.82)	0.017

[Table. Adjusted risk ratios for hepatotoxicity endpoint using Poisson regression models]

CONCLUSIONS: It is critical to monitor for hepatotoxicity in the postpartum when most events occur. ARV regimen type and cotrimoxazole use should also be considered in decisions on when to optimally initiate IPT in pregnant and postpartum women.

OAB0506

VALIDATION OF A LABORATORY-BASED REFERENCE TEST FOR TB-LAM AND FLOW-TB, A NOVEL POINT-OF-CARE TB DIAGNOSTIC ASSAY, IN A HIGH-HIV-PREVALENCE CLINICAL COHORT FROM KWAZULU-NATAL, SOUTH AFRICA

A.E. Shapiro[1], M.W. Ngwane[2], Z.P. Magcaba[2], D. Boyle[3], J. Cantera[3], L. Lillis[3], B. Mullins[4], T. Wittwer[4], H. Hannah[5], J. Warrick[4], S. Berry[4], D.J. Beebe[4], D.P.K. Wilson[6,2], P.K. Drain[1]
[1]University of Washington, Global Health and Medicine (Infectious Diseases), Seattle, United States, [2]Umkhuseli Innovation and Research Management, Pietermaritzburg, South Africa, [3]PATH, Seattle, United States, [4]Salus Discovery, Madison, United States, [5]University of Washington, Global Health, Seattle, United States, [6]University of KwaZulu-Natal, Edendale Hospital, Internal Medicine, Pietermaritzburg, South Africa

BACKGROUND: A first-generation point-of-care urine lipoarabinomannan (LAM) assay has low sensitivity to diagnose active tuberculosis (TB). We developed and validated a second-generation reference assay and point-of-care (POC) test to detect LAM for active TB diagnosis in people with and without HIV.

METHODS: We selectively enrolled adults with and without pulmonary TB at Edendale Hospital in KwaZulu-Natal, South Africa. We collected sputum for confirmatory TB testing and urine for LAM detection. We tested urine samples in the clinic laboratory using the Determine LAM Ag (Abbott) and FLOW-TB assay (Salus Discovery) as POC tests. We also conducted reference quantitative LAM testing using the MesoScale Diagnostic (MSD) electrochemiluminescence assay with 3 separate capture/detection monoclonal antibody combinations. We calculated the diagnostic accuracy for each assay, using sputum Xpert MTB/RIF and/or TB culture as the reference test.

RESULTS: Among 139 adults (45% female), 74% were HIV-positive and 88% had microbiologically confirmed pulmonary TB. The lab-based LAM reference assay had high diagnostic accuracy using the Otsuka S20/A194 (OA) antibody combination (83% sensitivity, 91% specificity) and the KI24/A194 (KA) antibody combination (81% sensitivity, 73% specificity). The MSD-LAM reference assay had 86% sensitivity and 89% specificity for diagnosing pulmonary TB among the 70 participants with TB culture-confirmed results. In LAM-positive persons, the median LAM concentration measured by MSD-LAM was 295 pg/ml (IQR 43-1541 pq/ml) using OA antibodies and 330 pg/ml (IQR 67-3909) using KA antibodies. FLOW-TB sensitivity, compared to TB Xpert reference testing, was 71% (80% in HIV-positive participants) and specificity was 67%. The FLOW-TB assay detected LAM in 80% of samples with LAM as measured by the MSD-LAM reference assay, whereas the Abbott LAM test detected LAM in 27% of samples with LAM as measured by the MSD-LAM reference assay.

Diagnostic test (Ab pair) vs. reference test	MSD (KA) vs. TB Xpert N=112	MSD (OA) vs. TB Xpert N=112	MSD (KA) vs. TB culture N=70	MSD (OA) vs. TB culture N=70	MSD (KA) vs. TB Xpert, HIV+ N=79	MSD (OA) vs. TB Xpert, HIV+ N=79	FLOW (KA) vs. MSD (KA) N=70	FLOW (KA) vs. MSD (KA) HIV+ N=50	Abbott Determine vs. MSD (OA) N=112
Sensitivity	81%	83%	84%	86%	79%	87%	80%	89%	27%
Specificity	73%	91%	78%	89%	73%	91%	74%	73%	100%

CONCLUSIONS: The MSD assay can accurately measure low concentrations of LAM in urine with high sensitivity and specificity for active TB in HIV-positive and HIV-negative persons, and is a suitable benchmark for evaluating novel POC LAM assays. The novel second-generation FLOW-TB assay had markedly improved sensitivity over the existing POC LAM assay.

BACKGROUND: TB contact investigations as an active HIV case finding strategy in Mozambique: Lessons for high TB and HIV syndemic countries.

METHODS: TB index patient contact investigations (CI) were conducted in five (5) health facilities (HF) in Maputo Province, Mozambique, beginning in early 2017 through Oct 2019. CIs included at least one home visit of the TB case, enumeration of all household (HH) members, screening for TB symptoms per WHO guidelines for those present at the time of the visit, followed by confirmatory TB testing for presumptive patients. All contacts were offered home-based rapid HIV testing, and if positive, were referred to a local HF for treatment. HH member demographic characteristics and CI outcomes were entered into Infomóvel, a mobile-based platform, and downloaded into Excel for analysis.

RESULTS: 2,990 TB index patient HH were visited and 76.4% (4,749/6,217) of all contacts were screened for TB symptoms; 62.4% (2,963/4,749) had at least one symptom; 3.6% (107/2963) were new TB patients. The age-group specific proportions of new TB patients were 12.2% (57/466) among HH members >15 years; 1.5% (12/797) among those 6-14 years, and; 2.2% (38/1,700) among those < 5 years. Only 8.3% (394/4,749) of screened HH members knew their HIV status, and only 53.6% (192/358) of those with previously diagnosed HIV were on ART. Among those who did not know their HIV status and were tested, 8.1% (278/3,442) were newly identified HIV infections. Overall, 13.4% (636/4,749) of HH members were HIV positive.

CONCLUSIONS: TB CIs will identify a substantial proportion of unrecognized and untreated HIV and provide an important opportunity to provide TB preventive therapy that will interrupt TB progression and transmission and reduce mortality among PLHIV. TB CIs should play an essential role in achieving epidemic control in countries with high TB and HIV burdens.

OAB06 WEIGHT AND METABOLIC CHANGES & ART

OAB0602

WEIGHT GAIN AND HYPERGLYCEMIA DURING THE DOLUTEGRAVIR TRANSITION IN AFRICA

J. Ake[1], A. Esber[1,2], N. Dear[1,2], M. Iroezindu[1,3,4], E. Bahemana[1,5], H. Kibuuka[6], J. Owuoth[1,7,8], J. Maswai[1,7,8], C. Polyak[1,2], T. Crowell[1,2], AFRICOS Study Team
[1]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]U.S. Army Medical Research Directorate, Nairobi, Kenya, [4]Henry Jackson Foundation MRI, Abuja, Nigeria, [5]Henry Jackson Foundation MRI, Mbeya, Tanzania, United Republic of, [6]Makerere University Walter Reed Project, Kampala, Uganda, [7]Kenya Medical Research Institute, Nairobi, Kenya, [8]Henry Jackson Foundation MRI, Kisumu, Kenya

BACKGROUND: Clinical trials demonstrated weight gain upon initiation of dolutegravir-based regimens in sub-Saharan Africa, and reports of hyperglycemia have emerged during the programmatic rollout of TLD (tenofovir disoproxil fumarate/lamivudine/dolutegravir). We systematically examined the incidence of these conditions in the care and treatment setting.

METHODS: The African Cohort Study (AFRICOS) enrolled HIV-infected and uninfected participants at twelve PEPFAR-supported clinics in Uganda, Kenya, Tanzania and Nigeria. BMI was assessed six-monthly and glucose annually. Overweight/obese was defined as BMI > 25 kg/m2. Hyperglycemia was defined as fasting glucose>99, any glucose >199 or taking hypoglycemic medication. Incidence rates of becoming overweight/obese and developing hyperglycemia were calculated overall and by HIV status and treatment groups. Among HIV-infected participants without the conditions of interest upon enrollment, Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for TLD use and other potential risk factors for weight gain and hyperglycemia.

RESULTS: From January 2013-November 2019, 3,514 participants were enrolled including 2,043 (58%) females and 2,927 (83%) living with HIV with median age 38 (Interquartile range 31-46) years. Incidence for becoming overweight/obese was 72.33 (CI 66.22-78.99) cases/1,000PY overall (n=2,545) and 98.6 (CI 63.6-152.8) cases/1,000PY among participants on TLD (n=528). Hyperglycemia incidence was 52.01 (CI 47.28-57.21) cases/1,000PY overall (n=3,045) and 121.30 (CI 71.84-204.82) cases/1,000PY among participants on TLD (n=373). For each condition, those taking TLD consistently demonstrated the highest incidence across sites, ART naïve participants had the lowest incidence, and the geographically highest rates were observed in Nigeria. In time-to-event analysis, 436 participants became overweight/obese and 380 developed hyperglycemia. Those taking TLD had increased rates of becoming overweight/obese compared to those taking non-TLD ART (HR 2.73; CI 1.67-4.48) after adjusting for site, gender, age and depression. While participants on TLD had an increased HR compared those on non-TLD ART in the unadjusted model (1.81; CI 1.04-3.14), this difference was not statistically significant (HR 1.12; CI 0.65-1.93) after adjustment for site, gender, age and enrollment BMI.

CONCLUSIONS: TLD use was associated with increased incidence of weight gain and hyperglycemia in this cohort. We observed regional differences in both conditions and an independent effect of TLD on becoming overweight/obese.

OAB0603

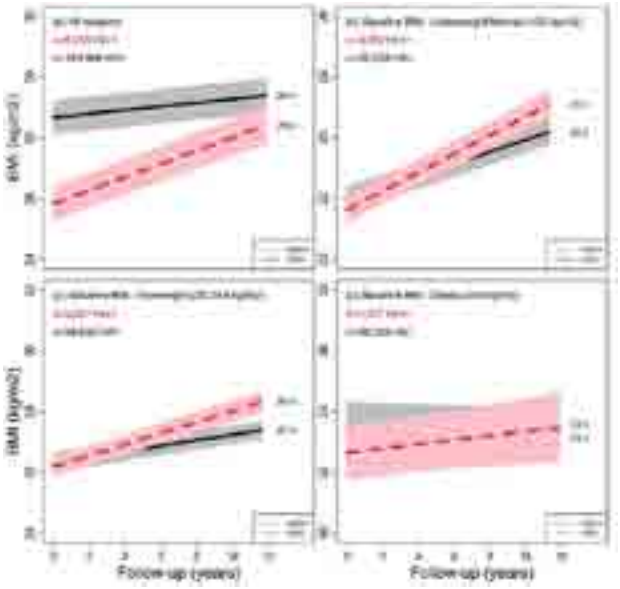
CHANGES IN BODY MASS INDEX OVER TIME IN PERSONS WITH AND WITHOUT HIV

M. Silverberg[1], W. Leyden[1], S. Alexeeff[1], J. Lam[1], A. Anderson[1], R. Hechter[2], H. Hu[3], J. Marcus[4], Q. Yuan[2], W. Towner[2], M. Horberg[3]
[1]Kaiser Permanente Northern California, Division of Research, Oakland, United States, [2]Kaiser Permanente Southern California, Research & Evaluation, Pasadena, United States, [3]Kaiser Permanente Mid-Atlantic States, Mid-Atlantic Permanente Research Institute, Rockville, United States, [4]Harvard Medical School and Harvard Pilgrim Health Care Institute, Population Medicine, Boston, United States

BACKGROUND: Adults with HIV (HIV+) may experience increases in body mass index (BMI) over time after antiretroviral therapy (ART) initiation. It is unknown whether BMI in HIV+ adults has approached adults without HIV (HIV-).

METHODS: We conducted a cohort study during 2005-2016 of HIV+ adults (≥18 years) who were members of Kaiser Permanente Northern California, Southern California, or Mid-Atlantic States, integrated healthcare systems with longstanding HIV registries and electronic health records. HIV- were matched 10:1 to HIV+ by age, sex, race/ethnicity, medical center, and calendar year. We restricted analyses to those with recorded baseline BMI; HIV+ were further restricted to ART initiators. Using mixed effects models, we compared changes in BMI over time for HIV- (reference) and HIV+ adults, both overall and in baseline BMI subgroups: underweight/normal (<25 kg/m^2); overweight (25-29.9 kg/m^2); and obese (≥30 kg/m^2). Multivariable models included terms for HIV status, time, HIV*time interaction, age, race/ethnicity, sex, year, substance use disorders, smoking, census-based education/income, insurance type, and common comorbidities.

RESULTS: The study included 8,256 HIV+ and 129,966 HIV- adults. Mean baseline BMI (kg/m^2) was 29.3 for HIV- and 26.2 (P<0.001) for HIV+. In adjusted models, the average annual change in BMI was 0.06 kg/m^2 for HIV- (reference) and 0.16 kg/m^2 (P<0.001) for HIV+. Adjusted changes in BMI by HIV status with 95% confidence bands are presented in the Figure. For all patients (panel a), the average BMI at 12 years was 28.4 and 29.4 for HIV- and HIV+ adults, respectively. For all baseline BMI categories (Figure, panels b-d), HIV+ adults had faster BMI increases over time compared with changes for HIV- adults.



[Figure. Adjusted changes in BMI by HIV status and baseline BMI]

CONCLUSIONS: HIV+ adults initiating ART have more rapid increases in BMI over time compared with demographically similar HIV- adults. This may adversely impact efforts to reduce the risk of BMI-related comorbidities in HIV+ adults, such as cardiovascular disease.

OAB0604

WEIGHT GAIN BEFORE AND AFTER SWITCH FROM TDF TO TAF

P. Mallon[1], L. Brunet[2], R. Hsu[3,4], J. Fusco[2], K. Mounzer[5], G. Prajapati[6], A. Beyer[6], M. Wohlfeiler[3], G. Fusco[2]
[1]University College Dublin, School of Medicine, Dublin, Ireland, [2]Epividian, Durham, United States, [3]AIDS Healthcare Foundation, New York, United States, [4]NYU Langone Health Center, Internal Medicine, New York, United States, [5]Philadelphia FIGHT, Philadelphia, United States, [6]Merck & Co., Inc., Kenilworth, United States

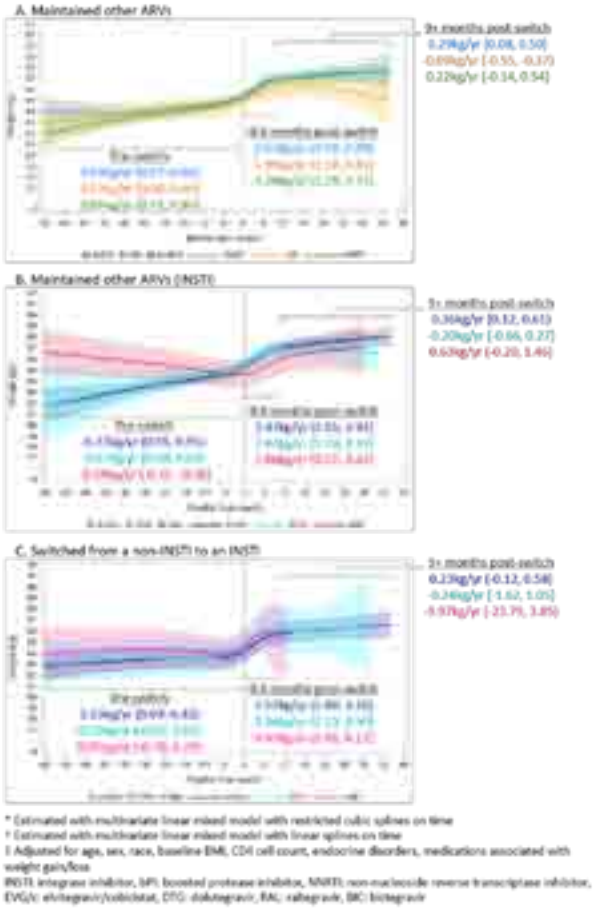
BACKGROUND: Although significant weight gain has been reported with use of some integrase inhibitors (INSTI), concurrent use of tenofovir alafenamide (TAF) has also been implicated. We aimed to examine weight changes in people living with HIV (PLWH) who switched from tenofovir disoproxil fumarate (TDF) to TAF.

METHODS: ARV-experienced, virologically-suppressed PLWH in the OPERA cohort who switched from TDF to TAF were included if they maintained all other ARVs or switched to an INSTI. We modeled weight change before/after switch to TAF using linear mixed models (random intercepts, restricted cubic splines on time), adjusting for age, sex, race, (age-sex, race-sex interactions), BMI, CD4 count, endocrine disorders and concurrent medications that could modify weight.

RESULTS: Demographics of 6,919 PLWH included were similar whether they maintained other ARVs or switched to INSTI (Table). Although modest weight gain over time was observed with TDF use (0.23 to 0.67 kg/year), switch to TAF was associated with early, pronounced weight gain (1.80 to 4.47 kg/year, Figure) in adjusted models. This effect with TAF switch was observed both in those who maintained other ARVs and those switching to an INSTI (regardless of which INSTI agent was used). Weight gain tended to slow down or plateau approximately 9 months after switch to TAF; bictegravir lacked sufficient data beyond 9 months.

	Maintained NNRTI, n=1,454	Maintained bPI, n=747	Maintained INSTI, n=3,288	Switched to INSTI, n=1,430
Age, median (IQR)	45 (34, 54)	51 (42, 57)	44 (33, 52)	49 (39, 56)
Female, n (%)	276 (19)	155 (21)	501 (15)	253 (18)
Black, n (%)	591 (41)	292 (39)	1,206 (37)	543 (38)
Hispanic, n (%)	348 (24)	190 (25)	865 (26)	373 (26)
BMI (kg/m^2), median (IQR)	27 (24, 31)	27 (24, 31)	26 (24, 30)	27 (24, 30)
CD4 cell count, median (IQR)	717 (542, 939)	608 (441, 826)	654 (475, 868)	668 (493, 875)
Endocrine disorders, n (%)	272 (19)	190 (25)	677 (21)	325 (23)
Medications associated with weight gain, n (%)	404 (28)	275 (37)	989 (30)	486 (34)
Medications associated with weight loss, n (%)	268 (18)	170 (23)	652 (20)	273 (19)

[Table. Characteristics at switch from TDF to TAF]



[Figure. Predicted weight over time on TDF and TAF and estimated rate† of weight gain (95% CI)‡]*

CONCLUSIONS: In this large, diverse cohort of PLWH, switching from TDF to TAF was associated with pronounced weight gain immediately after switch, regardless of concurrent INSTI use. That this effect was observed across regimens suggests an independent effect of TAF on weight.

OAB0605

WEIGHT CHANGES AFTER SWITCHING TO DORAVIRINE/LAMIVUDINE/TDF IN THE DRIVE-SHIFT TRIAL

P. Kumar[1], M. Johnson[2], Z.J. Xu[3], E. Martin[3], P. Sklar[3], W. Greaves[3]
[1]Georgetown University School of Medicine, Washington DC, United States, [2]Royal Free Hospital, London, United Kingdom, [3]Merck & Co., Inc., Kenilworth, United States

BACKGROUND: Initiation of antiretroviral therapy (ART) often leads to weight gain. Greater weight gain has been observed with integrase inhibitors than with protease inhibitors (PI) or non-nucleoside reverse transcriptase inhibitors (NNRTI), and with tenofovir alafenamide (TAF) vs tenofovir disoproxil fumarate (TDF). In treatment-naïve clinical trials of doravirine (DOR), mean weight gain over 96 weeks was similar to the average change in adults without HIV.

We conducted a post-hoc analysis of weight changes in DRIVE-SHIFT, a phase 3 trial in which adults with HIV-1 who were virologically suppressed for ≥6 months switched to DOR/3TC/TDF on Day 1 (immediate switch group, ISG) or after continuing their prior regimen for 24 weeks (delayed switch group, DSG).

METHODS: Mean weight change from time of switch was calculated for ISG and DSG at 24 weeks (24W) post-switch and for ISG only at 48 weeks (48W) post-switch, overall and by demographic subgroup (Men, Women, Black, White, Hispanic) and prior regimen (PI, NNRTI, Elvitegravir/TAF).

RESULTS: 670 participants (447 ISG, 223 DSG) entered the trial (84.5% male, 76.4% white, mean age 43.3 years). Post-switch weight data were available at 24W for 629 participants (ISG+DSG) and at 48W for 408 participants (ISG only). Weight gains after switch to DOR/3TC/TDF were small: mean 0.6 kg (95% CI: 0.4, 0.9) at 24W and 0.7 kg (0.4, 1.1) at 48W. Observed weight gain at 48W post-switch was nominally lower in women (0.3 kg) vs men (0.8 kg), in white participants (0.6 kg) vs black (1.3 kg) or Hispanic participants (1.3 kg), and after switching from a boosted PI (0.6 kg) vs an NNRTI (1.3 kg). In the small group who switched from elvitegravir/TAF, mean weight change was -0.4 kg at 48W post-switch.

	24 Weeks after Switch (ISG + DSG)			48 Weeks after Switch (ISG only)		
Group	N	Baseline Mean (95% CI)	Mean Change (95% CI)	N	Baseline Mean (95% CI)	Mean Change (95% CI)
Overall	629	79.2 (77.3, 80.5)	0.6 (0.4, 0.9)	408	79.5 (77.8, 81.2)	0.7 (0.4, 1.1)
Men	530	79.9 (78.5, 81.2)	0.8 (0.4, 0.9)	339	79.9 (78.2, 81.6)	0.8 (0.5, 1.2)
Women	99	75.6 (71.4, 79.8)	0.3 (-0.1, 1.2)	69	77.6 (72.2, 83.0)	0.3 (-0.8, 1.4)
Black	80	83.4 (79.2, 88.9)	1.4 (0.5, 2.3)	51	85.8 (79.5, 93.2)	1.3 (-0.3, 2.8)
White	484	79.2 (77.8, 80.5)	0.4 (0.1, 0.7)	312	79.1 (77.4, 80.9)	0.6 (0.2, 1.0)
Hispanic/Latino	105	76.3 (73.3, 78.8)	1.2 (0.7, 1.8)	66	76.2 (73.2, 79.2)	1.3 (0.6, 2.1)
Prior PI	441	79.3 (77.2, 80.8)	0.6 (0.3, 1.0)	286	79.9 (77.8, 82.0)	0.8 (0.2, 1.6)
Prior NNRTI	162	77.9 (75.3, 80.5)	0.9 (0.5, 1.4)	90	77.7 (74.6, 80.9)	1.3 (0.6, 2.0)
Prior Elvitegravir/TAF	26	85.7 (79.4, 93.0)	-1.2 (-2.5, 0.1)	30	82.6 (76.0, 89.1)	-0.4 (-2.4, 1.5)

CI = Confidence interval by t-distribution.

[Table: Mean weight change (kg) from baseline in DRIVE-SHIFT]

CONCLUSIONS: Weight changes among participants switching to DOR/3TC/TDF were modest and similar to the average change observed in adults without HIV in the US.

OAB0606

IMPROVED METABOLIC PARAMETERS AFTER SWITCHING FROM TAF-BASED 3- OR 4-DRUG REGIMEN TO THE 2-DRUG REGIMEN OF DTG/3TC (DOLUTEGRAVIR/LAMIVUDINE): THE TANGO STUDY

J. van Wyk[1], M. Ait-Khaled[1], J. Santos[2], S. Scholten[3], M. Wohlfeiler[4], F. Ajana[5], B. Jones[1], M.C. Nascimento[1], A. Tenorio[6], D. Smith[7], J. Wright[8], B. Wynne[6]
[1]ViiV Healthcare - UK, Brentford, United Kingdom, [2]Hospital Virgen de la Victoria, Málaga, Spain, [3]Praxis Hohenstaufenring, Cologne, Germany, [4]AIDS Healthcare Foundation, Miami Beach, United States, [5]Centre Hospitalier de Tourcoing, Tourcoing, France, [6]ViiV Healthcare, Research Triangle Park, United States, [7]Albion Centre, Sydney, Australia, [8]GlaxoSmithKline, Stockley Park, United Kingdom

BACKGROUND: Primary outcomes from TANGO demonstrated that switching to DTG/3TC is non-inferior at 48 weeks to continuing a 3-/4-drug TAF-based regimen (TBR) in virologically suppressed PLWH. Switching from TDF to TAF or using boosting agents has been associated with weight gain and dyslipidemia.

METHODS: Here we summarize changes over 48 weeks in weight, lipids, fasting glucose and insulin as well as prevalence at Week 48 of insulin resistance (IR) (defined as HOMA-IR ≥2), and metabolic syndrome (MS) (International Diabetes Federation definition). Subgroup analyses by boosting status of the baseline regimen were performed.

RESULTS: At baseline (BL), participants were randomized to either DTG/3TC (N=369) or TBR (N=372). Most participants were male (92%) and white (79%), median age was 40 years, and 74% received a boosting agent. Mean weight changes were small and comparable between arms. Changes in lipids, including TC:HDL ratio, generally favoured the DTG/3TC group. Changes in fasting glucose were small across arms; changes in fasting insulin favoured the DTG/3TC arm and were more pronounced in the unboosted group (Table). At Week 48, proportions with HOMA-IR ≥2 were 65% (BL=69%) and 74% (BL=68%) in the DTG/3TC and TBR arms, respectively (odds ratio 0.59 [CI:0.40, 0.87]; p=0.008), with differences favouring DTG/3TC more pronounced in the boosted group (Table). At Week 48, proportions with MS were 11% (BL=10%) and 12% (BL=11%) in the DTG/3TC and TBR arms, respectively; adjusted treatment differences favoured DTG/3TC in the unboosted group (Table).

CONCLUSIONS: Switching from 3-/4-drug TAF-based regimens to the 2-drug regimen of DTG/3TC led to similar small increases in weight, but general improvements in other metabolic health parameters, over 48 weeks. More pronounced differences favouring DTG/3TC were noted compared to the unboosted TAF-based group for fasting insulin and metabolic syndrome, and to the boosted TAF-based group for lipids and insulin resistance.

OAB07: YOUTH AND CHILDREN/PEDIATRICS/ WOMEN

OAB0702

OVERLAPPING SIGNIFICANT LIFE EVENTS ARE ASSOCIATED WITH HIV VIRAL NON-SUPPRESSION AMONG YOUTH IN CLINICS IN RURAL EAST AFRICA

F. Mwangwa[1], E. Charlebois[2], W. Olio[3], J. Ayieko[3], D. Black[2], J. Peng[2], J. Kabami[1], L. Balzer[4], M. Petersen[5], B. Kapogiannis[6], M. Kamya[7], D. Havlir[2], T. Ruel[2], SEARCH YOUTH Team
[1]Infectious Disease Research Collaboation, Kampala, Uganda, [2]University of California, San Francisco, San Francisco, United States, [3]Kenya Medical Research Institute (KEMRI) Centre for Microbiology Research (CMR), Nairobi, Kenya, [4]University of Massachusetts Amherst, Amherst, United States, [5]University of California, Berkeley, Berkeley, United States, [6]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Rockville, United States, [7]Makerere University College of Health Sciences, Kampala, Uganda

BACKGROUND: The HIV-care continuum among Youth Living with HIV (YLWH) is thought to be influenced by life events that may be part of normal psycho-social development but affect engagement with treatment. However, data on the prevalence of disruptive life events among YLWH in rural sub-Saharan Africa and their association with viral suppression are limited.

METHODS: SEARCH Youth (NCT0384872) is a cluster-randomized trial testing a package of youth-focused interventions in 28 HIV clinics in rural Uganda and Kenya. In the intervention arm, a tab-

let-based care-planning tool is used to assess potential barriers to treatment including alcohol use, HIV disclosure status, and major recent life-events: start/stop of school or employment, change in residence, divorce/separation or relationship strife, new sexual partner, family death, sickness, incarceration, family strife, and pregnancy or birth. We used multivariable logistic regression adjusted for clinic clustering to evaluate the association of potential barriers to treatment and age with viral suppression (<400 copies/mL, any ART status) at the time of enrollment.

RESULTS: Among 900 participants (83% female), 885 (98%) completed HIV viral load testing. The age distribution (years) of subjects was 19% 15-17, 32% 18-20, 29% 21-22, and 20% 23-24. ART had been started at enrollment (12%), ≤6 months prior (21%), or >6 months prior and they remain in (62%) or have since disengaged from care (4%). The most common life events were pregnancy (16%), moving (16%), sickness (9%), start/stop job or school (9%), family death (8%), relationship strife or divorce/separation (8%), and a new sexual partner (8%). Overlapping (≥2) life-events and alcohol were associated with viral non-suppression, while increasing age and disclosure were associated with suppression (Table).

Predictor of viral suppression	Prevalence in YLHIV	Adjusted Odds Ratios (95% CI)
Overlapping (2 or more) events	17% (151/900)	0.52 (035-0.77), p=0.001
Alcohol Use	17 % (155/900)	0.56 (0.38-0.84), p=0.004
Increasing age	n/a	1.08 (1.02-1.15), p=0.011
Disclosure of HIV status to family members	81% (727/900)	2.00 (1.4-2.8), p<0.001
Disclosure of HIV status to partner	54% (483/900)	1.71 (1.2-2.4), p=0.001

CONCLUSIONS: In this contemporary cohort of youth living with HIV in rural Africa, overlapping major life-events, alcohol use, and lack of disclosure were associated with viral non-suppression. Systematic and routine assessment of life events could allow providers and patients to identify and address barriers to treatment, potentially improving clinical outcomes in this vulnerable population.

OAB0703

IMPROVING PEDIATRIC INDEX TESTING: DATA FROM 12 PEPFAR-SUPPORTED COUNTRIES IN SUB-SAHARAN AFRICA

H.T. Wolf[1], K. Battey[2], M. Mujawar[2], R. Bhatkoti[2], E. Rivadeneira[2], B. Phelps[3], M. Grillo[4], T. Al-Samarrai[1], J. Gross[2]
[1]Office of the Global AIDS Coordinator, Washington, United States, [2]Centers for Disease Control, Division of Global HIV and Tuberculosis, Center for Global Health, Atlanta, United States, [3]U.S. Agency for International Development, Washington, United States, [4]U.S. Department of Defense, San Diego, United States

BACKGROUND: Finding HIV-positive children is critical to close the pediatric treatment gap in resource-limited settings; 80% of children living with HIV (CLHIV) still not receiving treatment live in 12 PEPFAR-supported sub-Saharan African countries. Testing pediatric contacts of HIV-positive persons yields high positivity rates, and often identifies asymptomatic CLHIV. This report describes the roll-out of pediatric HIV index testing and resulting yield in PEPFAR-supported countries.

METHODS: We analyzed PEPFAR HIV testing program data for children 1-14 years of age, disaggregated by age-band (1-4, 5-9, 10-14), from October 1, 2017 to September 30, 2018 (FY18) and October 1, 2018 to September 30, 2019 (FY19) for 12 sub-Saharan African countries. The change in proportion of index tests and resulting yield from FY18 to FY19 was assessed using a one-sample Wilcoxon signed rank sum test.

RESULTS: The testing yield across all modalities increased from 1.0% (FY18) to 1.4% (FY19) with 101,206 HIV-positive tests in FY19. The proportion of index testing conducted increased from 9% (FY18) to 12% (FY19) (p<0.001) and the proportion of HIV-positive tests from index testing increased from 17% to 28% in FY18 to FY19 (p<0.001). In FY19, 40% of all index testing occurred in 5-9-year-olds who contributed 36% of all positives; index testing in 1-4-year-olds had the highest yield (4.5%). Eight countries had statistically significant increases in the proportions of index tests from FY18 to FY19: Cameroon [OR=1.41, CI 1.38-1.44], Ethiopia [OR=10.13, CI 9.91-10.36], Kenya [OR=1.90, CI 1.89-1.92], Malawi [OR=1.28, CI 1.24-1.31], Nigeria [OR=2.13, CI 2.08-2.18], South Africa [OR=2.36, CI 2.32-2.40], Tanzania [OR=2.40, CI 2.38-2.42], and Zambia [OR=1.98, CI 1.96-2.00]. However, South Africa, Nigeria, Uganda and Malawi had less than 7% of HIV tests from index testing.

CONCLUSIONS: Index testing is a high-yield approach to find CLHIV in PEPFAR supported settings. Implementation has improved but is sub-optimal and must be prioritized, particularly in high-burden settings.

BIOMARKER ASSESSMENT OF INFANT ADHERENCE TO ISONIAZID PROPHYLAXIS IN A PRIMARY TB INFECTION PREVENTION TRIAL IN KENYA

S. LaCourse[1], D. Leon[2], N. Panpradist[2], B. Richardson[3,4], E. Maleche-Obimbo[5], J. Mecha[6], D. Matemo[6], J. Escudero[4], J. Kinuthia[6,7], B. Lutz[2], G. John-Stewart[1,4,8,9]
[1]University of Washington, Department of Medicine, Division of Allergy and Infectious Diseases, Seattle, United States, [2]University of Washington, Department of Bioengineering, Seattle, United States, [3]University of Washington, Department of Biostatistics, Seattle, United States, [4]University of Washington, Department of Global Health, Seattle, United States, [5]University of Nairobi, Department of Pediatrics and Child Health, Nairobi, Kenya, [6]Kenyatta National Hospital, Department of Research and Programs, Nairobi, Kenya, [7]Kenyatta National Hospital, Department of Reproductive Health, Nairobi, Kenya, [8]University of Washington, Department of Pediatrics, Seattle, United States, [9]University of Washington, Department of Epidemiology, Seattle, United States

BACKGROUND: Data are lacking regarding infant tuberculosis (TB) prevention therapy adherence. We assessed prevalence and cofactors of isoniazid (INH) prophylaxis (IPT) adherence using a low-cost dipstick in a TB prevention trial of HIV-exposed Kenyan infants.

METHODS: Infants 6 weeks of age were randomized to 12-months daily INH vs. no INH. For infants randomized to INH, standardized adherence questionnaires were administered to caregivers at follow-up visits (10 weeks, 3, 6, 9, 12 months of age, and 12 months post-randomization). Urine was collected for an INH dipstick test that changes color with INH metabolite detection within 30 hours of ingestion. We compared self-reported adherence to urine re-

sults and evaluated correlates of positive INH dipstick with relative risk regression using generalized linear models clustered by participant.

RESULTS: Among 97 infants randomized to INH with ≥1 urine result, baseline median age was 6.3 weeks (IQR 6.0-6.4), 41 (43.3%) were female. All mothers were on ART; 69 (71.1%) initiated ART prior to pregnancy and 6 (6.7%) had HIV viral load (VL) >1000 copies/ml. Seventy-three mothers (75.3%) previously received IPT; 10 (10.3%) reported history of TB.

One-hundred fifty-five urine tests were performed among 97 infants (54 [55.6%] 1 test, 29 [29.9%] 2 tests, 14 [14.4%] ≥3 tests) with 77 (49.7%) positive tests. Urine tests were positive in approximately 50% of infants with maternal-reported optimal INH use (>90% pills taken since last visit) (48/94), INH taken ≤24 hours (69/134), or no missed doses past 3 days (72/136).

Positive urine INH test was associated with maternal secondary education (RR 1.5 [95%CI 1.1-2.2, p=0.02]), increased household rooms (RR 1.2 per room [95%CI 1.0-1.5, p=0.02]), maternal HIV VL <1000 copies/ml (RR 2.1 [95%CI 1.1-4.0], p=0.02]), and report of no missed doses past 3 days (RR 2.4 [95%CI 1.0-5.6], p=0.05). Infant sex, age at visit, maternal history of TB or IPT were not associated with adherence.

CONCLUSIONS: Urine biomarker assessment suggests over-reported infant INH adherence. Association of maternal education and viral suppression with increased infant INH adherence suggests maternal understanding of medication rationale and success in their own medication adherence predicts infant adherence. Biomarker monitoring may be useful to evaluate and motivate infant medication adherence.

OAB0705

RATES OF CERVICAL LESIONS BY AGE AND PREVIOUS SCREENING STATUS AND ENHANCING TREATMENT AMONG WOMEN LIVING WITH HIV (WLHIV) IN SUB-SAHARAN AFRICA WITHIN THE GO FURTHER PARTNERSHIP

D.H. Watts[1], J. Albertini[1], C. Cazier[2], A. Shakarishvili[3], A. Prainito[1], H. Kusmich[2], N.J. Heard[1], E.P. Vallejo[1], D. Birx[1]
[1]U. S. Department of State, Office of the Global AIDS Coordinator, Washington, United States, [2]George W. Bush Institute, Dallas, United States, [3]UN Joint Programme on AIDS, Geneva, Switzerland

BACKGROUND: WLHIV are at increased risk of persistent HPV infection and invasive cervical cancer (ICC). Optimal age at initiation of screening and timing of follow up for WLHIV are unknown. We assessed the rates of abnormalities by age and screening status among WHLHIV and evaluated factors associated with treatment.

METHODS: In May 2018, PEPFAR, the George W. Bush Institute, and UNAIDS launched the Go Further partnership; Merck joined in 2019. PEPFAR provided support in eight countries with high HIV prevalence for rapid scaling of bi-annual screening with visual inspection with acetic acid (VIA) for WLHIV aged 25-49 or per national guidelines and single screening for women >49. Semi-annual data included age, type of screening (first, rescreen or follow up one year after treatment), VIA findings (negative, positive – precancerous lesions, or suspect ICC), and treatment. Scale up began in Q4 of FY2018. Programmatic data, in country reviews, and GIS mapping were used to assess factors associated with treatment rates.

RESULTS: Through September 2019, 567,267 screenings were performed: 488,977 first screenings, 73,265 repeat, and 5,025 follow up after treatment. The rate of pre-cancer and suspected ICC were 6.5% and 1.5% at first screen, 0.9% and 0.2% in rescreens, and 11.9% and 7.1% after treatment. The rate of cervical pre-cancerous lesions and suspected ICC by age are below.

Age	Negative n (%)	Positive n (%)	Suspected ICC n (%)
15-19	6152 (93.8%)	352 (5.4%)	53 (0.8%)
20-24	30648 (92.0%)	2306 (6.9%)	355 (1.1%)
25-29	94106 (91.5%)	7625 (7.4%)	1091 (1.1%)
30-34	100823 (91.7%)	7630 (6.9%)	1463 (1.3%)
35-39	87065 (91.5%)	6716 (7.1%)	1419 (1.5%)
40-44	74356 (91.6%)	5364 (6.6%)	1435 (1.8%)
45-49	56178 (92.8%)	3235 (5.3%)	1119 (1.8%)
50+	44815 (92.4%)	2110 (4.4%)	1563 (3.2%)
Unknown Age	27229 (93%)	1627 (5.6%)	432 (1.5%)

Procurement issues, need for LEEP training, and lack of space were associated with treatment delays; mapping site level results to equipment placement can alleviate treatment backlog.

CONCLUSIONS: Rates of pre-cancerous lesions and suspected ICC after treatment were high, suggesting follow up screening sooner than one year. The rates of pre-cancerous lesions and suspected ICC were high across age bands, suggesting screening should start before age 25 for WLHIV. Aligning treatment availability to sites with high VIA-positive numbers can improve treatment rates.

OAB0706

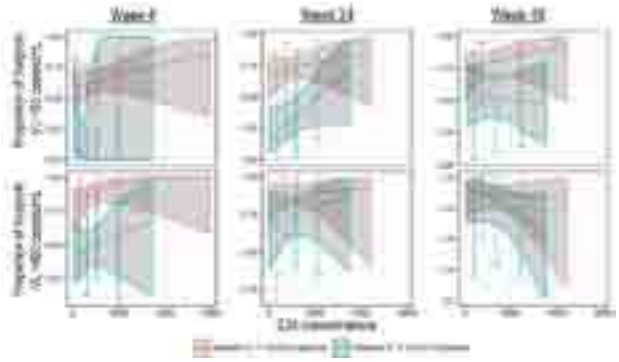
PLASMA EXPOSURE-VIRAL LOAD RESPONSE ANALYSIS FOR DOLUTEGRAVIR IN CHILDREN WITH HIV-1: RESULTS FROM IMPAACT P1093

R. Singh[1], E. Acosta[2], A. Buchanan[3], J. Green[4], C. Brothers[3], A. Wiznia[5], C. Alvero[6], M. Farhad[6], M. Bartlett[7], S. Popson[7], E. Townley[8], R. Hazra[9], K. George[10], T. Ruel[11], C. Vavro[3], M. Baker[12], and The P1093 Team
[1]GlaxoSmithKline, Collegeville, United States, [2]University of Alabama, Birmingham, United States, [3]ViiV Healthcare, Research Triangle Park, United States, [4]ViiV Healthcare, London, United Kingdom, [5]Albert Einstein College of Medicine, Bronx, United States, [6]Harvard T.H. Chan School of Public Health, Boston, United States, [7]Frontier Science Foundation, Amherst, United States, [8]National Institute of Allergy and Infectious Diseases, Rockville, United States, [9]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States, [10]Family Health International, Durham, United States, [11]University of California, San Francisco, United States, [12]ViiV Healthcare, Nyon, Switzerland

BACKGROUND: The approval of antiretroviral dosing in children is generally based on matching adult pharmacokinetic exposure parameters. However, higher variability in pediatric exposures suggests that efficacy may not be presumed to be identical to that in adults. Therefore, we evaluated the relationship between dolutegravir (DTG) exposure and virologic response in children.

METHODS: P1093 is a Phase I/II, open-label PK and safety study. The probability of virologic response (VR, HIV-1 RNA <50 or <400 copies/mL at Weeks 4, 24 and 48) was modelled as a function of DTG exposure (C24, Cavg or AUC0-24) based on sampling between days 5-10, weeks 4, 12 and 24; covariates included baseline viral load (VL), CD4+ count, CDC HIV infection stage and baseline VL ≥100,000 copies/mL. Logistic regression analyses were performed using NONMEM (version 7.4.3).

RESULTS: A total of 143, 135 and 112 VL observations were available at Weeks 4, 24 and 48, respectively. DTG exposure parameters (C24, AUC0-24 and Cavg) were not predictive of VR within the dose ranges tested, suggesting that exposures were at the maximum of the exposure-response curve. This may also be attributed to small sample size per dose and higher PK variability. Figure 1 shows exposure-response relationships for short and long-term (VR) versus C24. Baseline VL ≥100,000 copies/mL was a significant predictor of response and associated with a lower probability of achieving a VR of HIV-1 RNA <50 copies/mL (p<0.001).



[Figure 1. Viral load response rate versus C_{24}]

CONCLUSIONS: In IMPAACT P1093, a wide range of exposures (C24, AUC0-24 and Cavg) were observed at tested doses. DTG exposure metrics did not predict VL response, suggesting that the doses tested maintained exposures near maximum drug effect, while baseline VL remained a significant predictor of response. These results suggest that matching pediatric PK exposure parameters to those in adults is a reasonable approach for dose determination of DTG-containing formulations.

OAC01 ADOLESCENT GIRLS AND YOUNG WOMEN: EVALUATIONS INCLUDING DREAMS EVALUATION

OAC0102

THE IMPACT OF THE DREAMS PACKAGE ON HIV INCIDENCE AMONG YOUNG WOMEN WHO SELL SEX IN ZIMBABWE: A NON-RANDOMISED PLAUSIBILITY STUDY

S.T. Chabata[1], B. Hensen[2], T. Chiyaka[1], P. Mushati[1], S. Musemburi[1], . Dirawo[1], J. Busza[2], S. Floyd[2], I. Birdthistle[2], J.R. Hargreaves[2], F.M. Cowan[1,3]
[1]Centre for Sexual Health and HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

BACKGROUND: DREAMS aims to reduce new HIV infections among adolescent girls and young women through a targeted evidence-based intervention package. In a non-randomised study, we estimated its impact on HIV incidence among young women who sell sex (YWSS) in Zimbabwe.

METHODS: In two cities where DREAMS was implemented (2017-2019) and four towns without DREAMS implementation, respondent-driven sampling was used to recruit YWSS aged 18-24. At enrolment in all sites, consenting YWSS were offered HIV testing and referred to existing services for sex workers. In DREAMS sites only, oral pre-exposure prophylaxis (PrEP) and referral to other DREAMS services were available to YWSS. We followed up YWSS after two years. Using Poisson regression with follow-up time estimated as the time between interviews or half of this for those who sero-converted, we compared HIV seroconversion rates among YWSS between DREAMS and non-DREAMS sites. We adjusted for age, education, marital status, self-identification as a sex worker, STI symptoms, sexual partners in the past month, and HIV prevalence at enrolment. The study was powered to detect a 40% reduction in HIV incidence over 2 years.

RESULTS: Of 1859 HIV-negative women enrolled, 1019 (55%) were followed-up for 1896 person-years. Half of YWSS (48%) in DREAMS sites had been offered PrEP; 144 (28%) had ever started PrEP but few (12%) continued it (Table).

	DREAMS (N=538) n/N (%)	Non-DREAMS (N=481) n/N (%)	Comparison P-value
Attendance to Sisters with a Voice Clinic in past 12 months	317/538 (58.9)	135/480 (28.1)	<0.001
Attended Sisters with a Voice community mobilisation meeting in the past 12 months	73/537 (13.6)	27/480 (5.6)	<0.001
Attendance to PSI New Start Centre in past 12 months	135/538 (25.1)	56/480 (11.7)	<0.001
Attendance to Sisters with a Voice Clinic or PSI New Start Centre in past 12 months	381/538 (70.8)	164/480 (34.2)	<0.001
Ever been offered PrEP	150/521 (28.8)	4/450 (0.9)	<0.001
Ever taken PrEP	144/521 (27.6)	1/450 (0.2)	<0.001
Currently taking PrEP	63/521 (12.1)	0/450 (0.0)	<0.001
Recently HIV tested (within 6 months prior to the survey)	356/537 (66.3)	226/478 (47.3)	0.518
Social Protection services			
Receipt of cash transfer/educational subsidy in past 12 months	32/538 (6.1)	0/480 (0.0)	<0.001
Participation in continuing education programme in past 12 months	35/538 (3.9)	0/480 (0.0)	0.003

[Table. Comparison of interventions available through DREAMS and accessible to women in non-DREAMS sites through non-DREAMS partners, by arm]

Social protection service uptake was minimal (<5%). Among YWSS from DREAMS sites, HIV incidence was 3.1/100 person-years, compared to 5.3/100 person-years in non-DREAMS sites (RR=0.59; 95%CI 0.38-0.93). In adjusted analyses, there was little difference in HIV incidence between the DREAMS and non-DREAMS sites (RR=0.74; 95%CI 0.43-1.29; p=0.3).

CONCLUSIONS: We found limited evidence of a large impact of DREAMS on HIV incidence among YWSS in two Zimbabwean cities. Identifying approaches that enhance access to social services combined with delivery of biomedical interventions including PrEP remains critical for YWSS.

OAC0103

EFFECTS OF ECONOMIC SUPPORT AND COMMUNITY DIALOGUE ON ADOLESCENT SEXUAL BEHAVIOUR: FINDINGS FROM A CLUSTER-RANDOMISED CONTROLLED TRIAL IN ZAMBIA

H.K. Hegdahl[1], I.F. Sandøy[1]
[1]University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway

BACKGROUND: With a HIV prevalence twice that of their male counterparts and a high incidence of adolescent pregnancies, girls and young women in Sub-Saharan Africa are disproportionately affected by sexual and reproductive health problems (SRH). The objective of this study was to measure the effectiveness of

economic support alone or in combination with a community intervention, on sexual activity, contraceptive knowledge and contraceptive behaviour of adolescent girls.

METHODS: Data come from a cluster-randomised trial in rural Zambia. Recruitment was conducted between March and July 2016, and all girls from grade 7 in 157 selected schools were eligible to participate. Schools were randomised to either economic support, combined economic support and community dialogue, or control. Economic support consisted of cash transfers to girls and their parents, and payment of school fees for girls continuing to grade 8 and 9. The community dialogue consisted of community and youth meetings that aimed to enhance SRH knowledge and supportive community norms. The interventions lasted from 2016 to 2018, and outcomes were measured at the end of the intervention period. Comparisons between the arms were made using generalised estimating equations. All analyses were by intention-to-treat.

RESULTS: In total 4922 girls assented to participate. The mean age was 13.6 years at baseline and 16.1 years at the end of the intervention period. The response rate at the end of the intervention period was 89.4%. The proportion of girls reporting recent sexual activity was markedly lower in the combined arm (RR 0.73; 95% C.I. 0.60 – 0.89) and slightly lower in the economic arm (0.85; 95% CI 0.69 – 1.05) than in the control arm. Knowledge of modern contraceptives was higher in the combined than in the other two arms, but only significantly different from the economic arm (combined vs. economic RR 1.17; 95% C.I. 1.00 – 1.36; combined vs. control RR 1.16; 95% C.I. 0.95 – 1.43). No intervention effect was found on reported current use of modern contraceptives.

CONCLUSIONS: Economic support combined with community dialogue increased contraceptive knowledge and reduced sexual activity more than economic support alone, and may in turn reduce the risk of SRH problems. However, contraceptive use was not affected.

OAC0104

WHAT IS THE IMPACT OF DREAMS ON HSV-2 ACQUISITION AMONG AGYW IN RURAL KWAZULU-NATAL, SOUTH AFRICA?

N. Mthiyane[1], N. Chimbindi[1], T. Zuma[1], J. Dreyer[1], I. Birdthistle[2], S. Floyd[2], A. Gourlay[2], T. Smith[1], K. Baisley[2], N. McGrath[3], G. Harling[4], J. Seeley[2], M. Shahmanesh[4]
[1]Africa Health Research Institute, Durban, South Africa, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University of Southampton, Southampton, United Kingdom, [4]University College London, London, United Kingdom

BACKGROUND: In South Africa, adolescent girls and young women (AGYW) are at high risk of acquiring HIV and other sexually transmitted infections such as Herpes Simplex Virus type-2 (HSV-2). HSV-2 is a marker of unprotected sex and direct risk factor for HIV acquisition. We evaluated the impact of combination HIV prevention DREAMS (Determined, Resilient, Empowered, AIDS-free, Mentored and Safe) Partnership introduced in 2016 on HSV-2 infection in AGYW living in a rural area of South Africa where lifetime HIV acquisition risk is over 50%.

METHODS: We analysed data collected from a representative cohort of AGYW aged 13-22 selected from the general population in uMkhanyakude, KwaZulu-Natal. We collected data at three annual timepoints (2017-2019) on uptake of DREAMS interventions and collected dried blood spots for HSV-2 testing. HSV-2 seroconversion dates were estimated as the midpoint between date of last negative and first positive test; participants that remained negative throughout the study were censored at last visit date. We estimated HSV-2 prevalence and incidence rates and used Poisson regression to compare rate ratios among DREAMS beneficiaries (AGYW who were invited at any timepoint in 2016-2018 to participle in any DREAMS activity) and non-beneficiaries (AGYW never invited).

RESULTS: Of 2184 AGYW enrolled and tested for HSV-2 at baseline, 553 (25.3%) were HSV-2 positive. Of the remaining 1631, 1397 (85.7%) provided at least one follow-up test. HSV-2 incidence was 15.4 per 100 person-years (PY; 95%CI: 13.6–17.5). Incidence was non-significantly lower (14.3/100 PY) among DREAMS beneficiaries compared to non-DREAMS beneficiaries (16.9/100 PY). In age-adjusted analyses incidence rates were not significantly different between DREAMS beneficiaries and non-beneficiaries (overall: adjusted Rate Ratio (aRR) 0.97, 95%CI 0.75- 1.26; for 13-17y: aRR 1.24, 95%CI 0.84-1.83; for 18-22y: aRR 0.77, 95% CI 0.53-1.13).

CONCLUSIONS: We found little evidence of an impact of DREAMS on incidence of HSV-2 among AGYW in this setting with high HSV-2 and HIV prevalence. Sexual and reproductive health interventions need to be scaled up to reach vulnerable young people to prevent rapid acquisition of infections soon after sexual debut.

OAC0105

INCORPORATING PREP INTO STANDARD OF PREVENTION IN A CLINICAL TRIAL IS ASSOCIATED WITH REDUCED HIV INCIDENCE: EVIDENCE FROM THE ECHO TRIAL

D. Donnell[1], I. Beesham[2], J. Welch[3], R. Heffron[4], M. Pleaner[2], L. Kidoguchi[4], T. Palanee-Phillips[2], K. Ahmed[5], D. Baron[2], E. Bukusi[4], C. Louw[6], T. Mastro[3], J. Smith[2], J. Batting[2], M. Malahleha[5], V. Bailey[5], M. Beksinska[2], H. Reese[2], J. Baeten[4], ECHO Trial Consortium
[1]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Diseases, Seattle, United States, [2]University of Witwatersrand, Durban, South Africa, [3]FHI 360, Durham, United States, [4]University of Washington, Seattle, United States, [5]Setshaba Research Center, Tshwane, South Africa, [6]University of Pretoria, Pretoria, South Africa

BACKGROUND: As oral PrEP becomes standard of prevention globally, its potential impact on HIV incidence in clinical trials of new prevention interventions is unknown. In the ECHO Trial, conducted between 2015 and 2018, PrEP was incorporated into standard of prevention from 2017. We assess the effect of access to PrEP on HIV incidence in this natural experiment.

METHODS: At 12 sites in four countries (Eswatini, Kenya, South Africa, Zambia), women were randomized to receive one of three contraceptives (copper IUD, DMPA-IM and levonorgestrol implant) and followed quarterly for up to 18 months to determine the impact of contraceptive use on HIV acquisition. The present analyses are limited to the South African sites (9 of 12 trial sites, 74% of trial enrollment), because PrEP access was offered onsite by the study team in 2018, accompanied by additional staff training; in the other three sites PrEP was offered off-site through demonstration and implementation projects. Using Poisson regression with GEE, we compared HIV incidence pre- vs. post-PrEP access, limited to quarterly visit months at which PrEP access was available on-site and, in a sensitivity analysis, to the 180 days before and after access.

RESULTS: 2043 women had follow-up time after on-site PrEP access began, of whom 543 (27%) initiated PrEP. A total of 12 HIV seroconversions were observed in 556 person-years (incidence

2.16 per 100 person-years) after PrEP access, compared to 133 HIV seroconversions in 2863 person-years (4.65 per 100 person-years) before PrEP access (IRR 0.451, p=0.009). Limiting to the 180 days post- vs. pre-access showed similar results (incidence 2.29 vs. 5.00 per 100 person years, IRR 0.434, p=0.016). Prior to PrEP access, HIV incidence was similar for women who did and did not have opportunity (based on enrollment date) to access PrEP on-site.

CONCLUSIONS: Access to PrEP as part of standard of prevention in a clinical trial among women in South Africa was associated with a halving of HIV incidence, when about a quarter of women started PrEP. Providing access to PrEP on-site as part of the standard of care package for prevention may result in decreased HIV incidence in future HIV prevention trials.

OAC0106

CONSENT COMPREHENSION AND WAIVER OF CAREGIVER CONSENT FOR MINORS PARTICIPATING IN SENSITIVE RESEARCH: VIEWS OF ADOLESCENT GIRLS AND CAREGIVERS IN WESTERN KENYA

L. Oluoch[1], K. Agot[1], M. Ochillo[1], G.-N. Wango[2], M. Omoya[1], N. Ounda[1], H. Thirumurthy[3]
[1]Impact Research and Development Organization, Research, Kisumu, Kenya, [2]Nyanza Initiative for Girls' Education & Empowerment, Kisumu, Kenya, [3]University of Pennsylvania, Philadelphia, United States

BACKGROUND: Adolescents under the age of consent often miss out on effective biomedical HIV interventions because they do not participate in trials. Researchers generally focus on adults to avoid dealing with the requirement of caregiver (CG) permission for minors to participate in research. We explored understanding of the consent by CG and adolescent girls (AG) and their views on waiver of CG consent.

METHODS: We conducted in-depth interviews (IDIs) with AG and CG, enrolled though the DREAMS program. The topics elicited information on: how to administer the consent to ease comprehension; components of the consent difficult or easy to understand; views on waiver of caregiver consent on general and sensitive research topics such as on HIV, sexually-transmitted infections, pregnancy, and contraceptives. The sessions were audio-recorded and transcribed; thematic approach was used to code the transcripts based on discussion topics.

RESULTS: We conducted 33 IDIs with AG aged 15-17 years and 40 with CG aged 23-52 years. Although both AG and CG expressed fatigue with the 'hard', 'compact' and 'long' contents of the informed consent, elements found specifically difficult were: apparent contradictions e.g., with voluntarism ('you invite us to join a study then tell us we can withdraw or not answer questions'); confusion with multiple durations, e.g., for IDI, study, paper data storage, electronic data storage; subject matter of research, such as 'how saliva can carry HIV'. AG also found research terms in local language difficult to understand, e.g., compensation for time, voluntarism, ethical oversight, etc.

Both AG and CG preferred reading sub-titles then staff reads text and asks questions; they suggested group discussion to aid understanding. Waiver of CG consent for minors on various reproductive health topics was rejected: 57.5-81.8% by AG and 37.5-100% by CG; however, if research topic is sensitive and may reveal sexual relationships of AG to their CG, 67% of AG preferred giving own consent.

CONCLUSIONS: AG and CG find consent documents generally long and technical. Waiver of CG consent was rejected by both AG and CG; however, if it leads to involuntary disclosure of AG's sexual behaviour, most AG but not CG recommend waiver.

OAC02 CAN WE ACHIEVE UTT? WHAT CAN UTT ACHIEVE?

OUTREACH-BASED HIV TESTING APPROACH FROM TEST & TREAT PROJECT IN TANZANIA: MID-TERM RESULTS

G. Martelli[1], L. Van Duffel[1], I. Amiri Salehe[1], F. Cavallin[2], E. Cosmas Kwezi[1], G. Putoto[3], G. Torelli[1], T. Rinke de Wit[4], A. Pozniak[5], B. Mwesiga Desderius[6], A. Bortolani[3]
[1]Doctors with Africa CUAMM, Shinyanga, Tanzania, United Republic of, [2]Independent Statistician, Solagna, Italy, [3]Doctors with Africa CUAMM, Padua, Italy, [4]Amsterdam Institute for Global Health and Development (AIGHD), Amsterdam, Netherlands, [5]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom, [6]Bugando Medical Centre, Mwanza, Tanzania, United Republic of

BACKGROUND: The Test & Treat project is implemented in Tanzania by the Diocese of Shinyanga and CUAMM - Doctors with Africa. This project offers universal HIV testing and access to decentralized antiretroviral treatment through 4 Care and Treatment Clinics in Shinyanga and Simiyu regions, where estimated HIV prevalence is 5.9% and 3.9% respectively (Tanzania HIV Impact Survey, 2017).

METHODS: HIV testing and counseling activities were offered through extensive community outreaches, special events and facility-based services. The current cross-sectional study provides midterm results at 26 months (May 2017 – June 2019), stratified by sex and age. Aggregated data were collected from governmental testing registers.

RESULTS: A total 255,329 HIV tests were performed: 198,451 (77.7%) during testing campaigns in the villages, 44,286 (14.4%) in the health facilities and 12,592 (4.9%) during special events' outreaches. Gender distribution varied among testing modalities: females represented 53.8% (23,809) among those who tested in the health facilities, while males were the majority in the community (54.4%, 114,835 among testing campaigns and special events). Over one third of tests (n=102,427 41%) were performed among first-time testers. At multivariable analysis, higher rate of first-time testers was associated with being tested in the community versus in the facilities (RR 1.07, 95% CI 1.05 to 1.09; p<0.0001), with males (RR 1.05, 95% CI 1.04 to 1.07; p<0.0001) and with younger age (RRs ranging from 1.08 to 5.87 in age classes; p<0.0001). The overall HIV positivity rate was 1.2%, ranging from 0.7% in the community to 3.8% in the health facilities. HIV positivity rate was higher in females, both in the community (0.9% vs. 0.5%, p<0.0001) and in the health centres (4.2% vs. 3.4%, p<0.0001), among those with higher age classes (RR 1.68, 95% CI 1.62 to 1.73; p<0.0001) and the first-time testers (RR 1.93, 95% CI 1.80 to 2.08; p<0.0001).

CONCLUSIONS: Test &Treat project facilitated HIV testing in Shinyanga and Simiyu yielded relatively low numbers of newly identified HIV patients, complementary to ongoing efforts by National AIDS Control Program and others. More targeted efficient strategies to reach 'the first 90' are recommended, such as index testing or hot spot testing.

OAC0203

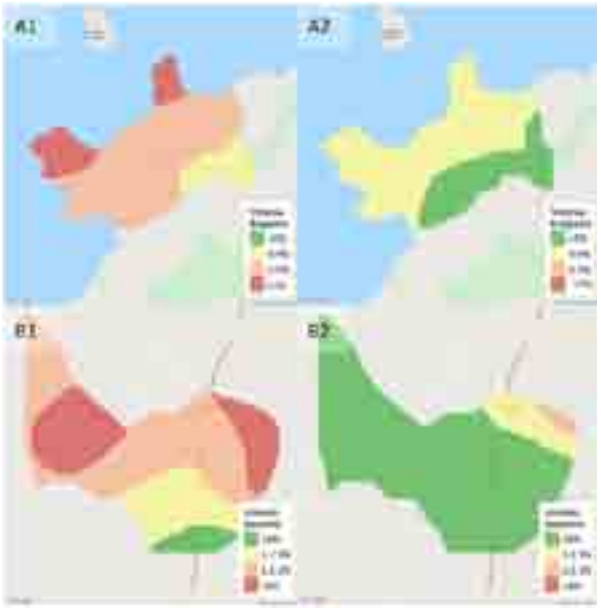
GEOGRAPHIC HOTSPOTS OF HIGH POPULATION HIV VIREMIA AND ASSOCIATION WITH HIV INCIDENCE IN A UNIVERSAL TEST-AND-TREAT SETTING IN RURAL UGANDA AND KENYA

J. Peng[1], J. Kabami[2], J. Ayieko[3], F. Mwangwa[2], M. Atukunda[2], E. Charlebois[1], G. Chamie[1], D. Kwarisiima[2], L. Balzer[4], M. Kamya[5], D. Havlir[1], M. Petersen[6]
[1]University of California, Department of Medicine, San Francisco, United States, [2]Infectious Disease Research Collaboration, Kampala, Uganda, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]University of Massachusetts, Amherst, United States, [5]Makerere University, Kampala, Uganda, [6]University of California, Berkeley, United States

BACKGROUND: In the context of universal ART eligibility and increasing viral suppression, geospatial heterogeneity in HIV viremia could clarify drivers of transmission and improve intervention targeting. We evaluated the geospatial distribution of viremia before and after universal test-and-treat (UTT) implementation and its relation to HIV incidence.

METHODS: In 2013-2014, 10 West Ugandan and 12 Kenyan communities in the SEARCH study (NCT01864603) were census-enumerated with residential GPS coordinates recorded; 90% underwent HIV testing and HIV-RNA measurement, with repeat testing after 3 years. All HIV+ persons were eligible for ART at or after baseline. A moving 2-km Gaussian kernel was used to calculate local viremia (% of all adults with HIV-RNA >1000 cps/mL) at baseline and endpoint. Geographic clusters were detected using Tango's scan statistic. Within-community association between local viremia and incidence was evaluated with cluster-robust Poisson regression.

RESULTS: Among 106,164 adults aged≥15 years, median local viremia was 2.0% in Uganda and 3.7% in Kenya at baseline and declined to 0.8% in Uganda and 1.8% in Kenya after three years (Figure).



[Figure: Heatmap of baseline and year 3 follow-up viremia in Nyamrisra comunity in Kenya (A1 and A2) and Rubaare community in Uganda (B1 and B2), created using a 2-kilometer Gaussian kernel.]

11 communities (5 Uganda, 6 Kenya) had viremia clusters at baseline; 4 of these (2 Uganda, 2 Kenya) plus 3 new communities had clusters at year 3. At baseline, persons living closer to a road or the Lake Victoria coast had higher local viremia; these associations were attenuated after UTT. In Kenya, where HIV incidence declined by 43% during the study, every 1% absolute increase in local viremia was associated with a 32% increase in HIV incidence (IRR: 1.32, 95% CI: 1.14-1.52). In Uganda, where HIV incidence did not decline despite similar reductions in viremia, local viremia did not predict incidence (IRR: 0.96, 95% CI: 0.78-1.17).

CONCLUSIONS: In the context of UTT, HIV viremia declined but geographic hotspots of viremia remained, suggesting a role for geospatially-targeted testing and care engagement strategies.

OAC0204

IMPACT OF UNIVERSAL TESTING AND TREATMENT ON SEXUAL RISK BEHAVIOUR AND HSV-2: EVIDENCE FROM THE HPTN 071 (POPART) TRIAL IN ZAMBIA AND SOUTH AFRICA

E. Wilson[1], D. Donnell[1], T. Skalland[1], A. Moore[2], N. Mandla[3], J. Bwalya[4], N. Kasese[4], R. Dunbar[3], K. Shanaube[4], B. Kosloff[5,4], O. Laeyendecker[6], Y. Agyei[6], D. Lennon[6], G. Hoddinott[3], P. Bock[3], S. Fidler[7], R. Hayes[5], H. Ayles[5,4]
[1]Fred Hutchinson Cancer Research Center, Seattle, United States, [2]FHI 360, Durham, United States, [3]Stellenbosch University, Cape Town, South Africa, [4]Zambart, Lusaka, Zambia, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Johns Hopkins Univ. School of Medicine, Baltimore, United States, [7]Imperial College, London, United Kingdom

BACKGROUND: HPTN 071 (PopART) was a cluster-randomized trial of a combination HIV prevention strategy, including universal HIV testing and treatment (UTT) conducted between 2013-2018 in 21 high HIV prevalence communities in Zambia and South Africa. HIV incidence was significantly reduced in the trial arm which included universal HIV testing and treatment according to national guidelines (Arm B), with a lesser effect in the full UTT arm (Arm A), compared to standard of care (Arm C). We investigate if the intervention changed sexual behaviour.

METHODS: A population cohort of ~2000 randomly selected adults (18-44) in each community (N=48,301) was followed for 3 years to evaluate the impact of the trial on HIV, HSV-2 and sexual behaviour (N= 27,501 completed final visit). Differences in self-reported sexual behaviour were assessed using a two-stage method for matched cluster-randomized trials. HSV-2 incidence, as a marker of sexual risk, was measured in participants negative at enrollment with blood drawn at the final visit.

RESULTS:

Risk Variable	Sub-group	Mean of community proportions at final study visit			Adj Prev ratio A vs C (95%CI)	P Values	Adj Prev ratio B vs C (95% CI)	P Values
		Arm A	Arm B	Arm C				
HSV-2 incidence	Overall	11.6%	9.55%	11.9%	0.89 (0.73, 1.08)	0.199	0.76 (0.63, 0.92)	0.010
	Men	7.48%	5.25%	7.82%	0.93 (0.63, 1.38)	0.700	0.64 (0.43, 0.95)	0.030
	Women	14.1%	12.4%	14.8%	0.89 (0.73, 1.07)	0.190	0.81 (0.67, 0.98)	0.035
	Women	5.18%	4.93%	4.71%	1.01 (0.78, 1.30)	0.950	1.02 (0.78, 1.31)	0.902
Multiple sexual partners in last 12 mo.	Overall	1.95%	4.01%	4.17%	0.63 (0.29, 1.35)	0.210	1.05 (0.49, 2.26)	0.892
	Men	5.35%	9.12%	10.8%	0.65 (0.32, 1.31)	0.205	0.87 (0.43, 1.75)	0.661
	Women	1.08%	2.25%	1.63%	0.68 (0.24, 1.99)	0.450	1.53 (0.53, 4.45)	0.396
No condom use at last sex	Overall	60.3%	62.6%	62.4%	0.89 (0.79, 1.01)	0.064	0.98 (0.87, 1.11)	0.778
Sexual debut during PopART, if had never had sex at enrollment	Overall	72.8%	74.1%	73.3%	0.99 (0.84, 1.18)	0.926	1.00 (0.85, 1.19)	0.979

[Table 1: Arm comparison of change in sexual risk outcomes]

No significant changes in self-reported sexual behaviour were observed as a result of the intervention (Arms A or B versus C) (Table 1). The percentage of HSV-2 negative participants who acquired HSV-2 during the trial was 11.6% in Arm A, 9.6% in Arm B and 11.9% in Arm C. Mirroring the trial's HIV incidence result, HSV-2 incidence was lower by 11% (95% CI -8%, 27%,p = 0.2) in Arm A versus C, and by 24% (95% CI 8%, 37%, p = 0.01) in Arm B versus Arm C. Similar results held for men and women, with fewer HSV-2 infections observed in Arm B compared to Arm C.

CONCLUSIONS: There was no evidence that PopART interventions caused sexual risk disinhibition. HSV-2 incidence mirrored HIV-incidence, underscoring the potential importance of the correlation between HSV-2 and HIV susceptibility.

OAC0205

INCREASED TARGETED HIV TESTING AND REDUCED UNDIAGNOSED HIV INFECTIONS AMONG GAY AND BISEXUAL MEN IN NEW SOUTH WALES, AUSTRALIA 2010-2018

P. Keen[1], P. Patel[1], H. McManus[1], T. Duck[2], D. Callander[3,1], C. Selvey[2], C. Power[2], R.T. Gray[1], K. Vickie[4,1], J. Asselin[5], P. Read[6,1], K. Johnson[7], B.R. Bavinton[1], A.E. Grulich[1], R. Guy[1], on behalf of the NSW HIV Prevention Partnership Project
[1]The Kirby Institute, UNSW Sydney, Faculty of Medicine, Sydney, Australia, [2]NSW Ministry of Health, Sydney, Australia, [3]Columbia University, Spatial Epidemiology Lab, New York City, United States, [4]Sydney Sexual Health Centre, Sydney, Australia, [5]Burnet Institute, Melbourne, Australia, [6]Kirketon Road Centre, Sydney, Australia, [7]ACON, Sydney, Australia

BACKGROUND: In New South Wales (NSW), approximately 80% of HIV diagnoses occur among gay and bisexual men (GBM). In 2012 and 2016, the NSW Government released strategies aiming to increase HIV testing frequency among GBM and virtually eliminate HIV transmission. A range of HIV testing initiatives were introduced and expanded, and key indicators developed to evaluate their impact.

METHODS: Seven HIV indicators were measured during 2010-2018: (1) state-wide total HIV laboratory tests; (2) number of GBM attending cost-free publicly-funded HIV testing services; (3) 12-monthly HIV testing uptake; (4) annual HIV testing frequency; (5) HIV testing concurrently with a STI diagnosis; (6) HIV positivity; and (7) proportion of men with undiagnosed HIV among GBM living with HIV. Data were collected from existing passive and sentinel surveillance systems and mathematical modelling. Indicators were stratified by Australian vs. overseas-born.

RESULTS: Overall, 43,560 GBM attended the HIV testing services within the sentinel system (22,662 Australian-born, 20,834 overseas-born, 64 unknown) from 2010-2018. The number of attendees increased from 5,186 in 2010 to 16,507 in 2018. There were increasing trends (p<0.001 for all) in 12-monthly HIV testing uptake (83.9% to 95.1%); concurrent HIV testing with a STI diagnosis (68.7% to 94.0%); annual HIV testing frequency (1.4 to 2.7); and a decreasing trend (p<0.01) in HIV positivity (1.7% to 0.9%). Increases in testing were similar in Australian-born GBM and overseas-born GBM. However, among GBM living with HIV in NSW, there were decreasing trends in the estimated undiagnosed HIV proportion overall (9.5% to 7.7%) and in Australian-born GBM (7.1% to 2.8%), but an increasing trend in overseas-born GBM (15.3% to 16.9%) (p<0.001 for all).

CONCLUSIONS: Over the nine-year study period, more than three times more GBM attended the HIV testing services demonstrating increased demand for testing. Among these men, HIV testing was optimised reaching very high levels of uptake and frequency by 2018. The decline in the estimated undiagnosed proportions in GBM indicates HIV testing initiatives were well targeted in this group, reaching a very low level of undiagnosed HIV by 2018. Future initiatives should focus on addressing the higher undiagnosed proportion among overseas-born GBM and achieving further increases in testing frequency.

OAC0206

ESTIMATED TIME FROM HIV INFECTION TO DIAGNOSIS, 50 U.S. STATES AND THE DISTRICT OF COLUMBIA, 2014–2017

N. Crepaz[1], R. Song[1], S. Lyss[1], H.I. Hall[1]
[1]Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: In the United States, 38% of HIV transmissions occur from persons with undiagnosed HIV infection. Delayed diagnosis reduces opportunities to improve health outcomes of persons with HIV and to prevent HIV transmission. To inform local prevention efforts, we examined time between HIV infection and diagnosis (Infx-to-Dx) at the jurisdiction level.

METHODS: We analyzed data reported to the National HIV Surveillance System (NHSS) through June 2019 from 50 U.S. States and the District of Columbia for HIV diagnoses occurring among persons aged >13 years during 2014–2017. We calculated the interval between HIV infection and diagnosis by using HIV infection dates estimated based on a CD4 depletion model and HIV diagnosis dates reported to NHSS. Trends during 2014–2017 in the median number of months for Infx-to-Dx intervals were examined by using estimated annual percentage change.

RESULTS: During 2014–2017 in the United States, 157,412 HIV diagnoses occurred. The median Infx-to-Dx interval decreased from 43 months for persons with HIV diagnosed in 2014 to 40 months for persons with HIV diagnosed in 2017, a 2.3% annual decrease (P <0.001). Infx-to-Dx intervals shortened significantly during 2014–2017 in the South and the West (Table) which accounted for 71.2% of all HIV diagnoses during 2014–2017. In 41 jurisdictions with reliable estimates in 2017 (relative standard errors < 30%), median Infx-to-Dx intervals were <36 months for 10 (24.4%) jurisdictions, 36–47 months for 23 (56.1%), and ≥48 months for 8 (19.5%).

Region	2014 Median Month (IQR) No. of HIV Diagnosis	2015 Median Month (IQR) No. of HIV Diagnosis	2016 Median Month (IQR) No. of HIV Diagnosis	2017 Median Month (IQR) No. of HIV Diagnosis	Estimated Annual Percentage Change P value
Northeast	42 (0–106) N = 6,671	46 (0–107) N = 6,224	41 (0–105) N = 5,861	42 (0–102) N = 5,623	-1.5 p = 0.428
Midwest	46 (0–108) N = 5,111	39 (0–100) N = 5,357	46 (0–104) N = 5,292	41 (0–96) N = 5,231	-1.4 p = 0.645
South	45 (0–106) N = 20,294	42 (0–103) N = 20,487	41 (0–102) N = 20,399	41 (0–100) N = 19,874	-3.1 p < 0.0001
West	38 (0–100) N = 7,862	38 (0–98) N = 7,711	37 (0–96) N = 7,944	37 (0–95) N = 7,473	-1.6 p < 0.0001
Total	43 (0–106) N = 39,938	41 (0–102) N = 39,777	41 (0–102) N = 39,495	40 (0–99) N = 38,201	-2.3 p < 0.0001

CONCLUSIONS: During 2014–2017, the median time from HIV infection to diagnosis shortened nationally and particularly in southern and western states, suggesting better access to testing. However, delayed HIV diagnosis is substantial; one in two persons

with HIV diagnosed in 2017 was infected at least 40 months before diagnosis. That the median Infx-to-Dx interval was longer than 36 months for three-quarters of jurisdictions underscores the importance of addressing local barriers to early diagnosis.

OAC03 HARM REDUCTION: ARE WE MAKING PROGRESS?

OAC0302

DRUG OVERDOSES ARE REDUCING THE GAINS IN LIFE EXPECTANCY OF PEOPLE LIVING WITH HIV (PLWH) IN BRITISH COLUMBIA, CANADA

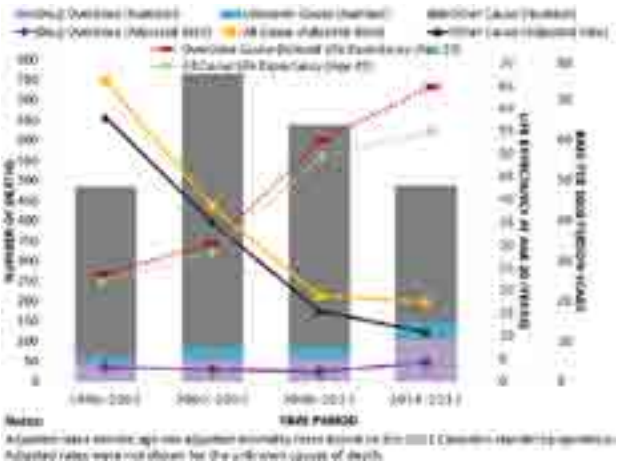
M. St-Jean[1], X. Dong[1], D.M. Moore[1,2], P. Sereda[1], K. Salters[1], R.S. Hogg[1], T.L. Patterson[3], R. Barrios[1], J.S. Montaner[1], V.D. Lima[1]
[1]British Columbia Centre for Excellence in HIV/AIDS, Epidemiology and Population Health, Vancouver, Canada, [2]University of British Columbia, Department of Medicine, Vancouver, Canada, [3]University of California, Department of Psychiatry, San Diego, United States

BACKGROUND: Overdose deaths have substantially increased in British Columbia (BC) since 2014; a public health emergency was declared in 2016. People living with HIV (PLWH) are disproportionately affected by substance use. We assessed the impact of illicit and pharmaceutical drug overdoses on life expectancy (LE) among PLWH in BC and identified factors associated with overdose mortality using competing risk methodology.

METHODS: PLWH were aged ≥20 years, initiated antiretroviral therapy (ART) between 1-Apr-1996 and 30-Dec-2017 in the Drug Treatment Program, and were followed until 31-Dec-2017, last contact date, or death date. We calculated all-cause and overdose cause-deleted LE at age 20 from abridged life tables. A subdistribution hazard model was built. Time-fixed covariates (at ART initiation) included gender, HIV exposure category, and ART initiation year (continuous). Time-varying covariates (6-month intervals) included age (continuous [years]), CD4 count (cells/mm^3), % suppressed viral load (VL), and time period. Overdose mortality was the outcome in the presence of competing mortality of other causes.

RESULTS: Overall, 10362 PLWH had a median age of 40 (25th-75th percentiles:33-47) years and follow-up of 6.93 (2.84-12.39) years; 26% were people who injected drugs (PWID). The largest loss in LE attributed to overdose occurred during the current 2014-2017 overdose era (2.5-5-fold higher than other periods). In 2014-17, the estimated LE at age 20 is 55 years. However, when overdose deaths are deleted, the estimated LE becomes 65 years (10 years greater) (*Figure 1*). Factors with elevated overdose hazards included the current overdose era (adjusted subhazard ratio [aSHR] 4.73 95% Confidence Interval, 2.07-11.38) relative to the harm reduction era (2002-2007), PWID (aSHR 7.88, 4.82-12.87) relative to men who have sex with men, VL not tested (aSHR 4.73, 3.54-6.31) and <100% suppression (aSHR 1.68, 1.20-2.36) relative to 100% suppression.

CONCLUSIONS: Survival gains, by virtue of combination ART, have been dramatically reduced due to the current overdose crisis.



[Figure 1: Mortality and life expectancy trends for individuals initiating ART in British Columbia, Canada, 1996-2017.]

OAC0303

HARM REDUCTION REVISITED: THE CAUSAL EFFECT OF THE DUTCH APPROACH TOWARDS PEOPLE WHO INJECT DRUGS ON HIV, HEPATITIS B AND C INFECTION RISK

D.K. van Santen[1,2,3], A. Boyd[1,4], A. Master[1], S. Lodi[5], M. Prins[1,6]
[1]Public Health Service of Amsterdam, Infectious Disease Research and Prevention, Amsterdam, Netherlands, [2]Burnet Institute, Disease Elimination, Melboune, Australia, [3]Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia, [4]Stichting HIV Monitoring, Amsterdam, Netherlands, [5]Boston University, Department of Biostatistics, Boston, United States, [6]University of Amsterdam, Amsterdam, Netherlands

BACKGROUND: Early implementation of low-threshold harm-reduction programs (HRP) (opiate substitution therapy (OST) and needle and syringe exchange programs (NSP)) in the Netherlands might have contributed to the major decline in incidence of human immunodeficiency virus (HIV), hepatitis C virus (HCV) and hepatitis B virus (HCV). We aimed to assess the causal effect of HRP participation on risk of these infections among persons who inject drugs (PWID).

METHODS: We emulated a target trial using observational data from the Amsterdam Cohort Studies (1985-2014). We included PWID who ever used opioids, had a recent history of injecting drug use (IDU) and had a negative antibody test. Follow-up was analysed in interval-time risk-sets with a maximum duration of two years. Follow-up was calculated from the earliest date all eligibility criteria were met (i.e. baseline), until individuals were no longer compliant, HIV, HCV or HBV seroconversion, lost to follow-up, reached administrative censoring date or completed the 2-year follow-up interval; whichever occurred first. The intervention arms were: complete HRP participation (OST: ≥60 mg methadone and NSP: 100% coverage, or OST: any dose if no recent IDU) versus no/partial HRP participation (OST: <60 mg and/or NSP: <100% coverage). Marginal structural Cox-regression models were used to estimate causal hazards ratios (HR) for each infection separately, including inverse probability weights of treatment and censoring.

RESULTS: Of 983 PWID participants, 653, 143 and 310 PWID were HIV-negative, HCV-negative and HBV-negative, respectively, and considered eligible. We observed 70 HIV, 48 HCV and 50 HBV seroconversions during follow up. Compared to no/partial

HRP, complete HRP participation led to a decreased risk in HIV (HR=0·56, 95%CI:0·33-0·92), HCV (HR=0·12, 95%CI:0·05-0·29) and HBV (HR=0·29, 95%CI:0·15-0·56) acquisition.

CONCLUSIONS: Harm reduction programs led to a major decrease in HIV, HCV and HBV acquisition among PWID from Amsterdam. To the best of our knowledge this is the first study reporting causal estimates for HRP on infection risk. These findings reinforce the need to implement or scale up low-threshold HRP to prevent on-going transmission among PWID.

ARE HARM REDUCTION PROJECTS FOR PEOPLE WHO INJECT DRUGS IN UKRAINE IMPROVING HIV PREVENTION AND TREATMENT OUTCOMES?

A. Trickey[1], N. Semchuk[2], T. Salyuk[2], Y. Sazonova[2], O. Varetska[2], J.G. Walker[1], A.G. Lim[1], J. Stone[1], P. Vickerman[1]
[1]University of Bristol, Population Health Sciences, Bristol, United Kingdom, [2]Alliance for Public Health, Kiev, Ukraine

BACKGROUND: People who inject drugs (PWID) in Ukraine have high prevalences of HIV and hepatitis C virus (HCV). The Global Fund to fight AIDS, Tuberculosis, and Malaria has funded non-governmental organisations (NGOs) in Ukraine since 2003 to provide PWID with needle and syringe distribution, condoms, HIV and HCV testing, and to improve linkage to opioid substitution therapy (OST) and HIV treatment. However, due to policy changes the Global Fund is scaling back support in Ukraine. We investigated whether contact with these NGOs is associated with improved HIV prevention and treatment outcomes among PWID.

METHODS: Five rounds of integrated bio-behavioural survey data (2009 [N=3962], 2011 [N=9069], 2013 [N=9502], 2015 [N=9405], and 2017 [N=10076]) among PWID in Ukraine (including HIV/HCV testing and questionnaires) were analysed using mixed-effect logistic regression models (mixed-effects: city, year). These regression models assessed associations between being an NGO client and various behavioural, OST, HIV testing, and HIV treatment outcomes, adjusting for demographic characteristics (age, gender, lifetime imprisonment, registration in a drug abuse clinic, education level). We also assessed associations between being an NGO client and being HIV-positive or HCV-positive, likewise adjusting for demographic characteristics (as above).

RESULTS: NGO clients were more likely to have received HIV testing ever (adjusted odds ratio [aOR] 5.53, 95% confidence interval [95%CI]: 5.10-6.00) or in the last year (aOR 3.44, 95%CI: 3.27-3.63), to have used condoms at last sexual intercourse (aOR 1.30, 95%CI: 1.23-1.37) and sterile needles at last injection (aOR 1.37, 95%CI: 1.20-1.57), to be currently (aOR 4.08, 95%CI: 3.38-4.93) or ever (aOR 2.76, 95%CI: 2.53-3.01) on OST, and to have in the last year received syringes (aOR 151.72, 95%CI: 136.56-168.57) or condoms (aOR 45.19, 95%CI: 42.24-48.35). PWID who were HIV-positive (aOR 1.40, 95%CI: 1.32-1.48) or HCV-positive (aOR 1.57, 95%CI: 1.49-1.64) were more likely to have contact with NGOs, with HIV-positive PWID in contact with NGOs more likely to be registered at AIDS centers (aOR 2.30, 95%CI: 1.82-2.90) and to be on antiretroviral therapy (aOR 1.52, 95%CI: 1.32-1.76).

CONCLUSIONS: Contact with PWID targeted NGOs in Ukraine is associated with consistently better preventive, HIV testing, and HIV treatment outcomes, suggesting a beneficial impact of Global Fund programming.

OAC0305

ASSESSING IMPLEMENTATION AND IMPACT OF AN EDUCATIONAL INTERVENTION FOR SAFER INJECTION AMONG PEOPLE WHO INJECT DRUGS IN EUROPE: A MULTI-COUNTRY MIXED-METHOD STUDY

P. Roux[1], C. Donadille[1], C. Magen[1], E. Schatz[2], R. Stranz[3], A. Curado[4], T. Tsiakou[5], L. Verdes[6], P. Carrieri[1], A. Ben Charif[7]
[1]INSERM - Aix Marseille University, SESSTIM, Marseille, France, [2]Correlation Network, Amsterdam, Netherlands, [3]AIDES, Paris, France, [4]GAT, Lisbon, Portugal, [5]PRAKSIS, Athens, Greece, [6]ARAS, Bucarest, Romania, [7]CERSSPL - Université de Laval, Laval, Canada

BACKGROUND: The implementation and scaling up of harm reduction (HR) interventions are essential to reduce HIV and HCV transmission among people who inject drugs (PWID) in Europe. The Individually Tailored Support and Education for Safer Injection (ITSESI) is an evidence-based educational intervention for PWID. While ITSESI has been preliminarily evaluated in France (AERLI intervention in Roux et al, 2016), showing to reduce HIV and HCV risk practices, this study aimed to implement and evaluate ITSESI at European level.

METHODS: We performed a mixed-method implementation study. The quantitative component involved a non-randomized controlled trial, while the qualitative component involved face-to-face interviews and focus groups. We conducted this study between 2018 and 2019 within HR programs in Bulgaria, Greece, Portugal, and Romania, by enrolling 307 adult PWID. Our intervention (ITSESI) consisted to observe injection practices of PWID and to provide an educational exchange with trained field workers. Participants were allocated to the usual services (control group) or the intervention group. Primary outcome was the effectiveness of ITSESI defined as the reduction of HIV and hepatitis C virus (HIV-HCV) risk practices. We used RE-AIM QuEST framework to assess effectiveness of ITSESI and other dimensions (e.g., reach, adaptation). We used a multivariable mixed logit model to analyze the primary outcome. Qualitative data was analyzed thematically to provide future investigations.

RESULTS: Out of 307 eligible PWID, 203 participated (66%) in the complete follow-up. Among them, 60.6% received ITSESI. HIV-HCV risk practices dropped from 27.1% to 14.8% in the intervention group, while it remained stable in the control group (20.0%). PWID who received ITSESI were less likely to report HIV-HCV risk practices (adjusted odds ratio [95% confidence interval]: 0.27 [0.11, 0.70]). Our qualitative data showed importance to adapt some components of ITSESI and involve stakeholders such as field workers and PWID as proactive research partner in order to make implementation of ITSESI more accessible and acceptable across Europe.

CONCLUSIONS: We demonstrated the effectiveness of ITSESI in reducing HIV-HCV risk practices in the European context. Our findings provide important understandings of the adaptation and implementation of ITSESI that are relevant for a large-scale implementation of ITSESI across Europe.

PROGRESS IN HIV PREVENTION INTERVENTIONS UPTAKES AMONG PEOPLE WHO INJECT DRUGS IN UNGUJA ISLAND, ZANZIBAR: ANALYSES OF BIO-BEHAVIORAL SURVEYS IN 2007, 2012 AND 2019

S. Haji[1], F. Khalid[1], C. Said[2], S. Mohamed[1], A.U. Khamis[1], A.A. Othman[1], E. Matiko[3], S. Welty[2], A. Khatib[1], G. Mgomella[3], W. McFarland[2]
[1]Zanzibar Integrated HIV, Hepatitis, Tuberculosis, and Leprosy Programme (ZIHHTLP), Zanzibar Ministry of Health, Stonetown, Tanzania, United Republic of, [2]University of California, Institute for Global Health Sciences, San Francisco, United States, [3]US Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Zanzibar has a concentrated HIV epidemic among key populations, including people who inject drugs (PWID) who are at elevated risk of acquiring HIV from both injection practices and exchange of sex for drugs. We aimed to measure HIV prevalence, HIV acquisition risk factors, and access to, and uptake of HIV prevention and care services over the last 12 years among PWID in Unguja, Tanzania.

METHODS: We conducted cross-sectional bio-behavioral surveys (BBS) of PWID conducted in 2007, 2012, and 2019 in Unguja. PWID were recruited into BBS using respondent-driven sampling (RDS). A total of 499, 408, and 419 PWID were surveyed in 2007, 2012, and 2019, respectively. Participants' information was collected through an interviewer-administered questionnaire among consenting PWIDs aged 15+ who reported to have injected in the last three months. HIV status was assessed using the national rapid test algorithm with return of results. Point estimates were adjusted for Respondent Driven Sampling. F-test P-values (2012-2019 comparison) and 95% CI confidence intervals were calculated.

RESULTS: HIV prevalence among PWID in Unguja Island decreased from 16.0% [95% CI: 11.4-21.2] in 2007, to 11.3% [95% CI: 7.7-15.2] in 2012, to 5.1% [95% CI: 2.6-7.5] in 2019. The proportion of PWID who had tested for HIV and received their results in the past one year increased from 13.3% in 2007, to 38.0% in 2012, to 44.1% in 2019 (p<0.001). Access to clean needles also increased over time, from 52.7% and 52.1% in 2007 and 2012, respectively, to 86.6% in 2019 (p<0.001). Concurrently, the proportion of PWID who reported using a previously used needle in the past one month decreased from 53.8% in 2007 to 29.1% in 2012 to 18.7% in 2019 (p<0.001).

CONCLUSIONS: We noted reduction of HIV prevalence and increase in self-reported awareness of HIV status among PWID, which is key to linkage and retention in ART. Our results suggest that preventive interventions targeting PWID have been well taken up. Although significantly reduced, HIV prevalence and related risk behaviors persist at levels warranting enhanced efforts to reach all PWID with primary prevention and harm reduction services, especially, eliminating the use of non-sterile needles.

FEASIBILITY OF IMPLEMENTATION, ACCEPTABILITY AND PRELIMINARY EFFECTS OF A PILOT, PEER-LED HIV SELF-TESTING INTERVENTION IN A HYPERENDEMIC FISHING COMMUNITY IN RURAL UGANDA

J.K. Matovu[1,2], L. Bogart[3], J. Nakabugo[4], J.M. Gitta[4], J. Kagaayi[5], D. Serwadda[4], R.K. Wanyenze[4], A. Ko[6], A. Kurth[7]
[1]Makerere University School of Public Health, Disease Control and Environmental Health, Kampala, Uganda, [2]Busitema University Faculty of Health Sciences, Mbale, Uganda, [3]RAND Corporation, Santa Monica, United States, [4]Makerere University School of Public Health, Kampala, Uganda, [5]Rakai Health Sciences Program, Kalisizo, Uganda, [6]Yale University, Epidemiology of Microbial Diseases, New Haven, United States, [7]Yale University, School of Nursing, New Haven, United States

BACKGROUND: Novel interventions are urgently needed to reach young people and adult men, who continue to show low HIV testing and linkage to HIV care rates compared to other populations. We assessed the feasibility of implementation, acceptability, and preliminary effects of a pilot, peer-led oral HIV self-testing (HIVST) intervention in Kasensero; a hperendemic (HIV prevalence: 37%) fishing community along the shores of Lake Victoria in rural Uganda.

METHODS: This prospective cohort study was conducted among young people (15-24 years) and adult men (25+ years) between May and August 2019. The intervention entailed distribution of HIVST kits by 34 trained "peer-leaders" who were local people selected from existing social networks and trained in HIVST distribution processes. Each peer-leader nominated up to 20 members from their social network who were screened for eligibility; up to 10 eligible members were enrolled into the study. Peer-leaders received up to 10 kits (one for each member) to distribute to eligible members of their social networks. Eligible social network members were followed up at 1-month post-baseline to assess uptake of HIVST and other associated outcomes. This intervention was deemed to be feasible if peer-leaders distributed up to 70% of the kits they received; and acceptable if >80% of the respondents self-tested for HIV. Data were analysed using STATA (version 14.1).

RESULTS: Of 298 (87.6%) enrolled into the study, 56.4% (n=168) were aged 15-24 years, 67.5% (n=201) were males, while 21.1% were engaged in fishing or fishing-related activities. Sixty-nine percent (n=206) had ever heard about oral HIVST. Peer-leaders distributed 296 (99.3%) kits. Ninety-seven percent (n=286) of those who received the kits self-tested for HIV, based on self-reports and returned used kits. HIV prevalence was 7.4% (n=21); 57.1% (n=12) were first-time HIV-positive testers. One-hundred per cent (n=12) of first-time HIV-positive testers sought confirmatory HIV testing (as recommended) and 10 (83.3%) were confirmed as HIV-positive. Nine of the ten (90%) confirmed first-time HIV-positive testers were linked to HIV care.

CONCLUSIONS: Our findings show that implementation of a social network-based, peer-led HIVST intervention in a hyperendemic fishing community is highly feasible, acceptable, and achieves high linkage to HIV care among newly diagnosed HIV-positive individuals.

OAC0403

HIV SELF-TESTS FREE DISTRIBUTION IN BRAZIL: AN EFFECTIVE STRATEGY FOR REACHING UNDIAGNOSED KEY POPULATIONS

M. Villares[1], A. Bigolin[1,2], L. Martins de Aquino[1], P.C. Gaspar[1,3], J. Boullosa Alonso Neto[1], N. Denilse de Araujo[1], G. Fernando Mendes Pereira[1]
[1]Brazilian Ministry of Health, Department of Diseases of Chronic Condition and Sexually Transmitted Infections, Brasilia, Brazil, [2]Federal University of Santa Catarina, Postgraduate Program in Pharmacy, Florianópolis, Brazil, [3]University of Brasilia, Postgraduate Program in Collective Health, Brasilia, Brazil

BACKGROUND: In 2018 there were 900.000 PLHIV in Brazil, of which 15% were unaware of their status. Innovative strategies are fundamental to increase access to testing, specially in countries with concentrated epidemics. In December 2018, Ministry of Health of Brazil (MoH) implemented a pilot strategy for free of charge distribution of 400,000 HIV self-tests (HIVST) in the public health system, aiming to reach undiagnosed people. This strategy, carried out in eight states, consisted in delivering up to six HIVST in three situations: for PrEP users to give to peers or partners; at places of sociability of key population (KP) by health teams and civil society organization (CSO); and secondary distribution for people tested in Health Services (HS). This study aimed to presenting the profile of people reached by the strategy.

METHODS: We collected HIVST distribution data through a form hosted in a monitoring system (SIMAV), with questions regarding demographics, sexual behavior, previous testing and number of tests taken, filled upon test delivery, which were afterwards analyzed.

RESULTS: By December 31, 2019, MoH distributed 51,906 HIVST, of which 45,052 HIVST were distributed to 16,364 people who filled the forms. Out of those people, 22% were 18-24 years old and 21% were 25-29 years old; black people accounted for 43% of completed forms, MSM accounted for 54% and trans people accounted for 4%. 25% were in PrEP.

Among those not in PreP, 20% were first time testers (32% among those aged 18-24), 14% had last tested for HIV over two years before and 37% tested less than six months. People in PrEP took an average of 3.3 HIVST to peers and partners, while other people took an average of 2.4 HIVST.

CONCLUSIONS: Preliminary data suggest that strategy is reaching the target population for HIVST, including young people and first time testers, raising the potential to reach undiagnosed. People in PrEP are potential secondary distributors. These results encouraged expansion for another six states in 2020. Innovative efforts to reach trans people are of special interest and should be increased.

OAC0404

TRUST: RESULTS OF AN HIV SELF-TESTING INTERVENTION FOR BLACK OR AFRICAN-AMERICAN TRANSGENDER WOMEN (TGW) AND GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN (MSM) IN NEW YORK CITY

V. Frye[1], V. Nandi[2], M. Paige[1], J. McCrossin[2], G. Ortiz[2], D. Lucy[2], D. Usher[2], D. Hoover[3], M. Gwadz[4], P. Sullivan[5], L. Wilton[6]
[1]CUNY School of Medicine, Community Health and Social Medicine, New York, United States, [2]New York Blood Center, Project ACHIEVE, New York, United States, [3]Rutgers University, New Brunswick, United States, [4]New York University, Silver School of Social Work, New York, United States, [5]Emory University, Rollins School of Public Health, Atlanta, United States, [6]Binghamton University, Department of Human Development, Binghamton, United States

BACKGROUND: Increasing HIV testing, the gateway to prevention/care, is critical to eliminating racial disparities and ending the HIV epidemic in the United States. HIV self-testing (HST), an alternative to clinic-based testing, is private, convenient and acceptable and may increase consistent/frequent testing.

METHODS: We evaluated a behavioral intervention to increase HST to support consistent HIV testing among Black or African-American transgender women (TGW) and men who have sex with men (MSM) and/or TGW via a randomized controlled trial. We enrolled eligible "index" participants in "friend pairs" between (mid-2016 to 2017) with every three-month follow-up over one year. The single-session intervention arm provided counselor-delivered HIV testing (as friend pairs), training on HST, and identification and practice of optimal peer support. The time/attention control arm provided counselor-delivered testing individually (results shared in pairs) and generic, didactic self-screening (including HST) information. Both arms received HST kits and testing reminders every 3 months. A modified intent-to-treat analysis, using GEE models with an independent structure and time as a cluster, of 98 intervention and 99 control "index" participants (only) was conducted.

RESULTS: Retention ranged from 78-82% at -3 and 6-months and 63-88% at 9- and 12-months across arms. In the intervention arm, the proportion of participants reporting HST in the past three months increased from baseline (2%) to 3-month (57%) and 6-month (54%) follow-up. In the control arm, the proportion of participants reporting HST in the past three months increased from baseline (7%) to 3-month (42%) and 6-month (42%) follow-up. The difference in the increases was statistically significant by arm at $p<.05$ and $p\leq.05$ at 3- and 6-month follow-up, respectively, but not at 9- and 12-month follow-up. Intervention arm participants were approximately twice as likely to HST at 3-month (OR 2.24; 95% CI: 1.12-4.47) and 6-month (OR: 1.94; 95% CI: 1.00-3.75) follow-up, compared with control arm participants.

CONCLUSIONS: The TRUST intervention increased HST over 6 months of follow-up, but impact was attenuated at 9 and 12 months. The intervention integrates HST skills-building and peer support to reduce barriers to HST, representing a promising approach to increasing consistent testing among subpopulations for whom consistent testing would be most beneficial.

OAC0405

FEASIBILITY OF INDEX TESTING AMONG INCARCERATED PEOPLE: EARLY RESULTS FROM FOUR CORRECTIONAL FACILITIES IN ZAMBIA

C.N. Moonga[1], H. Smith[2], L.K. Mwango[3], C. Zulu[2], C. Masumba[2], L. Kashela[2], M. Chilinya[2], K. Kaputula[2], K. Nkwemu[4], A. Mwila[4], J. Okuku[4], M. Mujansi[3], C.W. Claassen[3], M. Herce[2-5]
[1]Centre for Infectious Disease Research in Zambia, TB Department, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia, Implementation Science, Lusaka, Zambia, [3]University of Maryland—Baltimore (UMB), Centre for International Health, Education, and Biosecurity (CIHEB), Lusaka, Zambia, [4]U.S. Centers for Disease Control and Prevention (CDC), Lusaka, Zambia, [5]University of North Carolina at Chapel Hill, Chapel Hill, United States

BACKGROUND: Incarcerated people in Zambia face a disproportionately high HIV burden estimated at 27%–30%. Until recently, targeted HIV testing services (HTS), such as index testing, have not been implemented in correctional settings. We began providing consensual and confidential HIV partner notification services in four Zambian correctional facilities and offered index testing services to HIV-positive inmates with active community tracing of their partners. Traced contacts were offered HTS and HIV prevention and treatment services. We assessed the effectiveness of this program.

METHODS: In these four correctional facilities, entry and exit screening for HIV, tuberculosis, and sexually transmitted infections is offered as part of routine care. All HIV-positive inmates are immediately linked to HIV treatment, care, and support. In February–September 2019, all inmates with new HIV diagnoses were offered index testing services by trained providers during post-test counseling. Index patients were asked to provide contact information for their sexual partners per Ministry of Health guidance. Index contacts were traced by phone or home visit. Sexual contacts were counseled and tested for HIV. If HIV-positive, they were linked to antiretroviral therapy (ART), and HIV-negative contacts were linked to combination prevention.

RESULTS: Of the 175 (Female-27, Males-148) inmates offered index testing, 166 (Female-27, Male-139) (94.9%) accepted (Table). 293 (Female-223, Male-70) sexual contacts were identified (elicitation ratio: 1:1.8). Of these, 109 (Female-42, Male-67) (37.2%) were contacted: 59 (Female-23, Male-36) (54.1%) already knew their status and were receiving ART, and 50 (Female-19, Male-31) (45.9%) tested for HIV. Of those tested, positivity was 30% (15/50). Of those with a new HIV diagnosis, 10 (Female-6, Male-4) (66.7%) were linked to ART, but 5 (Female-3, Male-2) (33.3%) declined treatment, citing preference for couples' HTS or retesting at the clinic closest to home.

Steps in Index Testing Cascade	Total (N, %)	Female (n, %)	Male (n,%)
Offered Index	175, 100%	27, 15.4%	148, 84.6%
Accepted Index	166, 94.9%	27, 16.3%	139, 83.7%
Contacts Elicited	293, 100%	223, 76.1%	70, 23.9%
Contacts Traced	109, 37.2%	42, 38.5%	67, 61.5%
Contacts Known Positive on ART	59, 54.1%	23, 39.0%	36, 61.0%
Contacts Tested for HIV	50, 45.9%	19, 38.0%	31, 62.0%
New HIV-Positive Contacts (Testing Yield)	15, 30.0%	9, 60.0%	6, 40.0%
Contacts Linked to ART	10, 67.7%	6, 60.0%	4, 40.0%
Contacts Declining Treatment	5, 33.3%	3, 60.0%	2, 40.0%

CONCLUSIONS: Index testing in correctional facilities is feasible and results in high testing yield.

OAC0406

WHAT'S A LAB GOT TO DO WITH IT? ALLIANCES WITH PRIVATE LABORATORIES ENHANCE HIV-CASE FINDING AMONG AT-RISK MSM AND TRANSGENDER WOMEN IN CENTRAL AMERICA

A. Cabrera[1], S. Lungo[1], C. Palma[1]
[1]Population Services International, Guatemala City, Guatemala

BACKGROUND: Under the USAID Combination Prevention Program for HIV in Guatemala, El Salvador, Honduras, Nicaragua, and Panama, the Pan American Social Marketing Organization (PASMO) implements offline and online interventions to increase HIV testing services (HTS) uptake among at-risk MSM and transgender women (TW), and link reactive cases to care. HTS is performed by PASMO counselors, laboratory technicians, or private laboratories, the latter of which must complete training and sensitization exercises to provide quality key population (KP)-friendly services. Although the public sector generally provides HTS for free, difficult to access, "hidden" MSM and TW populations often prefer private health services due to fear of stigma, discrimination, and confidentiality breaches in the public sector.

DESCRIPTION: PASMO uses a Unique Identifier Code (UIC) to track program participants from initial engagement through entry in care. Print or online vouchers are used to refer to HTS. Vouchers received by private laboratory partners are collected by PASMO on a bi-monthly basis. On a monthly basis, PASMO enters the monitoring data into its management information system, allowing it to track the number of individuals reached, percentage of individuals who receive HTS, HIV-case finding yield (number of reactive cases identified per number of tests), and percentage linked to care.

LESSONS LEARNED: From October 2018 to September 2019, PASMO reached a total of 17,897 MSM and TW across the five countries through offline and online interventions of which 13,197 (748%) received HTS, and 720 were reactive (yield of 1 of every 17). PASMO counselors performed 6,877 of the tests with 298 reactive cases identified (1 of every 23), whereas private laboratories performed 6,320 tests and detected 422 reactive cases (1 of every 15 tests). Private laboratories identified 59% of all reactive cases identified by the program during the year.

CONCLUSIONS/NEXT STEPS: With this program's focus on most at-risk and "hidden" MSM and TW groups, the partnerships with private laboratories play a significant role in HIV case finding, producing improved yield, and helping expand the access of difficult to access KPs to HTS services throughout the region.

OAC0407

COMMUNITY MOBILIZATION TO IMPROVE ENGAGEMENT IN HIV TESTING, LINKAGE TO CARE, AND RETENTION IN CARE IN 15 VILLAGES IN SOUTH AFRICA: THE TSIMA CLUSTER-RANDOMIZED CONTROLLED TRIAL

S.A. Lippman[1,2], A. Pettifor[3,2], D. Rebombo[4], M. Kang-Dufour[1], C. Whiteson Kabudula[2], R. Twine[2], R. Mathebula[4], A. Julien[2,3], R. West[1], T.B. Neilands[1], A. Gottert[5], R. Wagner[2], N. Haberland[5], J. Pulerwitz[5], I. Sanne[6], F.X. Gómez-Olivé[2], D. Peacock[4], K. Kahn[2]
[1]University of California, Department of Medicine, San Francisco, United States, [2]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), University of the Witwatersrand, School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa, [3]University of North Carolina, Epidemiology, Chapel Hill, United States, [4]Sonke Gender Justice, Cape Town, South Africa, [5]Population Council/Project SOAR, Washington, D.C. and New York, United States, [6]University of the Witwatersrand, Clinical HIV Research Unit, Department of Medicine, Faculty of Health Sciences, Johannesburg, South Africa

BACKGROUND: Increasing HIV testing and early treatment initiation is key to ending HIV. Community Mobilization (CM) - which goes beyond service provision or outreach and engages communities in a process to collectively enact change - has significant potential to increase HIV services uptake. CM interventions have rarely been rigorously evaluated.

METHODS: We randomized 15 villages in the MRC/Wits-Agincourt health and socio-demographic surveillance site, South Africa, to intervention or control. The intervention engaged residents to address social barriers to HIV testing and treatment – poor awareness of HIV care (especially treatment as prevention); fear/stigma; and gender norms that deter accessing care. Activities were delivered through mobilizers and trained volunteers over three years in public spaces and homes. We assessed differences in HIV testing uptake, linkage to and retention in care among 18-49 year old residents in intervention vs control villages over time (in 3-month increments) using data from 9 public clinics serving the area. Intention-to-treat analyses included generalized estimating equations stratified by sex and accounting for clustering.

RESULTS: Among 38,392 residents, 13,404 had documented clinical visits between August 2015 and July 2018. HIV testing uptake increased quarterly by 13% and 11% in intervention men and women as compared to 9% and 10% among control men and women ($p<0.05$); though annual testing among men never exceeded 10%. With more individuals entering care over time, retention fell ~2% per quarter among men and women, but less rapidly among intervention compared to control women ($p<0.01$). There were no effects on linkage to care.

	aRR	95% CI	p-value	aRR	95% CI	p-value	aRR	95% CI	p-value
Among Men	A: Testing among HIV-negative (n=18060)			B: Linkage in 3 mos after positive test (n=284)			C: Retention among those in care (n=924)

Control x time	1.10	(1.09-1.11)	<0.01	1.00	(0.96-1.04)	0.91	0.977	(0.97-0.98)	<0.01

*indicates significant effect of intervention as compared to control ($p<.05$); time is quarterly increase over 3 years

[Table: Effect of the Tsima Community Mobilization Trial on Testing, Linkage, and Retention by Intervention arm over time]

CONCLUSIONS: CM was associated with improvements in testing among men and women and retention among women, demonstrating that raising consciousness and activities addressing social barriers to HIV service engagement can increase HIV service use. However, even with extensive outreach among men, few accessed testing. CM programing should be paired with efforts to improve service delivery and bring services to the community.

OAC05 NEXT STEPS IN PREP

OAC0502

IMPLEMENTING A PREP POPULATION MANAGEMENT TOOL IN THE ELECTRONIC HEALTH RECORD OF A LARGE INTEGRATED HEALTHCARE SYSTEM

C. Bruno[1], G. Gallitero[2], R. Herbers[3], Y. Hussain[4], M. Ballesca[5], M.J. Silverberg[6], L. Hurley[6], D.P. Nguyen[3], J.L. Marcus[7], C.B. Hare[3], J.E. Volk[3]
[1]Kaiser Permanente, Infectious Diseases, Vallejo, United States, [2]Kaiser Permanente, Oakland, United States, [3]Kaiser Permanente San Francisco, San Francisco, United States, [4]The Permanente Medical Group Consulting Services, Emeryville, United States, [5]Kaiser Permanente, Internal Medicine, Vacaville, United States, [6]Kaiser Permanente Division of Research, Oakland, United States, [7]Harvard Medical School and Harvard Pilgrim Health Care Institute, Population Medicine, Boston, United States

BACKGROUND: As of March 31, 2019, over 10,000 patients had received a prescription for HIV preexposure prophylaxis (PrEP) at Kaiser Permanente Northern California, an integrated health care delivery system that includes clinical care, pharmacy services and insurance coverage for 4.2 million members. Given the rapid uptake of PrEP, efficient population management tools are needed to support PrEP adherence and monitor laboratory follow-up.

DESCRIPTION: A PrEP population management tool was created and integrated into an EPIC electronic health record (EHR) in 2016. This tool uses real-time pharmacy and clinical data to generate a list of patients who are prescribed tenofovir disoproxil fumarate/emtricitabine or tenofovir alafenamide/emtricitabine for PrEP. The tool captures demographic data, pharmacy information (e.g., PrEP refill dates), and laboratory data (e.g., HIV antibody and creatinine test dates and results), and allows providers to sort by these variables. Related clinical information such as sexually transmitted infection diagnoses and hepatitis B status are also included. Providers can send secure electronic messages to thousands of patients simultaneously with reminders for overdue medication refills, laboratory follow-up, or new clinical updates regarding PrEP.

LESSONS LEARNED: Overall, the implementation of this tool has resulted in significant operational efficiencies, with thousands of PrEP users being safely monitored by only a few providers. PrEP users overdue for laboratory follow-up and/or prescription refills are easily identified and contacted. However, the resources needed to develop the EHR-based tool were substantial, including a team of technology experts, clinicians, and project managers working in collaboration. An estimated 250 hours were spent in development. Many providers were initially reluctant to use the new technology given the additional training needed, initial investment of time to ensure data accuracy, and adjustment in workflow. Modifications to the tool are possible, but require additional time and resources.

CONCLUSIONS/NEXT STEPS: EHR-based PrEP population management tools allow for efficient and targeted outreach to patients who are overdue for laboratory monitoring, need adherence support, may benefit from a change in PrEP medication, or have discontinued PrEP and may benefit from restarting. Ongoing technology resources and provider training will be needed as the tool evolves to accommodate emerging PrEP medications, dosing schedules, and delivery mechanisms.

OAC0503

PREP 2-1-1 EDUCATION INCREASES PREP UPTAKE AND PRESERVES EFFECTIVE PREP COVERAGE IN A LARGE NURSE-LED COMMUNITY-BASED SEXUAL HEALTH CLINIC IN SAN FRANCISCO

J. Broussard[1], J. Bena[1], P.-C. Crouch[2], B. Taylor[1], M. Chavez[1], R.M. Grant[1,2]
[1]San Francisco AIDS Foundation, San Francisco, United States, [2]University of California, San Francisco, United States

BACKGROUND: PrEP 2-1-1 dosing (i.e., "on-demand" dosing) with TDF/FTC for anal sex is not endorsed by the CDC and has limited utilization in the U.S., despite research and experience showing its effectiveness and appeal among people who otherwise might not take PrEP. To increase knowledge and use of PrEP 2-1-1, the sexual health clinic Magnet of San Francisco AIDS Foundation implemented a PrEP 2-1-1 program.

METHODS: Current and prospective PrEP clients were enrolled in a prospective cohort study, receiving an intervention about daily and 2-1-1 PrEP dosing with an educational handout and evidence that both dosing strategies are safe and effective for MSM, although 2-1-1 dosing had not been reviewed by the FDA. Participants selected their dosing and received standard of care, adherence counseling, and HIV/STI/creatinine testing. PEP was offered within 72 hours if a potential HIV exposure not covered by PrEP occurred. Weekly online surveys collected sex and PrEP information.

RESULTS: From March 1, 2019 to November 30, 2019, 3106 subjects (72% current PrEP clients; 28% new clients) received the intervention. Median age was 31 years; 98% were cis-gender MSM. For new PrEP clients, 77% elected daily, and 23% elected 2-1-1. For current daily PrEP patients, 83% chose only daily dosing, 17% switched to 2-1-1. PEP use was rare in both groups: daily (0.8%), 2-1-1 (1.4%; P=0.22). A higher proportion of 2-1-1 users (3.3%) reported PrEP-less or condomless sex versus daily PrEP users (1.3%;p<.001). 63 people (2%) reported starting PrEP due to PrEP 2-1-1 and would not have accessed daily PrEP otherwise. PrEP 2-1-1 awareness increased across Magnet from 53% before the study to 69%. There were zero HIV infections in the 2-1-1 (262 years follow-up) or daily PrEP (1231 years follow-up) groups. Daily PrEP clients took more pills (4.85/week) than 2-1-1 clients (1.59/week, SD 2.01; p<0.00001). During weeks with anal sex, daily clients took 5.36 tablets, 2-1-1 took 2.92 (P<0.00001).

CONCLUSIONS: Providing 2-1-1 dosing information increased uptake of PrEP, was a popular dosing option, and reduced medication use by three-fold while preserving high rates of effective use. This supports recent recommendations for 2-1-1 dosing among MSM from WHO and IAS-USA.

OAC0504

VALIDATION OF SELF-REPORTED MEASURES OF OPTIMAL PREP ADHERENCE AMONG MSM IN 4 U.S. CITIES

J. Chapin-Bardales[1], C. Sionean[1], R. Haaland[1], A. Holder[1], V.A. Butts[1], A. Martin[1], E.K. Sey[2], K.A. Brady[3], H.F. Raymond[4], J. Opoku[5], I. Kuo[6], G. Paz-Bailey[1], C. Wejnert[1], for the NHBS Study Group
[1]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [2]Los Angeles County Department of Public Health, Los Angeles, United States, [3]Philadelphia Department of Public Health, Philadelphia, United States, [4]Rutgers University, Newark, United States, [5]District of Columbia Department of Health, Washington D.C., United States, [6]George Washington University, Washington D.C., United States

BACKGROUND: Adherence to HIV pre-exposure prophylaxis (PrEP) is key to its effectiveness as a prevention method. Self-reported PrEP adherence measures could allow for monitoring adherence in non-clinical-trial settings where biological testing poses cost, time, and logistical challenges. We evaluated validity of self-reported PrEP adherence measures among men who have sex with men (MSM) in 4 U.S. cities.

METHODS: In 2017 National HIV Behavioral Surveillance, eligible MSM aged ≥18 years were recruited via venue-based sampling and completed a survey, HIV testing, and dried blood spot (DBS) collection. DBS from HIV-negative participants who reported PrEP use in the past month were tested for tenofovir diphosphate (TFV-DP) by liquid chromatography mass spectrometry. Biological optimal adherence was defined as TFV-DP ≥1250 fmol/punch (consistent with 7 doses/week) and considered gold standard. Three self-reported optimal adherence measures were examined: (1) missed 0 doses in past 30 days, (2) missed 0 doses in past 7 days, and (3) Wilson's 3-item adherence scale. Focused on capturing optimal adherence prevalence and limiting false positives, we calculated positive predictive values (PPVs) and false positive rates (FPRs) overall and by population characteristics.

Positive predictive values and false positive rates comparing self-reported and biological measures of optimal PrEP adherence among men who have sex with men in four U.S. cities—National HIV Behavioral Surveillance, 2017

	Optimal adherence (7 doses/week)[1]					
	Missed 0 doses, past 30 days (N=325)		Missed 0 doses, past 7 days (N=326)		Wilson scale[2] (N=323)

Philadelphia	44	36	42	54	38	31
San Francisco	85	26	76	61	84	26
Washington DC	61	64	70	64	58	52

Abbreviations: PPV, positive predictive value; FPR, false positive rate (i.e., 1-specificity)
[1]Gold standard was defined as tenofovir diphosphate (TFV-DP) detected in dried blood spots via liquid chromatography mass spectrometry at a concentration of ≥1250 fmol/punch (consistent with 7 doses/week on average).
[2]The Wilson adherence scale (Wilson et al. 2016) consisted of 3 items and was adapted for measuring PrEP adherence. Optimal adherence was considered as reporting zero missed doses in past 30 days, "always" taking PrEP the way you were supposed to in past 30 days, and doing an "excellent" job at taking PrEP in past 30 days.

RESULTS: PPVs were similar for the three measures of optimal adherence (~73%) and FPRs were lowest for past-30-day missed 0 doses (41%) and Wilson scale (35%) measures. PPVs and FPRs of all optimal adherence measures varied by population characteristics; within each demographic subgroup, PPVs were similar across measures while FPRs were lowest and at similar magnitudes for the past-30-day missed 0 doses and Wilson scale measures.
CONCLUSIONS: Self-reported optimal PrEP adherence measures had moderate validity; no measure demonstrated high PPV or low FPR overall and all measures had PPVs and FPRs that varied by population characteristics. Of self-reported measures, the past-30-day missed 0 doses item may be minimally sufficient to capture optimal adherence. Nevertheless, biological testing remains important to measuring PrEP adherence.

OAC0505

FACTORS ASSOCIATED WITH EARLY CONTINUATION (EC) OF PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG YOUNG MSM (YMSM) IN BRAZIL, PERU AND MEXICO: THE IMPREP STUDY

V.G. Veloso[1], E.H. Vega-Ramirez[2], B. Hoagland[1], K.A. Konda[3], S. Bautista-Arredondo[4], J.V. Guanira[5], T. Torres[1], M.C.P. Oliveira[6], H. Vernandere[4], A. Farias[7], M.V.G. Lacerda[8], M. Benedetti[1], S. Diaz[9], P.M. Luz[1], R.I. Moreira[1], J. Moreira[10], I.d.C. Leite[1], B. Grinsztejn[1], C. Cáceres[3], ImPrEP Study Team

BACKGROUND: PrEP implementation in Latin America is very limited; awareness is lower among YMSM. ImPrEP is an ongoing demonstration study assessing safety and feasibility of same day PrEP for MSM and TGW in Brazil, Peru and Mexico. We report results on PrEP EC and associated factors among YMSM.
METHODS: HIV uninfected, ≥18 years old, reporting 1+ risk criteria were enrolled and initiated PrEP on the same day; creatinine and STI testing were performed. Main outcome for this analysis was PrEP EC (attendance to first 2 follow-up visits within 150 days of PrEP initiation) among YMSM (18-24).
RESULTS: Among 7273 enrolled (February 2018- November 2019) 1843 (25.3%) were YMSM; 957(51.9%), 607(32.9%) and 279(15.1%) from Brazil, Peru and Mexico; 1390 (75.4%) non-white, 607 (33.0%) with < secondary level of education; Condomless receptive anal sex and having ≥ 4 sexual partners in the previous 3 months were reported by 1203 (65.3%) and 1053 (57.1%). Baseline active syphilis, rectal chlamydia and rectal gonorrhea prevalence were 8.7% (95% CI: 7.3%-10.2%), 13.1% (95% CI: 11.3%-15.0%) and 10.3% (95% CI: 8.7%-12.1%). Only 14 (0.9%) had eGFR <60 mL/min. HIV incidence was 1.8%/100 PY (95% CI:1.0%-2.9%) during 858.1 PY of PrEP use. Overall EC was 67.2%; Brazil: 77.3%; (95% CI: 74.3%-80.0%), Mexico: 72.3%; (95%CI: 63.8%-79.8%), Peru: 44.9%;(95%CI: 44.9%-49.8%). Lower chance of PrEP EC was observed among nonwhite (aOR=0.68; 95% CI:0.50-0.92), less educated (aOR=0.66; 95% CI: 0.51-0.86), Peruvians (aOR=0.24; 95% CI: 0.19-0.31), unaware of partner serostatus (aOR=067; 95% CI:0.47-0.95), those coming to the site for reasons other than PrEP (aOR=0.55; 95% CI:0.39-0.78), those reporting no condomless receptive anal sex (aOR=0.74; 95% CI:0.57-0.95), with no prior PEP use (aOR=0.61; 95% CI: 0.42-0.87).

Table. Factors associated with PrEP EC among YMSM enroled in ImPrEP

CONCLUSIONS: ImPrEP successfully enrolled vulnerable YMSM. Efforts to increase awareness and strategies to support those at higher social vulnerability are urgently needed to increase PrEP benefits among YMSM in Latin America.

OAC0506

FACTORS ASSOCIATED WITH UPTAKE OF EVENT-DRIVEN AND DAILY REGIMEN OF PRE-EXPOSURE PROPHYLAXIS AMONG GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN (GBMSM) IN TAIWAN: 2019 HORNET PREP SURVEY

S.W.-W. Ku[1,2], C.-W. Li[3], P. Huang[4], C. Strong[5], A. Garner[6], S. Howell[6], T.-H. Wu[2], J.C. Liao[5], N.-Y. Ko[7], A. Bourne[8]
[1]Taipei City Hospital Renai Branch, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [2]HIV Education And Research Taiwan (H.E.A.R.T), Taipei, Taiwan, Province of China, [3]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Department of Internal Medicine, Tainan, Taiwan, Province of China, [4]University of California, Department of Communication, La Jolla, United States, [5]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Department of Public Health, Tainan, Taiwan, Province of China, [6]Hornet Networks Limited, Los Angeles, United States, [7]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Department of Nursing, Tainan, Taiwan, Province of China, [8]La Trobe University, Australian Research Centre in Sex, Health& Society, Melbourne, Australia

BACKGROUND: PrEP has been implemented in Taiwan since 2016, and a 2017 survey recruiting via gay app "Hornet" found that 1.3% and 1.7% of GBMSM respondents respectively reported using daily and event-driven (ED) PrEP. In a repeat of the survey in 2019 we sought to establish factors associated with both daily and ED uptake.

METHODS: We conducted a survey by convenience sampling of the users of a social networking application for GBMSM in Taiwan, with a design similar to the previous 2017 one. The survey was conducted between November 22nd and December 22th, 2019. The survey included 34 questions regarding basic demographics, HIV serostatus, risk behaviors, PrEP awareness, willingness and mode of use. Responses from the same IP address were excluded.

RESULTS: There were a total of 3,026 responses, of which 2,554 were eligible for analysis. Among those who reported HIV-negative or unknown serostatus, 227 respondents reported current PrEP use. Only 28.6% reported daily PrEP, use, while the remainder did so on an event-driven basis. There were no statistical differences in the manner of use according to basic demographics, pre-survey PrEP awareness, previous post-exposure prophylaxis use, STI diagnosis, chemsex, or condomless anal intercourse. The major reasons given for daily use over ED regimen were: (1) "I can't plan having sex in advance" (67.2%); (2) "I feel more confident in protection" (56.3%); (3) "It's easier for me to remember taking pills" (53.1%). Contrastingly, respondents preferred ED over daily PrEP because: (1) "I have less frequent sex" (63.3%); (2) "It's more affordable" (56.3%); (3) "I can plan having sex in advance" (51.9%). Multivariable logistic regression revealed a greater number of sexual partners (more than 9 vs. 0-9 partners in the past 12 months) had significant correlation with current PrEP users adopting daily rather ED regimen (AOR 2.37, 95% CI 1.18-4.75, p=0.015).

CONCLUSIONS: Our survey found ED PrEP has been adopted preferably over daily PrEP among GBMSM community in Taiwan. To scale up PrEP use further, we should consider prioritizing promotion of the ED regimen and address ED PrEP-specific issues, including relevant knowledge pertaining to effective use and adherence.

OAC06 PLEASURE, PREVENTION, OR FEAR: FAR REACHING EFFECTS OF ONLINE MESSAGING AND MHEALTH INTERVENTIONS

OAC0602

PROMOTING ANAL HEALTH AND PLEASURE WITH A COMMUNITY-DRIVEN SOCIAL MARKETING CAMPAIGN

E. Land[1], E. Jost[1], A. Hattori[1], R. Roybal[1]
[1]San Francisco AIDS Foundation, San Francisco, United States

BACKGROUND: Anal fissures, rectal STIs, improper rectal douching and anal health concerns can increase HIV risk among people having receptive anal sex, including MSM. Yet stigma and embarrassment can keep MSM from seeking health care for these concerns, free anal health resources for MSM are not widely available online, and platforms like Facebook/Instagram restrict the kind of sexual health information that can be promoted. This social marketing campaign leveraged the lived experience of MSM community members and expertise of MSM providers to develop stigma-free anal health resources to promote better health.

DESCRIPTION: From 2017 - 2018, San Francisco AIDS Foundation (SFAF) developed: 1) a "Butt Health" webpage; 2) two community surveys on douching and pain during anal sex; 3) articles by MSM and clinicians giving first-person perspectives and information on anal warts, fisting, anal douching, booty bumping and more; and, 4) a stylized cartoon "Douchie" mascot for articles, social media, and printed materials. 575 people took the surveys, and personal experiences from surveys were shared in online articles. A modest advertising budget of $150 resulted in a 6.84% clickthrough rate (CTR) on Facebook ($0.10/click), performing better than any other SFAF paid campaign and far exceeding the average healthcare industry standard CTR of 0.83%. In the first two months, 76,481 individuals visited sfaf.org/butthealth, and today, campaign content generates 35% of all traffic to sfaf.org largely through organic search.

LESSONS LEARNED: Anal health topics are of high interest to MSM and other populations at risk for HIV. Elevating real-world experiences of anal health conditions, pleasure, and comfort alongside information from a trusted community health organization successfully engaged online audiences. Eye-catching, playfully-designed materials accounted for the wide reach of the campaign. Later iterations of this sex-positive campaign were flagged as "pornographic" content on Facebook, Twitter, and Google, limiting our ability to run paid promotions.

CONCLUSIONS/NEXT STEPS: Health campaigns promoting pleasure perform well for online audiences who may be at risk for or living with HIV. While online spaces are restrictive of sex-positive content, optimizing audience targeting and graphics for organic sharing on social channels increases the reach of sexual health campaigns.

OAC0603

DELETERIOUS EFFECT OF TRUVADA LAWSUIT ADVERTISEMENTS ON ATTITUDES AND DECISIONS TOWARDS PREP AMONG SEX AND GENDER MINORITY YOUTH AT RISK FOR HIV

P.A. Serrano[1], E. Daubert[1], A. Muñoz[1], S.G. Hosek[1,2], A.L. French[1,2]
[1]Ruth M. Rothstein CORE Center, Chicago, United States, [2]John H. Stroger, Jr. Hospital of Cook County, Chicago, United States

BACKGROUND: In 2019, misleading lawsuit advertisements against Gilead Sciences regarding Truvada were launched and anecdotal evidence suggested the advertisements motivated some users to discontinue PrEP. This study aimed to ascertain the effects of the advertisements on attitudes and decisions about PrEP among participants in the Keeping it LITE study, an ongoing virtual cohort of sexual and gender minority youth vulnerable to HIV.

METHODS: A 10-item survey, including close and open-ended questions regarding the advertisements, was administered online to participants enrolled in the cohort who were HIV uninfected, 13-34 year olds who have sex with partners assigned male at birth. Participants met at least one of the following criteria in the last 6 months: oral sex; condomless anal sex; bacterial STI; or sex with an HIV+ partner. Quantitative and qualitative data were analyzed using descriptive and inferential analysis in SAS, and thematic analysis, respectively.

RESULTS: From November to December 2019, 1485 (53.7%) of those eligible participated (mean age 26.8 (sd=4.87); 54.9% White, 19.1% Latinx, 9.6% Black, and 16.9% Other; 82% cisgender men, 10.6% transmasculine, and 7.3% transfeminine). Prior PrEP use was reported by 43%, and use within the past 6 months was 32.7%. Almost half (722) were aware of the lawsuit and most (86.3%) had viewed an ad on social media. Of those aware who answered subsequent questions (n=704), 18.7% reported quitting or deciding not to initiate PrEP use, and 32.1% reported the advertisements changed their opinions about PrEP. Participants with higher education were significantly less likely to quit or to decide against initiating PrEP use (OR = 0.29, 99% CI 0.14-0.61). In open ended responses, participants expressed safety concerns (75.25%), distrust towards the pharmaceutical industry (16.4%), and interest in alternative prevention options (8.4%).

CONCLUSIONS: The Truvada lawsuit advertisements reached a large, diverse group of youth at high risk of HIV throughout the USA. These advertisements produced hesitancy to initiate Truvada-based PrEP and increased fears of potential side effects of Truvada. These results illustrate the deleterious public health effects of such direct advertising and distrust of the pharmaceutical industry and support the efforts by public health advocates to mitigate the negative effects of these advertisements.

OAC0604

PROMOTING UPTAKE OF HIV SERVICES USING SOCIAL MEDIA INTERVENTIONS AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN GHANA

S.E. Owusu[1], S.K. Wosornu[2], K.M. Diaba[3]
[1]Maritime Life Precious Foundation, Programs, Takoradi, Ghana, [2]Maritime Life Precious Foundation, Executive Director, Takoradi, Ghana, [3]WAPCAS, Programs, Accra, Ghana

BACKGROUND: Social media is becoming a safe environment for communication among MSM in Ghana. MSM are increasingly soliciting potential sexual partners through social media platforms rather than geographic hotspots. Many MSM are “hidden” and engage in risky sexual behaviors, but are not reached by HIV programs targeted at physical outreach locations. A differential approach to community mobilization on social media platforms was introduced to increase uptake of HIV testing among hidden MSM.

DESCRIPTION: A social media mobilizer was trained to engage MSM through social networking platforms such as Facebook and Grindr. IEC materials were developed and posted on selected social media platforms to raise awareness regarding HIV services among the hidden population. MSM who accessed these platforms were engaged through one–on-one interaction and online counselling by the trained mobilizer. MSM recruited were given different timed appointments to access services at the Drop-In-Center.

LESSONS LEARNED: Data from January to June 2019 shows that social media reached out to more high risk MSM than through in-person outreach at hotspots. Among 166 new MSM that were recruited through social media, 113 (68%) had not been tested for HIV within the last six months. Physical outreach reached 431 new MSM; 133 (31%) had not been tested within the last six months. 59% of MSM recruited through social media engaged in inconsistent use of condoms for casual anal sex, compared to 38% identified at hotspots.

HIV positivity rate was higher among those tested through social media outreach compared to hotspot outreach. 125 MSM tested through social media; 32 were diagnosed HIV positive (25.6% HIV+ yield). 396 MSM were tested through physical outreach at hotspots; 28 were diagnosed HIV positive (9% HIV+ yield).

CONCLUSIONS/NEXT STEPS: Confidential and accessible health services through social media encourages hidden MSM to seek HIV services themselves. There is high need to invest in newer approaches of HIV programming that take into account changing times and community dynamics.

Linking MSM to services through social media has shown to deliver higher HIV+ yield among hard to reach MSM. Hence, implementing partners should use social media as an effective tool for sharing behavior change messages to reach hidden MSM.

OAC0605

LYNX: A PILOT RANDOMIZED CONTROLLED TRIAL OF A MOBILE HEALTH HIV TESTING AND PREP UPTAKE INTERVENTION FOR YOUNG MEN WHO HAVE SEX WITH MEN

H. Scott[1], K. Coleman[1], J. Vinson[1], A. Garcia[2], R. Muench[3], M.E. Enriquez-Bruce[2], K. Bojan[3], P.A. Serrano[3], T. Oyedele[3], E. Enrique-Bruce[2], P. Emmanuel[2], J. Jones[4], K. Muessig[5], C. Horvitz[5], S. Mullin[4], J. Roberts[5], S. Buchbinder[1], P. Sullivan[4], L. Hightow-Weidman[5], A. Liu[1]
[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of South Florida, Tampa, United States, [3]Ruth M. Rothstein CORE Center, Chicago, United States, [4]Emory University, Atlanta, United States, [5]University of North Carolina, Chapel Hill, United States

BACKGROUND: HIV in the US disproportionately affects young men who have sex with men (YMSM), especially Black and Latinx YMSM. Delays in HIV testing, undiagnosed sexually transmitted infections (STI), and low uptake of pre-exposure prophylaxis (PrEP) all contribute to this disparity. We developed and pilot tested an mHealth intervention to increase HIV testing and PrEP uptake among YMSM.

METHODS: HIV-uninfected YMSM aged 15-24 years who had not tested for HIV in the past 3 months and were not currently on PrEP were enrolled. Participants were randomized 2:1 to the LYNX mobile app intervention with the Sex Pro HIV risk assessment, a sexual diary, geo-location of HIV/STI testing and PrEP clinics, PrEP information and videos, and access to home HIV/STI testing; or control (CDC HIV testing and PrEP information) and followed remotely for 6 months. The primary outcomes were feasibility and acceptability of Lynx, HIV testing, and PrEP uptake assessed via CASI.

RESULTS: From October 2018-April 2019, 61 participants were enrolled and overall retention was 80% at 6 months. The median age was 20.5 years, 38% were White, 33% were Latinx, and 24% were Black. At baseline, participants reported a median of 2 male sexual partners in the past three months. During the 6 month intervention, participants spent a median of 41 minutes using the app. App acceptability was high with a median System Usability Scale Score of 73.8; and 87% of intervention participants reporting they would recommend the app to a friend for HIV/STI testing and PrEP. Almost all (95%) intervention arm participants ordered an HIV test kit, and 50% reported testing at home. At 6 months, a higher proportion of intervention participants reported HIV testing although this was not statistically significant (70% vs 50%, p=0.17). Overall, PrEP uptake was low with only 16% of YMSM initiating PrEP by 6 months with no difference between intervention and control (13% vs 22%, p=0.45).

CONCLUSIONS: The Lynx intervention showed high acceptability in YMSM, and shows promise for increasing HIV testing among this vulnerable population. However, PrEP uptake was low and more support is likely needed to remove barriers to PrEP access for YMSM in the US.

OAC0606

THAT'S HOW WE ROLL! USING HUMAN-CENTERED DESIGN TO ALLOW THE COMMUNITY VOICE TO DESIGN AN EDUCATIONAL CAMPAIGN, SOCIAL MEDIA AND DIRECT-TO-CONSUMER COMMUNICATION FOR PREP ROLLOUT IN ZAMBIA

M. Njelesani[1], S. Maher[2], A. Chipukuma[1], M. Nyumbu[1], C. Madevu-Matson[2], A. Fullem[2], M. Chikuba-McLeod[1]
[1]JSI Research & Training Institute, Inc., Lusaka, Zambia, [2]John Snow, Inc., Boston, United States

BACKGROUND: In May 2018, USAID DISCOVER-Health (DISCOVER), implemented by JSI Research & Training Institute (JSI) was among the first implementers to support MOH PrEP scale-up in Zambia. At start-up, PrEP rollout took place in an information vacuum, with little community access to credible PrEP information for individual decision-making and/or collective action to create a supportive environment for PrEP. Using a Human-Centered Design (HCD) process, DISCOVER extended its support to MOH to develop innovative strategies, interventions and products to ensure that PrEP rollout grounded in the realities of end-users. DISCOVER leveraged its SBC technical capacities towards the development of media campaigns that support PrEP uptake and continuation. As an outcome of the HCD process, DISCOVER supported the MOH to develop a national HIV prevention brand and campaign: Zambia Ending AIDS, with a sub-campaign for PrEP education and demand-generation.

DESCRIPTION: DISCOVER developed digital innovations to support client management and client access to information, including SBC products such as the Zambia Ending AIDS Facebook page, direct-to-consumer communication platform through a free USSD short-code service to enable access to basic information about PrEP and help end-users find PrEP facility locations. On the provider-side, DISCOVER designed and developed an end-user-informed HCW app, which provides guidance on PrEP administration, including counselling skills, and is electronically linked to PrEP management system.

LESSONS LEARNED: By developing and supporting direct-to-consumer communication (including Facebook and YouTube, USSD short-code, and adverts on TV/radio), DISCOVER provided correct PrEP information to support rollout. These platforms allow people to privately and anonymously access reliable information. Between April and September 2019, DISCOVER saw 1.97M Facebook visits, 9.9M TV and radio ads seen/heard; 59,261 accesses to USSD short-code; 27,889 inquiries about the nearest PrEP facility; sent 9,018 PrEP auto-appointment reminders; and sent 5,038 PrEP adherence-support messages, leading to 5,175 new clients on PrEP at DISCOVER sites alone (242).

CONCLUSIONS/NEXT STEPS: Lack of information and misinformation can discourage PrEP uptake and derail effective HIV prevention. Use of HCD to inform communication and demand-creation allows insightful participatory engagement with end-users. Innovative direct-to-consumer communication platforms provide correct information; facilitate two-way communication; increase PrEP utilization—all contributing to sustaining gains towards HIV epidemic control in Zambia.

OAC07 PMTCT 2020: SUCCESSES IN MOTHERS AND CHILDREN

OAC0702

OUTCOMES OF HIV-EXPOSED BUT UNINFECTED CHILDREN IN SOUTH AFRICA OVER 5 YEARS: COMPARISON TO UN-EXPOSED PEERS

M. Rotheram-Borus[1], J. Stewart[2], E. Almirol[1], M. Tomlinson[2]
[1]Univ. of CA, Los Angeles, United States, [2]Stellenbosch University, Stellenbosch, South Africa

BACKGROUND: Researchers have documented extensively the benefits of mothers adhering to the tasks to Prevent Mother to Child Transmission (PMTCT), typically based on clinic samples. Yet, after 12 months, there is far less information on HIV exposed and uninfected children born to Mothers Living with HIV (MLH). This study examines a broad range of child outcomes over five years for HEU compared to their HIV-unexposed and uninfected (HUU) peers living in the same communities.

METHODS: Almost all (98%) of pregnant women in 24 neighbourhoods in Cape Town, South Africa were recruited in pregnancy and reassessed at multiple time points over five years with high retention (from 96% to 85.2% at 2 weeks post birth, 0.5, 1.5, 3 and 5 years). The growth, hospitalizations, and cognitive and behavioral development of HEU children (n=363) of MLH were compared to HUU children (n=787) of mothers living without HIV over time.

RESULTS: Approximately 9% of mothers and children died over 5 years, similar across maternal serostatus. Over time, HEU children had significantly lower weight-for-age z-scores (WAZ) than HUU at the post-birth and 18 month assessments, but not at any later time point. For height-for-age z-scores (HAZ), we observed differences between HEU and HUU at 6 and 18-months, but not at any later follow-up. At 5 years, growth measures, such as HAZ scores, WAZ scores, and whether a child was stunted or malnourished, were similar among HEU children and HUU children. There were no other differences in cognitive abilities (based on the Bayley Scales at 1.5 years or the Kaufmann scales at 3 and 5 years), behavioral measures (the Achenbach Child Behavior Checklist and the Strengths and Difficulties Questionnaire), or hospitalizations among HEU and HUU children over 5 years.

CONCLUSIONS: Unexpectedly, the outcomes of HEU children were similar to their HUU peers. As broad diffusion of antiretroviral therapies occurs and mothers are surviving and living less symptomatic lives, their children appear to similar to peers not exposed to HIV.

OAC0703

IMPACT OF PMTCT PROGRAMS ON MOTHER AND CHILD OUTCOMES IN COLOMBIA

E. Martinez Buitrago[1], M.P. Posada[2], J. Pardo[3], H.F. Mueses[4], J.C. Alzate-Ángel[5], M. Mantilla[6], L. Arévalo[7], D. Alzamora[8], J. Stand[9], S. Valderrama-Beltrán[10], C. Gonzáles[11], O. Sussmann[12], M. García[13], O.L. Ramos[14], J. Franco[15], J.W. Tobón[16], GRUPO VIHCOL (VIH de Colombia)
[1]Universidad del Valle, Internal Medicine Department, Cali, Colombia, [2]SIES Salud Medellín, Medellín, Colombia, [3]CEPAIN Cali, Cali, Colombia, [4]Corporación de Lucha Contra el SIDA, Cali, Colombia, [5]Corporación de Investigaciones Biológicas, Medellín, Colombia, [6]CEPAIN Colombia, Bogotá, Colombia, [7]CEPAIN Bogotá, Bogotá, Colombia, [8]Vivir Bien IPS, Cartagena, Colombia, [9]CEPAIN Cúcuta, Cúcuta, Colombia, [10]Universidad Pontificia Javeriana, Bogotá, Colombia, [11]SIES Salud Cali, Cali, Colombia, [12]Asistencia Cientifica de Alta Complejidad, Bogotá, Colombia, [13]SIES Salud Armenia, Armenica, Colombia, [14]CEPAIN Neiva, Neiva, Colombia, [15]SIES Salud Pereira, Pereira, Colombia, [16]CEPAIN Villavicencio, Villavicencio, Colombia

BACKGROUND: Real-world data on pregnancy complications and newborn outcomes in HIV pregnant women are scarce in Latin America. To characterize the effectiveness of HIV PMTCT programs in Colombia, we search for pregnancies in HIV-1 infected women that had delivery or pregnancy terminated before December 31st, 2018, from 15 centers of the Colombian HIV Group (VIHCOL), an HIV nationwide network.

METHODS: Retrospective univariate and bivariate descriptive analysis, using central trend and dispersion measures, frequencies, and percentages, non-parametric Kruskal-Wallis group comparison tests, and chi-2 with Fisher's correction. All data on in Stata version 12.

RESULTS: A total of 273 HIV positive pregnant women were included with a median age at the pregnancy diagnosis of 26.4 years (15.11- 43.3). An almost half (47.6%) had their HIV infection diagnosed following mandatory screening during pregnancy with a median gestational age of 17.5 weeks (p25-p75=12-25.5), and started ART at 18 weeks (p25-p75=14-27); 102 (37.4%) were known HIV positive before the pregnancy with a mean time of HIV diagnosis of 3.6 years (p25-75= 0.99-6), of which 84 (30.8%) became pregnant on active ART; 9 women (3.3%) had diagnosis on delivery. Median CD4 count and viral load (p25-p75) at the time of pregnancy diagnosis and at the end of pregnancy were 428 cells/mm3 (289-582), 3287 copies/mL (52-16799), 500 cells/mm3 (349-683), and 0 copies/mL (0-40), respectively. 29 (18.5%) of 157 women with available data were late presenters (≥28 weeks of pregnancy). Viral load at the end of pregnancy was undetectable in 178 women (77.4%), and above 1000 copies/mL in 21 (9.1%). Lopinavir/ritonavir plus 2 NRTI was the cART most prescribed (n=135, 52.1%). Cesarean section was the delivery method in 245 women (89.74%). Regarding birth outcomes, only two preterm deliveries (4.7%), one small-for-gestational-age infant (4.33%), one birth defect (microcephaly) were reported, and there were no MTC transmissions.

CONCLUSIONS: This is the first report in Colombia of a nationwide HIV pregnant women and newborn cohort combined outcomes of PMTCT programs. Our data confirmed that combining early diagnosis of HIV and referral to care in HIV centers results in few pregnancy-related complications, rare poor birth outcomes, and no vertical transmissions.

OAC0704

DECLINING TREND OF HIV MOTHER-TO-CHILD TRANSMISSION IN BRAZIL: A NOVEL ESTIMATION METHOD BASED ON PROGRAMMATIC DATA

A.R.P. Pascom[1], A.A.C.M. Ferreira[1], L.N. da Silveira[1], F.F. Fonseca[1], M.A. de Freitas[1], R.E.G.G. Pinho[1], G.F.M. Pereira[1], J.A. Pinto[2]
[1]Ministry of Health of Brazil, Department of Diseases of Chronic Condition and STI, Brasilia, Brazil, [2]Universidade Federal de Minas Gerais, Faculdade de Medicina, Belo Horizonte, Brazil

BACKGROUND: Prevention of mother-to-child transmission (PMTCT) of HIV has been a priority in Brazil. However, the challenge remains of having specific indicators to better guide public health policies. We aimed to present a novel method to estimate mother-to-child transmission rate (MTCTR) in Brazil, and to analyze its trends during 2010-2017.

METHODS: We used programmatic data from antiretroviral therapy (ART) and HIV viral load (HIV-VL) national systems to identify HIV-exposed children (H-EC) under one year old (yo). HIV infection criteria was: 1) having at least one ART dispensation; or 2) presented the first HIV-VL≥10,000copies/mL; or 3) presented at least two VL≥5,000copies/mL; or 4) had a single HIV-VL≥5,000copies/mL. In addition, all children aged ≤10yo who had at least one ART dispensation were classified as vertically infected. We also estimated the number of H-EC by subtracting the number of pregnancy losses from the number of pregnant women living with HIV. The MTCTR was calculated as the ratio between infected-children and the exposed ones. We fitted generalized additive models to assess trends in the number of infected-children and in the MTCTR.

RESULTS: We estimated 107,734 H-EC and identified 4,765 HIV-infected children; an overall MTCTR of 4.4%. The number of infected-children decreased from 684 to 361, in 2010 and 2017, respectively (p<0.001). Likewise, MTCTR declined 52% during the analyzed period (p<0.001), reaching 2.9% in 2017. MTCTR decline went from 15% to 38% in 2010-13 and 2014-17, respectively, coinciding with the ART scale-up in Brazil.

	2010	2011	2012	2013	2014	2015	2016	2017
HIV-infected (n)	684	651	607	602	556	517	507	361
HIV-exposed (n)	11,354	11,503	11,654	11,807	11,962	12,119	12,278	12,454
MTCT rate (%)	6.0	5.7	5.2	5.1	4.6	4.3	4.1	2.9

[Table 1: Number of HIV-infected, -exposed children and mother to child transmission rates by year of birth. Brazil, 2010-2018]

CONCLUSIONS: We presented a more sensitive method to estimate MTCTR which is being used to monitor and guide public PMTCT policy. Since 2013, when Brazil implemented treatment for all, including pregnant women, there was a higher decrease in MTCTR. Therefore, we believe that the declining trends showed in this study will be persistent, aligned with public health polices, indicating that MTCT elimination is an attainable target in Brazil.

OAC0705

PREVENTION OF MOTHER-TO-CHILD TRANSMISSION (PMTCT) OF HIV IN KHAYELITSHA, SOUTH AFRICA: A CONTEMPORARY REVIEW OF THE SERVICE 20 YEARS LATER

F. Phelanyane[1,2], A. Boulle[1,2], E. Kalk[1]
[1]University of Cape Town, Centre for Infectious Disease and Epidemiology Research, Cape Town, South Africa, [2]Western Cape Government Health, Cape Town, South Africa

BACKGROUND: The first Prevention of Mother-To-Child Transmission of HIV (PMTCT) pilot programme the Western Cape (WC), South Africa, was launched in Khayelitsha in 1999. All public health facilities in the WC share a unique patient identifier allowing linkage across all electronic health systems through the Provincial Health Data Centre (PHDC), an African Health Information Exchange within WC Department of Health. We aimed to describe recent PMTCT uptake and quantify MTCT risk factors based on routine data consolidated through the PHDC.

METHODS: Retrospective observational cohort analysis of all live-born linked mother-infant pairs in which the HIV positive mother attended antenatal care in Khayelitsha in 2017. Descriptive statistics assessed coverage along the PMTCT cascade. Logistic regression analysis quantified risk factors associated with transmission, and a Cox-proportional hazard model assessed time to and associations with maternal virologic failure.

RESULTS: Antenatal prevalence in the cohort was 31.3%, MTCT (among live-born linked infants with evidence of HIV outcome in the PHDC) was 1.8% at 12 months post-partum. 88.3% of women knew they were HIV positive at their first antenatal visit, of whom 77.9% were already on ART; 74.9% of the entire cohort received a viral load test around birth (up to 3 months post-partum), 70.1% were virologically suppressed. Early infant diagnosis coverage was sub-optimal with birth HIV-PCR (within 7 days of birth) coverage of 78.1%, and an even lower proportion (64.5%) of infants who tested negative had a repeat test around 10-weeks. Older maternal age was protective against MTCT (a 10-year increase in age reduced MTCT by 15%) and virologic failure (age <25 almost doubled the risk of virologic failure). Post-partum ART initiation (compared to antenatal initiation) increased MTCT risk by 7-fold.

CONCLUSIONS: Although most women present to care already knowing their HIV status, ART initiation and uptake of viral load testing could still be improved. MTCT proportion, reliant on PCR alone, continues to be underestimated due to sub-optimal HIV-PCR coverage; HIV data from multiple sources, consolidated in an HIE suggested higher MTCT than program-reported HIV-PCR testing alone. Further work is needed to determine whether women who initiated ART post-partum seroconverted post-partum or failed to link to ART during pregnancy.

OAC0706

ELIMINATION OF MOTHER TO CHILD TRANSMISSION OF HIV: PRACTICE AND PROGRESS IN ZHEJIANG PROVINCE, CHINA

X. Zhang[1], L. Qiu[2], D. Chen[2]
[1]Women's Hospital Zhejiang University, Women's Health, Hangzhou, China, [2]Women's Hospital Zhejiang University, Hangzhou, China

BACKGROUND: Background: Elimination of mother-to-child transmission(EMTCT) of HIV is globally advocated. In this study, we describe the progress and practice of EMTCT in Zhejiang province, China.

METHODS: In Zhejiang, HIV screening is routinely provide to pregnant women during antenatal health care (ANC) . Early antiretroviral therapy (ART) is offered to women with HIV, including safe delivery. Early infant diagnose(EID) of HIV is tested at 42 days and 3 months. HIV antibody screening is offered to child with negative result of EID at 12 months and 18 months. Maternal and child health care activities, community support strategies, home visits are retention strategies. In the study, we analyzed the progress and practice in EMTCT during 2015-2019.

RESULTS: Totally, over 3 million pregnant women received HIV screening. HIV screening coverage has remained high level, with 99.02% in 2015, 98.82% in 2016,99.15% in 2017,99.01% in 2018 and 99.09% in 2019. HIV positive incidence in pregnant women was stable at 0.02%. ART coverages were 85.22%, 84.09%, 91.35%, 98.20% and 96.23% from 2015-2019, respectively, with significant rising trend (X2trend=22.112,P<0.001). ART coverage gap between resident and migrant bridged obviously. During the period, ART coverage increased from 79.73% to 95.45% in migrant(X2trend =20.507,P<0.001) and maintained over 98% in resident. EID proportion grew from 87.36% to 95.51% over years. HIV from mother to child transmission rates (MTCT) decreased from the highest level in 2016 with 4.48% to 1.18% in 2019. We has strongly integrated EMTCT with ANC, maternal and child heath care, and sexual disease prevention. Broad social mobilization is playing a crucial role in EMTCT.

[Figure 1: ART coverage for HIV pregnancy women]

CONCLUSIONS: With the increases in ART and EID coverage, the improvement of social support, we observed a decrease rate of HIV MTCT and friend social atmosphere for HIV women and their infants.

OAC08 PREP AT SCALE

OAC0802

SUCCESSFUL NATIONAL PREP SCALE-UP IN AUSTRALIA: EVALUATION OF UPTAKE, ADHERENCE, DISCONTINUATION AND HIV SEROCONVERSION FROM APRIL 2018 TO SEPTEMBER 2019 USING NATIONAL DISPENSING DATA

N. Medland[1], R. Guy[1], A. Grulich[1], B. Bavinton[1], P. Keen[1], J. Ellard[2], F. Jin[1], H. Paynter[2], H. McManus[1]
[1]Kirby Institute, University of New South Wales, Sydney, Australia, [2]Australian Federation of AIDS Organisations (AFAO), Sydney, Australia

BACKGROUND: PrEP has been government subsidised in Australia since April 2018 and actively promoted to community and doctors. We used national dispensing data for PrEP and antiretroviral therapy (ART) to evaluate the success of the national program.

METHODS: Using linked de-identified dispensing records of all government-subsidised PrEP, for each patient we calculated days covered or without PrEP (assuming daily dosing) and proportion of days covered (PDC) for the most recent 90 days. We examined rates and predictors of recent nonadherence/intermittent use (90-day PDC < 60%) and discontinuation (> 120 days without PrEP). We defined incident HIV infection as initiating ART > 60 days after initiating PrEP.

RESULTS: Uptake was rapid and sustained with 6,491 people initiating during the first quarter; declining to 3,403 in the most recent quarter. Over eighteen months 29,619 patients were dispensed 6,745,967 PrEP tablets; 98.7% were male and the median age was 35 years (IQR 28-45). Just above a quarter (25.9%) discontinued PrEP. The median 90-day PDC was 93.3% (IQR 67-100%). Independent predictors of 90-day PDC < 60% and/or discontinuation included female sex, younger age-group, patient and doctor non-inner-urban location, lower doctor PrEP-caseload, and more disadvantaged patients (see table).

The HIV incidence rate was 0.95/1000PY (24cases/25197PY) and was higher during PrEP gaps than days covered (1.66/1000PYs [14/8,443PYs] vs 0.60/1000PYs [10/16,754PYs], incident rate ratio 2.78, p=.007).

	n	90 day PDC < 60%	aOR	p	Discontinued	aOR	p
Total	29,618	20.1%			25.9%

<=100 patients	13,741 (46.4%)	24.9%	1.52	<.001	19.5%	1.73	<.001
> 100 patients	15,878 (53.6%)	18.0%	ref	-	34.9%	ref	-
Subsidy							
Routine	26,506 (89.5%)	20.6%	ref	-	24.9%	ref	-
Additional	3,112 (10.5%)	24.4%	1.11	.07	35.2%	1.32	<.001

[Table: Rates and predictors of 90-day PDC <60% or discontinuation.]

CONCLUSIONS: Australia's national government-subsidized PrEP program has scaled up rapidly. The high proportion of patients using less-than-daily-dosing may include appropriate intermittent PrEP. Uptake, adherence and discontinuation in women may reflect appropriate use under guidelines or the selective focus on promoting PrEP to gay and bisexual men. This study identified characteristics of patients and doctors to be targeted to improve retention/adherence and/or additional forms of HIV prevention.

OAC0803

UPTAKE OF PRE-EXPOSURE PROPHYLAXIS AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN PEPFAR-SUPPORTED COUNTRIES, 2017-2019

P. Patel[1], E. Scholar[2,3], K. Sato[3,4], R. Eakle[2], U. Kanagasbai[1], C. Cooney[3], J. Saul[3,1], J. Albertini[3]
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]US Agency for International Development, Crystal City, United States, [3]US Department of State, Washington DC, United States, [4]Peace Corps, Office of Global Health and HIV, Washington DC, United States

BACKGROUND: The U.S. President's Emergency Plan for AIDS Relief's (PEPFAR) first implemented pre-exposure prophylaxis (PrEP) for HIV prevention through the Determined, Resilient, Empowered, AIDS-Free, Mentored and Safe (DREAMS) Initiative in 2016. Early research noted barriers for PrEP use among adolescent girls and young women (AGYW) were lack of policies, low demand, low risk perception, hesitancy by providers, and stigma.
DESCRIPTION: PEPFAR supports PrEP implementation per the WHO guidelines. Programs screened persons who tested HIV-negative for eligibility and offered PrEP as part of combination prevention with follow-up, including repeat HIV testing and counseling, at 3-month intervals. Platforms providing comprehensive services for AGYW were leveraged. We examined two PEPFAR indicators, using the FY19Q4 MER structured dataset, and narratives to understand the extent of and barriers to PrEP uptake from fiscal year 2017 to 2019.
LESSONS LEARNED: From 2017-2019, 265,770 total clients initiated PrEP and the number of countries offering PrEP doubled (Figure). Of 168,258 initiations among women, 51% were among AGYW with a significant increase per year: 8,788 in 2017; 21,225 in 2018; 54,959 in 2019 (Figure). Among AGYW, 20-24 year old women represented a significantly higher proportion of PrEP initiators than adolescents (15-19 years)(67% versus 33%, p<0.001). Barriers to use were addressed through outreach efforts, including mobile sites, use of technology to educate and support AGYW, media campaigns, and engaging peers in program implementation. We saw a 2.5 fold increase in PrEP use among AGYW from 2018 to 2019 (Figure); by 2019, all but one DREAMS country was implementing PrEP. Currently, 162,506 persons remain on PrEP; 29% are AGYW.
CONCLUSIONS/NEXT STEPS: Since 2016, PrEP use among AGYW has grown significantly. Adherence and low risk perception remain challenging and related tools are needed to improve PrEP use among AGYW. Still, AGYW represented a significant proportion of women who initiated and continued PrEP, contributing to epidemic control.

[Figure. Uptake of pre-exposure prophylaxis (PrEP) in 24 PEPFAR-supported countries, by age, sex, and subpopulation, 2017-2019]

OAC0804

PREP UPDATE IN WOMEN IN THE US FROM 2012-2017

J. Guest[1], J. Jones[1], F. Mouhana[1], A. Siegler[1], R. Mera Giler[2], P. Sullivan[1]
[1]Emory University, Epidemiology, Atlanta, United States, [2]Gilead, San Francisco, United States

BACKGROUND: Pre-Exposure Prophylaxis (PrEP) is recommended for heterosexual women with an HIV-positive partner, recent bacterial STI, high number of sex partners, inconsistent condom use, commercial sex work. PrEP can reduce HIV risk by >92%. Reduction in incidence requires significant coverage of those at risk. These commercial data show the first five years of PrEP in uninfected women who initiate emtricitabine/tenofovir disoproxil fumarate (Truvada®) for PrEP.
METHODS: Data are from linked pharmacy and claims data representing >90% of US prescriptions. A validated algorithm was applied to exclude Truvada use for treatment of HIV or HBV infection or post-exposure prophylaxis. Data from 2012-2017 are presented. 2017 HIV diagnoses were used as an epidemiological proxy for PrEP need. The PrEP-to-need ratio (PnR) (number of PrEP users divided by new HIV diagnoses) was used to describe distribution of prescriptions relative to need.
RESULTS: Rates of PrEP use in women has steadily increased since 2012 (68.57/100,000 women) to a rate of 783.98/100,000 women in 2017 (p<0.001 for trend). Rates are highest in 25-34 year olds with 2,770 women using PrEP in 2012, 27,556 in 2017. Rates are consistently highest in the Northeastern (NE) states. For 25-35 year olds in 2017, the NE rate was 328.9/100,000 compared to rates of 158.6 (Midwest), 154.4 (West), and 139.6 (South); p<0.0001. In comparison, HIV incidence in the NE is15-18% of total new infections across these years while 50-51% of all new infections occurred in the South. The PnR was highest in the West (32.6), lowest in the South (8.4).
CONCLUSIONS: There has been >1100% increase in PrEP utilization in the US in women. PrEP use is highest for ages 25-34 years, lowest in 55+. While PrEP uptake has been lowest in the Midwest and West, this is where HIV incidence is the lowest for women. PrEP use is significantly higher for women in the NE although incidence of HIV infections for women in the NE Is 1/3 that seen in the South where rates of PrEP are significantly lower. PrEP has the potential to substantially reduce the number of new HIV infections though we need continued advocacy for PrEP access and funding.

OAC0805

LOWER THAN EXPECTED HIV INCIDENCE AMONG MEN AND WOMEN AT ELEVATED HIV RISK IN A POPULATION-BASED PREP STUDY IN RURAL KENYA AND UGANDA: INTERIM RESULTS FROM THE SEARCH STUDY

C.A. Koss[1], D.V. Havlir[1], J. Ayieko[2], D. Kwarisiima[3], J. Kabami[3], M. Atukunda[3], Y. Mwinike[3], G. Chamie[1], F. Mwangwa[3], A. Owaraganise[3], J. Peng[1], W. Olilo[2], K. Snyman[1], B. Awuonda[2], T.D. Clark[1], D. Black[1], J. Nugent[4], L.B. Brown[1], C. Marquez[1], H. Okochi[1], K. Zhang[1], C.S. Camlin[1], V. Jain[1], M. Gandhi[1], C.R. Cohen[1], E.A. Bukusi[2], E.D. [1]University of California, San Francisco, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]University of Massachusetts, Amherst, United States, [5]Makerere University College of Health Sciences, Kampala, Uganda

BACKGROUND: Limited HIV incidence data exist among PrEP users in generalized epidemic settings, particularly outside of known high-risk groups and with variable adherence. We sought to evaluate (1) HIV incidence and (2) clinical outcomes among seroconverters in a population-based PrEP study in rural Kenya and Uganda.

METHODS: During community-wide and key population HIV testing of 76,132 individuals ≥15-years in 16 communities in the ongoing SEARCH study (NCT01864603), PrEP was offered to persons at elevated HIV-risk (based on serodifferent-partnership, machine learning-based risk-score, or self-identified HIV-risk). Follow-up occurred at facilities or community-based sites at weeks 4, 12, and every 12-weeks. Among seroconverters, we offered same-day ART initiation and analyzed VL, tenofovir hair-levels (LC-MS/MS), and drug resistance. Using Poisson regression with cluster-robust standard errors, we compared HIV incidence among PrEP initiators with repeat testing to incidence among propensity score-matched historical controls (2015-2017; before PrEP availability) in the same communities, adjusted for risk-group (serodifferent-partners, women 15-24 years, widow(er)s, fishing/bar/transport workers, alcohol-users).

RESULTS: From 6/2016-4/2019, of 15,623 individuals at elevated HIV-risk, 5,447 (35%) initiated PrEP (51% male; median age 30-years [IQR 24-39]; 19% serodifferent-partnership); 78% of PrEP initiators had subsequent HIV testing. At week 60, 54% (2,778/5,142 eligible) attended a follow-up visit and 33% reported current HIV-risk, of whom 75% self-reported PrEP adherence (≥1 dose/last 3 days). Over 7,143 person-years of follow-up, HIV incidence was 0.35% (95%CI:0.21-0.49%) among PrEP initiators versus 1.42% among matched controls, representing a 79% reduction in incidence (aIRR 0.21, 95%CI:0.08-0.55; p=0.002). Of 25 seroconverters (68% women, 56% ≤30 years; median VL=5,871 copies/ml), 96% started ART (most same-day); 18/18 (100%) of those with repeat VL after ART start achieved VL<1,000 copies/ml. Seven (28%) seroconverters reported taking PrEP ≤30 days before seroconversion; 6 had tenofovir hair-levels indicating 4-7 doses/week taken. Of 10 participants with HIV genotyping, one with intermittent PrEP adherence confirmed by hair-levels had transmitted NRTI/NNRTI mutations (D70N/K70R/K219Q/K103N/P225H), plus FTC resistance possibly related to PrEP use (M184V).

CONCLUSIONS: Population-level PrEP offer (2016-2019) in 16 communities in rural Uganda and Kenya was associated with 79% lower HIV incidence among PrEP initiators with follow-up HIV testing than among recent (2015-2017) matched controls in the absence of PrEP.

OAC0806

PROGRAMMATIC OUTCOMES OF PRE-EXPOSURE PROPHYLAXIS (PREP) IN A RESOURCE CONSTRAINT HIGH HIV INCIDENCE SETTING IN ESWATINI

A. Aung[1], B. Kerschberger[1], C. Mamba[1], Q. Mpala[1], N. Ntshalintshali[1], R. Nesbitt[1], E. Mabhena[1], M. Daka[1], M. Nzima[1], M.-L. Tombo[1], S. Matse[2], A. Telnov[3], B. Rusch[3], A. Gonzalez[3], I. Ciglenecki[3]
[1]Médecins Sans Frontières, Operational Center of Geneva (OCG), Nhlangano, Eswatini, [2]Eswatini National AIDS Programme, Ministry of Health, Mbabane, Eswatini, [3]Médecins Sans Frontières, Geneva, Switzerland

BACKGROUND: Pre-exposure prophylaxis (PrEP) is recommended for people at substantial risk of HIV infection, yet programmatic evidence from resource constraint high HIV incidence settings remains scarce. Eswatini national AIDS programme and Médecins Sans Frontières conducted a pilot implementation study in Shiselweni region of Eswatini to assess the programmatic feasibility of PrEP provision in public sector.

METHODS: Between September 2017 and January 2019, HIV-negative adults (≥16 years) were prospectively offered PrEP (tenofovir+lamivudine) in 12 community, primary, and secondary health facilities of predominant rural setting. The target populations were young (16-25 years), pregnant, and lactating women, key populations (MSMs, sex-workers), HIV negative partners of serodiscordant couples, and patients with sexually transmitted disease. We used frequency statistics to characterize the PrEP cascade and multivariate regression analysis to describe predictors of PrEP initiation and continuation.

RESULTS: Of 1824 clients assessed for PrEP eligibility, the majority were reached through primary care sites (80.8%), sexual reproductive health consultations (47.9%), and were women (79.6%). Almost half were aged 16 to 24 years (44.8%), most had finished secondary education (69.9%), and 16.2% lived in a serodiscordant relationship. A total of 497 (27%) clients initiated PrEP with 430 (86.5%) on the day of risk assessment and the remaining 67 within a median of 9 (IQR 3 – 32) days. Predictors of PrEP initiation were client's self-interest in PrEP (adjusted odds ratio [aOR] 13.46; 95% CI 7.62 – 23.78), having an HIV-infected partner (aOR 3.55; 95% CI 2.17–5.81), and lactating women (aOR 1.66; 95% CI 1.05– 2.61). Cumulative hazard of PrEP continuation was 48.3%, 40.4%, 29.2% and 21.9% at 3, 6, 12 and 18 months. The risk of discontinuation was less in individuals with self-interest in PrEP (adjusted hazard ratio [aHR] 0.61; 95% CI 0.41 – 0.89) and clients with a seropositive partner (aHR 0.43; 95% CI 0.28 – 0.65), while it was increased in lactating women (aHR 1.78; 95% CI 1.21 – 2.62) and same-day PrEP initiation (aHR 1.52, 95% CI 1.04 – 2.22).

CONCLUSIONS: The provision of PrEP appeared feasible in this rural public sector. Self-reflection of risky behaviour and living in serodiscordant relationship indicated strong engagement, yet initiation and retention rates were relatively low.

OAC0807

PREP CONTINUUM OF CARE AND NEW HIV INFECTIONS: LONG-TERM FOLLOW-UP IN A LARGE CLINICAL COHORT

J. Volk[1], J.C. Hojilla[2], L. Hurley[2], M.J. Silverberg[2], J. Skarbinski[3], D.D. Satre[2], C.B. Hare[1], S. Alexeeff[2], J.L. Marcus[4]
[1]Kaiser Permanente San Francisco, Infectious Diseases, San Francisco, United States, [2]Kaiser Permanente Division of Research, Oakland, United States, [3]Kaiser Permanente Oakland, Infectious Diseases, Oakland, United States, [4]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, United States

BACKGROUND: Few studies have examined long-term PrEP outcomes. We characterized the PrEP continuum of care and new HIV infections over more than five years of clinical follow-up.
METHODS: We used electronic health record data to identify Kaiser Permanente Northern California members who were linked to PrEP care during July 16 2012 - March 31 2019, defined as a PrEP referral or clinical encounter. PrEP prescription was defined as a prescription written by a provider, initiation as a pharmacy fill ≤6 months after linkage, and persistence as <120 days since last day of PrEP in possession based on pharmacy fills. Persistence analyses were among those with ≥6 months of health plan enrollment, with censoring at death or disenrollment. We used unadjusted log-binomial regression to identify factors associated with linkage, prescription, initiation, and persistence.
RESULTS: Among 12,963 patients linked to PrEP care, 95% were male, and 50% were White, with 21% Latinx, 15% Asian, and 7% African American. Of those, 10,310 (80%) received a prescription and 8571 (66%) initiated. We observed 12,810 person-years of PrEP use (mean 1.9 years/person). PrEP persistence was 73%, 64%, 60%, 57%, and 56% at 1, 2, 3, 4, and 5 years, respectively. Of the 2525 who were not persistent on PrEP, 932 (37%) restarted. Compared to White patients, African Americans were less likely to receive a PrEP prescription (risk ratio [RR] 0.87; 95% CI 0.83-0.91) or initiate PrEP (RR 0.81; 0.76-0.86), and more likely to discontinue (RR 1.18; 1.04-1.34]. There were 136 new HIV infections, including 42/12,963 (0.32%) at the time of PrEP linkage, 37/2653 (1.4%) among those who were linked to care but never received a prescription, 13/1739 (0.75%) among those who received a prescription but never initiated, 38/2525 (1.5%) among those who discontinued, and 6/4238 (0.14%) among those who were persistent on PrEP. The six diagnosed with HIV who were persistent on PrEP all self-reported suboptimal adherence.
CONCLUSIONS: We observed high levels of PrEP uptake and persistence over five years and no new HIV infections with consistent use. Efforts are needed to reduce racial inequities and support persistence during periods of HIV risk.

OAD01 BREAKING THE SILENCE OF STIGMA: INNOVATIVE APPROACHES

"LIVING WITH HIV DOES NOT MEAN YOU SHOULD LOSE HOPE": THE IMPORTANCE OF ASSESSING RESILIENCE WITHIN THE PLHIV STIGMA INDEX 2.0

B.A. Friedland[1], A. Gottert[2], L. Nyblade[3], S. Kentutsi[4], D. Diouf[5], U. Tamoufe[6], J. Hows[7], L. Sprague[8], C. Mallouris[9], S. Geibel[2], U. Amenyeiwe[10], F. Anam[11], S.D. Baral[12], J. Pulerwitz[2]
[1]Population Council, Center for Biomedical Research, New York, United States, [2]Population Council, HIV and AIDS Program, Washington, DC, United States, [3]RTI International, Washington, DC, United States, [4]National Forum of PLHIV Networks in Uganda (NAFOPHANU), Kampala, Uganda, [5]Enda Sante, Dakar, Senegal, [6]Metabiota, Yaounde, Cameroon, [7]D.R.A.G: Development Research Advocacy Governance, Amsterdam, Netherlands, [8]UNAIDS, Geneva, Switzerland, [9]UNAIDS, Johannesburg, South Africa, [10]US Agency for International Development, Office of HIV/AIDS, Prevention, Care and Treatment (PCT) Division, Washington, DC, United States, [11]Doctors Without Borders (MSF) Southern Africa, HIV/TB Advocacy Coordinator, Africa Region, Johannesburg, South Africa, [12]Johns Hopkins University, Baltimore, United States

BACKGROUND: The People Living with HIV (PLHIV) Stigma Index -- implemented by and among PLHIV -- is the most widely used survey documenting stigma and discrimination experienced by PLHIV globally. After nearly a decade of implementation experience, and reflecting revised treatment guidelines, the 2008 survey was updated through a consultative process (2016-2017). A key recommendation was to assess resilience – positive adaptation within the context of significant adversity – alongside stigma. A 10-item PLHIV Resilience Scale (PLHIV-RS) was therefore developed and validated. PLHIV's opinions of the new questions are presented.
METHODS: The PLHIV-RS assesses whether HIV status has had a positive/neutral/negative effect on meeting needs, such as ability to cope with stress, find love, contribute to community, or practice a religion. Along with testing the quantitative survey in Cameroon, Senegal and Uganda (n=1,207), 60 cognitive interviews (20 per country) and 8 focus groups (Uganda only) were conducted by PLHIV interviewers to assess face validity and perceived importance of survey questions, including the PLHIV-RS. Respondents, including key populations such as men who have sex with men and sex workers, were purposively sampled to represent a broad range of opinions. Audio recorded interviews/focus groups were translated into English and analyzed thematically.
RESULTS: Respondents consistently said the resilience questions were important and relevant, and that the specific items were comprehensive. Several key themes emerged: being asked and answering the resilience questions was therapeutic, allowing respondents to reflect on the positive ways in which they are coping with, and even benefiting from their HIV-positive status ("..[the questions] show that we can play an important role in society"); the questions imply that "PLHIV have the same desires as other people;" and the questions are important for capturing how well PLHIV are accepting their status, and that data generated can help providers know where additional support is needed.
CONCLUSIONS: This qualitative evaluation of the PLHIV-RS underscored the importance to PLHIV of asking about resilience alongside adversities. Implementing the PLHIV-RS as part of the Stigma Index 2.0 should be prioritized as a meaningful, appreciated experience for PLHIV, along with helping to inform and assess interventions to improve the lives of PLHIV.

OAD0103

FRAGILE LIVES. GAY SHAME, HIV STIGMA, SUBSTANCE USE AND STRUCTURAL FACTORS GREATLY AFFECT LATINO GAY MEN LIVING WITH HIV IN SAN FRANCISCO, CALIFORNIA: IMPLICATIONS FOR MENTAL HEALTH INTERVENTIONS GLOBALLY

A. Maiorana[1], E. Santiago Rodriguez[1], S. Hughes[1], J. Sauceda[1]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States

BACKGROUND: In the USA, while the focus remains on HIV care engagement outcomes, little progress has been made in addressing the multiple intersections of stigma, mental health, substance use and structural factors affecting Latino gay men living with HIV. We explored these intersections to show where interventions should focus to improve quality of life and sustain HIV outcomes.
METHODS: We conducted 16 semi-structured interviews in English or Spanish with USA and foreign-born Latino gay men living with HIV and depression (PHQ-9 score > 10) at San Francisco General Hospital. Guided by an intersectional stigma framework and thematic analysis, we examined gay shame, HIV stigma, mental health, substance use and social inequities among participants.
RESULTS: Participants (age 28-56) were lower income, and two-thirds were monolingual Spanish speakers. Most participants reported viral suppression but some acknowledged poor adherence and potential disengagement from HIV care because of methamphetamine, cocaine, and alcohol use, and ongoing challenges with depression and daily functioning. For most, their mental health states intersected with HIV stigma, feelings of shame, guilt, and regret related to their sexual orientation, and trauma from prior bullying, physical, emotional and/or sexual abuse. Their daily life was punctuated by different affective states: sadness, anxiety, fear, and fatigue, which led to social isolation. Affective states and social isolation intertwined with the structural factors they faced: unstable/unsafe housing and limited income in an expensive city. Of those undocumented immigrants, finding employment and housing was difficult and intertwined with the fear of potential deportation. Some used the Spanish terms “angustia” (anguish) and “desesperación” (desperation/despair) to refer to their mental states. Although half had received prior depression treatment with mixed satisfaction, some used the Spanish term “desahogarse” to describe the chance to undrown themselves of their feelings during the study interviews, reflecting their need for other services.
CONCLUSIONS: Sustaining, not just achieving, optimal HIV care outcomes, requires that programs and interventions take an intersectional approach to try to address the complex issues, including HIV stigma and internalized homophobia, that affect the wellbeing of Latino gay men. However, we also must address the structural barriers that negatively affect their circumstances and quality of life.

OAD0104

FAMILY SUPPORT AS A SOURCE OF RESILIENCE TO COUNTER HIV-RELATED STIGMA AMONG ADULTS ON ANTIRETROVIRAL THERAPY IN URBAN ZIMBABWE

T.B. Masvawure[1], J.E. Mantell[2,3], M. Mapingure[4], J. Zech[5], C. Gwanzura[6], T. Apollo[6], G. Musuka[4], R. Boccanera[7], M. Msukwa[8], G. George[9], M. Strauss[9], M. Rabkin[5,10]
[1]College of the Holy Cross, Health Studies Program, Center for Interdisciplinary Studies, Worcester, United States, [2]Columbia University Division of Gender, Sexuality and Health, New York, United States, [3]New York State Psychiatric Institute, New York, United States, [4]ICAP Zimbabwe, Harare, Zimbabwe, [5]ICAP at Columbia University, New York, United States, [6]Ministry of Health and Child Care, Harare, Zimbabwe, [7]Health Resources and Services Administration (HRSA), Rockville, United States, [8]ICAP South Africa, Pretoria, South Africa, [9]University of Kwa-Zulu Natal, Health Economics and HIV and AIDS Research Division (HEARD), Durban, South Africa, [10]Columbia University Mailman School of Public Health, Depts of Medicine and Epidemiology, New York, United States

BACKGROUND: HIV-related stigma continues to be a major threat to achieving HIV epidemic control as it can deter individuals from HIV testing, linkage to care, adherence to antiretroviral therapy (ART), and retention in treatment programs. We present findings, from a PEPFAR-funded study, on the role of family support in helping adults on ART manage HIV-related stigma in Harare, Zimbabwe.
METHODS: We conducted 8 focus group discussions (FGDs) with 26 women and 28 men aged 18-49 years on ART recruited from 7 high-volume public-sector health facilities in Harare and 35 interviews with healthcare workers (HCWs) at the same sites. Data were analyzed in Dedoose using inductive and deductive approaches.
RESULTS: Both female and male FGD participants reported pervasive HIV-related stigma in their families and communities. Most thus preferred to keep their HIV status secret. Nevertheless, many had disclosed to a family member, usually a parent, spouse or sibling. These family members became key sources of psycho-social support and often shielded participants from stigma. Family members provided protection from violence and rejection by disclosing on participants’ behalf (“I told him [my brother]. My brother...talked to my husband and my husband accepted my status.”) and by keeping participants’ statuses hidden from other family members (“I told my mother...the rest do not know my status, so I’m not shy [ashamed] when I am with them.”). Family members also encouraged participants to enroll and remain in treatment despite others’ stigmatizing comments and offered practical support by collecting ARVs when participants couldn’t get time off work without arousing suspicion or risking disclosure to employers. Most HCWs highlighted non-disclosure to family members as a key barrier to retention in HIV care (“Maybe at home your family does not know that you are taking ARVs...so you can’t explain to them that you have to go to the clinic.”).
CONCLUSIONS: Family members can act as key allies in managing HIV-related stigma, fostering resilience among people living with HIV and supporting treatment adherence. However, it is equally important to ensure that supportive family members have access to psychosocial services to prevent burnout.

OAD0105

SYMBOLIC VIOLENCE IN HEALTHCARE AS A BARRIER TO HIV PREVENTION AND CARE FOR YOUNG TRANS WOMEN IN BRAZIL

E.C. Wilson[1], E.M. Jalil[2], N. Martinez Fernandez[2], A.L. Ferreira[2], C.V. Castro[2], C.M. Jalil[2], L. Kamel[2], I. Moura[2], C. Souza[2], D. Bezerra[2], L. Monteiro[2], V.G. Veloso[2], B. Grinsztejn[2]
[1]San Francisco Department of Public Health/University of California, Trans Research Unit for Equity/Epidemiology and Biostatistics, San Francisco, United States, [2]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

BACKGROUND: Examination of interactions that reinforce domination of oppressed groups is important for identifying intervention targets to address stigma. Bourdieu's concept of symbolic violence provides a framework for understanding experiences of marginalized groups in the healthcare setting. Young trans women are seen as transgressing current gender norms and face extremely high stigma in the Brazilian society, including in the universal healthcare system. This study was conducted to describe the ways symbolic violence manifests in healthcare interactions and structures for young trans women in Brazil who are at risk for or living with HIV.

METHODS: We conducted content analysis of qualitative interview data collected with young trans women ages 18-24 years old and with clinical providers who practice in the universal healthcare system in Rio de Janeiro, Brazil. Ten young trans women and 10 providers were interviewed. Audio files were transcribed and translated from Portuguese into English. Findings are described.

RESULTS: Most young trans women expressed distrust of the medical system based on prior discrimination and mistreatment by front line and clinical staff. Providers shared that colleagues knew little and had stigmatizing attitudes and beliefs about trans people. Overt discrimination manifested in individual behaviors like the unwillingness to use the social name of young trans women. Young trans women avoided the healthcare system, and thus had limited use of HIV prevention and care services. Young trans women also described limitations in the availability of medical services to meet their medical transition healthcare needs, resulting in structural violence wherein only a sub-set of their medical needs could be met.

CONCLUSIONS: Young trans women avoid healthcare as a survival mechanism to prevent further experiences of discrimination and ostracization. Healthcare avoidance reinforced systems of exclusion and presents increased health risks as medical HIV prevention and care needs were not being met. Structural barriers to medical transition care presented further symbolic violence and eliminated an avenue for reaching young trans women to engage them in healthcare. Strategies aimed at sharing knowledge and building trust with young trans women, and availability of medical transition care can begin to dismantle the continuum of violence and promote healthcare engagement.

OAD0106

A COUNSELLING INTERVENTION TO ADDRESS HIV STIGMA AT ENTRY INTO ANTENATAL CARE IN TANZANIA: RESULTS FROM A PARALLEL RANDOMIZED CONTROLLED PILOT STUDY

M. Watt[1], L. Minja[2], S. Sao[3], H. Osaki[2], R. Mwamba[3], G. Kisigo[3], B. Knettel[3], J. Ngocho[2], J. Renju[4], B. Mmbaga[2]
[1]University of Utah, Population Health Sciences, Salt Lake City, United States, [2]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [3]Duke University, Duke Global Health Institute, Durham, United States, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: Routine HIV testing and counselling during antenatal care (ANC) is an important catch point for new HIV diagnoses and can be an innovative site for addressing HIV stigmatizing attitudes among the general population. We developed Maisha, a counselling intervention implemented during routine ANC, to reduce HIV stigmatizing attitudes among women and their partners presenting for first ANC.

METHODS: A parallel two-arm pilot trial was conducted in two facilities in Moshi, Tanzania. Eligible consenting women and their partners attending their first ANC visit completed a baseline survey and were randomized to intervention or standard of care. Participants assigned to the intervention condition watched a short video followed by a brief counselling session delivered by trained lay counsellors that aimed to address misconceptions about HIV transmission and HIV stigmatizing attitudes and prepare participants for an HIV test. Participants with high stigmatizing attitudes were randomly selected for a 3 month follow up survey to measure the efficacy of Maisha. An 18-item scale was used to measure stigmatizing attitudes, with subscales of moral judgement and social distancing. ANCOVA models were used to assess potential intervention effects.

RESULTS: Between April and November 2019, we enrolled 1041 women and 494 men. At baseline, the intervention (n=760) and control (n=775) groups were statistically similar on all variables of interest (i.e. demographics and stigmatizing attitudes (p>0.05)). To date, 218 participants (90 controls and 128 intervention) have completed the follow up survey. After controlling for baseline scores, intervention participants had significantly lower stigmatizing attitudes (F (1,163) = 5.42, p=0.021) and anticipated stigma scores (F (1,158) = 4.35, p=0.039) than control participants. In a subscale analysis, intervention participants had significantly lower moral judgment at follow up compared to the control (F (1,163) = 12.34, p = 0.001), but there was no significant difference between conditions in interpersonal distancing (F (1,163) = 2.28p = 0.133).

CONCLUSIONS: The Maisha intervention successfully reduced stigmatizing attitudes towards people living with HIV (PLWH) amongst HIV negative individuals, and reduced anticipations of stigmatizing reactions if they tested seropositive. Further research is needed to improve how Maisha content addresses the issue of interpersonal distancing from PLWH.

OAD0202

ZAMBIA MALE CHARACTERIZATION STUDY: INSIGHTS TO INFORM HIV PROGRAMMING TO INCREASE MEN'S HIV SERVICE UTILIZATION

M. Chikuba-McLeod[1], M. Chisashi[1], P. Chungulo[1], L. Cicciò[1], A. Fullem[2], S. Illingworth[3], C. Madevu-Matson[2], M. Musonda[3], M. Njelesani[1], H. O'Bra[3]
[1]JSI Research & Training Institute, Inc., Lusaka, Zambia, [2]John Snow, Inc., Boston, United States, [3]USAID, Lusaka, Zambia

BACKGROUND: Male HIV service access/utilization is low in Zambia. The purpose of the Zambia male characterization study, conducted by the USAID DISCOVER-Health project implemented by JSI, was to characterize and understand the male sexual partners of adolescent girls and young women (AGYW) at risk of HIV, in order to better target and improve HIV programs for males, and reduce HIV transmission among AGYW.

METHODS: The mixed methods study was conducted sequentially in 2017/18 in three urban DREAMS districts. A quantitative survey among AGYW characterized their male sexual-partners. A subsequent qualitative survey among 123 males 20-34 years old (15 focus-group-discussions and 9 in-depth-interviews), defined men's health-seeking behaviours and the interventions required to increase their access to and utilization of HIV services, including testing, treatment (ART), circumcision, and condoms.

RESULTS: Fear and apprehension about HIV and health system shut-out emerged as the main barriers for men's access to/use of HIV services. The men in this study fear HIV. Most of the men living with HIV (MLHIV) they know were diagnosed late, with symptomatic HIV; they do not have many examples of MLHIV who are strong, healthy and well. They view HIV as emasculating, isolating and weak, and HIV diagnosis as the start of embarrassing/stigmatizing ill-health to early death. Many believe they have HIV from high-risk behavior, but are too afraid to test. Unlike women 20-34 who have significant health system contact, men feel shut-out of the health system and have little access to reliable health/HIV information to inform their health choices. Equally ill-informed peers are the primary source of information about HIV/health. Most do not know the benefits of early diagnosis or that with ART one can live healthy and strong. Men initially self-medicate and/or use faith/traditional healers for healthcare. When the problem persists/worsens, they go to the clinic.

CONCLUSIONS: For Zambia to achieve HIV epidemic control by 2020, a key gap must be addressed: finding, engaging, and sustaining the missing men, particularly men 20-34 (among the least virally-suppressed) in HIV services. These insights should be used to improve HIV programs to support men to access/utilize HIV services more, towards HIV epidemic control.

UNIQUE AND SHARED CORRELATES OF INTIMATE PARTNER VIOLENCE PERPETRATION AND SEXUAL RISK BEHAVIOR AMONG SOUTH AFRICAN ADOLESCENT BOYS

N. Tarantino[1,2], C. Matthews[3,4], S. Sun[1,2], L. Orchowski[1,2], A. Harrison[5,4], N. Abrahams[3], A. Berkowitz[6], M. Akande[5], C. Kuo[4,5]
[1]Alpert Medical School of Brown University, Providence, United States, [2]Rhode Island Hospital, Providence, United States, [3]South Africa Medical Research Council, Cape Town, South Africa, [4]University of Cape Town, Cape Town, South Africa, [5]Brown University School of Public Health, Providence, United States, [6]Alan Berkowitz Consulting, Mount Shasta, United States

BACKGROUND: South Africa is a global priority setting for tackling the interacting HIV and sexual violence epidemics. Adult perpetration of intimate partner violence (IPV) is often associated with engagement in sexual risk behaviors (SRBs) relating to HIV acquisition or transmission. However, this relationship is less understood among adolescents. Guided by theory, this study explores the association between factors predictive of IPV perpetration and SRB among adolescent boys.

METHODS: Boys (ages 15-17; N=80) participated in a gender-tailored intervention pilot trial focused on IPV perpetration and HIV risk behavior prevention. Boys were recruited from a Cape Town community with high HIV prevalence. Baseline data associations among risk factors and target outcomes were analyzed. Past-year perpetration of IPV (i.e., forced sexual petting or oral, vaginal, or anal sex) and past 3-month SRB (i.e., condomless sex, sex with multiple partners, and sex while using alcohol/drugs) were measured. Significant bivariate correlates of IPV perpetration and SRB, including demographic/socio-economic factors, violence/trauma exposure, family functioning, and IPV/SRB-related attitudes and norms, were entered in multivariate regression models.

RESULTS: Rate of IPV perpetration was 51%; rates of SRB ranged from 33% to 49%. IPV perpetration was correlated with SRBs (rs = 0.30-0.36). Bivariate analyses revealed common correlates associated with a lower likelihood of IPV perpetration and SRB: greater equitable gender beliefs and ability to negotiate sexual consent; positive norms related to condom use; and safer attitudes towards sex and condoms. Other correlates were unique to IPV perpetration (e.g., food insecurity) or SRB (e.g., violence exposure). Multivariate models revealed that higher food security, better family communication, and safer attitudes towards sex, and lower violence exposure, more equitable gender beliefs, and higher sexual consent negotiation ability were associated with lower odds IPV perpetration and SRB, respectively.

CONCLUSIONS: Gender and sexual risk-related norm perceptions/misperceptions, beliefs, and attitudes possibly explain the association between IPV and SRB among adolescent boys in South Africa and should be focused by prevention efforts. Addressing IPV in an adolescent-tailored manner needs also to include targeting family factors. More research is needed to further uncover unique risk factors relating to IPV perpetration and SRB during adolescence, including access to resources and violence/trauma exposure.

OAD0204

AN ALARMING PREVALENCE OF GENDER-BASED VIOLENCE EXPERIENCES AMONG HIV HIGH RISK POPULATION IN CAMBODIA

P. Chhoun[1], C. Wieten[1], S. Tuot[1], C. Brody[2], S. Kros[3], S. Yi[1,4,5]
[1]KHANA Center for Population Health Research, Chamkarmorn, Cambodia, [2]Touro University California, Public Health Program, College of Education and Health Sciences, Vallejo, United States, [3]Ministry of Health, Provincial Health Department, Siem Reap, Cambodia, [4]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [5]Touro University California, Center for Global Health Research, Vallejo, United States

BACKGROUND: A growing body of international research identifies women working in the sex and entertainment industry as a high-risk group for exposure to gender-based violence (GBV). Female entertainment workers (FEWs) is one of the HIV high risk population in Cambodia. Despite the recognized vulnerability of these women, their experiences with GBV remain understudied. This study aims to examine the prevalence of GBV among one HIV high risk population in Cambodia and identify factors associated with their victimization.

METHODS: A cross-sectional study was conducted as part of the mid-term survey for the Mobile Link project in November 2019. A structured questionnaire was programmed in Kobo Humanitarian Response Platform and offline-used for face-to-face interviews with 600 FEWs from three provinces and a capital city in Cambodia. The study participants were recruited from different entertainment venues using a stratified random sampling method. The questionnaire collected data on socio-demographic characteristics, gender inequity norm, and GBV. Bivariate and multivariable logistic regression analyses were performed to identify risk factors for GBV victimization.

RESULTS: Of the total, 60.5% women had experienced a form of GBV during their lifetime, of whom 37.5% experienced it in the past six months. The prevalence of emotional abuse, forced substance use, physical abuse, and forced sex was 51.5%, 25.0%, 20.6%, and 2.9%, respectively. Forced substance use and forced sex were mainly perpetrated by clients, physical abuse by intimate partners, and emotional abuse by others. FEWs victimized by clients (RRR=0.19, 95%CI=0.07-0.53) and others (RRR=0.11, 95%CI=0.03-0.44) were less likely to be married compared to victims of intimate partner violence. Factors associated with sexual harassment were working in beer gardens (AOR=2.39, 95% CI =1.20-4.73) and restaurants/cafés (AOR=1.65, 95% CI=1.01-2.69), and having high adherence to gender inequity norms (AOR=3.21, 95% CI=1.42-7.25).

CONCLUSIONS: FEWs in Cambodia experience high levels and unique forms of GBV as they are confronted with different types of perpetrators. Interventions need to be tailored to fit the specific needs and experiences of FEWs working in different entertainment venues. Interventions aimed at reducing client-perpetrated violence should specifically focus on forced substance use and forced sex, while physical abuse by intimate partners should also be addressed.

OAD0205

GENDER-BASED VIOLENCE PERPETRATION BY MALE SEXUAL PARTNERS OF ADOLESCENT GIRLS AND YOUNG WOMEN IN HAITI: DEMOGRAPHIC AND HIV CORRELATES

O. Desinor[1], J. McOwen[1], K. Francoise[2], E. Felker-Kantor[3], J. Michel[4], K. Andrinopoulos[3]
[1]United States Agency for International Development, Health, Port au Prince, Haiti, [2]Ministry of Public Health and Population, Port au Prince, Haiti, [3]Tulane School of Public Health and Tropical Medicine, Global Community Health and Behavioral Sciences, New Orleans, United States, [4]Pentagone Consulting Group, Port au Prince, Haiti

BACKGROUND: Globally, women who experience gender-based violence (GBV) have been shown to be at higher risk for HIV. Male perpetrators of GBV report higher risk HIV behaviors (multiple partners, sex worker patronage, and inconsistent condom use). GBV is potentially an important determinant of HIV vulnerability for AGYW in Haiti, but limited information exists about the characteristics of men who perpetrate GBV.

METHODS: A cross-sectional survey was administered to adult men in Port-au-Prince (PaP) (n=500) and St. Marc (n=300) reporting an AGYW sexual partner in the last 12 months. Men were recruited using respondent-driven-sampling, and asked to report on their HIV-related behaviors, and perpetration of emotional and sexual/physical violence with their most recent AGYW partner. Statistical analysis included bivariate and multivariate logistic regression with appropriate RDS sampling weights. Results are presented separately for each city.

RESULTS: The most common form of emotional violence reported by men was trying to control what their partner does (72.5% in PaP, 64.9% in St. Marc). Emotional violence perpetration was more common among men with higher levels of education (adjusted odds ratio (AOR) 11.09, p=0.000 in PaP and 5.55, p=0.092 in St. Marc), and higher income in PaP (AOR 2.20, p=0.004). Men who reported emotional violence perpetration in PaP were more likely to use condoms with their AGYW partner (AOR 1.79, p=0.071). In terms of physical violence, 7.5% of participants in PaP and 7.0% of participants in St. Marc reported ever having hit, pushed, slapped, punched, or kicked their AGYW sexual partner. A higher proportion reported ever having forced their AGYW partner to have sex (17.2% of participants in PaP and 19.8% in St. Marc). In multivariate analysis, men in St. Marc who report physical/sexual violence perpetration were more likely to report high-risk sexual behavior (multiple concurrent partnerships and being six or more years older than their partner) (AOR 3.06, p=0.011) and less likely to report condom use (AOR 0.39, p=0.009).

CONCLUSIONS: In Haiti physical/sexual violence perpetration is linked to higher risk sexual behavior for men and may increase their partner's HIV vulnerability. It is important to include GBV interventions in HIV programming.

OAD0206

RATIONAL REASONING AND (NON) DISCLOSURE OF SEXUAL ASSAULT BY FEMALE STUDENTS IN A UNIVERSITY IN ESWATINI: IMPLICATIONS FOR HIV PREVENTION

F. Shabalala[1], N. Masilela[2], P. Ndlangamandla[2], S. Masuku[2], R. Fielding-Miller[3]
[1]University of Eswatini, Community Health Nursing, Mbabane, Eswatini, [2]University of Eswatini, Community Health Nursing Science, Mbabane, Eswatini, [3]University of California, Global Health and Medicine, San Diego, United States

BACKGROUND: Sexual violence is strongly linked to an increased risk of HIV acquisition, and one in three women around the world will experience some form of sexual violence in their lifetime. While post-exposure prophylaxis medications, counselling, and other forms of support that may decrease some of the attendant risk of HIV are available to survivors of assault in many global settings, they can only be accessed if survivors choose to disclose that an assault has happened. Increasing safe and supported sexual assault disclosure is an important step in addressing the links between HIV and gender based violence. We analyzed a sample of female university students in Eswatini who had experienced sexual assault in their lifetime to identify factors associated with the choice to disclose.

METHODS: Participants were a random sample of female students enrolled fulltime at the University of Eswatini, drawn from a list of all students at time of study. Analyses were conducted on a subsample of women (n=188) who reported experiencing sexual assault in their lifetime. We assessed the prevalence and correlates of disclosure, testing the hypothesis that financial reliance on a perpetrator would be a strong predictor of nondisclosure

RESULTS: We sampled 372 female students. Of these, 51% (n=188) reported lifetime penetrative sexual assault. Only 43% of survivors (n=80) reported ever disclosing their assault to anyone. In our analyses, economic variables were not associated with disclosure. Believing one's friends would support her if she was assaulted by a boyfriend was associated with disclosure (OR 2.16, 95% CI: 1.18 – 3.92) and believeing she would be supported if assaulted by a stranger was marginally associated (OR 1.79, 95% CI: 0.99 – 3.25). Among participants who never disclosed, 10% cited financial reliance on their perpetraor. Being responsible for a child was marginally associated with nondisclosure because of financial reliance (OR 3.3, 95% CI: 0.93 – 11.81).

CONCLUSIONS: The majority of sexual assault survivors never disclosed their assault to anyone. Programs to reduce HIV risk for survivors of sexual assault must consider both women's social and financial landscapes to create holistic policies.

CHARACTERIZING STRATEGIES USED BY HIV-INFECTED SMALLHOLDER FARMERS TO MITIGATE THE EFFECTS OF CLIMATE CHANGE IN THE NYANZA REGION OF KENYA

T. Nicastro[1], C.R. Cohen[2], N. Beyeler[3], S. Jawouro[4], G. Odhiambo[4], E.A. Bukusi[4], S.D. Weiser[5]
[1]University of California, National Center of Excellence in Women's Health, San Francisco, United States, [2]University of California, Obstetrics and Gynecology, San Francisco, United States, [3]University of California, Institute for Global Health Science, San Francisco, United States, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]University of California, HIV and Infectious Diseases, San Francisco, United States

BACKGROUND: Severe weather events pose risks to HIV health among infected individuals relying on farming for livelihoods and food. Little information exists on strategies rural people living with HIV (RPLHIV) adopt to cope with severe weather events. We used qualitative methods to characterize strategies used by HIV-infected farmers to mitigate climate change impacts.

METHODS: We interviewed 40 HIV-infected-individuals in 2018 enrolled within the *Shamba Maisha* cluster-randomized control trial, a multisectoral agricultural and financial intervention to improve HIV health outcomes among RPLHIV in Kisumu, Homa Bay and Migori counties in Kenya (NCT02815579). We used purposive sampling to select participants from diverse geographies. In-depth interviews were conducted in participants' native language, transcribed, translated into English and double-coded. Thematic content analysis followed an integrated inductive-deductive approach.

RESULTS: Participants reported severe weather (droughts and flooding) became more severe over time, leading to significant losses in livestock, crop yields, infrastructure, and income, posing threats to their HIV health through increased food insecurity, lack of money for transportation, and displacement from flooded homes. Mitigation strategies included short-term coping such as reduced number of meals, eating lower-quality food, walking long distances to clinic, displacement to safer regions, and skipping medications if no food was available. People also described longer-term adaptation strategies such as farming plot expansion, farming infrastructure investments, individual requests for larger distributions of medications, allocating more money towards savings, diversifying crops, and securing non-farming employment. According to participants, these efforts were driven by their complete dependence on farming to support their basic needs, while also noting the importance of farming yields and availability of food in order to adhere to their ART medications. Gender may play a role in mitigation strategies utilized because male farmers may have more access to some resources than female farmers, such as land, farming machinery, and available time.

CONCLUSIONS: These data provide useful information on how RPLHIV adapt to impacts of severe weather events, which can help guide development of climate responsive support systems, including those that prevent wide-spread interruptions in ART adherence. More work is needed on gender-specific adaptation strategies so that interventions and programs are responsive to the needs of all RPLHIV.

OAD0303

RANDOMIZED CONTROLLED TRIAL OF NURSE-LED LAY VILLAGE WOMEN ON BEHAVIOURAL AND NUTRITIONAL INTERVENTION FOR WOMEN LIVING WITH HIV/AIDS IN INDIA: 18 MONTHS FOLLOW-UP

A. Nyamathi[1]
[1]University of California, Sue & Bill Gross School of Nursing, Irvine, United States

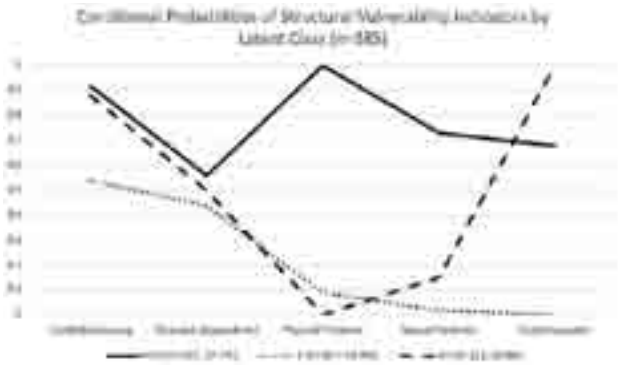
BACKGROUND: Long-Term Impact of a nurse-led behavioral and nutrition intervention, supported by Asha (lay village women), and focused on improving the health of WLH/A in India. Health parameters include Depressive Symptoms, CD4 levels, Body Mass Index [BMI]) and Hemoglobin. Women Living with HIV/AIDS (WLH/A) in rural India face extreme health disparities, challenging adherence to Antiretroviral (ART) Treatment. Nutritional deficits including anemia exacerbate disease progression.
METHODS: After extensive formative research, we conducted a four-arm quasi-experimental trial with 600 women recruited from primary-health centers. The 4 programs each included group-education sessions and Asha support and differed on the nutritional component: 1) Asha-supported standard education (SE) alone; 2) SE + nutrition education (+NE); 3) SE + nutrition supplements (+NS); or 4) SE + nutrition education and supplements (+NENS). The intervention was delivered over 6 months. Assessments occurred at baseline, and month 6 (post-intervention), 12, and 18, with 100% retention. Multilevel modeling examined effects of program over time.
RESULTS: At baseline, mean age was 34 years and CD4 level was 447.4. 100% of the women were anemic. At 18-month follow-up, Program 4 experienced greatest improvements in CD4 counts compared to the Program 1. For BMI, Programs 3 and 4 exhibited greater gains compared to Program 1. All programs improved depressive symptom scores and ART adherence from baseline to 18-month follow-up; no severe anemia at 18-months.
CONCLUSIONS: A low-cost Nurse-led and Asha-supported behavioral and nutritional intervention improved health parameters sustained at 18-month follow-up. Future research should explore this model in other communities and infectious diseases.

OAD0304

HOW DOES HIV RISK DIFFER BY CO-OCCURRING STRUCTURAL FACTORS? A LATENT CLASS ANALYSIS OF STRUCTURAL VULNERABILITY INDICATORS AMONG CISGENDER FEMALE SEX WORKERS IN BALTIMORE, MARYLAND, USA

C. Tomko[1], K. Schneider[2], D.F. Nestadt[1], R.H. White[1], R. Musci[2], M. Kaufman[1], S.G. Sherman[1]
[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior, and Society, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Mental Health, Baltimore, United States

BACKGROUND: Structural vulnerability (SV) posits that a group's social position can constrain behaviors owing to conflict with existing power structures, elevating risk for health disparities. Little research has examined how HIV risk differs by the co-occurrence of SV indicators (e.g. violence, economic strains) among female sex workers (FSW), a key population in the HIV epidemic grossly understudied in the US.
METHODS: We recruited 385 cisgender FSW 18 years+ in Baltimore, Maryland via mobile van. Participants completed survey, HIV rapid test, and self-administered chlamydia and gonorrhea tests. Using latent class analysis, we sought to identify typologies of SV based on clustering of SV indicators experienced in the past 6 months: unstable housing, financially dependent on someone else, client-perpetrated physical or sexual violence, and hungry "because there was not enough food" at least weekly. Number of latent classes was determined by relevant fit statistics (AIC, BIC, LRT). Mplus commands dcat and dcon performed bivariate tests of significance between latent classes and categorical and continuous variables, respectively, while accounting for class.
RESULTS: Participants were a median 37 years old, 36% Black, and 58% injected drugs in the past 6 months. Baseline HIV prevalence was 7% with 16% and 18% testing positive for gonorrhea and chlamydia, respectively. A 3-class model emerged: economic factors (housing, financial dependence) only (E); economic and hunger (EH); highest SV (HSV) (Fig.1). Significant differences between classes include: condomless sex with clients (p=0.002), injecting drugs (p<0.001), chlamydia infection (p=0.04), internalized sex work stigma (p=0.03), and depression (p<0.001) and PTSD (p<0.001) symptoms.



[Figure. Conditional probabilities of structural vulnerability indicators by latent class (n=385)]

CONCLUSIONS: Clear patterns of SV and HIV risk exist among FSW in the US. Results demonstrate the importance of employing a social determinants of health perspective in reducing HIV burden in this population, with the study providing nuances as to how to target subgroups to potentiate interventions' impacts among this key population.

OAD0305

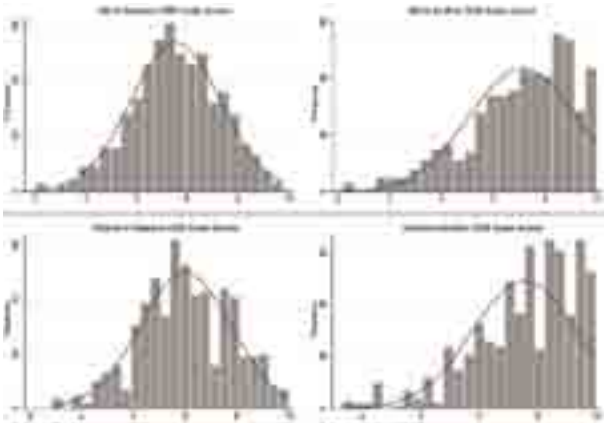
GAINING TRACTION: PROMISING SHIFTS IN GENDER NORMS AND INTIMATE PARTNER VIOLENCE DURING AN HIV PREVENTION TRIAL IN SOUTH AFRICA

A. Gottert[1], J. Pulerwitz[1], N. Haberland[1], R. Mathebula[2], D. Rebombo[2,3], K. Spielman[1], R. West[4], A. Julien[5], R. Twine[6], D. Peacock[2,7,8], M.-S. Kang Dufour[4], F.X. Gómez-Olivé[6], A. Pettifor[5,6], S.A. Lippman[4,6], K. Kahn[6]
[1]Population Council, HIV and AIDS Program, Washington, United States, [2]Sonke Gender Justice, Agincourt, South Africa, [3]Independent Consultant, Johannesburg, South Africa, [4]University of California, Division of Prevention Science, Department of Medicine, San Francisco, United States, [5]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [6]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, Agincourt, South Africa, [7]Promundo, Washington, United States, [8]School of Public Health and Family Medicine, University of Cape Town, Division of Social and Behavioural Sciences, Cape Town, South Africa

BACKGROUND: HIV and violence prevention programs increasingly seek to transform gender norms among participants, yet how to do so at the community level, and subsequent pathways to behavior change, remain poorly understood. We assessed shifts in endorsement of equitable gender norms, and intimate partner violence (IPV), during a three-year community-based trial of an HIV 'treatment as prevention' intervention in rural South Africa.

METHODS: Cross-sectional household surveys were conducted with men and women ages 18-49 years, in eight intervention and seven control communities, at 2014-baseline (n=1,149) and 2018-endline (n=1,189). Gender norms were measured by the GEM Scale. Intent-to-treat analyses assessed intervention effects and change over time. Qualitative research with 59 community members and 38 staff examined the change process.

RESULTS: Two-thirds of men and half of women in intervention communities had heard of the intervention/seen the logo; half of these had attended two-day workshop(s). Regression analyses showed a 15% improvement in GEM score over time, irrespective of the intervention, among men ($p<0.001$) and women ($p<0.001$). Younger men (ages 18-29) also had decreased odds of reporting past-year IPV perpetration over time (aOR 0.40; $p<0.05$), while younger women had lower odds of reporting IPV over time in intervention vs. control communities (aOR 0.53; $p<0.05$).



[Figure 1. Histograms depicting shifts in the distribution of gender norms scores (GEM Scale) between baseline and endline (irrespective of study arm), among men and women]

Qualitative data suggest that gender norms shifts may be linked to rapidly-increasing media access (via satellite TV/smartphones) and consequent exposure to serial dramas modeling equitable relationships. Workshop activities that fostered couple-communication skill-building and critical reflection around gender norms further supported IPV reductions.

CONCLUSIONS: There was a population-level shift towards greater endorsement of equitable gender norms between 2014-2018, potentially linked with escalation in media access. There was also an intervention effect on reported IPV among women, although not among men. Societal-level gender norm shifts can create enabling environments for interventions to find new traction for violence and HIV-related behavior change.

OAD0306

MODIFYING SOCIAL ACTION THEORY TO CONCEPTUALISE SOCIAL AND STRUCTURAL FACTORS AND THEIR IMPACTS ON HIV TREATMENT ENGAGEMENT

S.M. Topp[1], C. Mwamba[2], L.K. Beres[3], I. Sikazwe[2], C.B. Holmes[4], M.E. Herce[5,2], A. Sharma[2]
[1]James Cook University, Townsville, Australia, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [3]Johns Hopkins University, Baltimore, United States, [4]Georgetown University, Washington DC, United States, [5]University of North Carolina, Chapel Hill, United States

BACKGROUND: Long term engagement and retention in HIV treatment is an ongoing challenge to national treatment programs, yet behavioral models on which many retention-promoting programmes are built, do not adequately account for the role of social and structural determinants. Based on secondary analysis, we interrogated Ewart's Social Action Theory as a promising approach to conceptualizing not just which, but how, social and structural factors and their interaction influence HIV treatment engagement.

METHODS: Thematic summaries from three empirical qualitative data-sets documenting patient and provider experiences of HIV treatment engagement and disengagement in Zambia (2012/13, 2015/16) and Malawi (2018) were analysed for congruence with Social Action Theory (SAT). We conducted iterative comparison of thematic summaries to theoretical constructs relating to context, self-change processes and action-states respectively.

RESULTS: Qualitative validation demonstrated a high degree of congruence with SAT across data-sets. Patients' experience of illness (physiological state) community HIV-related knowledge and attitudes, gender and cultural norms (relationship systems), work place and health facility contexts (organisational systems), and experiences of poverty and food security (socioeconomic settings) combined to create a critical 'context' in which individuals' operated. Individual's knowledge and understanding which informed both imagined and real possibilities of HIV and treatment (generative capabilities), personal acceptance or denial of status and expectations of seeking treatment (motivations), capacity to disclose as well as relationships with health providers (social interactions) combined to form dynamic responses influencing engagement decision behaviors. The relative influence of spouses or close family members (social interdependence), combined with immediate physiological outcomes of treatment (side effects, recovery and/or illness), completed a dynamic loop feeding back into the 'contextual' experience of illness and personal affect.

CONCLUSIONS: The challenge of how to strengthen engagement in HIV treatment in both general and targeted epidemics remains ubiquitous, yet also paradoxically context-specific. Social Action Theory extends current models by more consciously linking social and structural factors (particularly structural poverty, power-dynamics, and health system drivers) to well-recognised behavioral drivers of engagement. It provides a promising tool for conceptualizing 'whole-of-system' planning for improving HIV retention accounting for the dynamic relationship between factors while remaining sufficiently flexible to use across political, cultural and geographic settings.

OAD04 PANORAMIC VIEW OF DRUG USE AND HIV

OAD0402

A NEW GENERATION OF DRUG USERS IN ST. PETERSBURG, RUSSIA? A PRELIMINARY TESTING OF THEORY OF DRUG GENERATIONS BASED ON A MIXED-METHODS PILOT STUDY OF YOUNG HARD DRUG USERS

P. Meylakhs[1], S. Friedman[2], D. Ompad[3]
[1]National Research University Higher School of Economics, International Centre for Health Economics, Management, and Policy, St. Petersburg, Russian Federation, [2]NYU Langone, New York, United States, [3]NYU College of Global Public Health, New York, United States

BACKGROUND: Russia has a widespread injection drug use epidemic with high prevalence of HIV and HCV among people who inject drugs (PWID). Thus, HIV prevalence among PWID in St. Petersburg is around 60%, HCV - 95%. Most research to date was concentrated on older cohorts, mostly opioid users, of PWID while young drug users in Russia have not received proper attention. The goal of the pilot study was to gain some preliminary understanding of possible drug generation's change. Our theoretical approach was 'drug generation theory', according to which drug generations succeed each other when a previously fashionable drug falls into disrepute.

METHODS: Mixed methods study of young (age 18 - 26) hard (opiates, stimulants, NPS) drug users in St. Petersburg using HIV and HCV oral tests (OraQuick) in addition to behavioral data (10 semi-structured interviews and 40 structured interviews).

RESULTS: Almost half (49%) of the sample used amphetamines, 21% used amphetamines and mephedrone (NPS) – also a stimulant (thus, 70% of the sample used only stimulants). Only 18% ever used opioid (and only episodically). Mean IDU experience was 4.2 years. 0 HIV cases and 2 HCV cases were detected among 30 PWID subsample. None of the participants shared a syringe in the last 12 months. Opioid use, syringe sharing and HIV and HCV statuses were heavily stigmatized. The informants avoided older (30+) PWID. Qualitative data shows some of the participants used opioids episodically but were disappointed by their effects.

CONCLUSIONS: These data indicate that a new generation of drug users in St. Petersburg may have emerged. Though the sample was small, the discrepancies—0% vs. 65% on HIV and 7% vs. 95% on HCV can hardly be attributed to chance. Thus, this cohort seems to be much safer in its injection practices than older PWID cohorts. It is also opiate aversive in comparison to older cohorts. Thus, this generation of drug users can be called "amphetamine generation" or given the rapid spread and popularity of stimulant type NPS "stimulants generation." The pilot data give some confirmation to the theory of drug generation's change. However, given the small sample size these conclusions are very preliminary.

OAD0403

HIV AND HEPATITIS C VIRUS CO-INFECTION AMONG PEOPLE WHO INJECT DRUGS IN CAMBODIA: FINDINGS FROM A NATIONAL SURVEY USING RESPONDENT DRIVEN SAMPLING METHOD

C.H. Saing[1], P. Chhoun[2], N. Chann[3], S. Tuot[2], P. Mun[3], S. Eng[2], S.C. Choub[2], S. Yi[2,1,4]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [3]National Center for HIV/AIDS, Dermatiology and STD, Surveillance Unit, Phnom Penh, Cambodia, [4]Touro University California, Center for Global Health Research, Vallejo, United States

BACKGROUND: Despite the evidence of the relationship between human immunodeficiency virus (HIV) and hepatitis C virus (HCV) in people who inject drugs globally, studies on the co-infection among this key population remain scarce in resource-poor countries. This study was therefore conducted to explore the prevalence of and factors associated with HIV/HCV co-infection among people who inject drugs in Cambodia.

METHODS: This study was conducted in 2017 as part of the National Integrated Biological and Behavioral Survey. The Respondent Driven Sampling method was used to recruit participants in 12 provinces for face-to-face interviews and HIV and HCV testing. Weighted multivariable logistic regression analysis was conducted to identify risk factors associated with HIV/HCV co-infection. This study was approved by the National Ethics Committee for Health Research.

RESULTS: This study included 286 people who inject drugs with a mean age of 31.6 (SD= 7.5) years. The prevalence of HIV and HCV was 15.2% and 30.4%, respectively. Almost one in ten (9.4%) of the total study population were co-infected with HIV and HCV. After adjustment, the odds of HIV/HCV co-infection was significantly higher among participants who were female (AOR= 2.17, 95% CI= 1.03-6.08), were in the older age group of 35 and older (AOR= 3.67, 95% CI= 1.04-9.80), were widowed/divorced/separated (AOR= 3.25, 95% CI= 1.76-13.94), were living on the streets (AOR= 4.83, 95% CI= 1.23-9.02), and had received methadone maintenance therapy in the past year (AOR= 4.02, 95% CI= 1.13-18.96) compared to their respective reference group. The odds was significantly lower among participants who reported having attained ≥10 years of formal education compared to those who had attained only primary education or lower (AOR= 0.68, 95% CI= 0.15-0.96).

CONCLUSIONS: The prevalence of HIV/HCV con-infection among people who inject drugs in Cambodia is considerably high, particularly in older and more vulnerable subgroups. Tailor-made interventions are required to increase access to culturally sensitive harm reduction interventions to prevent both HIV and HCV infection. In addition, there is an opportunity to expand HCV screening, diagnosis, and treatment in this key population given its small population size and the availability of new directly-acting antiviral agents in the country.

OAD0404

EFFECTS OF CIGARETTE SMOKING AND SUBSTANCE USE ON HIV VIRAL SUPPRESSION OVER TIME IN A COHORT OF YOUNG MEN WHO HAVE SEX WITH MEN

M. Kalmin[1], H. Aralis[2], M. Li[1], M. Javanbakht[3], P. Gorbach[3], S. Shoptaw[1]
[1]UCLA, Family Medicine, Los Angeles, United States, [2]UCLA, Biostatistics, Los Angeles, United States, [3]UCLA, Epidemiology, Los Angeles, United States

BACKGROUND: Cigarette smoking and substance use behaviors often co-occur in HIV-positive populations. Although smoking and substance use have been linked to HIV viral suppression (VS), limited data are available on their independent and joint effects on VS longitudinally. Determining whether there is an interaction between these behaviors on VS over time could inform syndemic approaches in managing HIV.

METHODS: The Men who have sex with Men and Substance Use Cohort at UCLA Linking Infections, Noting Effects (mSTUDY) is a cohort study primarily among men of color in Los Angeles, CA. This analysis included mSTUDY participants enrolled from 2014 to 2018 who were HIV-positive, reported being prescribed antiretroviral therapy (ART), and had available data on smoking and substance use. Independent and joint effects of time-varying smoking (at least one cigarette/day) and substance use (opiates, fentanyl, cocaine, amphetamine-type stimulants, or nitrites) on VS (viral load < 200 copies/mL) at each six-month follow-up visit were estimated using a mixed-effects logistic regression model, accounting for repeated measures and adjusting for time, age, race/ethnicity, employment, and history of psychiatric illness.

RESULTS: Among 227 HIV-positive participants with a median follow-up of two years, 126 (56%) reported smoking, 181 (80%) reported using substances other than cannabis, and 205 (90%) experienced viral suppression at least once over follow-up. At each visit, participants who reported smoking had significantly decreased adjusted odds of experiencing VS compared to nonsmokers (aOR=0.59, 95% CI: 0.36-0.97). Similarly, participants who reported using substances other than cannabis had less than half the adjusted odds of experiencing VS compared to those reporting either cannabis only or no drug use (aOR=0.46, 95% CI: 0.28-0.74). There was not a significant interaction between smoking and substance use on VS at each six-month visit.

CONCLUSIONS: Reported cigarette smoking and substance use other than cannabis independently reduced the odds of experiencing VS at each six-month visit. However, individuals who reported both smoking and using substances other than cannabis did not experience an enhanced decreased odds of VS compared to either smoking or substance use alone. Further research will focus on ways to understand the roles of smoking and substance use over time in this study population.

OAD0405

PREP AWARENESS AND PERCEIVED HIV STIGMA AMONG PEOPLE WHO INJECT DRUGS, SAN FRANCISCO, 2018

D. Veloso[1], H. Xie[1], J. Lin[1], D. Miller[1], W. McFarland[1,2]
[1]San Francisco Department of Public Health, Center for Public Health Research, San Francisco, United States, [2]University of California, San Francisco, United States

BACKGROUND: "Getting to Zero" efforts require achieving zero HIV stigma. Unfortunately, interventions to reduce stigma lag behind HIV treatment to reduce mortality and PrEP to prevent infection. Research has shown HIV stigma as a barrier to prevention options such as PrEP; however, the direction of this association may go both ways. Education on PrEP may reduce HIV stigma as people at risk become aware of effective ways to prevent infection. Meanwhile, awareness of PrEP's ability to prevent HIV transmission is low among people who inject drugs (PWID) compared to other populations at risk. We therefore analyzed data from a community-based survey of PWID in San Francisco to illuminate the effects of PrEP awareness on perceptions of HIV stigma.

METHODS: PWID were recruited through respondent-driven sampling from July-December 2018. Eligibility criteria included San Francisco residence, 18 years of age or older, and injection of drugs within the past twelve months. Participants completed a structured survey including questions on PrEP awareness and ranking of how strongly they agreed with the statement, "Most people in San Francisco would discriminate against someone with HIV."

RESULTS: Among 464 participants, 38.1% were ≥50 years old, 55.0% were non-white, 66.5% were male-identified, 78.0% were unstably housed, and 9.1% had previously tested HIV positive. Among HIV-negative PWID, 37.2% were aware that PrEP could prevent HIV transmission from sharing injection equipment, and 38.8% agreed that most people would discriminate against someone with HIV. Black/African Americans (OR 3.61, 95%CI 2.14-6.08; p < 0.01) and Hispanics (OR 1.93, 95%CI: 1.05-3.57; p=0.035) had greater perceptions of HIV stigma compared to white PWID. Those who perceived less HIV stigma were more likely to be aware of PrEP (OR 1.55, 95%CI 1.04-2.30, p=0.030) and know that PrEP can prevent HIV transmission through sharing injection equipment (OR 1.66, 95%CI 1.09-2.51 p=0.018).

CONCLUSIONS: Increased promotion of PrEP for prevention of transmission through sharing injection equipment is needed among PWID together hand-in-hand with HIV stigma reduction programs. Getting to zero HIV infections may increasingly depend upon HIV stigma reduction as the remaining infections increasingly occur among groups experiencing intersecting stigma and discrimination.

OAD0406

ASSOCIATIONS OF RECREATIONAL DRUG USE WITH HIV-RELATED SEXUAL RISK BEHAVIOURS AMONG MEN WHO HAVE SEX WITH MEN IN JAPAN: RESULTS FROM THE CROSS-SECTIONAL LASH STUDY

T. Miwa[1], M. Yamaguchi[2], T. Ohtsuki[1], C. Wakabayashi[3], S. Nosaka[1], Y. Ikushima[1], M. Tarui[1]
[1]PLACE, Tokyo, Japan, [2]Bunan Hospital, Saitama, Japan, [3]Saitama Prefectural University, Department of Health Sciences, Saitama, Japan

BACKGROUND: While there are indications that recreational drug use promotes high-risk sexual behaviours among men who have sex with men (MSM), there is a scarcity of recent research focusing in Japan which has made a series of legislative changes surrounding drug control over the past decade. This research aims to assess recreational drug use patterns among MSM in Japan and evaluate their potential associations with HIV-related sexual risk behaviours.

METHODS: Between September 2016 and October 2016, study participants were recruited in a cross-sectional behavioural survey through a geosocial networking application for MSM. Participants were asked to complete an anonymous, self-administered online questionnaire which included information on sexual behaviours and drug use.

RESULTS: The mean age of the 6,921 respondents who were included in the analysis was 33.8 (95% CI: 33.6 – 34.0). 25.4% (1756/6921) of them reported that they had used recreational drugs some time in their life, and 11.3% (780/6921) in the past six months. The most commonly used drugs in the past six months were erectile dysfunction drugs (7.6%), alkyl nitrites (4.1%) and codeine-containing cough medicines (1.8%). Drug users were more likely than non-drug users to be older, have lower education level, self-identify as homosexual (gay), drink alcohol almost every day, know their HIV status, and have a better knowledge of HIV/STI. Recreational drug use in the past six months were independently associated with each of the following high-risk sexual behaviours in the same period: (i) >5 sexual partners (aOR = 2.70, 95% CI: 2.30 – 3.17); (ii) unprotected anal intercourse (aOR = 2.88, 95% CI: 2.43 – 3.42); (iii) group sex (aOR = 2.60, 95% CI: 2.22 – 3.05); and (iv) sex work (aOR = 2.30, 95% CI: 1.67 – 3.16).

CONCLUSIONS: This study suggests that recreational drug use is common among MSM in Japan amid tighter controls in the country. Furthermore, drug users were more likely to report high-risk sexual behaviours despite having a better knowledge of HIV/STI. Instead of merely prohibiting the use of drugs, it is important for the public and the private sector to work in concert to develop community outreach programmes to minimise the harm caused by drug use.

OAD05 POWERING HIV TESTING: TOWARDS THE TARGET

OAD0502

THE ROLE OF POPULAR OPINION LEADERS IN DISTRIBUTING HIV/SYPHILIS SELF-TESTS AMONG MEN WHO HAVE SEX WITH MEN IN CHINA

N. Yang[1], Z. Yi[2], W. Huang[3], D. Wu[4,5,6,7], W. Tang[6,7,5]
[1]University of Minnesota Medical School, Minneapolis, United States, [2]Centers for Disease Control, Department of HIV Control, Zhuhai, China, [3]Emory University, Atlanta, United States, [4]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [5]Social Entrepreneurship to Spur Health, Guangzhou, China, [6]University of North Carolina at Chapel Hill-Project China, Guangzhou, China, [7]Dermatology Hospital of Southern Medical University, Guangzhou, China

BACKGROUND: Novel strategies are needed to increase HIV testing, especially among key populations like men who have sex with men (MSM). Targeting MSM popular opinion leaders (POL) for distributing self-tests may increase access to HIV testing.

METHODS: This was a secondary analysis of a cohort study in Zhuhai, China. Men 16 years or older, born biologically male, ever had sex with a man, and applying for HIV/syphilis dual self-test kits were enrolled as indexes. Indexes who scored in the top 15% of a sexual influencer scale were deemed POL (Cronbach alpha 0.87). All indexes received up to five self-tests per application and were encouraged to distribute self-tests throughout their social networks. Recipients (alters) were instructed to upload their self-test results and complete a survey. The primary outcome was the average alters recruited per index. Poisson regression was used to calculate the rate ratio (RR) of recruitment by POL versus non-POL.

RESULTS: From June 17, 2018 to November 12, 2019, 371 indexes successfully applied for self-tests, 64 of whom were POL and 307 were non-POL. Compared to non-POL, more POL had disclosed their MSM status (86% vs. 67%, p<0.01) and were MSM community volunteers (20% vs. 3%, p<0.01). Eighty percent of all indexes had prior HIV testing, with no significant difference between POL and non-POL. Two hundred seventy-eight alters returned a verified test result. The average recruitment was 1.7 alters per POL index, versus 0.5 alters per non-POL index (RR 3.19, 95% CI 2.51-4.05). POL were also more efficient than non-POL at recruiting first-time testers (RR 2.57, 95% CI 1.73-3.83), HIV-positive alters (RR 5.48, 95% CI 1.99-15.12), and syphilis-positive alters (RR 4.80, 95% CI 1.20-19.18). Alters of POL were more likely than alters of non-POL to live rurally (47% vs. 25%, p<0.01), have a below-college education (55% vs. 41%, p=0.02), and have multiple male sexual partners in the past 6 months (43% vs 30%, p=0.03).

CONCLUSIONS: POL were more efficient than non-POL at distributing self-tests among MSM, and reached alters with higher risk for HIV/syphilis but less access to testing. Future randomized control trials are warranted to explore POL targeting for self-test distribution.

OAD0503

HOUSEHOLD COUPLES-BASED HIV SELF-TESTING IS EFFECTIVE IN PROMOTING MALE TESTING, IDENTIFYING DISCORDANT COUPLES, AND LINKING POSITIVE PARTNERS TO CARE: RESULTS FROM THE WENZA HURU STUDY IN KISARAWE, TANZANIA

J. Mbwambo[1], C. Bailey[2], V. Fonner[2], T. Rutayuga[1], K. O'Reilly[2], J. Ntogwisangu[1], I. Hamidu[1], B. Singh[2], M. Sweat[2]
[1]Muhimbili University of Health and Allied Sciences, Psychiatry, Dar es Salaam, Tanzania, United Republic of, [2]Medical University of South Carolina, Psychiatry and Behavioral Sciences, Charleston, United States

BACKGROUND: Many HIV infections in sub-Saharan Africa occur within stable couples, yet engaging couples in testing together is uncommon. Men are less likely to test for HIV than women. Serodiscordant couples are typically overlooked in HIV prevention despite being high-risk. HIV self-testing has been proven highly acceptable, accurate, and preferred over clinic-based testing. We assessed whether engaging couples as a dyad in HIV self-testing would promote testing uptake, disclosure of test results, identification of serodiscordant couples, and engagement in care for positive partners.

METHODS: In Kisarawe, Tanzania we recruited 446 cohabitating couples (aged 18 years or older, with at least one member aged 55 years or less) via door-to-door sampling. Couples received pre-test education and two OraQuick® Rapid HIV-1/2 test kits, then answered a brief survey. Two-weeks later we returned, offered rapid blood-based HIV testing, and conducted an additional survey. Post-test referral and counseling were offered if HIV+. At six months, a random subset of 30 participants completed a brief follow-up survey to assess care engagement for HIV+ participants.

RESULTS: 65% of households had a cohabiting couple, 76% of couples were home when contacted, and 89% of those couples accepted self-test kits. We enrolled 446 couples (N=892). The 2-week follow-up rate was 89% (n=796). Of those, 97% (n=775) had used the self-test kit, 72% (n=558) tested together with their partner, and 97% (n=748) disclosed their self-test result to the partner. Over 90% of participants found the kits easy to use and trustworthy, were satisfied with the experience, and would recommend self-testing to a friend. HIV prevalence was 3.9% (n=31), two-thirds (n=20) of whom were positive partners in serodiscordant relationships. The overall serodiscordancy rate was 5.2% (n=20/388 couples with complete data). Only 25% of negative partners reported knowing their partner's positive status prior to self-testing. Among 22 HIV+ persons completing the 6-month follow-up survey, 82% (n=18) enrolled in HIV care.

CONCLUSIONS: Household-based couples HIV self-testing was highly acceptable, increased male testing, almost universally facilitated couples jointly testing, identified a large number of discordant couples, yielded high disclosure of test results within couples, and resulted in high rates of linkage to care for HIV-infected participants.

OAD0504

HIGH ACCEPTABILITY OF HIV SELF-TESTING IN AN ONLINE RANDOMISED CONTROLLED TRIAL FOR MEN WHO HAVE SEX WITH MEN IN ENGLAND AND WALES

T.C. Witzel[1], L. McCabe[2], M.M. Gabriel[2], P. Weatherburn[1], D. Ward[2], A.J. Rodger[3], Y. Collaco Moraes[2], C. Bonell[1], R. Pebody[4], J. Harbottle[5], M. Gafos[6], A. Speakman[3], F. Lampe[3], A.N. Phillips[3], D.T. Dunn[2], S. McCormack[2], F.M. Burns[3]
[1]London School of Hygiene and Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom, [2]Medical Research Council Clinical Trials Unit, University College London, London, United Kingdom, [3]University College London, Institute for Global Health, United Kingdom, [4]NAM Aidsmap, London, United Kingdom, [5]SH24, London, United Kingdom, [6]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom

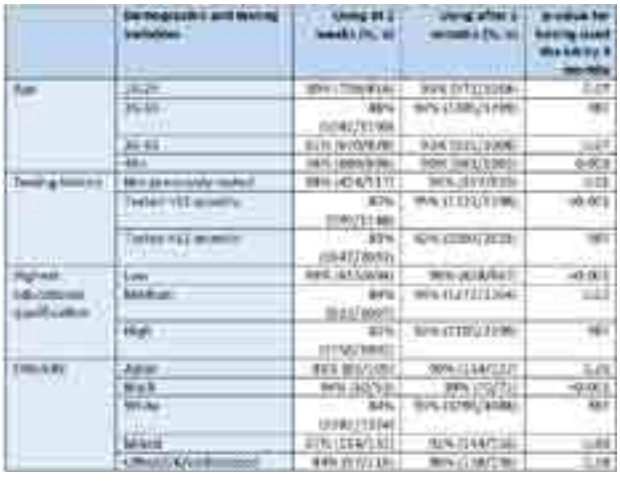
BACKGROUND: SELPHI is an online randomised controlled trial evaluating whether free HIV self-testing (HIVST) increases the rate of HIV diagnoses compared to standard of care. SELPHI recruited 10,111 cis and trans men who have sex with men (MSM), =>16 years old, without diagnosed HIV, reporting lifetime anal sex, and resident in England or Wales. We describe baseline characteristics and intervention acceptability.

METHODS: Individuals, recruited through geo-location hook-up apps and social media, registered with SELPHI then completed an online enrolment survey before randomisation. Initial randomisation was to Baseline Test (BT) arm to receive one free HIVST kit (BioSURETM) or no HIVST kit (nBT). Post-randomisation follow-up surveys were sent at two-weeks asking about kit use and at three-months asking about kit use and intervention acceptability.

RESULTS: 10,111 men were randomised (6049 BT; 4062 nBT); median age 33 years (IQR 26-44); 89% white; 20% born outside UK; <1% trans men; 47% degree educated; 15% never tested for HIV; 8% ever used PrEP; 4% currently using PrEP.

Of 6049 randomised to BT, 65% (n=3895) completed a two-week survey, by which time 96% (n=3728) had received the kit and 84% (n=3128) had used it. Kit use rose to 93% (n=4262) after 3-months. Men over the age of 46 were least likely to have used their kit, while those with lower educational qualifications and black ethnicity were most likely (table 1).

Acceptability was high: 97% (3584/3682) found the instructions easy to understand, 97% (3538/3630) the test simple to use and 98% (3625/3687) reported an overall good experience.



[Table 1: Use of HIVST by time point by key demographic and testing characteristics]

CONCLUSIONS: HIVST was acceptable and uptake substantial; the vast majority of participants reported using their kit by 3-months. Encouragingly, men with least educational qualifications and those of black ethnicity were most likely to use their kits, ameliorating known health inequalities related to access to testing.

OAD0505

APPROACH TO SCALE AND OPTIMIZE CASE FINDING TO MINIMIZE THE GAP IN UNAIDS FIRST 90 TARGET IN NEPAL

P.K. Thakur[1], M. Cassell[2], U. Shrestha[1], Y.R. Sapkota[1], D.P. Bhandari[1], K. Bam[1], A. Shrestha[1], R.P. Khanal[1], B. Shrestha[1]
[1]FHI 360, Kathmandu, Nepal, [2]FHI 360, Vietnam, Vietnam

BACKGROUND: The HIV epidemic in Nepal is concentrated among members of key populations who face both elevated infection risks and obstacles to accessing lifesaving HIV services. While 56% of all people living with HIV (PLHIV) in Nepal have an HIV diagnosis and are receiving treatment, an estimated 8,000–9,000 do not know their status. The USAID- and PEPFAR-supported LINKAGES project in Nepal introduced index testing to both improve PLHIV support and focus testing services among individuals more likely to have had exposure to HIV.
DESCRIPTION: Over the course of a year, the project expanded capacities to implement index testing in 17 districts in Nepal. In the process of providing treatment support in community and clinical settings, index testing was offered to both newly and previously identified PLHIV. A provider-facing tracking tool was developed to confidentially support and monitor successful referrals of the biological children and sexual and injecting partners of PLHIV to testing, treatment, and prevention services. We analyzed program data through this tool to identify opportunities to improve beneficiary support and program performance.
LESSONS LEARNED: From October 2018 to September 2019, index testing accounted for only 5% of the overall project-supported testing volume (2,835 of 54,518 individuals tested) but accounted for 44% of the number of individuals newly diagnosed with HIV (423 of 972). Of the individuals newly diagnosed through index testing, 87% (366 of 423) were successfully linked to treatment which accounted for 40% of total individuals linked to treatment (366 of 905). Index testing has distinguished itself as an efficient strategy to focus and enhance testing services to close gaps in ensuring 90% of all PLHIV know their status in Nepal.
CONCLUSIONS/NEXT STEPS: The relatively low volume of index testing compared to other testing approaches suggests important opportunities for further expansion. The project will continue this expansion, seeking guidance from both index clients and providers for ongoing improvement. In addition, the high case-detection rate among the contacts of index clients suggests a need to prioritize prevention and HIV pre-exposure prophylaxis (PrEP) support among these networks.

OAD0506

IMPROVING HIV TESTING USING A COMMUNITY-BASED HIV+PARENTING PROGRAM IN RURAL LESOTHO: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

M. Tomlinson[1], M. Marlow[1], S. Skeen[1], S. Mofokeng[1], M. Makhetha[1], S. Gordon[1], L. Sherr[2], L. Cluver[3]
[1]Stellenbosch University, Institute for Life Course Health Research, Department of Global Health, Cape Town, South Africa, [2]University College London, London, United Kingdom, [3]University of Oxford, Oxford, United Kingdom

BACKGROUND: Since 1990, the lives of 48 million children under the age of 5 have been saved because of increased investments in reducing child mortality. However, despite these unprecedented gains, more than 200 million children in low and middle income countries (LMIC) cannot meet their developmental potential. Lesotho has high levels of poverty, HIV and malnutrition, all of which affect child development outcomes.
METHODS: In this cluster-randomised trial, we assessed the effectiveness of a manualised, HIV+parenting intervention – a early-years parenting plus intervention that included psychosocial stimulation, HIV testing and nutrition components. We randomly assigned 34 clusters (villages) to either the intervention or waitlist control arm (17 clusters per arm). Participants within villages were caregiver-child dyads, where the child was 12-60 months of age at the baseline assessment. The intervention consisted of eight weekly group sessions delivered at local village preschools, followed by a ninth top-up session one month later. Thereafter, mobile health events were hosted in both intervention and control clusters, offering HIV testing and other health services to all community members. The primary outcome was child HIV testing rates, as reported by their caregivers.
RESULTS: 1040 children and their caregivers (531 intervention; 509 control) were enrolled into the study. The intervention group showed higher child HIV-testing at three months and one-year post-intervention. The intervention group showed improved child receptive language at three months and one-year post-intervention. The intervention group showed improved child language development at one-year post-intervention. Child attention did not differ significantly between groups.
CONCLUSIONS: Community-based, integrated child health and development interventions, delivered to caregivers by trained community health workers, can improve targeted health behaviour, such as child HIV testing, and child language development one year after the end of intervention.

OAD06 PREP 360: PREP AROUND THE WORLD

OAD0602

PREVALENCE, TRENDS, AND CORRELATES OF HIV PRE-EXPOSURE PROPHYLAXIS (PREP) USE DURING SEXUAL EVENTS BY SEXUAL MINORITY MEN IN CANADA'S THREE LARGEST METROPOLITAN AREAS

N. Lachowsky[1,2,3], Z. Cui[3], N. Bacani[3], J. Sang[3,4], A. Lal[3], M. Messier-Peet[5], H. Apelian[5], A. Parlette[6], S.W. Noor[6], S. Skakoon-Sparling[6], J. Jollimore[2], D. Grace[7], D.M. Moore[3,4], G. Lambert[5], J. Cox[8], T.A. Hart[6,7], and the Engage Study Team
[1]University of Victoria, Public Health & Social Policy, Victoria, Canada, [2]Community Based Research Centre Society, Vancouver, Canada, [3]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [4]University of British Columbia, Vancouver, Canada, [5]Direction Régionale de Santé Publique de Montréal, Montreal, Canada, [6]Ryerson University, Toronto, Canada, [7]University of Toronto, Toronto, Canada, [8]McGill University, Montreal, Canada

BACKGROUND: While most behavioural research uses individuals as the unit of analysis, sexual event-level analyses provide more granularity. We examined prevalence, trends and correlates of sexual event-level PrEP-use among urban Canadian gay, bisexual, and other men who have sex with men (gbMSM).

METHODS: Beginning 02/2017, sexually-active gbMSM (cisgender and transgender) ≥16 years of age were recruited into a prospective cohort study using respondent-driven sampling (RDS) in Vancouver, Montreal, and Toronto. Follow-up data were collected every 6-12 months (depending on site) to 08/2019. At each visit, participants completed computer-assisted self-interview, including questions on up to their five most recent sexual encounters (different partners; past 6 months). Participants reported event-level PrEP-use for themselves and their partners. We used general estimating equations accounting for clustering by repeated visits and multiple events/participant to evaluate temporal trends (6-monthly prevalence) and correlates of PrEP-use. Multivariable models were built using backward selection to minimize QIC. Analyses applied RDS-II weights.

RESULTS: 2449 participants completed 4672 study visits and reported on 15071 sexual events, of which 31.6% included event-level PrEP-use. There was a significant temporal increase in PrEP-use (11.9% during 08/2016-02/2017 to 43.6% during 03/2019-08/2019, OR=1.34, 95%CI:1.24-1.44). Overall, PrEP-use was higher in Toronto (34.9%, AOR=1.72, 95%CI:1.25-2.38) and Vancouver (42.3%, AOR=1.86, 95%CI:1.34-2.57) compared with Montreal (22.9%). PrEP-use varied by participant-partner HIV status: 44.8% (n=684/1526) if serodifferent, 42.6% if serosame (n=3074/7208), and 18.7% (n=1003/5356) if status unknown partner. PrEP-use was positively associated with younger age (<30 versus 45+: AOR=2.05, 95%CI:1.36-3.08), higher income (>$60,000CAD versus <$30,000CAD: AOR=1.52, 95%CI:1.10-2.08), postsecondary education (AOR=1.75, 95%CI:1.08-2.81), one-time versus romantic partner (AOR=2.85, 95%CI:2.19-3.70), poppers-use (AOR=1.62, 95%CI:1.32-1.98), and expecting sex with that partner again (AOR=1.50, 95%CI:1.23-1.82). PrEP-use was negatively associated with Indigenous race/ethnicity (AOR=0.12, 95%CI:0.03-0.41), bisexual identity (AOR=0.34, 95%CI:0.20-0.59), living with HIV (AOR=0.22, 95%CI:0.15-0.34), and condom-use (e.g. condom-protected receptive anal sex: AOR=0.43, 95%CI:0.33-0.58).

CONCLUSIONS: Event-level PrEP-use increased threefold over the 2.5-year study period, approaching half of sexual events in the final time period; publicly-funded PrEP access varied over time, by jurisdiction (e.g. publicly-funded in Vancouver in 01/2018). Given differences by geography and social determinants (i.e. income, education, race/ethnicity, sexual orientation), comparisons across jurisdictions should inform PrEP policy, service delivery, and health promotion.

OAD0603

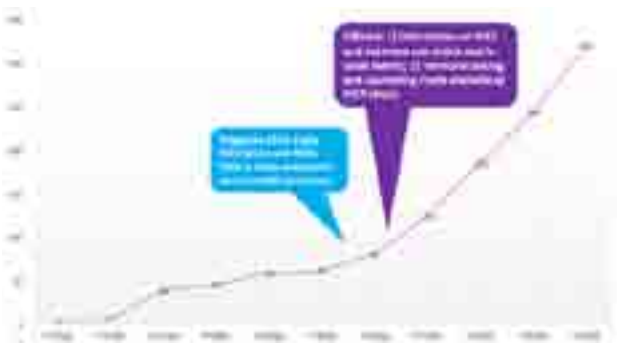
TRANS-FORMING PREP IN VIETNAM: RETHINKING SERVICE DELIVERY TO ENHANCE ACCESS AMONG TRANSGENDER WOMEN

K. Green[1], T. Tan Nguyen[2], M.C. Hoang Vu[3], T. Thi Tran[1], T. Minh Thi Nguyen[4], A.T. Duong[5], T. Minh Ngo[6], B. Ngoc Vu[1], H. Ngo[1], H.A. Doan[1]
[1]PATH, HIV & TB, Hanoi, Vietnam, [2]My Home, Ho Chi Minh City, Vietnam, [3]Vietnam Network of Transgender People, Hanoi, Vietnam, [4]Vietnam Administration of HIV/AIDS Control, HIV & TB, Hanoi, Vietnam, [5]Venus, Hanoi, Vietnam, [6]USAID, Hanoi, Vietnam

BACKGROUND: Although HIV prevalence among transgender women (TGW) who have sex with men in Vietnam is high (18%), awareness and uptake of PrEP is very limited. PrEP services were first made available in March 2017, and while there was a significant increase in PrEP enrollment among men who have sex with men and HIV sero-discordant couples, enrollment among TGW remained consistently low with an average of 3.4 new enrollments monthly over the first year. A rapid assessment identified that TGW were worried that PrEP would reduce the efficacy of feminizing hormones, and/or lead to severe side-effects.

DESCRIPTION: TGW leaders and the USAID/PATH Healthy Markets team co-formulated and advanced three key actions: 1) directly addressing hormone-PrEP drug interaction concerns through online content (primarily through a dedicated Facebook page), engagement with TGW peer experts (online and in-person), and small events that enabled Q&A with TGW peer experts and health workers; 2) training PrEP clinic staff and community providers in transgender competent care (provided by Tangerine Clinic in Bangkok) 3) offering routine hormone level testing and counseling at PrEP clinics.

LESSONS LEARNED: Through these combined efforts, average monthly TGW PrEP enrollment increased to 25.7 new clients per month – a 7.6 fold increase pre-intervention, as of the last quarter of measurement from September to December, 2019. TGW reported feeling more knowledgeable about PrEP and having greater confidence in taking it. However, while new enrollment increased substantially, early PrEP continuation at month three was 74% during the same time period, lower than the average. continuation rate across all populations (84.7%).



[Figure. Cumulative transgender women PrEP users March 2017-September 2019]

CONCLUSIONS/NEXT STEPS: To ensure PrEP is acceptable and accessible to TGW in Vietnam, services that aim to reach them need to offer trans-competent care and make efforts to address underlying concerns about PrEP use. In addition, TGW who wish to remain on PrEP may need additional support than is currently offered.

OAD0604

HIV RISK PERCEPTION AND SALIENCE ARE PARADOXICALLY ASSOCIATED WITH PRE-EXPOSURE PROPHYLAXIS (PREP) DISCONTINUATION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN LESOTHO

T. Chakare[1], A. Rozario[1], N. Nonyana[1], J. Berg[1], M. Strachan[2], R. Heffron[3]
[1]Jhpiego, TSEPO, Maseru, Lesotho, [2]Jhpiego, MER, Baltimore, United States, [3]University of Washington, Epidermiology, Maseru, Lesotho

BACKGROUND: Adolescent girls and young women (AGYW) are disproportionally infected with HIV in Lesotho with an annual incidence of 1.5% compared to 0.13% for their male counterparts. Despite the excellent protection provided by oral pre-exposure prophylaxis (PrEP), 78% of new AGYW PrEP users in Lesotho discontinue PrEP in the first month of use.
METHODS: We conducted a cross-sectional survey of current PrEP clients and recent drop-outs in three districts of Lesotho (Maseru, Berea, Leribe). An interviewer-administered questionnaire assessed demographics, sexual behavior, experiences with PrEP, depression symptoms using the PHQ-9, lifestyle choices, and a composite measure of salience and perceptions of HIV risk. Using univariate logistic regression, we identified factors associated with continued PrEP use and we adjusted statistically significant associations by age (18-21 or 22-24) which was determined a priori to be the most influential confounding factor.
RESULTS: One hundred and ninety-three (193) AGYW participated, of which 40 were new PrEP clients, 65 were continuing use without interruption, 72 had discontinued PrEP and not restarted, and 16 were restarting. Of the discontinuers, only 12.5% felt they were no longer at risk of HIV infection, but none were "doing other things to prevent HIV infection". Among the 72 who had discontinued, reasons reported for stopping varied: negative experience with provider (30.6%); side effects (19.4%); partner disapproval (5.6%); and, concern about being mistaken as HIV-positive (5.5%). Discontinuers showed a higher prevalence of depressive symptoms (37.5% vs 30.8, p=0.4) and recreational drug use (5.6% v 1.5%, p=0.2) than continuers, although not statistically significant. Having a higher HIV perception and salience score was associated with greater likelihood of being a discontinuer (median 9 versus 7, p=0.02) and remained significant after adjusting for age (p=0.04).
CONCLUSIONS: The majority of AGYW (88%) stopped PrEP despite feeling they were still at infection risk due to a mix of service-, product-, and community-level factors. HIV risk perception and salience were significantly higher among discontinuers than current users suggesting an unmet need among the former. Motivators other than risk need to be identified to compel AGYW to stay on PrEP, particularly those who are aware of their risk and attach importance to it.

OAD0605

WHO IS BEING DIAGNOSED WITH SYPHILIS WHILE ON PREP IN BRAZIL?

I. Ornelas Pereira[1], C. Habsckot Dutra de Barros[1], G.F. Mendes Pereira[1], M. Araújo de Freitas[1], A.R. Pati Pascom[1]
[1]Ministry of Health of Brazil, Department of Diseases of Chronic Condition and STI, Brasili, Brazil

BACKGROUND: Preexposure prophylaxis (PrEP) is safe and highly protective against HIV when adherence is ideal. Considering that individuals who can benefit from PrEP are also likely to be at increased STIs risk, we aimed to describe the profile of users diagnosed with syphilis while on PrEP and predictors of diagnosis after the second follow-up visit in the Brazilian daily dosing PrEP program (BPP).
METHODS: We used programmatic data from the Ministry of Health of Brazil, including individuals with two or more visits in BPP, between January 2018 and November 2019. We considered a syphilis diagnosis when it occurred on the second or any other subsequent visit. Multivariable logistic regression model was used to assess the likelihood of syphilis diagnosis while on PrEP considering demographic and behavioral predictors.
RESULTS: Among 8,566 enrolled PrEP users, 786(9%) had a syphilis diagnosis at second visit or later. Median age of diagnosed users was 33 yo (IQR28-39). Users from 40 to 49 years old were 48% more likely to be diagnosed for syphilis (aOR1.477,95%CI:1.100-1.983) as well as users who reported, in the first visit, having had STI symptoms in the past 6 months (aOR:1.486,95%CI:1.248-1.769). Compared to heterosexual cis men, transwomen were more than 6 times more likely to be diagnosed for syphilis (aOR:6,046; 95%CI: 5.599-14.063), and more than 5 times for MSM (aOR:5.627;95%CI: 2.625-12.062).Users who reported, in the first visit, having more than 10 sexual partners were 109% more likely to be diagnosed (aOR2.087,95%CI:1.673-2.603) than those who reported only one partner. No association was found with condom use frequency.

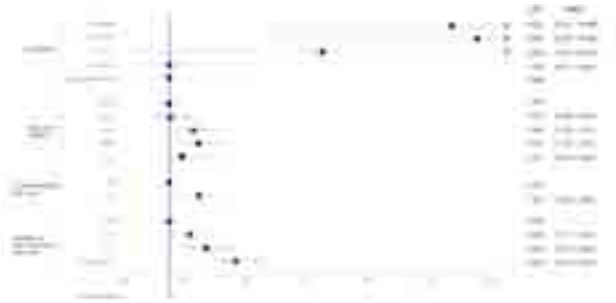


Figure. Multivariate regression model for syphilis diagnosis while on PrEP, Brazil, 2018-2019

CONCLUSIONS: It is crucial to take advantage of PrEP services to improve diagnosis and treatment of other STIs. Therefore, understanding characteristics of users most-likely to be diagnosed with syphilis while on PrEP may help health services to target the most affected populations with a more comprehensive "combination prevention" approach.

OAD0606

JUST4US: A THEORY-BASED PREP UPTAKE INTERVENTION STUDY FOR PREP-ELIGIBLE WOMEN IN TWO HIGHLY AFFECTED U.S. CITIES SHOWS FAVORABLE PREP-USE INTENTIONS BUT MANY BARRIERS ALONG THE PREP CASCADE

A.M. Teitelman[1], H.V. Tieu[2], A. Davis[3], R. Lipsky[1], C. Darlington[1], E. Iwu[4], B. Brawner[1], P. Shaw[3], K. Bond[5], V. Frye[6], B. Koblin[3]
[1]University of Pennsylvania, School of Nursing, Family and Community Health, Philadelphia, United States, [2]New York Blood Center, New York City, United States, [3]University of Pennsylvania, Philadelphia, United States, [4]Rutgers University, New Brunswick, United States, [5]New York Medical College, Health Behavior and Community Health, Hawthorn, United States, [6]City University of New York School of Medicine, New York, United States

BACKGROUND: Merely 2% of women eligible for PrEP take it in the U.S. We conducted an R34 feasibility pilot to assess preliminary efficacy of a theory-based PrEP uptake intervention for women. Formative research guided intervention development.

METHODS: Women ages 18-55 years were recruited from community sites (e.g., drug treatment, shelters), online, and through participant referral. Eligibility criteria were consistent with U.S. guidelines for PrEP initiation. Based on the Integrated Behavioral Model and the Theory of Vulnerable Populations, the Just4Us (J4U) intervention included an in-person, individually-tailored, technology-enhanced, 1-1.5 hour-long information, motivation, skill-building, problem-solving, and referral session with follow-up phone calls to support linkage to community-based PrEP care. The control arm (C) received a packet of handouts on PrEP facts, cost and PrEP providers. From 11/2018-10/2019, 83 women were enrolled and randomized 3:1 (61: J4U; 22: C). Participants completed baseline, immediate post-intervention and 3-month follow-up (3MFU) computer-assisted surveys, which included some open-ended questions. Descriptive analyses were conducted.

RESULTS: At baseline: mean age was 37 years (SD:12); 79% were Black, 26% Latina, 83% had recent economic insecurity; 50% recent drug use. At 3MFU (90% retention, n=75) there was a limited difference in having made an appointment to see a provider for PrEP (J4U: 25/54 [46%]; C: 9/21 [43%]); or PrEP initiation (J4U; 6/54 [11%]; C:2/21 [10%]) between study arms. Among those who had not yet initiated PrEP at 3MFU (n=67), slightly more Just4Us participants (21/48; 44%) planned to start PrEP in next 3 months than control participants (7/19; 37%). Uptake barriers identified included: concern about PrEP side effects; perceived adherence inability; low perceived HIV risk; structural barriers i.e., competing material priorities (e.g. housing, money, time, immediate health issues), provider discomfort with PrEP, and/or insurance issues.

CONCLUSIONS: The biggest step-off along the PrEP care cascade was between making an appointment for starting PrEP with their preferred provider and starting PrEP among both groups. Key personal and structural barriers were identified, notably limited provider PrEP knowledge. Just4Us shows promise as a woman-focused PrEP-uptake intervention. Next steps are intervention refinement based on these results and a study with a larger sample and longer follow-up to assess the efficacy of Just4Us.

OAD07 THE WHOLE PERSON: ADDRESSING ALL ASPECTS OF HEALTH OF PEOPLE LIVING WITH HIV

OAD0702

EFFECTS OF FINANCIAL INCENTIVES FOR CLINIC ATTENDANCE ON HIV VIRAL SUPPRESSION AMONG ADULTS INITIATING ANTIRETROVIRAL THERAPY IN TANZANIA: A THREE-ARM RANDOMIZED CONTROLLED TRIAL

C. Fahey[1], P. Njau[2], E. Katabaro[3], R. Mfaume[2], N. Ulenga[4], N. Mwenda[5], P. Bradshaw[1], W. Dow[1], N. Jewell[1], N. Padian[1], S. McCoy[1]
[1]University of California, Berkeley, United States, [2]Tanzania Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, United Republic of, [3]Health for a Prosperous Nation, Shinyanga, Tanzania, United Republic of, [4]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [5]Rasello, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Several trials demonstrate that financial incentives promote retention in HIV care and may improve antiretroviral therapy (ART) adherence. However, few evaluations have assessed impacts on a related biological outcome, nor compared the effectiveness of different incentive sizes. Moreover, complex delivery mechanisms used in previous studies may prove difficult to implement in practice. We sought to determine the effects of small, automated financial incentives for clinic attendance on viral suppression (VS) among patients starting ART in Tanzania.

METHODS: We conducted a three-arm parallel-group randomized controlled trial. At four clinics in Shinyanga region, we recruited HIV-positive adults (≥18 years) who initiated ART ≤30 days prior. Participants were individually allocated (1:1:1) to usual care (control group) or to additionally receive a monthly cash incentive, conditional on clinic attendance, in one of two amounts: 10000 TZS (≈US $4.50) or 22500 TZS (≈US $10.00). Cash transfers were delivered for up to six months via mobile health technology (mHealth), which monitored attendance and automatically disbursed mobile payments. We evaluated the relationship between incentive size and VS (<1000 copies/ml) at six months using logistic regression.

RESULTS: From April 24 to December 14, 2018, we randomized 530 patients (184 control; 172 smaller incentive; 174 larger incentive). At six months, approximately 73.0% of participants in the control group remained on ART and achieved VS, compared to 82.9% in the smaller incentive group [risk difference (RD)=9.9, 95% CI: 1.2–18.5] and 86.1% in the larger incentive group (RD=13.1, 95% CI: 4.5–21.5); the incentive groups did not significantly differ (RD=3.2, 95% CI: -4.6–11.0). Testing for trend showed a positive relationship between increasing incentive size and VS (OR=1.10 per 2500 TZS, 95% CI: 1.03 to 1.17, p-trend=0.003), although the pairwise comparisons suggest a threshold effect. Improvements were additionally found for all pre-specified secondary outcomes, including retention on ART, VS among those retained on ART, and appointment attendance.

CONCLUSIONS: Small, automated financial incentives improved retention in care and viral suppression among adults starting ART in Tanzania. These findings strengthen the evidence for implementing incentives within standard HIV care.

OAD0703

AN RCT IN ZIMBABWE FOUND AN INTERVENTION INCREASED PARENTAL DISCLOSURE OF HIV AND IMPROVED PARENT, CHILD, AND FAMILY OUTCOMES

M. Lightfoot[1], G. Kumalo-Sakutukwa[1], L. Pollack[1], A. Chingono[2]
[1]University of California, San Francisco, United States, [2]University of Zimbabwe, Harare, Zimbabwe

BACKGROUND: Globally, HIV status disclosure remains a key challenge facing parents living with HIV (PLH), who especially face challenges in disclosing their status to their non-adult children. Disclosure of one's status to family members is an important strategy for improving treatment and care outcomes. Robust studies are needed to test the impact of disclosure-support on family outcomes in sub-Saharan Africa where most families living with HIV reside. Our study examines the efficacy of an intervention to increase PLH's disclosure of their HIV status to their children and examines the impact of disclosure on family outcomes.

METHODS: We conducted a randomized controlled trial with 326 families (one parent and one randomly chosen adolescent child aged 10 – 18 years) recruited from 19 health centers in Mutoko District (Zimbabwe). PLH were assigned to either an: 1) experimental condition, 3-session disclosure intervention (n = 168) or 2) attention control condition, a 3-session nutrition intervention (n = 158). The intervention's impact was assessed over 18 months (recruitment, 3, 6, 12, and 18 months). The culturally tailored experimental and control interventions were conducted only with the parents and were delivered by study nurses.

RESULTS: PLH were predominantly female (79%) and had a mean age of 43.65. Children were 54% male and 48% were 10 – 13 years of age. Almost all PLH completed all 3 sessions of the intervention (89% disclosure, 93% nutrition) and 97% of parents and 94% of children completed the 18-month follow-up. Significantly more parents in the intervention condition (71.4%) reported disclosing to their child at the 3 month assessment compared to those in the control condition (26.8%; $\chi 2=62.51$, df=1, p<.001). Overall, at 18 months, parents and children in the intervention arm had better outcomes over the nutrition only arm, including better psychological functioning, and parental health behavior and coping, and fewer adolescent delinquent behaviors.

CONCLUSIONS: Our intervention provided families with important options for planning, care and support. Our study also provides guidance to organizations, such as ministries of health, on how to improve disclosure. Our findings lay the groundwork for future culturally tailored disclosure interventions.

OAD0704

IS RELUCTANCE TO RESTART ART A RISK OF ATI TRIALS?

G.E. Henderson[1], T. Jupimai[2], N. Ormsby[1], S. Rennie[1], R.J. Cadigan[1], K. Kuczynski[1], S.C. Isaacson[1], N. Phanuphak[3], E. Kroon[3], J. Ananworanich[4], D. Colby[3], C. Sacdalan[3], P. Prueksakaew[3], T. Luekasemsuk[3], H.L. Peay[5]
[1]University of North Carolina, Department of Social Medicine, Chapel Hill, United States, [2]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [3]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [4]University of Amsterdam, Amsterdam, Netherlands, [5]RTI International, Early Education, Disability, and Health Program, Durham, United States

BACKGROUND: Controversies surround analytic treatment interruption (ATI) in HIV remission trials. ATI is presented as a risk during informed consent, but it has also been perceived by volunteers as a benefit. Further, some acutely-diagnosed individuals perceive themselves to be particularly suited for ATI and the potential for long-term remission. Given these findings, is it possible that trials with ATI unintentionally foster reluctance to resume ART?

METHODS: From 2016-2019, we conducted longitudinal interviews with 54 participants in 4 HIV remission trials with ATI, assessing ATI experiences and attitudes about restarting ART. These trials recruited from the Thai SEARCH010 cohort, who are mainly male/MSM and diagnosed with acute HIV infection. For 34 participants in the two most recent trials, employing additional coding and thematic analyses, we explored factors that might predict reluctance to restart ART, including the primary reason for testing (after experiencing acute retroviral syndrome [ARS] or triggered by worry about a risky event), and ongoing side effects and/or psychosocial challenges with ART.

RESULTS: Participants in all 4 trials described ATI as a way to challenge their bodies. At trials' end, all but one participant experienced viral rebound. Response to their own rebound varied, from expecting this outcome, to regret about their "failed body." Most were disappointed but reported adjusting quickly. We found no evidence of more negative attitudes about ART after ATI, nor did participants report having or anticipating additional problems with adherence. In contrast, many participants indicated that rebound confirmed the importance of ART for their health. Among the smaller group in the two most recent trials, we found no support for associations among perceived ARS symptoms at diagnosis, pre-trial difficulties with ART, and attitudes about restarting ART.

CONCLUSIONS: It would be a major concern for trials with ATI if participants did not restart their ART. Despite expectations that pre-trial challenges with ARS and/or ART and experiences with ATI might impact ART resumption, we found no supporting evidence. In contrast, our data suggest that viral rebound during ATI may reinforce the need for ART adherence in acutely-diagnosed individuals. Additional research in other remission trial populations is needed.

PSYCHOSOCIAL CARE BUNDLES TO IMPROVE THE MENTAL HEALTH OF PEOPLE LIVING WITH HIV IN TAIWAN

S.-P. Lin[1], C.-Y. Hsieh[2], L.-F. Chen[2], S.-P. Huang[2], Y.-H. Liu[2], Y.-F. Chen[2], Z.-Y. Shi[1], Q. Ma[3]
[1]Taichung Veterans General Hospital, Internal Medicine, Infectious Disease, Taichung, Taiwan, Province of China, [2]Taichung Veterans General Hospital, Department of Nursing, Taichung, Taiwan, Province of China, [3]University at Buffalo, NYS Center of Excellence in Bioinformatics and Life Sciences Department of Pharmacy Practice, Buffalo, United States

BACKGROUND: Depression and anxiety are among the most common comorbidities among people living with HIV (PLWH). These mental health complications are associated with suboptimal outcomes including high mortality. Evidence has suggested that psychological interventions could improve mental health, quality of life, and HIV care outcomes. This study aimed to evaluate the effectiveness of bundle-designed psychosocial interventions in the reduction of anxiety and depression in PLWH enrolled in the Taiwan VA system.

METHODS: This prospective cohort study tested the effectiveness of a bundle-designed psychosocial intervention package (HIV-STAR) mainly including adherence, psychology, social support and individual case management. Anxiety and depression evaluation was performed using the Hospital Anxiety and Depression Scale (HADS) at the hospital admission and discharge. McNemar test was used to assess changes of HADS before and after HIV-STAR and between HIV-STAR and control. Logistic regression was performed to identify risk factors.

RESULTS: Among the 97 PLWH enrolled after screening, 36% were positive for anxiety and 30% for depression. The overall incidence of anxiety and/or depression was significantly decreased from 46% at admission to 23% at discharge after HIV-STAR with an average intervention duration of 14 days, ($p<0.001$). The mean score of HADS was 11.2 (SD, 7.4) at the admission and 8.1 (SD, 6.2) at the discharge ($p<0.001$). The historical control group without HIV-STAR did not show marked improvement. In multivariate analysis, female sex (OR=23.64; 95% CI, 1.43–392.26), current recreational drug use (OR=3.07; 95% CI, 1.16–8.13), and risk group for HIV infection other than MSM (OR=3.32; 95% CI, 1.02–10.86) were statistically significant associated factors with high HADS (≥ 8.0) at the discharge.

CONCLUSIONS: The high prevalence of mental health complications among PLWH in Taiwan underscores the importance of integrated psychosocial care. While the newly developed HIV-STAR has provided an effective intervention to reduce anxiety and depression in general, more advanced psychosocial care bundles will be warranted to address specific risk factors for intervention-resistant anxiety and depression.

OAD0706

FACTORS INCREASING USE OF SEXUAL AND REPRODUCTIVE HEALTH SERVICES AMONG PEOPLE LIVING WITH HIV (PLH) IN PERU. NEW NEEDS AND CONCERNS FROM PLH AND SEXUAL AND REPRODUCTIVE HEALTH PROVIDERS

C. Sandoval[1], J.-P. Jirón[1], J. Enciso[1], C. Cáceres[1]
[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria de Sexualidad, Sida y Sociedad, Lima, Peru

BACKGROUND: The rise of biomedical prevention has minimized efforts in social/behavioral prevention in HIV/STIs and sexual and reproductive health (SRH), sometimes failing to provide a broad perspective for client-provider interaction. To develop a Brief Sexuality Communication based on the Motivational Interviewing Model (MI) and Information, Motivation and Behavioral skills (IMB) framework, we conducted a formative study to assess the feasibility of implementing MI in public health facilities. We report findings for PLH.

METHODS: 18 In-depth-interviews with providers, 23 Focus-Groups with Key-populations, including 6 FG with PLH. Goal was to identify and understand PLH's SRH needs and perceptions, including provider-client interaction. Interviews were recorded, transcribed and analyzed using the Dedoose qualitative software.

RESULTS: PLH explained that a trust based interaction is crucial to attending SRH services. Otherwise, a discussion on sexuality would be impossible. They claimed providers must be sensitized on PLH issues, as some still blame them for their diagnosis based on prejudices about their sexual orientation, gender identity or sexual behavior. Moreover, in other services than SRH they use old markers ('white code') in their clinical records, leading to a stigmatizing treat. PLH expressed new SRH needs, they are concerned about to have children because sometimes providers tell them to avoid have children due to their diagnosis and their "life-style", women want to know about sexual consent and sexual/physical violence.

Providers lack training and sensitization on sexual-diversity, gender-identity and gender-based-violence. Their practice is still influenced by prejudices on sexuality stigmatizing PLH, so they avoid in-depth discussions about sexuality. However providers seemed willing to implement intervention thinking it would help fulfill PLH clients' expectations. Some realized that if people are treated with respect and care, they will demand SRH services.

CONCLUSIONS: Trust/friendly based interaction is crucial in a client-provider interaction where PLH can establish effective sexual/SRH communication. Sometimes their experiences suggest a degree of discrimination based on a stigmatized PLH condition. New PLH needs on SRH appear related to sexual and gender issues that must be address in public health system. Providers' efforts and dedication are valued, but it depends on each professional's ability to establish empathy and trust.

OAD08 TIKTOK: TIME'S RUNNING OUT FOR ADOLESCENT AND YOUNG PEOPLE'S HEALTH

OAD0802

PREDICTORS OF ATTEMPTED SUICIDE AMONG YOUTH LIVING WITH PERINATAL HIV INFECTION AND PERINATAL HIV EXPOSED UNINFECTED PEERS

P. Kreniske[1], C. Mellins[1], C. Dolezal[1], S. Espinel[1], C.-S. Leu[2], P. Fisher[3], J. Raymond[1], R. Robbins[1], N. Nguyen[1], A. Wiznia[4], E. Abrams[5]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, New York, United States, [2]Mailman School of Public Health, Columbia University, New York, United States, [3]New York State Psychiatric Institute, New York, United States, [4]Albert Einstein College of Medicine, Jacobi Medical Center, Bronx, United States, [5]ICAP at Columbia University, Mailman School of Public Health, New York, United States

BACKGROUND: Suicide is a global crisis and attempted suicide is a leading risk factor for completed suicide. Our recently published analysis from a longitudinal study (CASAH) of youth living with perinatally-acquired HIV infection (YLPHIV) and perinatally HIV-exposed but uninfected peers (YPHEU), showed significantly more YLPHIV attempted suicide vs YPHEU (24% vs 13%). To inform preventive interventions for these populations, we examined psychosocial and sociodemographic predictors of attempted suicide.
METHODS: YLPHIV and YPHEU participants in CASAH were recruited from four medical centers in New York City (n=340; mean age 12.5 years at baseline) and interviewed every 12-18 months with 7 follow-ups (FU) to date (mean age 24.5 years at FU 7). We compared youth who did and did not report a suicide attempt on a structured psychiatric interview at any FU on the following baseline variables; gender, sexuality, race, ethnicity, age, HIV status, city stress inventory score (CSI), negative stressful-life events, spirituality, social problem-solving inventory score, Tennessee self-concept score (TSCS), Child Depression Inventory (CDI), and among only YLPHIV, HIV-stigma – measured by the Social Impact Scale. We used two backward stepwise logistic regression models, one for the overall sample, and one for only YLPHIV, and each model predicted lifetime suicide attempt with baseline demographic and psychosocial variables.
RESULTS: At baseline, 51% of participants were female, 65% Black, and 42% Latinx. In the overall sample those who attempted suicide at any FU were more likely to: be YLPHIV (Adjusted Odds Ratio (AOR) 1.96 95% CI 1.06-3.62), Black (AOR=3.00, 95% CI 1.35-6.69), Latinx (AOR=2.88, 95% CI 1.29-6.40); have lower family self-concept (AOR=0.37, 95% CI 0.21-0.65); better social self-concept (AOR= 1.85, 95% CI 1.17-2.93); and higher depression scores (AOR= 1.06, 95% CI 1.00-1.13). In the second model, among only YLPHIV, attempted suicide was associated with lower personal self-concept (AOR=0.33, 95% CI 0.15-0.71), less spirituality (AOR=0.42, 95% CI 0.20-0.90) and greater HIV stigma (AOR=3.18, 95% CI 1.06-9.52).
CONCLUSIONS: Our analyses indicate mental health services should address YPHEU and YLPHIV self-concept and depression and stigma for YLPHIV. In addition, we see an urgent need for routine integration of suicide risk assessment into treatment for YLPHIV.

OAD0803

YOUNGER INITIATION OF SELLING SEX AND DEPRESSIVE SYMPTOMS AMONG FEMALE SEX WORKERS IN ESWATINI

A. Grosso[1,2], R. Fielding-Miller[3], S. Matse[4], Z. Mnisi[4], B. Sithole[5], S. Baral[6]
[1]Rutgers Institute for Health, Health Care Policy and Aging Research, New Brunswick, United States, [2]Rutgers School of Public Health, Urban-Global Public Health, New Brunswick, United States, [3]University of California, Department of Medicine, San Diego, United States, [4]Ministry of Health, Mbabane, Eswatini, [5]Health Communication Capacity Collaborative, Mbabane, Eswatini, [6]Johns Hopkins Bloomberg School of Public Health, Center for Public Health and Human Rights, Baltimore, United States

BACKGROUND: Youth who sell sex likely have complex mental health needs that may persist into adulthood and potentiate HIV transmission and acquisition risks. Preliminary evidence from female sex workers (FSW) in Malawi suggests negative mental health outcomes are more common among those initiating sex work as minors (MacLean, et al 2018), but additional research is needed on this understudied topic in Africa.
METHODS: FSW aged 18+ recruited through venue-based sampling from October-December 2014 in eSwatini completed a survey including a question about the age at which they started selling sex and the Patient Health Questionnaire (PHQ-9) to measure depressive symptoms. Younger initiators were defined as those who started selling sex prior to age 18. Bivariate and multivariable logistic regression analyses were conducted to assess associations.
RESULTS: 16.62%(128/770) of FSW with complete data on the PHQ-9 and age of initiation started selling sex as minors. Younger initiators had higher mean and median PHQ-9 scores and greater depression severity (Table 1). The prevalence of probable depression (PHQ-9 score ≥10) was 55.47%(71/128) among younger initiators, compared to 40.65%(381/642) among older initiators (p=0.002). Younger initiators were more likely to have probable depression (aOR 1.56;95% CI 1.03-2.37;p=0.037) after controlling for number of years selling sex, days per month selling sex, frequency of past-month condom failure, and anticipated healthcare stigma. Being orphaned before age 18 and carrying condoms less often were significantly associated with younger initiation but not probable depression. FSW who started selling sex to feed themselves or their families and those who did not know their HIV status were more likely to have probable depression, but these factors were not correlated with younger initiation.

	PHQ-9 score		Severity % (n)				
	Median	Mean	Minimal [0-4]	Mild [5-9]	Moderate [15-19]	Moderately severe [15-19]	Severe [20-27]
Started selling sex <18 (n=128)	11	10.45	20.31 (26)	24.22 (31)	30.47 (39)	14.84 (19)	10.16 (13)
Started selling sex 18+ (n=642)	8	8.93	28.82 (185)	30.52 (196)	20.72 (133)	10.59 (68)	9.35 (60)
Total (n=770)	9	9.18	27.40 (211)	29.48 (227)	22.34 (172)	11.30 (87)	9.49 (73)

[Table 1. Depression severity by younger or older age of initiation of selling sex among female sex workers in eSwatini, 2014]

Dependent variables ↓	Independent variables→	Selling sex <18	Probable depression	Current age	Orphaned <18	Number of years selling sex	Days per month selling sex	Number of times condom slipped off or broke in the last month	Frequency of carrying condoms when selling sex	Ever afraid of or avoided seeking healthcare due to fear of someone learning they sell sex	Does not know her HIV status
Selling sex <18	Odds ratio (95% Confidence Interval)	-	1.82 (1.24, 2.67)*	0.87 (0.83, 0.91)*	3.38 (1.89, 6.01)*	1.09 (1.05, 1.13)*	1.03 (1.00, 1.05)*	1.13 (1.01, 1.25)*	0.76 (0.62, 0.93)*	1.66 (1.11, 2.50)*	1.34 (0.81, 2.19)
	Adjusted odds ratio (95% Confidence Interval)	-	1.54 (1.02, 2.34)*	-	-	1.09 (1.05, 1.13)*	1.02 (0.99, 1.05)	1.05 (0.94, 1.18)	-	1.41 (0.90, 2.20)	-
Probable depression	Odds ratio (95% Confidence Interval)	1.82 (1.24, 2.67)*	-	1.00 (0.98, 1.03)	0.89 (0.51, 1.55)	1.03 (1.00, 1.06)*	1.02 (1.00, 1.04)*	1.28 (1.15, 1.42)*	0.89 (0.75, 1.07)	3.26 (2.32, 4.58)*	2.51 (1.68, 3.77)*
	Adjusted odds ratio (95% Confidence Interval)	1.56 (1.03, 2.37)*	-	-	-	1.01 (0.98, 1.04)	1.00 (0.98, 1.02)	1.21 (1.09, 1.35)*	-	3.12 (2.18, 4.45)*	-

[OAD0803 Table 2]

CONCLUSIONS: Depression among FSW in eSwatini was highly prevalent and linked to experiences of selling sex before age 18. Scaling up mental health interventions in the African context is needed for this key population.

OAD0804

DESIGNING FOR HOPE: ADDRESSING ADHERENCE BY LOOKING BEYOND THE PILL. A CO-CREATION APPROACH TO ADDRESSING MULTIDIMENSIONAL FACTORS THAT IMPACT ART ADHERENCE AND RETENTION AMONG ADOLESCENTS LIVING WITH HIV IN MOZAMBIQUE

S. Carey[1], B. Kolada[1], B. Olmedo[1], C. Shadwick[1], H. Singhal[1], J. Falcao[2], E.J. Abrams[2,3], L. Weinstein[1]
[1]IDEO.org, New York, United States, [2]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [3]Vagelos College of Physicians & Surgeons, Columbia University, New York, United States

BACKGROUND: Retention rates, adherence to antiretroviral treatment (ART), and viral suppression are alarmingly low among adolescents living with HIV (ALHIV), who are often poorly equipped to manage their disease during a time of rapid physical and psychological development. The CombinADO study aims to develop and test an adolescent-focused intervention to improve 90-90-90 targets among ALHIV in Mozambique. Formative work led by IDEO.org employed human-centered design (HCD) — a novel methodology that involves co-creating solutions with adolescents and testing them through rapid prototyping.

METHODS: In late 2019, IDEO.org led a 4-month co-creation and rapid prototyping process in and around 2 health facilities (HF) in Nampula, Mozambique. The HCD approach began with design research and co-creation activities — including individual interviews and focus groups using interactive methods like card sorting and storytelling. Findings were synthesized to inform the development of potential interventions. During the prototyping phase, the team sought to learn about effective strategies for engaging ALHIV and HF staff, collect further feedback from ALHIV to iterate the interventions, and test variations and combinations of the interventions.

RESULTS: The team interviewed 52 participants during the initial phase, which yielded 13 key insights used to inform potential interventions. Ninety-six participants tested 12 potential interventions during the rapid prototyping phase. The most critical finding was that social support alone is not sufficient to drive adherence among ALHIV. The journey of adherence relies on a more intrinsic foundation: hope for a future worth living for. In order to shift pill-taking behavior among adolescents, results suggested that ALHIV require support with three key inputs: contextually appropriate and culturally connected medical literacy; an increased sense of belonging through peer connection; and ongoing demystification and destigmatization messaging within the wider community.

CONCLUSIONS: HCD research allows for deep insight into the motivations, experiences, and needs of young people that impact adherence and retention among ALHIV. Co-creation builds trust among ALHIV and engages them in shaping the solutions that will be available to them—building ownership and confidence. Prototyping allows for multiple iterations before implementation—maximizing learning and improvements prior to a pilot investment.

OAD0805

FACTORS ASSOCIATED WITH POOR ADHERENCE AMONG NON-VIROLOGICAL SUPPRESSING SCHOOL GOING ADOLESCENTS: LESSONS FROM THE AIDS SUPPORT ORGANIZATION (TASO) IN MASAKA, UGANDA

G. Jjuuko[1]
[1]The AIDS Support Organization (TASO), Community Systems, Kampala, Uganda

BACKGROUND: According to the 90-90-90 UNAIDS ambitious target by 2020, viral load suppression is key among patients on antiretroviral therapy (ART). Whereas there is a growing number of people on ART, limited information is known about virological non-suppression and its major determinants among HIV-positive school going adolescents enrolled in many resource-limited settings. We investigated the factors leading to poor adherence among adolescents with non-suppressed viral load attending the Adolescent HIV/AIDS care clinic at The Aids Support Organization (TASO) in Masaka.

DESCRIPTION: Between January and December 2017, we identified adolescents with non-suppressed viral load attending the HIV clinic specifically those in upper primary and secondary school. Blood samples were taken to the central government laboratory for analysis and non – virological suppression was considered as

having ≥1000 copies/ml of blood. A six-month viral load testing interval followed by three months repeat for the non -suppressors was the selection criteria. Through one on one and group counseling by trained counselors, we identified adolescent with poor adherence (below 95%) to explore the causes.
Adolescents were grouped in age ranges of 10-13, 14 -17, and 18- 19 years respectively, and to each group a trained counselor, clinician and adolescent peer educator was attached to facilitate intensive adherence counseling. Information on social demographic characteristics and causes of poor adherence was collected using an interview guided questionnaire, data were analyzed using Stata 14.
LESSONS LEARNED: Out of 355 adolescents on ART, 325 (91.8%) had their viral loads taken; 127 (39%) had non- suppressed viral load, of which 47(37%) were boys and 80(63%) were girls. 17 (13.4%) of the non-suppressors had adherence above 95%, 110 (86.6%) had adherence below 95%. Reasons for non-adherence were; 54(42.5%) joined a candidate class for National promotional exams, 20(15.7%) changed care takers, 17(13.4%) joined a new school, 15(11.8%) joined boarding school, 13 (10.2%) took a self-drug holiday, 8 (6.3%) missed morning doses, and 119 (94%) of all had not disclosed to any one at school.
CONCLUSIONS/NEXT STEPS: Non-disclosure among School going adolescents is the leading cause of poor adherence hence there is need for interventions that promote disclosure.

ADOLESCENT HIV RESEARCH PARTICIPATION IN LOW- AND MIDDLE-INCOME COUNTRIES: ETHICAL CHALLENGES AND SOLUTIONS FROM SEVEN COUNTRIES AND A SCOPING REVIEW

S. Day[1], B.G. Kapogiannis[2], T.D. Ruel[3], S.K. Shah[4,5], E.C. Wilson[6,7], D.F. Conserve[8], J.D. Tucker[1,9,10]
[1]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Maternal and Pediatric Infectious Diseases Branch, Bethesda, United States, [3]University of California, Division of Pediatric Infectious Diseases and Global Health, Department of Pediatrics, San Francisco, United States, [4]Northwestern University Feinberg School of Medicine, Department of Pediatrics, Chicago, United States, [5]Ann & Robert H. Lurie Children's Hospital of Chicago, Mary Ann & J. Milburn Smith Child Health Research, Outreach, and Advocacy Center, Stanley Manne Children's Research Institute, Chicago, United States, [6]University of California, Department of Epidemiology and Statistics, San Francisco, United States, [7]San Francisco Department of Public Health, Trans Research Unit for Equity (TRUE), San Francisco, United States, [8]University of South Carolina, Department of Health Promotion, Education, and Behavior, Columbia, United States, [9]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States, [10]London School of Hygiene and Tropical Medicine, Faculty of Infectious Diseases, London, United Kingdom

BACKGROUND: Countries have varying ethical and legal guidance for adolescent participation in HIV research. Parental permission requirements effectively exclude some groups of adolescents from research. Excluding youth with or at risk of acquiring HIV can have the unintended consequences of limiting access to innovative prevention and care, and impairing progress in addressing the epidemic in low- and middle-income countries (LMICs). We examined ethical and practical challenges in adolescent research participation across seven LMICs and potential solutions for including adolescents in HIV-related research in LMICs.
METHODS: We report lessons from the field for seven countries with adolescent HIV studies in the PATC3H consortium. Supported by the U.S. NIH Eunice Kennedy Shriver National Institute of Child Health and Development, the consortium comprises HIV prevention and treatment studies among adolescents in Brazil, Kenya, Mozambique, Nigeria, South Africa, Uganda, and Zambia. We describe the ethical-legal frameworks for adolescent research participation in these countries and their associated ethical and practical challenges. PATC3H researchers reviewed seven scenarios to clarify these ethical-legal considerations.
Finally, we conducted a scoping review to supplement PATC3H experiences on strategies to enhance adolescent participation in LMIC HIV studies.
RESULTS: Consortium researchers identified many ongoing challenges, including limited guidance for determining whether adolescents can consent to research without parental permission, regulations that fail to account for the complexity of adolescent lived experiences (e.g., key population identities, related stigmas), and exclusion of many adolescents under 18 years old. We identified several strategies to enhance adolescent participation in LMICs' HIV studies, including adolescent independent consent, selective waiving of parental consent, and surrogate decision-making. Independent consent and waiving of parental consent under select study conditions can enhance participation among at-risk adolescents, including sexual and/or gender minorities.
Additionally, surrogate decision-makers (i.e. individuals providing consent in place of a parent or guardian) can be beneficial when parental/guardian involvement may be inappropriate or unavailable. Each of these solutions has been implemented in resource-constrained settings and helped to broaden adolescent participation.
CONCLUSIONS: Despite multiple barriers and uncertainties, we identified several practical strategies to enhance ethical participation of adolescents in LMIC HIV studies. This analysis supports the feasibility of expanding adolescent HIV research in LMICs.

OAD09 YOUNG @ HEART: AGEING AND HIV

OAD0902

CHALLENGES FACED BY A POPULATION AGING WITH HIV: BASELINE DATA FROM THE CORE HEALTHY AGING INITIATIVE (CHAI)

O. Adeyemi[1], A. Cameron[1], S. Porter[1], J. Barnes[1], J. Catrambone[1], CHAI 2.0 study group
[1]Cook County Health, Chicago, United States

BACKGROUND: As people with HIV (PWH) age, there are increasing medical and psychosocial comorbidities that impact quality of life (QOL). The CORE healthy aging initiative 2.0 (CHAI 2.0) was designed to better understand and address the medical and psychosocial needs including social isolation among PWH >60years receiving care at the CORE center, Chicago.
METHODS: Between 2/1/19 and 12/17/19, a needs assessment survey was distributed to PWH >60 years identified during clinic visits by CHAI peer navigators (ages 62 and 65). We present the cross-sectional analysis on 331 PWH who completed CHAI 2.0 baseline survey.

RESULTS:

Significant differences by Gender in CHAI 2.0			
	Male (n=287)	Female (N=119)	p-value
Talk to family about health problems?	41%	53%	p=0.025
Do you have any of the following concerns? Retirement planning	20%	11%	p=0.036
Do you have any of the following concerns? Sexual Health	7%	22%	p<0.000
Are you sexually active?	49%	25%	p<0.000

415 PWH>60 years with a median age of 64years (60—82) were surveyed. Seventy percent (n=287) were male, 30% female. Eighty-three percent (n=339) were African American, 9% white and 6% Hispanic/Latino. Seventy-nine percent (n=318) had been diagnosed with HIV>10years; 52%>20yrs. Eighty-two percent reported undetectable viral loads. 24% reporting taking >6 medications daily. current smoking was 37%, hypertension 50%, depression 30%, hyperlipidemia 25%, diabetes 20%, and kidney disease 14%. Thirty percent had >1 fall in the last 12 months. Fifty-five percent lived alone, 41% reported feeling lonely sometimes in the last month. Self-rated good/excellent in 57% and 37% had concerns about getting older with HIV. The top five concerns were money concerns (41%), living with HIV (37%), other medical concerns (30%), housing (29%) and who will care for me in old age (24%). Other concerns: memory issues (23%), stigma (21%), retirement planning (18%), loneliness (14%), finding a partner (14%), sexual health (14%) and mental health concerns (13%). 22% reported had not disclosed their HIV status to anyone outside of clinic staff.

CONCLUSIONS: Among older, predominantly African American PWH, 55% lived alone. The interplay of polypharmacy, social isolation, and comorbidities increase the risk of falls and other adverse outcomes. Programs addressing these issues remain important to optimizing QOL in PWH.

OAD0903

CLINICAL AND SOCIODEMOGRAPHIC CHARACTERISTICS ASSOCIATED WITH POOR SELF-RATED HEALTH ACROSS MULTIPLE DOMAINS AMONG OLDER ADULTS LIVING WITH HIV

D. Short[1], F. Spinelli[2], C. Okoli[3], P. De Los Rios[4]
[1]ViiV Healthcare, Innovation and Implementation Science, London, United Kingdom, [2]ViiV Healthcare, Medical Affairs North America, Research Triangle Park, United States, [3]ViiV Healthcare, Global Medical Team, London, United Kingdom, [4]ViiV Healthcare, Global Medical Sciences, Research Triangle Park, United States

BACKGROUND: Efforts to improve the wellbeing of older adults have sometimes focused on a single aspect of health; holistic approaches must however consider all aspects. We characterized older persons living with HIV (PLHIV) who consistently reported sub-optimal health on multiple domains.

METHODS: The 24-country 2019 Positive Perspectives survey included 648 PLHIV aged ≥50 years. Self-rated health was assessed across four health domains (physical/mental/sexual/overall), each of which was dichotomized as optimal ("Good"/"Very good") or sub-optimal ("Neither good nor poor"/"Poor"/"Very poor"). We tallied the number of domains suboptimal health was reported (overall domain also included to account for unmeasured sub-domains e.g., intellectual/emotional). Multinomial logistic regression among all older adults (n=648) measured for associations between health domains and various sociodemographic/clinical characteristics including past ART drug-drug interactions (DDIs), resistance, side effects, adherence, and polypharmacy (≥5 pills/day or taking medicines for ≥5 conditions), adjusting for gender and disease duration (p<0.05).

RESULTS: Median disease duration was 19 years. Overall, 82.7% reported ≥1 comorbidity, 54.6% polypharmacy, 10.8% past DDI, 16.7% past resistance, and 7.7% were very treatment-experienced (changed ART ≥4 times, including ≥once in past year because of resistance/poor tolerability). Common co-morbidities were hypertension (32.4%), hypercholesterolemia (30.4%), mental illness (26.5%), and insomnia (24.4%). Overall, 45.4% (294/648) reported suboptimal physical health, 39.4% (255/648) suboptimal mental health, 61.7% (400/648) suboptimal sexual health, and 47.2% (306/648) suboptimal overall health; Within mutually exclusive groups, 24.1% (156/648) reported suboptimal health on all domains. 24.4% (158/648) reported optimal health on all domains, 22.7% (147/648) on three domains only, 11.9% (77/648) on two domains only, and 17.0% (110/648) on one domain only. The strongest predictors of reporting sub-optimal health on all domains included having ≥2 co-morbidities (AOR=10.24, 95%CI=4.85-21.63), being dissatisfied with treatment (AOR=9.83, 95%CI=5.12-18.86), missing ART for ≥5 days/past month (AOR=7.52, 95%CI=3.52-16.07), and experiencing gastrointestinal ART side effects (AOR=6.72, 95%CI=3.48-12.99).

CONCLUSIONS: One-quarter of older adults reported suboptimal health on all domains; groups at greatest risk included those reporting poor adherence, polypharmacy, gastrointestinal side effects, and treatment dissatisfaction. Treatment optimization as part of holistic care may improve overall wellbeing.

KILLING TWO BIRDS WITH ONE STONE – RESPONDING TO HEALTH CHALLENGES OF THE ELDERLY LIVING WITH HIV AT AIDS INFORMATION CENTRE

I. Nume[1], H. Kizito[2]
[1]AIDS Information Centre, Prevention, Kampala, Uganda, [2]AIDS Information Centre, Programing, Kampala, Uganda

BACKGROUND: Global HIV/AIDS statistics (UNAIDS 2018) estimated 37.9 million people were living with HIV with an estimated 3.6 million aged 50 years or older (UNAIDS 2013). The majority of these (2.9 million) are in low-and middle-income countries where the percentage of adults 50 years or older living with HIV is above 10%. In high-income countries almost one-third of adults living with HIV are 50 years or older.

Elderly patients attending ART clinics have faced a number of challenges related to their HIV status although there have been limited interventions to address them. In sub-Saharan Africa this group has particularly been neglected despite the distinctive healthcare and socio-economic needs.

DESCRIPTION: The elderly clinic was started (July 2019) in response to challenges identified during a support group meeting for the elderly living with HIV specifically to address HIV related issues and promote screening and management of non-communicable diseases (NCDs). This clinic was composed of clients aged 50 years and above. Only elderly clients had visits scheduled on Fridays in order to reduce waiting time and allow adequate time for psychosocial support and comprehensive clinical reviews. Staff were sensitized to periodically update the list of elderly clients and the screening and psychosocial support these clients required.

LESSONS LEARNED:

- From July to December 2019 the number of elderly clients in the clinic increased from 118 (69 males, 49 females) to 130 (75 males, 55 females).
- Through basic screening we were able to newly identify clients with diabetes (7), hypertension (10), prostate disorders (3), mental illnesses namely depression (20), anxiety disorders (1) and mild dementia (15). Other ailments previously undocumented included arthritis and erectile dysfunction.
- Most clients could not afford some of the screening tests and where medically advised were referred to public facilities. However the majority didn't go because of socioeconomic reasons.
- Health workers lack knowledge about geriatric care and NCDs therefore not all clients are comprehensively screened.

CONCLUSIONS/NEXT STEPS: The elderly living with HIV require:

- Health workers trained to adequately respond to their health challenges.
- Provision of subsidized/ no cost comprehensive screening and standard health care packages

OAD0905

ASSESSING THE FACTOR STRUCTURE AND PSYCHOMETRIC PROPERTIES OF THE HIV/AIDS RESILIENCE ASSESSMENT TOOL IN A SAMPLE OF NYC-BASED HIV-POSITIVE GAY MEN AGED 50-69: THE GOLD STUDIES

K. Krause[1,2], P. Halkitis[3,2]
[1]Rutgers University School of Public Health, Social and Behavioral Sciences, Newark, United States, [2]Center for Health, Identity, Behavior and Prevention Studies, Newark, United States, [3]Rutgers University School of Public Health, Departments of Biostatistics and Urban-Global Health, Piscataway, United States

BACKGROUND: By 2025, people over 50 will constitute the majority of those living with HIV/AIDS (PLWHA) in the United States and similar projections are expected globally within the next decade. This aging population of PLWHA face different physical, mental, and psychosocial health challenges related to living with HIV/AIDS, the general aging process, and the long-term impact of being on antiretroviral treatment. Emergent literature suggests that resilience may act as a buffer to the negative impact of these myriad challenges. However, measuring resilience among PLWHA has been inconsistent. Given the variance of understanding and conceptualizing resilience in PLWHA, theoretically designed and validated instruments are needed specifically within the lens this population. To address this gap in the literature, we developed and examined the initial factor structure and psychometric properties of the 10-item HIV Resilience Assessment Tool (H-RAT).

METHODS: Data for the present cross-sectional study are drawn from n=250 gay HIV-positive men aged 50-69 living in New York City. Participants were sociodemographically diverse with regard to race/ethnicity, SES, age, and education. Exploratory (EFA) and Confirmatory Factor Analyses (CFA) along with tests of reliability and validity were conducted in this sample.

RESULTS: Results from the EFA indicated that a three-factor model was the most parsimonious solution based on eigenvalues and model fit. The items were examined for their underlying relationships and the three factors were labeled: adaptive coping, optimism, and effective coping. Taken together, the 10 items produced a Cronbach's alpha of 0.84 with the three sub-scales producing a Cronbach's alpha of at least 0.72. Convergent and discriminant validity were established using other psychosocial (e.g. grit, loneliness, etc.) and physical (e.g. BMI and blood pressure) outcomes.

CONCLUSIONS: The H-RAT is a psychometrically sound instrument to assess resilience among PLWHA. With three sub-scales compromising the H-RAT (adaptive coping, optimism, and effective coping) the multidimensional tool can be used in future research and clinical settings. Looking forward, we recommend continued testing in different populations of PLWHA to ascertain its stability within different groups, geographic locations, and over time. The H-RAT will help clinicians, researchers, and practitioners move towards a more holistic strengths-based approach to working with PLWHA.

OAD0906

"IS IT HIV OR JUST OLD AGE?" UNCERTAINTIES OF 'SUCCESSFUL' AGEING WITH HIV

C. Howard[1], L. Fitzgerald[2], A. Mutch[2]
[1]Queensland Positive People, Brisbane, Australia, [2]University of Queensland, Brisbane, Australia

BACKGROUND: Globally, the population of people living with HIV is ageing. In Australia, around half of all people living with HIV (PLHIV) are now over 50. Understanding 'successful ageing' for PLHIV is a critical question for researchers, HIV communities and policy makers.

METHODS: Living Positive in Queensland (LPQ), is a participatory qualitative longitudinal study examining ageing in people living long term with HIV. LPQ, one of the largest research projects of its kind to be undertaken internationally, interviewed 73 participants annually over three years. Inductive thematic analysis was used to draw themes from over 200 interviews. This presentation discusses participants' perceptions and experiences of ageing.

RESULTS: Participants described uncertainty about ageing, expressing ambivalence in the face of debates surrounding adverse HIV ageing discourses and unknown futures. Alongside uncertainties about health and increasing comorbidities, participants described uncertainty about social determinants of 'successful ageing'. Older participants, particularly those from the Pre-HAART era, experienced cumulative disadvantage related to disrupted employment trajectories, limited resources, long-term welfare access and limited social support arising from service cuts and the corresponding fracturing of communities. These issues generated worries about living and ageing in disadvantage.

Care for older people was often considered synonymous with residential aged-care. Having experienced stigma and discrimination in healthcare settings, many were concerned about discrimination in aged-care settings and worried the aged-care sector would not respond to the needs of PLHIV. Some participants described 'back up plans' of treatment non-adherence when confronted with accessing aged-care.

CONCLUSIONS: Ageing with HIV is biosocial, lived within diverse intersections of embodied experiences of HIV, generational, social, and locational contexts. 'Successful ageing' as it is currently portrayed in the broader ageing literature must move beyond individual actions and acknowledge the role of social determinants of health. HIV and ageing literacy; quality and culturally competent aged-care services; and coordination and partnership between the aged-care sector and HIV communities are urgently needed.

The presentation will consider how policy and program responses must integrate these elements in the development of services to move beyond the biomedical to address the social aspects of health and support 'Healthy ageing' for PLHIV.

OAE01 ACROSS THE CASCADE: RESEARCH METHODS IN IMPLEMENTATION SCIENCE

OAE0102

THE EFFECTIVENESS OF IMPLEMENTING UNIVERSAL HIV TREATMENT: A REGRESSION DISCONTINUITY ANALYSIS FROM ZAMBIA

A. Mody[1], I. Sikazwe[2], I. Eshun-Wilson[1], A. Mwila[3], L. Mulenga[4], M. Herce[2,5], K. Mweebo[3], P. Somwe[2], M. Wa Mwanza[2], T. Savory[2], K. Sikombe[2], L. Beres[6], J. Pry[2,1], C. Holmes[7], C. Bolton-Moore[2,8], E. Geng[1]
[1]Washington University in St. Louis, Division of Infectious Diseases, St. Louis, United States, [2]Centre for Infectious Diseases Research in Zambia, Lusaka, Zambia, [3]U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [4]Zambia Ministry of Health, Lusaka, Zambia, [5]University of North Carolina, Division of Infectious Diseases, Chapel Hill, United States, [6]Johns Hopkins University School of Public Health, Baltimore, United States, [7]Georgetown University, Center for Global Health and Quality, Washington, D.C., United States, [8]University of Alabama, Division of Infectious Diseases, Birmingham, United States

BACKGROUND: Universal treatment for all persons living with HIV (PLWH) has only been assessed under experimental conditions in cluster-randomized trials, but the public health effectiveness of actually implementing treat-all policies on the HIV care cascade under real-world conditions is not known.

METHODS: We used a regression discontinuity design (RDD) to assess the real-world effectiveness of Zambia's January 1,2017 adoption of universal HIV treatment. Using data from Zambia's routine electronic medical record, we analyzed ART-naïve adults newly enrolling in HIV care between January 1, 2016 to December 31, 2018 at 58 clinics supported by CDC/PEPFAR and the Centre for Infectious Disease Research in Zambia. We excluded patients enrolling 30 days prior to, and 90 days after, implementation to minimize bias from cross-over and clinic-to-clinic variations in guideline uptake. Under the assumption that those presenting immediately before and after this period are balanced on both measured and unmeasured characteristics, we estimated the effects of implementing treat-all on both ART initiation and retention in care on ART at 12 months (defined as any clinic attendance 9 to 15 months after enrollment and 6 months on ART). We also performed an instrumental variable (IV) analysis to obtain unbiased estimates of the effect of same-day ART initiation on 12-month retention.

RESULTS: Among 77,361 newly enrolling HIV patients (62.1% female, median age 32 years [IQR 26–39], median CD4 286 cells/μL [IQR 147–465]), implementing universal treatment increased same-day ART initiation from 42.2% to 78.9% (risk difference [RD] +36.7%, 95% CI 35.2-38.3%), ART initiation by 1 month from 69.6% to 89.1% (RD +19.6%, 95% CI 18.3-20.8%), and 12-month retention in care on ART from 53.4% to 62.7% (RD +9.1%, 95% CI 7.4-10.8%). An IV analysis demonstrated that same-day ART initiation due to universal treatment led to a 13.4% (95% CI 11.7-15.1%) increase in 12-month retention on ART.

CONCLUSIONS: Implementing universal HIV treatment in Zambia substantially increased same-day and overall ART initiation among newly enrolling patients. Retention in care also improved, but overall levels remained suboptimal and were lower than in randomized trials. Strategies that leverage the short-term impacts of universal treatment to cultivate long-term treatment success are needed.

OAE0103

UNDERSTANDING PREFERENCES FOR HIV CARE AMONG PATIENTS EXPERIENCING HOMELESSNESS OR UNSTABLE HOUSING: RESULTS OF A DISCRETE CHOICE EXPERIMENT

M. Conte[1,2,3], I. Eshun-Wilson[4], E. Geng[4], E. Imbert[1], M. Hickey[1], D. Havlier[1], M. Gandhi[1], A. Clemenzi-Allen[1,5]
[1]Division of HIV, ID and Global Medicine, University of California, San Francisco, United States, [2]Institute for Global Health Sciences, University of California, San Francisco, United States, [3]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, United States, [4]Division of Infectious Diseases, Washington University, St Louis, United States, [5]San Francisco Department of Public Health, San Francisco, United States

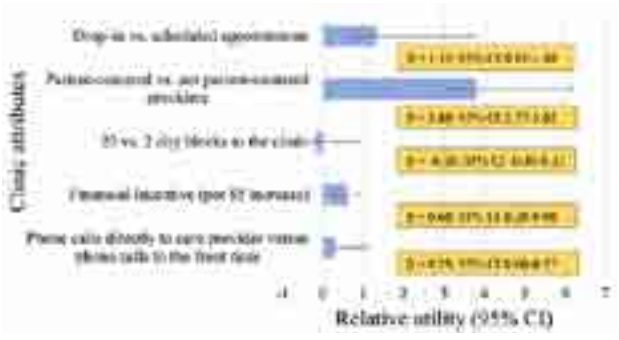
BACKGROUND: Homelessness and unstable housing (HUH) negatively impact primary care visit attendance, viral suppression and overall survival rates among people living with HIV (PLWH). To incorporate patient preferences into solutions for more effective care for HUH-PLWH, we quantified patient preferences and financial trade-offs across multiple possible HIV-service domains for this program using a discrete choice experiment (DCE).

METHODS: The San Francisco General Hospital's "Ward 86" HIV clinic has a 37% prevalence of HUH. We sequentially sampled Ward 86 patients reporting HUH who had missed primary care visit in the last year and recent viremia to conduct a DCE.

Subjects chose between two hypothetical clinics which varied by five service attributes: patient-centered care team ("get to know me as a person" versus not), gift cards ($10, $15 or $20/visit), drop-in versus scheduled visits, distance to clinic (2 versus 20 blocks), and direct phone communication to care team versus front-desk staff.

We estimated relative utility (i.e., preference) for attribute levels using mixed-effects logistic regression and calculated the monetary trade-off of preferred options.

RESULTS: Of 65 individuals enrolled, 61% were >40 years-old; 45% white; 77% male; 46% heterosexual; 56% lived outdoors or in emergency housing and 44% in temporary housing, Strongest preferences were for having patient-centered providers (β = 3.80; 95% CI 2.57-5.02) and drop-in clinic appointments (β = 1.33; 95%CI 0.85-1.80), with a willingness to trade $32.79 (95% CI 14.75 - 50.81) and $11.45 (95% CI 2.95 - 19.95) in gift cards/visit, respectively, for each component (Figure).



[Figure. Patient preference for clinic attributes]

CONCLUSIONS: HUH-PLWH, who live on the economic margins and who often lack basic subsistence, were nevertheless willing to trade significant financial gain in a DCE to have a personal relationship with and immediate access to the primary care team. These findings can inform "Ending the HIV Epidemic" by guiding innovative programming to improve retention in HIV care.

OAE0104

DRUG SHOPS ARE AN EFFECTIVE STRATEGY TO REACH ADOLESCENT GIRLS AND YOUNG WOMEN WITH HIV SELF-TESTING AND CONTRACEPTION: A RANDOMIZED TRIAL IN TANZANIA

L.A. Hunter[1], J.X. Liu[2], A. Rao[3], S. Napierala[4], A. Kalinjila[5], A. Mnyippembe[5], K. Hassan[5], R. Mfaume[6], P. Njau[5,7], S.I. McCoy[1]
[1]University of California, School of Public Health, Berkeley, United States, [2]University of California, Institute for Health and Aging, Bixby Center for Global Reproductive Health, San Francisco, United States, [3]CVS Health, Design and Innovation Lab, Boston, United States, [4]RTI International, Berkeley, United States, [5]Health for a Prosperous Nation, Dar es Salaam, Tanzania, United Republic of, [6]Shinyanga Regional Medical Office, Shinyanga, Tanzania, United Republic of, [7]Ministry of Health, Community Development, Gender, Elderly, and Children, National AIDS Control Programme, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Adolescent girls and young women (AGYW, ages 15-24) comprise 25% of new adult HIV infections in sub-Saharan Africa and disproportionately bear 44% of all reported unintended births. Located in nearly every community, drug shops are extensions of the health system which offer unparalleled reach of health services to underserved populations. Thus, we designed and evaluated a girl-friendly intervention to deliver HIV self-testing (HIVST) and contraception to AGYW at privately-owned drug shops in Tanzania.

METHODS: We conducted a 4-month randomized trial at 20 drug shops in Shinyanga, Tanzania, to determine if the Malkia Klabu ("Queen Club") intervention increased AGYW patronage, provision of HIVST and contraception, and health facility referrals to AGYW. Drug shops were randomized 1:1 to the intervention or comparison arm. Both intervention and comparison shops were provided with OraQuick HIVST kits to give AGYW customers for free. Intervention shops implemented Malkia Klabu, a loyalty program designed for AGYW using behavioral economics and human-centered design.

We measured AGYW patronage through time-location surveys at randomly selected 3-hour blocks at baseline (n=109) and endline (n=246). In intent-to-treat analyses, we used Poisson regression to estimate rate ratios via a difference-in-differences approach. We measured HIVST and contraception distribution and referrals with monitoring data. The trial was pre-registered (clinicaltrials.gov: NCT04045912).

RESULTS: Drug shops implementing Malkia Klabu had higher AGYW patronage at endline than comparison shops (mean AGYW per survey 2.86 vs. 0.91; rate ratio: 3.16; 95% confidence interval: 1.94, 5.16). Over the study period, intervention shops distributed 140% more HIVST kits to AGYW (1,275 vs. 532), provided more contraception (5,237 vs. 148 products), and made more referrals for HIV services (71 vs. 2) and family planning (379 vs. 43) to AGYW than comparison arm shops. No adverse events were reported.

CONCLUSIONS: The Malkia Klabu intervention dramatically increased AGYW patronage and HIVST and contraception distribution, despite HIVST being freely available at all participating shops. A future effectiveness and sustainability study is warranted to evaluate Malkia Klabu's impact on HIV diagnoses and unintended pregnancy among AGYW, assess its potential for scale up, and confirm underlying theories for behavior change.

OAE0105

THE IMPACT OF IMMEDIATE ART INITIATION ON PATIENTS' HEALTHCARE EXPENDITURES: A STEPPED-WEDGE CLUSTER-RANDOMISED TRIAL IN ESWATINI

J.I. Steinert[1], P. Geldsetzer[2,2], S. Khan[3], E. Mafara[3], C. Wong[3], K. Mlambo[3], A. Hettema[3], F. Walsh[3], C. Lejeune[3,3], S. Mazibuko[4], V. Okello[4], O. Ogbouji[5], J.-W. De Neve[6], S. Vollmer[7], T. Bärnighausen[6]
[1]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [2]Harvard T.H. Chan School of Public Health, Department of Global Health and Population, Cambridge, United States, [3]Clinton Health Access Initiative, Boston, United States, [4]Ministry of Health of the Kingdom of Eswatini, Mbabane, Eswatini, [5]Duke Global Health Institute, Durham, United States, [6]Heidelberg Institute of Global Health, Heidelberg, Germany, [7]University of Göttingen, Göttingen, Germany

BACKGROUND: Healthcare expenditures for HIV care pose a major economic burden on households in sub-Saharan Africa. Immediate initiation of antiretroviral therapy (ART) for all HIV-positive patients is thought to have important health benefits but it is unknown how this profound change in HIV care provision will affect patients' healthcare expenditures. This study, therefore, aims to determine the causal impact of immediate ART initiation on patients' healthcare expenditures in Eswatini.

METHODS: This stepped-wedge cluster-randomised controlled trial took place from September 1 2014 to August 31 2017. Fourteen public-sector healthcare facilities in rural and semi-urban Eswatini were paired and then randomly assigned to transition at one of seven time points from the standard of care (ART eligibility at CD4 counts of < 350 cells/mm3 until September 2016 and <500 cells/mm3 thereafter) to the immediate ART for all intervention (EAAA). During each of the study's eight steps, we administered a questionnaire to a random sample of HIV patients at each healthcare facility. The primary outcome was total patient-borne healthcare expenditures during the preceding 12 months. We used mixed-effects negative binomial regressions adjusted for secular trends and clustering at the facility level. This study is registered with ClinicalTrials.gov, number NCT03789448.

RESULTS: 2261 participants were interviewed over the study period. Participants in the EAAA phase reported a 45% decrease (RR: 0.55, 95% CI: 0.39, 0.77, p<0.001) – or a mean reduction of 8.73 USD (95% CI: -14.39, -3.09), in absolute terms – in their total past-year healthcare expenditures compared to the standard-of-care phase. Patients' healthcare expenditures for private and traditional healthcare providers were 93% (RR 0.07, 95% CI: 0.01, 0.77, p<0.001) lower in the EAAA than the standard of care phase. Self-reported health status was similar between study phases.

CONCLUSIONS: Despite a higher frequency of HIV care visits for newly initiated ART patients, immediate ART initiation lowered patients' healthcare expenditures, at least in part because they sought less care from private and traditional healthcare providers. This study adds an important economic argument to the World Health Organisation's recommendation for countries to abolish CD4-count-based eligibility thresholds for ART.

OAE0106

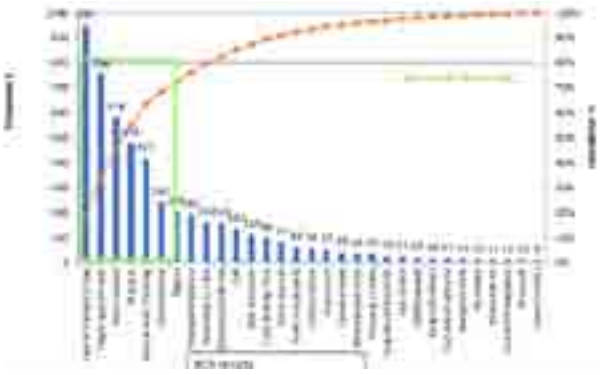
ROOT CAUSE ANALYSIS AS QUALITY IMPROVEMENT TOOL FOR IDENTIFICATION OF BARRIERS TO IMPROVE RETENTION IN HIV CARE: THE CASE OF UGANDA

W. Bikokye Kafeero[1], B. Elur[1], D. Bogere[2], S. Sendagala[1], J. Ssendiwala[3], P. Namukanja[2], A. Namale[2], J. Calnan[4], A.C. Awor[1], J. Ward[1]
[1]Division of Global HIV and TB Centers for Disease Control and Prevention, Strategic Information Branch, Kampala, Uganda, [2]Division of Global HIV and TB Centers for Disease Control and Prevention, Health Services Branch, Kampala, Uganda, [3]Makerere University, School of Public Health, Kampala, Uganda, [4]USAID, HIV/AIDS Services, Kampala, Uganda

BACKGROUND: In Uganda, 81% of PLHIV know their HIV status, 89% on ART and 78% virally suppressed (UNAIDS 2018). With more HIV+ clients starting treatment, there was a need to address the gaps in retention and viral suppression to enable achievement of the 95-95-95 targets by 2030. Continuous quality improvement (CQI) efforts to close the quality gaps in the HIV/AIDS care cascade have been previously implemented at small scale with pockets of success for , however, these efforts have not yield significantly visible results at national level.

DESCRIPTION: As of Dec 2018, Uganda reported 1,004,162 PLHIV receiving ART services. Between Oct-Dec 2018, 36,702 patients were reported as lost to follow-up (LTFU) Through implementation of Root Cause Analysis (RCA) initiative starting Jan 2019, patients initially categorized as LTFU were traced and interviewed by community peers or reached by phone by facility staff using a customized tool. The RCA as a tool for CQI was implemented to identify barriers to retention in care. The barriers identified and their frequencies ranked using Pareto analysis.

LESSONS LEARNED: Of the 36,702 patients initially categorized as LTFU, 5008 were traced by community peers or reached on phone by facility staff; 95% (4,758) were >15 years, 60% (3,005) females. From the RCA, of those LTFU were a result of lost clients reported lack of transport or long distance, 19% (950), forgot appointment; 15% (758) while travel away from home, sickness, or work accounted for 12%, 10% and 8.3% respectively.



CONCLUSIONS/NEXT STEPS: Large scale implementation RCA is feasible and useful in identifying gaps in service quality that impact programming. For retention, while roll out of differentiated service delivery may address transport challenges, further analysis is required to determine best solutions Disclaimer

OAE02 BREAKING THE CYCLE: FROM AID TO SUSTAINABLE DEVELOPMENT

OAE0202

SUSTAINING PROGRESS IN PREVENTION OF MOTHER-TO-CHILD HIV TRANSMISSION SERVICES – HOW LOW-VOLUME SITES HAVE AN IMPACT IN TANZANIA

R. van de Ven[1], C. Nnko[1], R. Lyimo[1], B. Kilama[1], D. Kajoka[2], J. Kalimunda[3], S. Kimambo[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, PMTCT Unit, Dodoma, Tanzania, United Republic of, [3]USAID Tanzania, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Prevention of mother-to-child transmission of HIV (PMTCT) services have been successfully rolled out across all health facilities offering maternal and child health services in Tanzania. However, in recent years, progress in PMTCT services uptake appears to have slowed. As part of the PEPFAR "pivot", which shifts attention and PEPFAR resources to high-volume sites, the Elizabeth Glaser Pediatric AIDS Foundation also shifted its direct site-level support from both high- and low-volume sites to high-volume sites only.

METHODS: A retrospective analysis was conducted for a two-year period (October 2017 - September 2019) to assess the uptake of PMTCT services nationally. We used the national DHIS2 database to extract aggregated, routine PMTCT data at national level, compiled the standard PMTCT indicators and analyzed the yearly performance trend. For the six EGPAF supported regions, we also compared PEPFAR supported sites to non-supported sites.

RESULTS: Comparing the periods October 2017-September 2018 and October 2018-September 2019, nationally the uptake of HIV testing among pregnant women remained at 97% (2,181,015/2,254,107). However, antiretroviral therapy (ART) initiation among newly identified women dropped from 90% (35,350/39,467) to 80% (28,240/35,500) and the uptake of early infant HIV diagnosis (EID) dropped from 57% (47,403/82,772) to 54% (46,069/85,020). During the October 2018- September 2019 period, the uptake of HIV testing among pregnant women between between EGPAF-supported high-volume sites (n=417) versus non-supported low-volume sites (n=1285) remained the same (97.1% vs 97.7%), but there is a significant difference in ART uptake (99% vs. 49%, p<.0001) and EID testing uptake (72% vs. 26%, p<.0001). These non-supported low-volume sites covered 45% (3,015/6,647) of the newly identified HIV-positive pregnant women within the year.

CONCLUSIONS: While the PEPFAR pivot has shifted efforts and resources for high-quality ART service delivery models to high-volume sites, services are not sustained at the low-volume non-supported sites. As these sites still cover nearly half of the newly identified pregnant women living with HIV, it has a negative impact on reaching elimination. Therefore, PMTCT programs need consistent support across all service delivery platforms and a reboot to address the challenges at low-volume sites to sustain the progress towards reaching elimination.

OAE0203

LIFE AFTER PEPFAR'S DIRECT SERVICE SUPPORT: PROGRAM SUSTAINABILITY AMONG SOUTH AFRICAN HIV/AIDS ORGANIZATIONS FUNDED BY PEPFAR

J. Chiliza[1,2], F. Feeley III[1], R. Laing[1], A. Brennan[1], D. Jackson[3], J. Arendse[4], K. Riffenberg[1], L. Tabbaa[1]
[1]Boston University, Department of Global Health, Boston, United States, [2]Boston University, Boston, United States, [3]University of the Western Cape, Bellville, South Africa, [4]Western Cape Government Health, Cape Town, South Africa

BACKGROUND: Public health practitioners have little guidance of how toplan for the sustainability of donor sponsored programs. The literature is broad and provides no consensus on a definition ofsustainability. This study used a robust mixed-methods methodology to develop a list of program sustainability factors to inform donor-funded programs.

METHODS: This study examined 61 health facilities in the Western Cape, South Africa, supported by four PEPFAR non-governmental organizations (NGO's) from 2007 to 2012. Retention in Care (RIC) was used to determine health facility performance. Sustainability was measured by comparing RIC during PEPFAR direct service, to RIC in the post PEPFAR period (2012 to 2015). Crude and adjusted risk differences were calculated to estimate the association between the type of government ownership, PEPFAR NGO support, ART treatmentpolicy change, size of ART patient cohort, human resource transition and our outcome of RIC at 12 and 24 months on ART.

Forty-three semi-structured in-depth interviews were conducted with key informants. The qualitative data was usedto examine how predictor variables were operationalized at a health facility and NGO level.

RESULTS: Though the linear regression models showed no difference in RIC pre and post 2012, our graphed descriptive results showed a dip in RIC among the majority of the study facilities in 2012/2013. The RIC decrease was likely due to PEPFAR's move from direct service to technical assistance: the decrease in the numbers of community health workers (CHW's) and a change in HIV treatment eligibility guidelines.

Our qualitative results suggest the following lessons for the sustainability of future programs:

- Sufficient and stable resources (i.e. financial, human resources, technical expertise, equipment, physical space)
- Investment in organizations that understood the local context and have strong relationships with local government
- Strong leadership at a health facility level.
- Some disease specific staff (i.e. clinical, administrative, community)
- Joint planning and formalized skill transfer:
- Local positive perceived value of the program
- Stable financial and political support for the program

CONCLUSIONS: Sustainability is complex, context dependent, and reliant on various processes and outcomes. This study suggests additionalhealth facility and community level staff should be employed in the health system to ensure RIC sustainability.

OAE0204

KEY POPULATIONS DOING IT FOR THEMSELVES: THE RISE OF SOCIAL ENTERPRISE APPROACHES TO INCREASE FINANCIAL SUSTAINABILITY OF THE COMMUNITY-BASED HIV RESPONSE

Y. Vu[1], K. Green[1], B. Vu[1], T. Ngo[2], T. Tran[1], K.O. Pham[3], T. Le[4], K. Do[5], S. Pham[6], P.A. Nguyen[3]
[1]PATH, Healthy Markets Project, Hanoi, Vietnam, [2]USAID, HIV Prevention, Hanoi, Vietnam, [3]CSIP, Hanoi, Vietnam, [4]Glink, Ho Chi Minh, Vietnam, [5]Galant, Ho Chi Minh, Vietnam, [6]G3VN, Ho Chi Minh, Vietnam

BACKGROUND: Despite a complex HIV epidemic, with a rise in HIV infections among men who have sex with men and transgender women, external financing for HIV prevention has declined significantly over the past ten years in Vietnam. Declining resources directly impacted the viability of fledgling key population (KP)-led civil-society organizations (CSOs) that were the backbone of community HIV prevention efforts.

DESCRIPTION: Starting in 2014, the USAID/PATH Healthy Markets (HM) project partnered with 25 KP-led organizations to co-grow areas of organizational health and wealth. This included: 1) measuring progress towards sustainability through a locally developed social enterprise organizational capacity assessment tool; 2) developing and implementing an organizational growth plan; 3) CSO mentoring from a local social enterprise incubator; and 4) supporting to generate market insights and accessing capital. Three distinct KP-led business (KPLB) models emerged: CSOs with integrated sales activities (mainly condoms); legally registered social enterprises selling health goods and services; and private clinics offering HIV and related health services.

LESSONS LEARNED: A 2019 assessment of organizational capacity and financial viability of a sample of nine KPLB found that all but one broke even by month eight of operations, with private clinics taking the longest time, and 100% reporting annual increases in sales and revenue. Overall profit for the nine KPLB increased from US$73,791 to US$129,685 between 2016 and 2018. All private clinics, 75% of social enterprises, and 67% of CSOs achieved their financial sustainability goals. The KPLB reported that the joint capacity assessment, business training, and tailored mentoring were most valuable in enabling their transition from CSO to a KPLB.

CONCLUSIONS/NEXT STEPS: As donor funds decline, and where public financing for KP CSOs is not assured, enabling financial independence is essential to sustain the presence of community-led HIV and related health service providers.

OAE0205

SUSTAINABILITY, HIV FINANCING, AND TRANSITION PREPAREDNESS: BUILDING FINANCING LITERACY TO STRENGTHEN THE HIV COMMUNITY RESPONSE

P.C. Loh[1], M.F. Teh[1], G. Gray[1]
[1]Australian Federation of AIDS Organisations (AFAO), NSW, Australia

BACKGROUND: HIV-financing and transition planning are relatively new and technical areas for key-population (KP) communities. Challenges remain for communities to understand the scope of HIV-financing, funding sustainability, and the urgency of transition planning. These knowledge areas are sometimes perceived as too technocratic, with low community literacy resulting in limited empowerment to drive advocacy and community mobilization.

DESCRIPTION: The Sustainable HIV Financing in Transition (SHIFT) Program was a two-year (2017-2018) Global Fund advocacy program implemented by the Australian Federation of AIDS Organisations (AFAO) aimed at empowering civil society organizations and KP networks to influence domestic HIV funding processes. SHIFT's objectives were to ensure a sustainable, cost-effective and strategically-allocated funding for HIV in four transition countries (Malaysia, Philippines, Indonesia, and Thailand).

LESSONS LEARNED: A crucial component of ensuring transition preparedness and sustainability of HIV responses is the meaningful inclusion of, and buy in from, KP groups. Two main challenges were noted:

Limited meaningful KP inclusion in country transition decision-making processes.

While there was KP representation on CCM and transition planning working groups, there is a lack of inclusion of their voices or is often tokenistic. As KP are perceived as not technically qualified in these knowledge areas, their inputs were often put aside, with discussions dominated by policymakers and government technocrats.

Limited community-literacy and awareness around HIV-financing and transition preparedness.

HIV-financing information and other key strategic data to advocate for KP investment and allocatively efficient funding are often dense and difficult to understand, given that community representatives have limited interest and capacity for technical jargon. HIV-financing information and other data need to be made more readily available and accessible at the community-level. Capacity development activities are needed to help KP communities better understand and utilize data for programmatic and financial advocacy.

CONCLUSIONS/NEXT STEPS: An empowered and informed civil-society, crucial to the success of a sustainable response in HIV financing, requires increased community understanding, awareness, and engagement on HIV-financing and transition. Technical HIV-financing and transition planning information need to be distilled into community-friendly knowledge products. Communities must be trained on how to use and transform this information into advocacy for effective increased KP-investments and allocatively efficient funding policies.

OAE0206

HIV INTEGRATION FOR A MORE SUSTAINABLE AND RESILIENT HIV RESPONSE IN LOW AND MIDDLE-INCOME COUNTRIES

C. Mann[1], M. Hijazi[1], S. Baker[1], H. Marqusee[1], C.A. Nguyen[2], R. Stanley[3], C. Piña[4]
[1]USAID, Washington, D.C., United States, [2]USAID, Hanoi, Vietnam, [3]USAID, Phnom Penh, Cambodia, [4]USAID, Santo Domingo, Dominican Republic

BACKGROUND: Much of the HIV/AIDS response has been financed by external donors, stabilizing the epidemic for many countries. This led to programmatic and external financing shifts as many countries approach sustained epidemic control. Now countries must increase domestic financing but minimize or eliminate out-of-pocket spending at point of care. Leveraging well-functioning social health insurance (SHI) or social protection schemes to include HIV/AIDS is one approach with recent success to increase domestic financing. This provides more sustainable and resilient HIV/AIDS service delivery systems.

DESCRIPTION: The PEPFAR-funded Sustainable Financing Initiative for HIV/AIDS (SFI) supports several countries to integrate HIV/AIDS services into SHI or social protection benefits package. In Vietnam, the project focused on integrating donor-supported HIV treatment centers into the public health system; enrolling people living with HIV/AIDS (PLHIV) into SHI; and domestically-financed antiretroviral (ARVs) procurement. In Cambodia, despite a challenging political environment, SFI supported passing a HIV/AIDS policy circular through evidence generation, continued engagement with government, and identifying champions for policy achievement. In the Domican Republic (DR), the project is working with government to integrate ARV financing into their SHI.

LESSONS LEARNED: In Vietnam, this work resulted in $5.9 million in ARVs procured domestically, enrolling 90% of HIV patients in SHI (36% in 2016), and integrating 87% of outpatient facilities into SHI-supported facilities. This provided savings of $5.9 million to PEPFAR with increased government contributions; a 3:1 return on investment. In Cambodia, the HIV/AIDS circular provides a 6-pronged approach for a more sustainable and equitable HIV/AIDS response. This includes all PLHIV being eligible for the Health Equity Fund (HEF) - providing free access to all health services and social protection schemes. SFI is supporting circular implementation, including a cost analysis for including PLHIV into HEF. In the DR, financing ARVs using SHI ensures commodity sustainability with shifting $3.7 million annually from government financing to regular insurance contributions, and potential savings by transferring procurement responsibilities.

CONCLUSIONS/NEXT STEPS: HIV integration into health insurance and social protection schemes provide a sustainable way to increase domestic financing while increasing coverage for care and treatment.

OAE03 HEALTH FOR ALL: UHC AND SOCIAL PROTECTION

OAE0302

THE EFFECT OF HEALTH INSURANCE TO HIV-POSITIVE CAREGIVERS CARING FOR ORPHANS AND VULNERABLE CHILDREN IN TANZANIA

K. Tani[1], A. Exavery[1], T. Mbwambo[1], J. Charles[1], E. Jerre[2]
[1]Pact Tanzania, Monitoring Evaluation Research and Learning, Dar es Salaam, Tanzania, United Republic of, [2]Pact Tanzania, Chief of Part, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Sustainable Development Goal 3 promotes universal health coverage to achieve well-being for all. In Tanzania, only 32% of the 55 million population are covered by health insurance, of which 72% is community health fund, 23% is national health insurance, and 3% is private insurance. This study explores the relation of having health insurance coverage and enrolling into HIV Care and Treatment Clinics (CTC) while holding other factors constant.

METHODS: A PEPFAR-funded orphans and vulnerable children (OVC) project collected individual and household data between April 2017 and September 2019 using a project-specific Family and Child Assets Assessment tool. The data was collected by lay community social welfare volunteers at household level during screening of the household at enrolment and repeated after two years of

service delivery. Data was analyzed for caregivers with known HIV status. The respondents who did not know their HIV status and/or refused to disclose were excluded from the analysis. The multivariate logistic regression was examined using Stata.

RESULTS: Of the 129,406 caregivers who declared their HIV status, 32.4% self-reported as HIV+ and, of these, 91.4% were enrolled in a CTC. Health insurance coverage was 15.8% at enrolment, and 24% at two-year reassessment. At enrolment (before OVC services) the presence of health insurance had no influence on HIV+ enrolment to CTC (OR=1.05 CI=0.89–1.24). At reassessment, the result depicted that HIV+ covered by health insurance were more likely to be enrolled to CTC (OR=0.1.61 CI=1.47–1.77). These effects were adjusted for respondent ability to cover the emergency medical needs (self-reported), age, sex and residence.

CONCLUSIONS: Although caregivers received a variety of needs-based services once enrolled into the project (including case management, counselling, economic strengthening, and escorted referrals),the inclusion of health insurance in the package of services opened up more demand and utilization of health care. The data suggests that insurance contributes to uptake of HIV services, even though the HIV services are free, because general health services were made more accessible With insurance the HIV+ can acquire the needed health services where available, without the barrier of limited resources, and this includes access to health services that complement their HIV care.

OAE0303

LEVERAGING PRIVATE PROVIDERS TO IMPROVE AND EXTEND HIV TREATMENT ACCESS IN SOUTH AFRICA: COST IMPLICATIONS FOR UNIVERSAL HEALTH CARE IN SOUTH AFRICA

L. Long[1,2,3], S. Girdwood[2,3], K. Govender[2,3], N. Lekodeba[3,2], S. Kgowedi[3,2], G. Meyer-Rath[1,2,3], J. Miot[2,3]
[1]Boston University, Global Health, Boston, United States, [2]University of Witwatersrand, Department of Internal Medicine, Johannesburg, South Africa, [3]Wits Health Consortium, Health Economics and Epidemiology Research Office, Johannesburg, South Africa

BACKGROUND: Despite significant gains towards HIV epidemic control in South Africa, expanding treatment access remains a priority. The proposed South African National Health Insurance aims to re-engineer primary healthcare by leveraging private-sector providers to achieve universal healthcare. We conducted a cost-outcome analysis to explore the possible implications of expanding HIV access using private providers.

METHODS: Four sites in South Africa's Gauteng province were included: two government, primary health clinics (PHC) (PUB1&PUB2), one NGO-run PHC which accesses public-sector drugs and laboratory tests (PRV1), and one contracted doctor model which utilises private clinicians to manage public sector patients (PRV2). We sampled adult HIV-positive patients initiating, or newly presenting for, HIV treatment at sites in 2017 and 2018 and followed them for 12 months. Retention in care with viral suppression (IC suppressed) at 12 months was the primary outcome.

Bottom-up costing from the provider perspective was based on patient-level resource usage. PRV1 charged patients a means tested fee of <USD5 per visit; PRV2 charged a donor-covered annual capitation fee per patient paid quarterly based on attendance. Costs are reported in 2019 USD.

RESULTS: Sites reported similar mean age, days in care, and number of visits. The public sites performed both the best(64%) and worst(33%) in terms of IC suppressed, with the private sites falling between. In the private models, uptake is higher in men and those most at need(lowest CD4); cost is variable but similar once non-clinical staff is excluded. Costs for non-clinical staff performing services that were largely not HIV-related drove the higher average cost for PRV1.

	Public Site 1 (PUB1), n=76	Public Site 2 (PUB2), n=75	Private Site 1 (PRV1), n=75	Private Site 2 (PRV2), n=75
Male, %	22%	28%	39%	47%

In care (IC)	61 (80%)	55 (73%)	47 (63%)	*58 (77%)*
Suppressed, n (%)	*49 (64%)*	*25 (33%)*	*31 (41%)*	*42 (56%)*
Suppression unknown, n (%)	*6 (8%)*	*26 (35%)*	*11 (15%)*	*9 (12%)*
Unsuppressed, n (%)	*6 (8%)*	*4 (5%)*	*5 (7%)*	*7 (9%)*
Not in care (NIC), n (%)	15 (20%)	20 (27%)	28 (37%)	17 (23%)
Lost after 1 visit, n (%)	*4 (5%)*	*3 (4%)*	*10 (13%)*	*3 (4%)*
Lost after >1 visit, n (%)	*11 (14%)*	*17 (23%)*	*18 (24%)*	*14 (19%)*
Avg total cost/px - all (12 mon)	$290	$188	$357	$239
Drugs - HIV	*$79*	*$76*	*$71*	*$69*
Drugs - Other	*$15*	*$4*	*$13*	*$13*
Laboratory tests	*$44*	*$24*	*$47*	*$41*
Staff costs - Clinical	*$100*	*$52*	*$87*	-
Staff costs - Non clinical	*$15*	*$20*	*$80*	-
Fixed costs	*$36*	*$13*	*$59*	*$116**
Avg total cost/px - IC suppressed	$332	$230	$475	$282
Avg total cost/px - IC suppression unknown	$324	$226	$511	$259
Avg total cost/px - IC unsuppressed	$279	$234	$481	$278
Avg total cost/px - NIC	$144	$77	$145	$106

*Capitated annual fee

[Table 1. Cohort demographics, outcomes and costs]

CONCLUSIONS: If we are to reach the goal of universal HIV treatment access we need to utilize existing resources across sectors. Using private providers to move towards universal healthcare may expand HIV treatment access to under-reached populations without significantly increasing costs nor reducing outcomes.

OAE0304

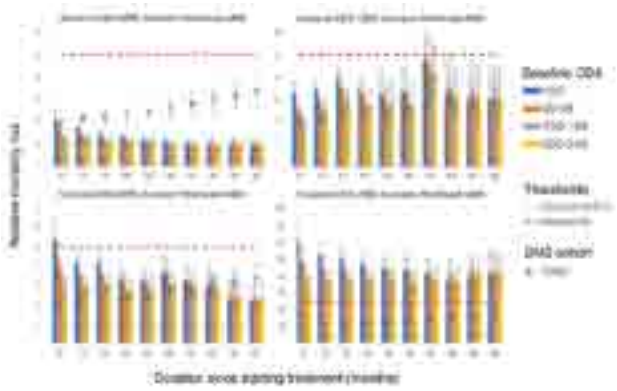
FUNERAL AND LIFE INSURANCE IN SOUTH AFRICA: HOW TYPE 2 DIABETES MELLITUS SURVIVAL CAN INFORM ACCESS TO AND AFFORDABILITY OF LIFE AND FUNERAL INSURANCE IN ADULTS WITH HIV-1

L. Sarkin[1], J. Ball[2], G. Maartens[1], M. Cotton[3], J. Nachega[4,5,6,7], R. Leisegang[3,1]
[1]University of Cape Town, Division of Clinical Pharmacology, Cape Town, South Africa, [2]Medscheme (Pty) Ltd, Aid for AIDS, Cape Town, South Africa, [3]Stellenbosch University, FAM-CRU, Department of Paediatrics & Child Health, Tygerberg, South Africa, [4]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [5]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [6]University of Pittsburgh Graduate School of Public Health, Departments of Epidemiology, Infectious Diseases and Microbiology, Pittsburgh, United States, [7]Stellenbosch University, Department of Medicine and Centre for Infectious Disease, Tygerberg, South Africa

BACKGROUND: Funeral insurance, and to some extent, life insurance are common in South Africa, and access to affordable policies for people living with HIV (PLWH) is important. Insurability is measured by relative rather than absolute mortality or life expectancy, but these data are not commonly reported.

METHODS: Using private medical scheme data from South Africa, we identified 3 patient groups: PLWH on antiretroviral therapy (ART), HIV-negative with type 2 Diabetes Mellites and on treatment (DM2), and a control group with neither. Relative all-cause mortality risk (relative risk) was estimated using a generalized linear model (GLM) assuming a Poisson error distribution and with expected numbers of deaths based on the control cohort mortality according to age, gender and population group specified as on offset; for PLWH, current CD4 count, viral load, baseline CD4 count, and time on ART are also included.

RESULTS: In the ART group, 8,920 deaths were observed recorded in 77,325 patients starting ART between 2000 and 2013 contributing 315,341 person-years of observation (PYO) (median follow-up of 3.23 years [IQR 2.04;5.30]). In the DM2 group, 7,970 deaths were recorded in 67,705 patients starting antihyperglycaemic therapy over the same period contributed 365,547 PYO (median follow-up of 6.20 years [IQR 3.85;9.53]). Our relative risk ratios compared with Kaulich-Bartz et. al. (2013) from a high-income setting. Using our methodology, 90% in the ART group had a relative risk from 6 months within the insurance industry threshold (i.e., <5 when compared to the control) and a lower or comparable relative risk to the DM2 group from 12 months – see Figure 1.



[Figure 1. Adjusted (multivariate) relative mortality risk (with bootstrapped 95% confidence intervals) by time-updated CD4 count and viral load, baseline CD4 count and duration since initiating ART. Benchmarks included: control (relative risk = 1), DM2 cohort and insurance industry threshold (relative risk = 5)]

CONCLUSIONS: Most PLWH have both insurable and comparable relative risk to DM2. Both current VL and CD4 were clearly prognostic over the whole period and therefore are likely to remain a requirement for life insurance, but not for HIV programs or funeral policies.

OAE0305

THE INFLUENCE OF HEALTHCARE FINANCING ON CARDIOVASCULAR DISEASE PREVENTION IN PEOPLE LIVING WITH HIV

A. Webel[1], J. Schexnayder[1], C.R. Rentrope[1], H. Bosworth[2], C. Hileman[3], N.L. Okeke[2], C. Longenecker[1]
[1]Case Western Reserve University, Cleveland, United States, [2]Duke University, School of Medicine, Durham, United States, [3]The MetroHealth System, Cleveland, United States

BACKGROUND: People living with HIV (PWH) are diagnosed with age-related comorbidities including cardiovascular disease (CVD) at higher than expected rates. Medical management of comorbidities frequently occurs in HIV specialty clinics. In recent years, changes in the healthcare financing for PWH in the U.S. has been dynamic. There is little evidence examining how healthcare financing characteristics shape primary and secondary CVD prevention among PWH. Our purpose was to examine the perspectives of PWH and their healthcare providers on how healthcare financing influences CVD prevention.

METHODS: As part of the NHLBI-funded PreCLUDE initiative, we conducted in-depth, semi-structured interviews with 34 multidisciplinary healthcare providers and 51 PWH at 3 U.S. HIV clinics from October, 2018 to March, 2019. Using Braun and Clark's (2006) thematic analysis framework, we examined barriers and enablers of CVD prevention for PWH related to health care financing.

RESULTS: Three themes emerged across sites and disciplines: (1) Health systems organized around relative value units (RVUs) experience pressures that may disincentivize CVD prevention efforts by HIV specialty care providers. Increasingly, HIV clinics are internally co-locating services such as smoking cessation and cardiovascular health clinics to prevent CVD. Yet, this expansion of services strains clinic personnel and processes in a way that threatens their effectiveness. (2) Grant-based services enable locally-tailored CVD prevention strategies but are limited by the funder's priorities. (3) While commercial insurances support innovative CVD prevention tools, PWH with these payers experience increased barriers compared to public insurances. Examples include potential discomfort in being referred to new primary care providers, co-pays for specialty visits with one's longstanding HIV provider, and challenges in medication authorization due to HIV and CVD drug interactions.

CONCLUSIONS: As healthcare financing for PWH evolves, an understanding of the effects of various payers on patient and provider behavior and responses of the healthcare systems in which this care is provided, is important. HIV specialty clinics can consider implementing comprehensive CVD prevention strategies into everyday HIV care that align with a dynamic reimbursement landscape. HIV clinics should also be at the forefront of advocating for healthcare delivery and reimbursement models responsive to the evolving medical needs of PWH.

OAE0306

TOWARDS UNIVERSAL HEALTH COVERAGE AMONG PEOPLE LIVING WITH HIV IN NIGERIA: ARE THEY WILLING TO ENROLL IN A HEALTH INSURANCE SCHEME?

B. Olakunde[1], T. Oladele[1], D. Ndukwe[1], S. Wakdok[1], D. Adeyinka[2,3]
[1]National Agency for the Control of AIDS, Department of Community Prevention & Care Services, Abuja, Nigeria, [2]Federal Ministry of Health, Department of Public Health, Abuja, Nigeria, [3]University of Saskatchewan, Department of Community Health and Epidemiology, Saskatoon, Canada

BACKGROUND: High out-of-pocket expenditures for HIV-related services can limit access to care, and also result in financial catastrophe, particularly among the poor. While these consequences can be avoided by providing financial protection through a health insurance scheme, it is largely unknown whether people living with HIV (PLHIV) in Nigeria will be willing to participate in it. In this study, we assessed willingness of PLHIV in Nigeria to enroll in and pay for a health insurance scheme.

METHODS: The study was a cross-sectional survey of 229 PLHIV 18 years and older receiving antiretroviral therapy in three secondary health facilities in the Federal Capital Territory, Nigeria. Data on sociodemographic characteristics, financial burden of HIV care,

knowledge of health insurance scheme, willingness to enroll for health insurance scheme, and the premium respondents were willing to pay was collected using a pre-tested semi-structured self-administered questionnaire. We performed descriptive statistics, and linear regression analyses to examine factors associated with the premium the respondents were willing to pay.

RESULTS: Approximately 67% (129/193) indicated willingness to enroll in an insurance scheme. The maximum monthly premium the respondents (n=126) were willing to pay ranged from N100 ($0.3) to N1000 ($3.2), with a median of N500 ($1.6). In the bivariate analyses, gender, education, marital status, and religion were significantly associated with the monthly premium the respondents were willing to pay. In the multivariate linear regression model which contained the significant factors at bivariate level, gender, education, and marital status remained significant. Females were willing to pay N108 ($0.4) more than males (p=0.014). Those who were single were willing to pay N141 ($0.5) more than the married respondents (p=0.004). Compared to those with tertiary education, those with secondary education were willing to pay N124 ($0.4) less (p=0.011).

CONCLUSIONS: About two-thirds of PLHIV in our study indicated interest in risk pooling to cover HIV services. However, they were only willing to pay a little premium. More information about health insurance and its benefits may improve willingness of PLHIV in Nigeria to enroll. Poor PLHIV may also require subsidies for enrollment into health insurance schemes.

OAE04 INNOVATION IN INITIATION, TREATMENT AND CARE: DIFFERENTIATED SERVICE DELIVERY

OAE0402

TREATMENT OUTCOMES IN A COMMUNITY PHARMACY ANTI-RETROVIRAL THERAPY PROGRAM

Y. Kambai Avong[1], G. Ayodele Kayode[2], E. Bosede Avong[3], B. Jatau[1], C. Mensah[4], P. Dakum[4]
[1]Institute of Human Virology Nigeria, Clinical, Abuja, Nigeria, [2]Institute of Human Virology Nigeria, Research, Abuja, Nigeria, [3]APIN, Clinical, Makurdi, Nigeria, [4]Institute of Human Virology Nigeria, Administration, Abuja, Nigeria

BACKGROUND: The use of community based models for scaling up HIV treatment has been recommended by the World Health Organization. In a community base project providing antiretroviral therapy, we investigated retention in care, adherence to medications and virologic suppression among the participants who willingly chose to refill prescriptions in registered Community Pharmacies (Co-Pharm). Viral suppression (<20 copies/mL) was the measure of outcome.

METHODS: This is a non-randomized intervention study. Adults living with HIV that were virologically suppressed (i.e., having a viral load of less than 20 copies/mL) were recruited and enrolled in a community based program where patients refilled prescription in registered Co-Pharm in northern Nigeria [Nasarawa state, Katsina state, Kano state and the Federal Capital Territory (FCT), Abuja, Nigeria], from January 2017 to June 2019. Sociodemographic and treatment data (medication regimen, prescription refill, retention in care and viral load) were collected. Baseline virologic suppression before patients devolved to the Co-Pharm was compared with the patients' virologic suppression data after twelve months of devolvement. Descriptive statistics and multivariable linear regression analysis were applied.

RESULTS: Twenty nine public hospitals and 64 registered community pharmacies were recruited. Of the 2,938 patients included in the analysis; 56.7% (1,665) were men and mean age was 53 years [SD= 3.2]. Majority of the patients were retained in care [98.1% (2,882)] and 85% (2,497) had optimal adherence (≥95%). Baseline log viral load was 3.7 (SD=1.2); no significant difference in median viral load (VL) before and after participants devolved to the Co-Pharm [before median VL = 2.9 log copies/mL [IQR-2.9 – 7.1] Vs after median VL = 2.9 log copies/mL [IQR=2.9 – 10].

CONCLUSIONS: Patients remained virologically stable with optimal adherence and retention in care. This suggests that patients who are already virologically suppressed may remain stable even if they are devolved from the hospitals to the Co-Pharm. Registered Co-Pharm linked to public hospitals may therefore provide a viable option for treating patients who are virologically suppressed. In developing countries, over-crowded hospitals could be decongested by allowing patients who are virologically suppressed to devolve to the Co-Pharm.

OAE0403

BUILDING CAPACITY FOR MANAGEMENT OF PATIENTS ON ADVANCED ART REGIMENS THROUGH GUIDED PRACTICE USING THE ECHO TELE-MONITORING MODEL IN KENYA

J. Humphrey[1], S. Ali[2], M. Alera[3], S. Goodrich[1], D. Litzelman[1,4], A. Gardner[1,2]
[1]Indiana University School of Medicine, Indianapolis, United States, [2]Moi University College of Health Sciences, Eldoret, Kenya, [3]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [4]Regenstrief Institute, Indiana University Center for Global Health, Indianapolis, United States

BACKGROUND: Increasing numbers of people with HIV are transitioning to advanced (i.e., second- and third-line) antiretroviral therapy (ART) regimens in resource-limited settings. Interventions are needed to scale-up the clinical capacity for management of these complex cases when virologic failure occurs. We evaluated the feasibility of implementing Project ECHO's teleECHO clinic training model at the Academic Model Providing Access to Healthcare in Kenya.

METHODS: From March-July 2019, HIV clinical staff at 19 public facilities throughout western Kenya participated in a teleECHO curriculum developed and led by HIV management experts in Eldoret, Kenya. Eight weekly sessions utilizing a case-based curriculum presented patients failing advanced ART regimens, followed by expert-led didactics based on Kenya National HIV treatment guidelines. Clinical officers (COs) at each site were purposefully sampled to complete pre- and post-intervention semi-structured surveys to investigate their knowledge and self-efficacy regarding the management of patients on advanced ART and the barriers/facilitators to implementing the intervention. The data were analyzed using descriptive and thematic analyses and paired t-tests. Viral suppression (<40 copies/mL) among the patients discussed was assessed at six months post-intervention.

RESULTS: A total of 245 clinical staff (68% female; median age 38 years; 68% with >5 years of experience providing HIV services) participated in the intervention (average 58 participants/session), including: nurses (22%), COs (25%), counsellors (32%), nutritionists

(7%), social workers (4%) and other staff (10%). Among 32 COs surveyed, pre/post surveys demonstrated improved ability and self-efficacy to monitor patients on second- and third-line ART, construct a multi-disciplinary team plan, and switch ART for patients failing second-line ART (p<0.05 for all). Facilitators to implementation included the interactive nature of the sessions, provision of pre-paid internet bundles, and regular access to expert consultants. Barriers included unstable internet connectivity at rural sites, technology issues, and schedule interruptions. Of 16 patients ages 4-64 years discussed during the sessions, the median number of months with continuous pre-intervention viremia was 47 (interquartile range 15-53), and 5 of 10 patients with an available viral load achieved suppression.

CONCLUSIONS: The teleECHO model is a feasible and scalable tool to improve the management of patients failing advanced ART regimens in resource-limited settings.

OAE0404

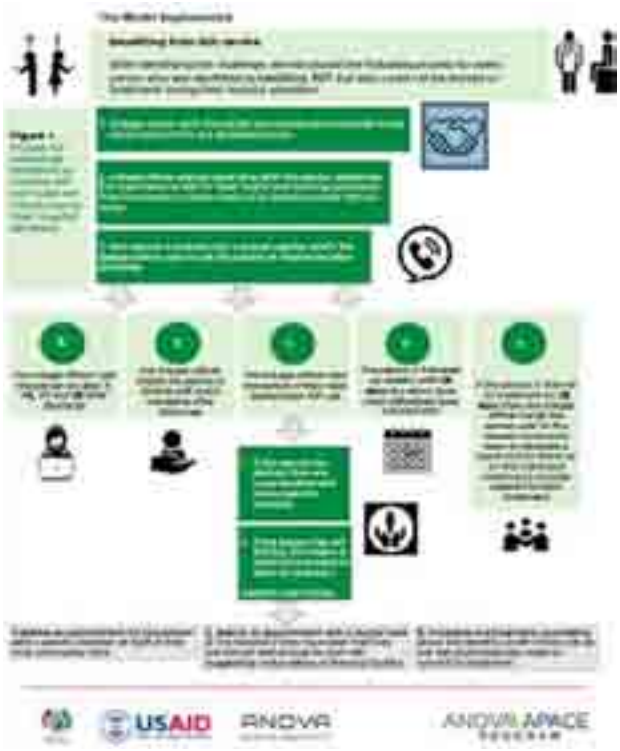
IMPROVING ANTIRETROVIRAL THERAPY INITIATION IN HOSPITAL AND AFTER DISCHARGE IN JOHANNESBURG, SOUTH AFRICA

M. Bisnauth[1], K. Rees[2], H. Struthers[3], J. McIntyre[4], N. Davies[5]
[1]University of Witwatersrand/Anova Health Institute, Public Health, Johannesburg, South Africa, [2]University of Witwatersrand, Community Health, Johannesburg, South Africa, [3]University of Cape Town, Division of Infectious Diseases and HIV Medicine, Johannesburg, South Africa, [4]University of Cape Town, School of Public Health and Family Medicine, Johannesburg, South Africa, [5]Anova Health Institute, Clinical Research, Johannesburg, South Africa

BACKGROUND: In South Africa, despite increasing access to antiretroviral therapy (ART), HIV -related mortality has changed very little over the last 5 years. Many people living with HIV are identified for the first time during an admission to hospital because of advanced HIV and related illnesses. Although same-day ART initiation has been implemented since October 2016, up to 40% of people diagnosed in hospital are either clinically ineligible or not psychologically ready to start antiretroviral therapy (ART) during their admission. After discharge, these clients often struggle to link to care and treatment at their local primary healthcare facility (PHC), leading to delays in ART initiation, and further morbidity and mortality.

DESCRIPTION: We implemented a linkage to care model (Figure 1) at the two largest hospitals, in Johannesburg, South Africa. The model supported people who were identified as needing ART to either initiate ART during their hospital admission or link to ART initiation at their local PHC as soon as possible after discharge. We used routine data to measure linkage rates before and after implementation.

LESSONS LEARNED: Before implementing the model, an average of 55% of clients needing ART were confirmed to have initiated treatment following hospital admission. After implementation, over 90% of clients had initiated ART within 28-days post-discharge (549 clients over 2 months). Poorly established referral pathways and communication between hospitals and PHCs can undermine linkage to ART care but a structured post-discharge client support model can help overcome these barriers. Delayed ART initiation is common due to acute clinical complications or lack of client psychological readiness to commit to lifelong treatment.



CONCLUSIONS/NEXT STEPS: Our model successfully improved linkage to ART and strengthened referral pathways between hospitals and PHCs following discharge. This model will be scaled-up to all hospitals in the district to minimise loss to follow up and positively impact HIV-related morbidity and mortality.

OAE0405

HEALTHCARE WORKERS PERSPECTIVES ON CLIENT VOLUMES AND WORKLOAD WITH DIFFERENTIATED SERVICE DELIVERY MODELS IN THE KINGDOM OF ESWATINI

A. Hughey[1], J. Tailor[2], A. Hettema[1], M. Rabkin[2], P. Preko[3], R. Kuwengwa[4], W. Reidy[3], S. Shongwe[5], N. Lukhele[6], H. Kambale[4]
[1]Clinton Health Access Initiative, Mbabane, Eswatini, [2]ICAP, Columbia University Mailman School of Public Health, New York, United States, [3]ICAP, CQUIN, New York, United States, [4]Ministry of Health, Eswatini National AIDS Program, Mbabane, Eswatini, [5]ICAP, CQUIN, Mbabane, Eswatini, [6]World Health Organization, Mbabane, Eswatini

BACKGROUND: In response to overcrowding at health facilities (HF) and the importance of client-centered care, Eswatini is scaling up less-intensive differentiated service delivery models (DSDM) for adults and adolescents doing well on antiretroviral therapy (ART). DSDM are anticipated to improve the satisfaction of both clients and healthcare workers (HCW) but little data are available on the HCW experience of DSDM implementation, including HCW perceptions on how clinic workload has been impacted by DSDM.

METHODS: We conducted a mixed-methods study to explore HCW perspectives on the impact of DSDM on client volumes and HCW workload. Between August and October 2019, we administered 172 quantitative surveys and conducted 20 semi-structured in-depth-interviews (IDI) with HCW representing multiple cadres, including expert clients, at 39 purposively selected HF in Eswatini. Quantitative data were analyzed using Stata 12 and interview transcripts were coded and analyzed using Dedoose.

RESULTS: Respondents included 78 nurses (45%), 53 expert clients (31%), 16 nursing assistants (9%) and smaller numbers of medical officers, community health workers, counsellors, pharmacy staff, and others. When asked about the impact of DSDM on the daily volume of ART clients, among the 67% of respondents stating there was an impact, 78% perceived a decrease while 22% perceived an increase in client volume. In IDIs, many HCWs described shorter client queues and waiting times. Reflecting on their individual workloads, 64% felt their workload had decreased with the advent of DSDM, 16% noted no change and 18% reported an increased workload. In IDIs, HCW noted that some DSDM were more labor intensive than others, noting the need for increased documentation for Community Antiretroviral Groups, pre-packing of medication and preparation of files for Fast Track, and working on Saturdays for Teen Club.

CONCLUSIONS: The majority of HCWs reported that DSD scale-up has decreased their workloads by reducing the volume of ART clients at HFs, but there is substantial heterogeneity in their responses. Understanding the impact of different DSDM and the impact on different HCW cadres will be important as DSDM are scaled up nationwide.

OAE0406

POP-UP CLINIC: A MULTICOMPONENT MODEL OF CARE FOR PEOPLE LIVING WITH HIV (PLHIV) WHO EXPERIENCE HOMELESSNESS OR UNSTABLE HOUSING (HUH)

E. Imbert[1], M.D. Hickey[1], A. Clemenzi-Allen[2], M. Conte[3], E.R. Riley[1], D.V. Havlir[1], M. Gandhi[1]
[1]University of California, Medicine, Division of HIV, ID and Global Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, San Francisco, United States, [3]Zucker School of Medicine at Hofstra/Northwell, Hempstead, United States

BACKGROUND: In San Francisco, homelessness is the single greatest risk factor for HIV viremia. At San Francisco General Hospital's "Ward 86" HIV clinic, over one-third of patients experience HUH, with increasing housing instability associated with higher likelihood of viremia, higher frequency of drop-in and emergency room visits, and lower adherence to primary care. UNAIDS "Getting to Zero" and U.S. "End the Epidemic" goals will not be achieved without innovative models of care and greater housing access for PLHIV-HUH. We launched "POP-UP" in January 2019, a no-appointment ("low-threshold"), incentivized primary care clinic, to address structural and individual-level barriers to care for PLHIV-HUH.

METHODS: POP-UP eligibility includes 1) HIV RNA ≥200 copies/mL or off ART, 2) HUH, and 3) ≥1 missed primary care appointment and ≥2 drop-in visits in the prior 12 months. Patients are identified through the electronic health record and clinic-based referrals. POP-UP provides drop-in primary care, which includes mental health and substance use treatment, housing assistance and case management, financial incentives, and patient navigation with frequent contact. We describe program uptake, ART initiation, return to care by 90 days post-enrollment, and cumulative incidence of first instance of viral suppression (HIV RNA<200) at 6 months post-enrollment, estimated via Kaplan-Meier.

RESULTS: 64 patients were enrolled into POP-UP from January-December 2019: 83% cis-men, 11% cis-women, 6% transgender/non-binary; 47% white, 36% black, 8% Latinx; 55% street homeless; 100% with a substance use disorder; 76% with a mental health disorder; and 39% with CD4<200. Among the 64 patients enrolled, 59 (92%) restarted ART, most at enrollment (median 0, IQR 0-12 days); 59 (92%) returned for follow-up within 90 days. Cumulative incidence of viral suppression at 6 months post-enrollment was 60% (95%CI 47-74%). Nine patients were unenrolled from the program (3 died, 1 moved, 2 transferred back to PCP, 3 for threatening behavior).

CONCLUSIONS: The POP-UP program at Ward 86 demonstrates early success in engaging viremic PLHIV-HUH in care and improving viral suppression. Low-threshold, high-contact primary care programs offering comprehensive services and incentives similar to POP-UP may improve patient outcomes for this vulnerable population in other urban settings.

OAE05: IT'S RAINING MEN: HOW TO EFFECTIVELY ENGAGE MEN INTO CARE

OAE0502

TRANSITION TO DOLUTEGRAVIR-BASED REGIMENS IMPROVES OVERALL VIRAL-LOAD SUPPRESSION IN THE NATIONAL ART COHORT IN MALAWI AND CLOSES THE GENDER GAP

T. Hamisi[1], T. Chimpandule[1,2], A. Jahn[1,2,3], B. Chiwandira[1], T. Kalua[1], R. Nyirenda[1]
[1]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [2]International Training and Education Center for Health, Department of HIV and AIDS, Lilongwe, Malawi, [3]University of Washington, Department for Global Health, Seattle, United States

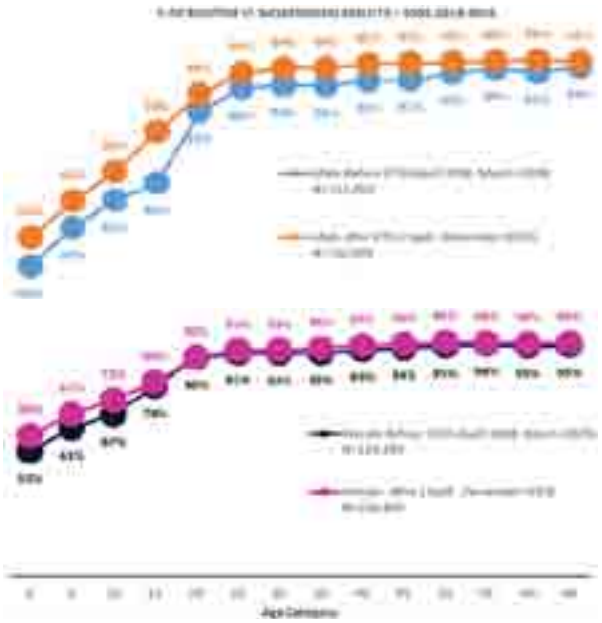
BACKGROUND: Malawi introduced dolutegravir (DTG)-based first-line regimens in January 2019, targeting all new and existing patients >20kg, but excluding women of reproductive potential due to concerns of risk of neural tube defects. Most adults transitioned from tenofovir/lamivudine/efavirenz (TLE) to tenofovir/lamivudine/dolutegravir; children 20-30kg to abacavir/lamivudine+dolutegravir. Confirmation of viral load suppression (VLS) was not required before transition due to limited monitoring capacity.

VL monitoring is scheduled 6 months from ART initiation and every 12 months thereafter. VLS rates were already high and it was unclear if DTG would yield additional population benefits.

DESCRIPTION: Before DTG-transition, 97% of all 805,254 patients on ART were on efavirenz- or nevirapine-based regimens and 92% of these were on TLE. Around 42% of patients received routine VL testing in the 12 months before transition; 89% of 334,233 results were <1000 copies/ml. VLS among women was 92-95% in age groups ≥25 years and it was consistently lower in men. VLS was much lower among children and adolescents, and boys had 5-12% lower VLS rates than girls.

By September 2019, 61% of all patients were on DTG-based regimens. VLS among the 311,956 results collected since the start of transition had increased to 93%. The VL gender gap in adults had disappeared. Boys and male adolescents showed the greatest increase in VLS.

LESSONS LEARNED: National lab information system (LIMS) data suggest an early increase in VLS following transition to DTG. The greatest increase was among patients selected for an early unconditional transition, where pre-transition VLS had been unsatisfactory.



[Figure. % of routine VL monitoring result <1000, 2018-2019]

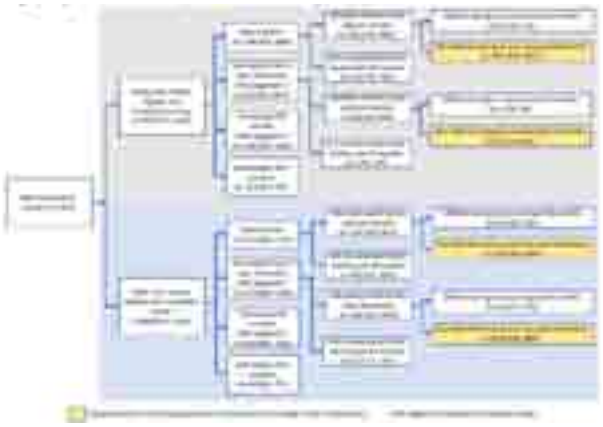
CONCLUSIONS/NEXT STEPS: Completion of the DTG transition for all patients over the coming months may further increase VLS, approaching 95%. Ongoing transition of children <20kg from nevirapine to lopinavir may improve VLS until convenient DTG-based formulations become available.
Inclusion of current regimen and further patient characteristics in LIMS will add value for cross-sectional and longitudinal program monitoring.

OAE0503

"MISSING MEN" OR MISSED OPPORTUNITY? MEN'S FREQUENT USE OF HEALTH SERVICES IN MALAWI

K. Dovel[1,2], K. Balakasi[2], S. Gupta[1,2], M. Mphande[2], I. Robson[2], P. Kalande[2], E. Lungu[2,2], A. Amberbir[2,1], J. van Oosterhout[2,1], S. Khan[3], N. Doi[3], B. Nichols[4,5]
[1]University of California, David Geffen School of Medicine, Division of Infectious Diseases, Department of Medicine, Westwood, United States, [2]Partners in Hope, Science Deptartment, Lilongwe, Malawi, [3]Clinton Health Access Initiative, Boston, United States, [4]Boston University, Department of Global Health, School of Public Health, Boston, United States, [5]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa

BACKGROUND: Men are underrepresented in HIV testing across sub-Saharan Africa. Community-based strategies are prioritized for reaching men, however, little is known about the frequency of men's facility attendance for non-HIV services, and if men attending facilities are offered HIV testing.
METHODS: We conducted a cross-sectional, community representative survey with men (15-64years) from 36 villages in rural Malawi. We used staged sampling to randomly select individuals using census data, and stratified by village and age. Primary outcomes were facility attendance (as client or guardian who supports services for others) and HIV testing within 24months. Descriptive statistics were conducted to examine facility visits among men in need of HIV testing.
RESULTS: 1,187/1,254 of men completed a survey, of whom 884 (74%) were adults (25+ years). 67 (6%) were known positive and excluded from analyses. 87% of young (≤24years) and 91% of adult (25+years) men attended a facility visit within 24months. 81% of facility visits were to outpatient departments. 58% of young and 38% of adult men were in need of HIV testing (i.e., tested >24 months ago or never tested). Among those in need of testing, ~81% of young and ~77% of adult men visited a facility within 24months for a non-HIV visit (Fig 1). Guardian visits comprised the majority of visits made. Only ~15% of men in need of testing were offered HIV testing services during recent facility visits. Reasons for not testing during recent facility visits were: not offered testing (32%); not at risk of HIV (19%); and (3) not ready to test (14%).



[Figure 1. Study flowchart: men's facility attendance and HIV testing (n=1254)

CONCLUSIONS: Most men regularly attended health facilities, especially outpatient departments. Men in need of testing were especially likely to attend facilities as a guardian, but few were offered HIV testing. HIV case finding interventions should capitalize on men's routine facility visits to reach the general male population.

OAE0504

FACTORS ENCOURAGING MEN TO TEST FOR HIV FOR THE FIRST TIME IN HPTN 071(POPART) COMMUNITIES IN ZAMBIA

M.M. Phiri[1], R. Kumar[1,2], T. Gachie[1,2], S. Floyd[2], A. Schaap[1,2], K. Shanaube[1], S. Fidler[3], S. Griffith[4], R. Hayes[2], H. Ayles[1,2], HPTN 071 Study Team
[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Imperial College, London, United Kingdom, [4]FHI 360, Durham, United States

BACKGROUND: HPTN071 (PopART) was a 3-arm, community-randomized trial in 21 Zambian and South African communities that demonstrated a reduction in HIV incidence following implementation of a combination prevention package including universal testing and treatment. The intervention was delivered in three annual rounds (ARs) of home-based, door-to-door visits including HIV testing services by a pair of Community-HIV-care-Providers (CHiPs) working in zones. We aim to determine whether household/CHiP-related factors influenced men to test for HIV for the first time in 8 Zambian intervention communities during AR3.
METHODS: The outcome was acceptance of HIV testing among men >18 years who had "never-tested" during AR3 (September 2016—December 2017). Individuals were considered "never-tested" if they: never self-reported previous HIV testing, did not verbally confirm their HIV-positive status in current or previous rounds, and did not test with CHiPs during previous rounds. A multi-level

logistic model (zone/household-nesting) was fitted adjusting for: community, whether other adults in the household accepted testing, whether participant was resident in previous ARs, whether CHiPs were intervention community residents, CHiP pair gender composition, and age of CHiP pair in relation to participant.

RESULTS: During AR3, 6,605/9,172 previously "never-tested" men (72.0%) accepted HIV testing. Factors associated with accepting testing are shown in Table 1. Uptake of testing was highest in mixed-gender households where another man or woman tested for HIV (aOR=21.68; 95%CI:16.06-29.28), and households of adult men where another man tested for HIV (aOR=14.85;95%CI: 12.12-18.2). The age of the CHiP pair affected uptake of first-time testing. Men had higher odds of testing when approached by a CHiP pair in which both were >5 years older than the participant (aOR=2.28;95%CI:1.82-2.87), compared to a pair of younger CHiPs.

Description	n / N (%)	Adjusted Odds Ratio (95% CI)	P-value
Any Adult Accepts Testing In The Participant's Household			
No other adult accepted testing in participant's household/bachelors	433/1642 (26.4)	Reference	
Another adult man or woman accepted testing in participant's household of adult men and women	5259/6505 (80.8)	14.85 (12.12,18.2)	<0.001
Another adult man accepted testing in participant's household of only adult men	913/1025 (89.1)	21.68 (16.06,29.28)	<0.001
CHiP Pair and Male Participant Age Difference			
Both CHiPs >5 yrs younger to participant	399/708 (56.4)	Reference	
Both CHiPs >5 yrs older to participant	3401/4440 (76.6)	2.28 (1.82,2.87)	<0.001
At least 1 CHiP is a peer of participant (within +/- 5yrs)	2133/3028 (70.4)	1.84 (1.46,2.30)	<0.001
mixed age pair: older (>5yrs) and younger (>5yrs) CHiPs	443/658 (67.3)	1.76 (1.29,2.40)	<0.001

[Table 1.]

CONCLUSIONS: Identifying positive role-models, such as older (and therefore respected) health providers, or other adults in the household who accept testing, increases first-time testing among men who have never-tested before.

OAE0505

IMPLEMENTATION OF HIV SELF-TESTING (HIVST) TO REACH MEN IN RURAL UMKHANYAKUDE, KWAZULU-NATAL, SOUTH AFRICA

N. Sithole[1], A.E. Shapiro[2], M. Krows[2], O. Koole[1], T.T. Schaafsma[2], D. Pillay[1], C.L. Celum[2], R.V. Barnabas[2]
[1]Africa Health Research Institute, Mtubatuba, South Africa, [2]University of Washington, Seattle, United States

BACKGROUND: African women have higher rates of HIV testing, HIV prevalence and ART coverage, and consequently men have lower survival rates. KwaZulu–Natal, South Africa has one of the highest HIV prevalence rates globally, where persons <35 yrs and men account for most of the people who have not been tested for HIV. HIV self-testing (HIVST) may overcome some of the barriers of facility-based HIV testing in order to identify HIV positive young persons and men and link them to care.

METHODS: Teams made up of a nurse, clinic research assistant, and 4 recruiters distributed HIVST kits in rural Umkhanyakude, KwaZulu-Natal from August – November 2018 with a focus on testing men. Places where men could be found such as workplaces (farms), social venues, taxi ranks and homesteads were used as HIVST distribution points. Community sensitisation was done through community advisory boards (CABs). In areas without CABs, permission to distribute kits was granted by the local chiefs. The Department of Health assisted with confirmatory testing and linkage at their facilities, and a 24-hour cell phone number was provided in case of an emergency.

RESULTS: Over 11 weeks , we distributed 2634 HIVST kits with 2052 (78%) kits distributed to aged < 35 yrs and 582 (22%) kits distributed to aged ≥ 35 yrs. 2591 (98%) kits were distributed to males and 43 (2%) were distributed to females. Of those, 2107/2634 (80%) used the HIVST kits and provided results to the study team, among whom 157/2107 (7%) tested positive. Of those who tested positive, 153/157(97%) were males .102/157(65%) did a confirmatory test and were initiated on ART. No emergencies were reported.

CONCLUSIONS: Large scale distribution of HIVST kits targeting men in rural Umkhanyakude is feasible, acceptable in the community, and effective at reaching men who have not tested for HIV. While two-thirds of persons who tested HIV positive initiated ART, additional linkage strategies are needed for those who do not link after HIVST. This testing strategy should be used as a tool to reach men in order to achieve 95 coverage in the UNAIDS testing and care cascade in KwaZulu-Natal.

OAE0506

UNDERSTANDING MEN WHO HAVE SEX WITH MEN (MSM) USING HUMAN-CENTERED DESIGN APPROACH IN ZIMBABWE

K. Chatora[1], C. Chang[2], H. Sithole[1], Z. Adell[2], N. Kunaka[1], K. Riger[2], C. Johnson[1], H. Ndondo[1], N. Taruberekera[1]
[1]Population Services International, Harare, Zimbabwe, [2]IDEO.org, San Francisco, United States

BACKGROUND: Like many African countries, Zimbabwe has a paucity of research on men who have sex with men (MSM). Against this backdrop, PSI Zimbabwe employed human-centered design (HCD) approaches to understand the lives of MSM and co-create solutions to improve their uptake of HIV prevention and treatment services. We explored the MSM journey to accessing services and created distinct archetypes based on barriers and motivators to service uptake.

DESCRIPTION: We used HCD techniques involving immersions, co-designing and prototyping solutions with the MSM community. We conducted 18 focus group discussions, 20 one on one interviews, 3 hotspot immersions and 3 observations across two urban areas over a two-week period. A total of 65 men from the MSM community and 5 service providers participated in this exploration. Thematic analysis was used to analyze the data.

LESSONS LEARNED: We identified 6 archetypes and a journey map detailing how each archetype accesses services. These archetypes included: The Glass Box - Identifies as gay only within the MSM community for fear of stigma; The Subtle Champion – Is an advocate providing social and health-related support to others; The Flag Bearer - Openly gay and unconcerned with societal stigma; The Dual Life - Conforms to heterosexual societal expectations and embraces his sexuality only in safe spaces; and The Conflicted Heart - Fighting the fact that he has just realized his attraction to men. Although the journey was fairly the same across all the archetypes there were some differences in experiences

by different archetypes which resulted in archetypes with more comfort self- identifying as MSM, like the Flag Bearer, being most likely to engage with HIV services. A gay man relates to HIV when a man he had sex with dies from HIV. He contemplates getting tested but fears social fall out. After testing, the need to disclose his MSM activity and a lack of provider empathy prevent him from returning.

CONCLUSIONS/NEXT STEPS: MSM archetypes and their journey to the uptake of HIV prevention and treatment services differ based on their mindsets and behavior. Understanding these archetypes presents an opportunity to tailor-make the provision of HIV services and mobilization activities to their unique needs.

OAE06 MONEY MAKES THE WORLD GO AROUND: DOMESTIC FINANCING FOR AN EFFECTIVE HIV RESPONSE

OAE0602

DOMESTIC PUBLIC SPENDING IN LOW-AND-MIDDLE-INCOME COUNTRIES 2006-2018: LEVELS AND TRENDS

D. Mattur[1], J.A. Izazola Licea[1], J. Javadekar[2]
[1]UNAIDS, Strategic Information, Geneva, Switzerland, [2]University of Geneva, Institute of Economics and Econometrics, Geneva, Switzerland

BACKGROUND: Domestic public investments in HIV/AIDS have consistently increased annually in LMICs. Understanding the correlates and predictors of domestic public spending on HIV can inform sustainability plans.

METHODS: Country reported domestic public AIDS spending data from Global AIDS Monitoring were considered. A panel of data using data from 2005-2018 from 114 low-and-middle-income countries were used for regression analysis resulting in 1224 country year data points. All the estimations are based on panel data random effects models.

A panel data regression using reports to UNAIDS for 2005-2018 from 114 low-and-middle-income countries were used for the analysis resulting in 1224 country year data points. All the regression estimates are based on panel data random effects models.

RESULTS: There are significant positive associations between the log of GDP per capita (1.058, <0.001) of a country and its level of domestic public spending on HIV. The ART coverage (15.75, <0.001) and the HIV prevalence (0.05, <0.01) were also significant predictors. No significant effect was found for ODA for HIV or other independent variables.

The domestic public resources per person living with HIV in 2018 was US$184 in East and Southern Africa, US$50.6 in West and Central Africa, US$363 in Asia and the Pacific, US$209 in the Caribbean, US$659 in Easter Europe and central Asia, US$ 1406 in Latin America, and US$479 in Middle East and North Africa.

Domestic public spending has increased 70% between 2010 and 2018. In 2018, domestic resources (public and private) constituted 56% of the global AIDS resources; the majority of these being public funds. With the observed flat lining of international resources, sustained and efficient domestic public spending will be key in achieving fast-track targets to end AIDS by 2030.

There are still large gaps in donor dependency across geographies, for example while 95% of AIDS resources in Latin America come from domestic resources on the other extreme of dependency the share of domestic resources is 38% and 27% in West Central Africa and the Caribbean respectively.

CONCLUSIONS: The main determinants of domestic public spending for HIV are, as expected: ability to pay (GDP per capita), burden of disease (HIV prevalence) and ART coverage.

OAE0603

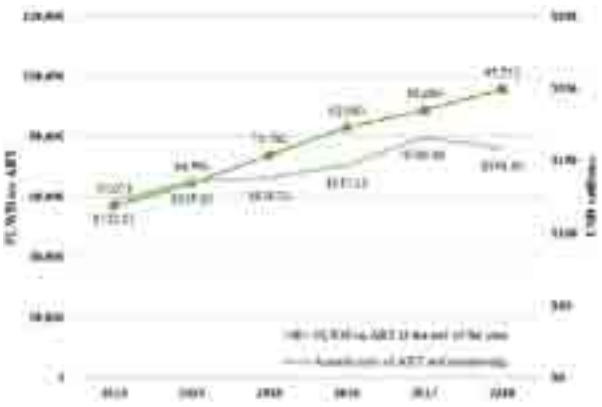
SCALING UP ANTIRETROVIRAL THERAPY IN A RESOURCE-LIMITED SETTING: MEXICO'S EXPERIENCE

M. Valenzuela-Lara[1], E. León-Juárez[2], P. Uribe-Zúñiga[3], C. Magis-Rodríguez[4]
[1]Emory University, Epidemiology, Atlanta, United States, [2]National Center for the Prevention and Control of HIV and AIDS (Censida), Mexico City, Mexico, [3]National Institute for Women (Inmujeres), Mexico City, Mexico, [4]Universidad Nacional Autónoma de México, Departamento de Salud Pública, Mexico City, Mexico

BACKGROUND: In 2013, the National Institute of Public Health of Mexico concluded that if the observed trends of antiretroviral therapy (ART) costs were maintained, and the number of people living with HIV (PLWH) on ART grew at the same observed rate, the current financial mechanisms in the Ministry of Health (MoH) would result insufficient by 2018. At the same time, evidence regarding the initiation of ART "as soon as possible" rapidly accumulated.

DESCRIPTION: As part of the national efforts to expand ART coverage and improve the optimal allocation of resources, the MoH implemented four key strategies: (1)a medical drug prescription monitoring group, which included the development and implementation of a prescription electronic algorithm according to the clinical guidelines, (2)encouraged competition among generic antiretroviral drug makers, (3)improved forecast accuracy and (4) data transparency.

LESSONS LEARNED: The prescription-monitoring group improve the quality of the prescription and allowed a more rational use of ART. The improvement of forecast accuracy and data transparency showed a more stable and attractive market which incentive competition. Finally, the number of available generic ARVs increase by 71% and achieved important savings. For example, the acquisition of efavirenz through a state-owned enterprise achieved a price reduction of 62% between 2014-2018; and the acquisition of the generics EFV/TDX/3TC and TDX/3TC, coformulations that were used in 74,188 of the 95,732 people on ART by the end of 2018, reached price reductions of 66 and 44%, resulting in savings of up to $68 million USD in 2019.



[Figure. Annual costs of ART and PLWH on ART in Mexico's Ministry of Health between 2013-2018]

CONCLUSIONS/NEXT STEPS: These strategies allowed a 68% increase in the number of people on ART between 2013-2018, while the expenditure only increased by 29%, generating savings of up to $125.4 million USD and contributing greatly to the sustainability of the universal access to ART program.

OAE0604

MAKING ARV MEDICINES AFFORDABLE: COMMUNITY ADVOCACY GOOD PRACTICE ON REDUCING ARV PRICE IN INDONESIA

A. Wardhana[1]
[1]*Indonesia AIDS Coalition, Jakarta, Indonesia*

BACKGROUND: Indonesia has an increasing HIV rate. Fueled by stigma and discrimination against the AIDS-affected population, the number of people living with human immunodeficiency virus (PLHIV) in the country is among the highest in the region. According to a government survey, roughly 640,000 people are living with HIV in Indonesia, with only 124,813 (19.49 percent) of them undergoing crucial antiretroviral (ARV) treatment. The country has the lowest antiretroviral therapy (ART) coverage in the region. Since 2004, ARV treatment has been given for free since the government provided full subsidies for ARV medicine procurement. However, due to the inefficiency of the procurement system, the price of ARV medicines procured by the government is among the highest in the world.

DESCRIPTION: A rational price structure analysis was developed in 2016, supported by many partners both nationally and internationally, to assess the cause of this exorbitant price as well as to recalculate the rational price. These findings, which was compiled into a briefing paper, was circulated widely to stakeholders. Several press conferences also were conducted to raise awareness on this issue to a broader society.

LESSONS LEARNED: During the MoH meeting in November 2019, it was decided that GoI will procure the ARV TLE by price of IDR 210.000 (UDS 15) per bottle. This price is 48% lower than the usual price. With total of 48.981 PLHIV consuming these packed regimens, the government will have an estimated IDR 114 billion of saving, which is roughly USD 8 million per year. This savings will be able to add 45.482 PLHIV on treatment, using the same regimen.

CONCLUSIONS/NEXT STEPS: The price reduction that resulted from the patient group's advocacy efforts by using price structure analysis is a certifiable success. This bold action should trigger more government measures to lower other ARV regimens' prices. This could be replicated with other medicines as well. IAC plan to replicate this success to analyse other medicines to ensure that medicines price for HIV and Tb cheaper thus can expand access to more people who need it.

OAE0605

INTRODUCING RESULT BASED FINANCING (RBF) MODEL TO SCALE UP OPIOID SUBSTITUTION THERAPY (OST) IN UKRAINE

Z. Islam[1], T. Prokhorova[1], V. Kolomiets[1], O. Masiuk[1], K. Shavchenko[1], N. Ivanova[1]
[1]*Alliance for Public Health, Treatment, Procurement and Supply Management, Kyiv, Ukraine*

BACKGROUND: Ukraine is implementing OST using methadone and buprenorphine since 2008 however, scale up and achieving national target for OST has been a challenge due to legal barriers and lack of motivation from the HCFs. Currently, only 4.2% of estimated PWID receives OST in Ukraine. Financial mechanism introduced under the health care reform in 2016 was an appropriate opportunity to introduce RBF model in order to scale up OST target in the country.

DESCRIPTION: RBF model within OST services is implemented under the modalities of direct contracting with 3 health care facilities and it aimed to improve access to OST for PWIDs by ensuring high quality services for clients; improve retention and introduce enhance monitoring mechanism for all OST services within new RBF model. Using incentivised monthly payments, simple billing system and direct contracting with the HCF for achieving target, has increased motivation of health care providers to scale up and improved retention in the program.

LESSONS LEARNED: 1038 OST patients were enrolled under the RBF service model from 2016 till 2019 in 3 different sites. The project selected 3 HCF sites similar to 3 RBF sites in terms of number of patients and the package of services provided. All results showed RBF-model indicators increased compared with HCF sites: patient's growth – by 16,4%, retention rate – by 24,1 %, number of patients on ART by 9,8%, retention rate of OST patients who received drugs within 7-10 days – by 17,5%.

Indicator	RBF model sites	Other HCFs	Difference between RBF model sites and Other HCFs
Number of patients as of 30.09.2016	751	660	
Number of patients as of 30.09.2019	1038	804	
Patient's enrollment growth	38,20%	21,80%	16,4%
Number of patients with HIV (as of 30.09.2019)	319	317	
Number of patients on ART (as of 30.09.2019)	316 (99,1%)	283 (89,3%)	9,8%
Percentage of OST patients who received drugs within 7-10 days (as of 30.09.2019)	711 (68,5%)	410 (51%)	17,5%
Retention rate of OST patients receiving treatment continuously for at least 6 months	74,10%	50,00%	24,1%

CONCLUSIONS/NEXT STEPS: While the payment for OST service provider is still under discussion and development of health care reform led by newly formed national health services, it is evident that a system of RBF method can be implemented within the government healthcare system of Ukraine. RBF is proven to improve attitudes of Head Doctors and representatives of oblast authorities towards acceptance and contributing to OST scale-up. RBF model should be implemented in all OST sites in Ukraine.

OAE0606

RESULTS FROM A PERFORMANCE-BASED FINANCING (PBF) PILOT TO INCENTIVIZE HIV CASE-FINDING AND VIRAL LOAD SAMPLE COLLECTION IN HAUT KATANGA IN THE DEMOCRATIC REPUBLIC OF THE CONGO (DRC)

D. Canagasabey[1], I. Thior[1], V. Cikobe[2], N. Meyer[1], J. Diarra[2], P. Kibwa[2], J.-C. Kiluba[2], L. Mueller Scott[1]
[1]PATH, Washington DC, United States, [2]PATH, Lubumbashi, Congo, Democratic Republic of the

BACKGROUND: In a time of stagnating international HIV/AIDS financing and increasingly ambitious targets to enable ending AIDS as a public health threat by 2030, identifying cost-effective and efficient financing methods is critical to ensure value for money and achieve more with available resources. Through the USAID-funded Integrated HIV/AIDS Project (IHAP), PATH piloted a PBF mechanism to incentivize efficient HIV case-finding and increase viral load sample collection.

DESCRIPTION: In October 2018, IHAP introduced a PBF mechanism across 106 project-supported health facilities in Haut Katanga Province. Instead of receiving 100% of monthly stipends regardless of site-level achievement against monthly targets, under the PBF mechanism, 40% of providers' monthly stipends were paid based on site-level achievement against select indicators, including:

- Number of newly diagnosed people living with HIV (PLHIV).
- Number of viral load samples collected and transported to laboratories for analysis.

Programmatic data was used to compare facility achievement in HIV testing, new PLHIV identified, testing yield, and viral load sample collection between the pre-pilot period (October 2017 through September 2018) and the pilot period (October 2018 through September 2019).

LESSONS LEARNED: Programmatic data showed an improvement in targeted indicators with the introduction of PBF. Incentivizing identification of HIV-positive individuals resulted in more efficient HIV testing, with less individuals tested but more PLHIV identified during the pilot period, leading to an increase in testing yield from 4.1% during the pre-pilot period to 5.6% during the pilot period. There was also a 52% increase in the number of viral load samples collected by facilities during the pilot period.

Indicators	Pre-pilot period (October 2017—September 2018)		Pilot period (October 2018—September 2019)	
	Mean	Median (Interquartile range)	Mean	Median (Interquartile range)
Number of people tested	40,587	40,897 (37,602 – 43,571)	37,705	36,300 (35,104–40,306)
Number of new PLHIV identified	1,674	1,648 (1,382–1,967)	2,127	2,006 (1,646 – 2,608)
Testing yield	4%	4% (3%-5%)	5%	5% (4%–6%)
Number of viral load samples collected	3,521	3,505 (2,647–4,395)	5,363	5,441 (4,588–6,138)

CONCLUSIONS/NEXT STEPS: Our analysis shows an improvement in HIV case-finding and viral load sample collection between the pre-pilot and pilot periods, suggesting that PBF positively affected facility achievement in targeted programmatic areas. Based on these results, IHAP is continuing implementation of PBF with project-supported facilities to incentivize behaviors to support the DRC achieve epidemic control.

OAE07 PREP-ING FOR SUCCESS: ADAPTATIONS FOR IMPROVING PREP UPTAKE

OAE0702

LOW PROPORTION AND RETENTION RATES AMONG THAI MEN WHO HAVE SEX WITH MEN USING EVENT DRIVEN PREP

T. Chinbunchorn[1], G. Pungpapong[1], O. Nampaisarn[1], S. Teerasakulpisal[1], S. Janyam[2], T. Sangprasert[3], P. Chanlearn[4], M. Avery[5], S. Mills[5], R. Vannakit[6], P. Phanuphak[1], N. Phanuphak[1], R. Ramautarsing[1]
[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Service Workers in Group, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Mplus, Chiang Mai, Thailand, [5]FHI360 and LINKAGES, Bangkok, Thailand, [6]Office of Publich Health, USAID Regional Development Mission Asia, Bangkok, Thailand

BACKGROUND: Men who have sex with men (MSM) can take oral pre-exposure prophylaxis (PrEP) either daily or event-driven (ED) to prevent HIV acquisition. However, ED-PrEP, defined as PrEP initiated 2-24 hours in advance of sex, uptake in Thailand has been low. We compared characteristics and retention of daily and ED-PrEP clients to profile the clients and their respective retention to PrEP.

METHODS: Data from June 2018 – June 2019 were analysed from Thailand's Princess PrEP program, which is implemented in 8 community based clinics. All MSM clients were offered the choice between ED and daily PrEP. Retention was determined at 1, 3 and 6 months after initiation. Effective use was defined as taking ED-PrEP as instructed, or taking more than 4 pills per week for daily PrEP.

RESULTS: 2,655 MSM clients initiated PrEP, 2,516 (94.8%) daily, 139 (5.2%) ED-PrEP. Median age was 30 years (IQR 25-35), 93.6% reported inconsistent condom use, 61.8% reported using any drugs including alcohol during sex. Reasons for choosing daily PrEP included: frequent sexual intercourse (36.6%), and not being able to predict or delay sexual intercourse (43.5%). Reasons for choosing ED-PrEP included: infrequent sexual intercourse (49.4%), being able to predict or delay sexual intercourse (32.8%), unwilling to take pills everyday (9.8%), and worried about side effects of daily PrEP (4.6%). Retention at Month 1, 3 and 6 was 31.6%, 35.2%, and 38.4%, respectively, for daily PrEP and 18.7%, 22.3%, and 23.7%, respectively, for ED-PrEP ($p<0.001$). During 3,830 daily PrEP visits, 1.5% reported taking < 4 pills/week, among them 0.6% reported inconsistent condom use. During 190 ED-PrEP visits, 5.3% reported taking ED-PrEP incorrectly during their sexual encounters, and 5.3% also reported condomless sex during those periods.

CONCLUSIONS: Low proportions of clients choose ED-PrEP and significantly lower retention rates compared to daily PrEP were observed. Clients who engage in condomless sex while incorrectly taking ED-PrEP should have counselled to understand potential risks. ED-PrEP knowledge distribution, emphasising retention and adherence, should occur concurrently with daily PrEP promotion as an alternative. Strategies such as technology-assisted pill reminder notifications should be explored to further facilitate ED-PrEP roll-out.

OAE0703

PREPTECH - INTEGRATION OF AN ON- AND OFF-LINE HOLISTIC PREP SOLUTION FOR YOUTH

R. Braun[1], B. Sheoran[1], L. Idelson[1], J. Lykens[1], J. Klausner[2]
[1]YTH Initiative, ETR, Oakland, United States, [2]UCLA, David Geffen School of Medicine and Fielding School of Public Health, Los Angeles, United States

BACKGROUND: In the United States, young men who have sex with men (YMSM) and transgender youth (TY) of color represent a high number of new HIV diagnoses annually. HIV pre-exposure prophylaxis (PrEP) is effective and acceptable to YMSM and TY of color; yet, PrEP uptake is low in those communities because of barriers including stigma, cost, adherence concerns, and medical distrust. PrEPTECH, a telehealth-based approach to PrEP initiation, may be a solution to those barriers.

DESCRIPTION: To pilot PrEPTECH, we enrolled 25 HIV-uninfected YMSM, aged 18–25 years, from San Francisco into a 180-day longitudinal study between November 2016 and May 2017. Participants received cost-free PrEP services through telehealth [i.e. telemedicine visits, home delivery of Truvada, and STI testing kits], except for 2 laboratory visits. Participants completed online survey assessments at 90 and 190 days querying PrEPTECH features and experiences, as well as PrEP adherence and stigma. The pilot demonstrated that PrEPTECH was confidential, fast, convenient, and easy to use, supporting participants to effectively access and maintain a PrEP regimen.

LESSONS LEARNED: Based on feedback from participants, we made several changes to the PrEPTECH platform to improve the user experience, and better reach key populations affected by HIV. We added an online pharmacy for PrEP distribution, in-home STI/HIV testing, and a telehealth platform to conveniently connect users to a PrEP provider. We also expanded the eligible participant definition to include TY [including but not limited to transgender men, transgender women, and gender non-conforming individuals], as well as increase the eligible age range to 15 through 27.

CONCLUSIONS/NEXT STEPS: Telehealth programs such as PrEPTECH can increase PrEP access for YMSM and TY of color by eliminating barriers inherent in traditional clinic-based models, support quick and convenient PrEP initiation, and transition users to a sustainable PrEP provider. Given promising pilot study findings, we are launching a multi-site randomized controlled trial to test the efficacy of PrEPTECH in enhancing PrEP uptake by comparing it to a knowledge-focused online website. We are also exploring opportunities to launch PrEPTECH in other countries most affected by HIV, including South Africa and India.

OAE0704

MONITORING CHARACTERISTICS OF EPISODIC HIV PRE-EXPOSURE PROPHYLAXIS (PREP) USE AMONG OVER 40,000 CLIENTS IN SUB-SAHARAN AFRICAN COUNTRIES PRESCRIBED DAILY ORAL PREP: INDEFINITE, CONTINUOUS USE NEITHER THE REALITY NOR THE GOAL

J. Reed[1], P. Shrestha[2], J. Mutegi[3], D. Were[3], A. Musau[3], B. Wakhutu[3], T. Chakare[4], A. Rozario[4], N.M. Nonyana[4], R. Manda[5], L. Maile[6], A. Christensen[7], J. Daud[7], B. Burure[7], R. Eakle[8,9], K. Curran[1], D. Mohan[2]
[1]Jhpiego an affiliate of Johns Hopkins University, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]Jhpiego, Nairobi, Kenya, [4]Jhpiego, Maseru, Lesotho, [5]USAID Lesotho, Maseru, Lesotho, [6]Lesotho Ministry of Health, Maseru, Lesotho, [7]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [8]United States Agency for International Development, Washington DC, United States, [9]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: Substantial drop-off rates of oral pre-exposure prophylaxis (PrEP) use within the first year are reported by many programs, which may be misconstrued as program failure. However, PrEP use may be non-continuous and still effective, since HIV risk fluctuates. Real-world PrEP use phenomena, like restarting and cyclical use, and the temporal characteristics of these use patterns are not well described.

METHODS: We analyzed demographic and clinical data routinely collected during client visits. A >14-day delay in returning for refill was defined as PrEP discontinuation. Clients resuming PrEP after discontinuation were deemed a restart. The initial start and subsequent restart(s) of PrEP defined the beginning of independent use cycle(s), with each continuing for as long as refills were obtained without delay. Using prescriptions as a proxy for actual use, we characterized duration on/off PrEP, and modeled the likelihood of spending time (in months) off PrEP using ordinal regression.

RESULTS: Through May 2019, Jhpiego-supported PrEP programs in Kenya, Lesotho, and Tanzania initiated 41,459 clients on a daily dosing (not event-driven) PrEP regimen. Among these, 10,809 (26.1%) discontinued and subsequently restarted PrEP at least once, with 20.7%, 27.5%, and 51.8% remaining off of PrEP for <30, 30-60, and 61+ days, respectively. The median days' duration of use for the first vs. subsequent use cycle(s) was 222 days. With each increase in cycle number, clients were 12.5% (11.1-14.8), 45.8%(26.4-60.1) and 24.1%(7.6-37.6) less likely to stay off PrEP for an extra month, in Kenya, Tanzania, and Lesotho programs, respectively. Females 15-24 yrs were 40.1% and 57.2% less likely to stay off PrEP for an extra month than the general population in Kenya and Lesotho, respectively.

CONCLUSIONS: PrEP users frequently cycle on and off PrEP, which may effectively protect them against HIV risk that is periodic. While duration of use didn't increase with cycle number, the duration spent off PrEP did decrease in all countries with subsequent use cycles, suggesting normalization of use with experience, particularly by young women. With the likely introduction of event-driven PrEP on the horizon, more nuanced measures of use are needed if successful use of PrEP is to be meaningfully distinguished from HIV treatment.

OAE0705

ORAL PRE-EXPOSURE PROPHYLAXIS (PREP) AND FAMILY PLANNING (FP) INTEGRATION TO IMPROVE PREP CONTINUATION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN (AGYW) IN KENYA

D. Were[1], A. Musau[1], P. Ongwen[1], M. Strachan[2]
[1]Jhpiego, Nairobi, Kenya, [2]Jhpiego, Baltimore, United States

BACKGROUND: Despite steady progress in uptake among AGYW, PrEP continuation remains a significant challenge in Kenya, with majority of the new PrEP initiates discontinuing their PrEP use within the first month. This study analyses PrEP continuation outcomes among AGYW within the context of integrated PrEP and FP delivery.

DESCRIPTION: Jilinde, a four-year PrEP scale-up project in Kenya, delivers PrEP for AGYW in Migori County through twelve sites that include public and private health facilities, drop in centers and community safe spaces. Demand creation for PrEP is conducted by peer educators at the community and AGYW referred to the diverse service delivery points for uptake and follow-up monitoring. PrEP is provided as part of integrated services that includes pregnancy and HIV prevention interventions. PrEP and FP counselling and services are offered concomitantly by the same provider during the same session, while follow-up services are synchronized.

LESSONS LEARNED: Overall, 2662 AGYW initiated PrEP between May 2017 to November 2019, of these 991 (37%) revisited at month-one. Further, there was an upward increase of FP uptake from 53 PrEP clients in 2017 to 618 in 2019, contributed by increasing PrEP uptake. Although continuation remained a consistent challenge, Jilinde observed slightly better month-one continuation rates among AGYW who concurrently initiated both PrEP and FP (39.4%), compared to AGYW who only initiated PrEP (36.2%). Routine service delivery data from Jilinde elucidates that AGYW using FP, compared to those who don't, have lower odds of discontinuation at month 1 (OR 0.71(0.53-0.93), (p=0.01) and similarly lower odds at month 3 (OR 0.55 (0.30-0.98), (p=0.04). This suggests that delivering PrEP combined with FP to AGYW might be working synergistically to improve persistence for both interventions.

CONCLUSIONS/NEXT STEPS: AGYW demonstrate an appetite for PrEP, but struggle with persistence. When PrEP is paired with FP, there is promise for better persistence compared to PrEP offered alone. These findings suggest that pairing biomedical HIV prevention interventions such as PrEP with sexual and reproductive health services has the potential to optimize continuation outcomes, but warrants further investigation.

OAE0706

THE USE OF COMMUNITY-BASED APPROACH AND TELEMEDICINE AS AN ALTERNATIVE OPTION IN PROVIDING HIV PRE-EXPOSURE PROPHYLAXIS IN THE PHILIPPINES

J.D. Rosadiño[1], J. Gonzales[1], J.O. Corciega[1], R. Pagtakhan[1], C. Lagman[1]
[1]LoveYourself, Inc., Manila, Philippines

BACKGROUND: The World Health Organization recommended the use of PrEP in addition to other prevention methods may be an option to halt and reverse the HIV epidemic in the Philippines. However, roll-out efforts and scaling up PrEP use remains low because of various barriers. This results in very few facilities offering PrEP. Learning from the experiences from its demonstration project, LoveYourself, in this project, aims to offer PrEP in various locations in the country through an alternative method of service delivery: community-based approach and telemedicine.

DESCRIPTION: LoveYourself has partnered with Hi-Precision Diagnostics, a medical diagnostics facility with over 50 branches all over the Philippines, in order to provide other access points of all the diagnostic tests needed in order to access PrEP. A client goes to a Hi-Precision facility, and access tests for HIV, Hepatitis B, Syphilis, and serum creatinine. Once done, the results will be sent directly to LoveYourself. LoveYourself then schedules a telemedicine session with the client in order to provide: a consultation with a physician, and PrEP coaching session with a trained LoveYourself volunteer. The coaching sessions include information about PrEP, such as uptake, adherence, and side-effects management. It also includes counseling for HIV, STI, and sexual health management. After the session, the PrEP is delivered to the client via courier, with options for both door-to-door delivery and pick-up at delivery points.

LESSONS LEARNED: The partnership of LoveYourself and Hi-Precision effectively adds over 50 access points of PrEP in the Philippines. About 14.1% of people who expressed interest to obtain PrEP via LoveYourself channels have expressed to get it via this process. The clients who have accessed this process have also provided their feedback on how to further improve this process. This process has also provided ways for people who want to access PrEP conveniently, especially to some clients who prefer to access PrEP discreetly.

CONCLUSIONS/NEXT STEPS: While the project aims to effectively offer multiple access points for PrEP in the Philippines, this process has also provided a new avenue for the community to access PrEP in a convenient way. Futher promotions are needed to make more people aware of this process.

LEADING FROM THE COMMUNITY: HOW KEY POPULATION ORGANIZATIONS IN VIETNAM TRANSFORMED FROM PEER SUPPORT GROUPS TO CLINICAL SERVICE PROVIDERS

B. Vu[1], T. Le[2], S. Le[3], P. Nguyen[4], H. Vu[5], D. Nguyen[6], K. Green[1], H. Phan[7], H. Ngo[1], A. Doan[1], T. Tran[1], G. Ha[1], A. Tran[1], T. Nguyen[8], L. Hang[8], T. Ngo[9], P. Tran[8], H. Nguyen[1], T. Phan[1], B. Nguyen[1], H. Van[10], L. La[11], G. Nguyen[12]
[1]PATH, HIV/TB, Hanoi, Vietnam, [2]Glink Social Enterprise, Ho Chi Minh City, Vietnam, [3]G3VN Social Enterprise, Ho Chi Minh City, Vietnam, [4]Blue Sky Social Enterprise, Ho Chi Minh City, Vietnam, [5]Vietnam MSM-TG Community Social Enterprise, Hanoi, Vietnam, [6]Green Trust Community-Based Organization, Hanoi, Vietnam, [7]Vietnam Administration for HIV/AIDS Control, Hanoi, Vietnam, [8]LIFE Center, Ho Chi Minh City, Vietnam, [9]USAID, Hanoi, Vietnam, [10]Ho Chi Minh City Center for Disease Control, Ho Chi Minh City, Vietnam, [11]Hanoi Center for Disease Control, Hanoi, Vietnam, [12]Dong Nai Center for Disease Control, Dong Nai, Vietnam

BACKGROUND: Reaching the last mile to achieve 95-95-95 and the goal of ending AIDS by 2030 requires breakthrough approaches. Key population (KP) leaders, government authorities and US-

AID/PATH Healthy Markets (HM) partnered to pilot and scale up KP–led HIV services as an critical way to increase reach and service uptake in Vietnam.

DESCRIPTION: Four key steps were employed to introduce and scale-up KP-led HIV services in Vietnam from late 2015 onward:
1) KP community-based organizations (CBOs) were enabled for the first time to pilot and then scale HIV lay and self-testing;
2) KP delivery of assisted partner notification services;
3) registration of first-ever KP owned and led clinics offering HIV and other health services; and
4) launching PrEP services.
The scope of KP-led HIV services expanded along with the transformation of KP groups from self-help groups to CBOs and social enterprises. In parallel, HM advocated for policy change by engaging the Ministry of Health (MOH) to endorse pilots, develop national guidelines, and amending regulations to facilitate nationwide scale-up.

LESSONS LEARNED: KP-led lay HIV testing reached first-time and infrequent testers and yielded high HIV-positive results. From Dec 2015 to Sept 2019, HM tested 124,285 clients through lay testing, 11,450 clients through self-testing, and 15,961 sexual and injecting partners through index testing, with HIV-positivity rates of 4.6%, 6%, and 9.2%, and antiretroviral therapy initiation of 94.8%, 94.1%, and 99.4%, respectively. KPs preferred PrEP services delivered by KP-led organizations. Among 3,631 PrEP users from Mar 2017 to Sept 2019, KP-led private clinics enrolled the majority of the users (81.4%). Promising pilot results served as a powerful tool for policy advocacy. As a result, Vietnam MOH approved national guidelines and nationwide scale-up plans for community HIV testing in 33 provinces and PrEP in 26 provinces out of 63 province of the country.

CONCLUSIONS/NEXT STEPS: KP-led HIV services are feasible, acceptable, and preferable by KPs and are therefore a critical addition to accelerating attainment of 95-95-95 and ending AIDS goals in Vietnam. KP-led HIV services has now been integrated as an essential part of the national action plan and national ending AIDS by 2030 strategy.

OAE0803

SCALING UP A LAY COUNSELOR-DELIVERED TRANSDIAGNOSTIC MENTAL HEALTH INTERVENTION (CETA) TO IMPROVE THE HIV CARE CASCADE IN SOFALA, MOZAMBIQUE

W. Hammett[1,2], A. Muanido[3], V. Cumbe[4,5], C. Mukunta[3], N. Manaca[3], L. Hicks[2], S. Dorsey[6], B. Wagenaar[1,2,7]
[1]University of Washington, Department of Global Health, Seattle, United States, [2]Health Alliance International, Seattle, United States, [3]Health Alliance International, Beira, Mozambique, [4]Sofala Provincial Health Directorate, Ministry of Health, Department of Mental Health, Beira, Mozambique, [5]Eduardo Mondlane University, Faculty of Medicine, Maputo, Mozambique, [6]University of Washington, Department of Psychology and Behavioral Sciences, Seattle, United States, [7]University of Washington, Department of Epidemiology, Seattle, United States

BACKGROUND: Evidence shows that common mental illnesses are associated with poor HIV treatment outcomes and that lay-counselor-delivered mental health therapies can improve symptoms of common mental illness among HIV+ patients in low- and middle-income countries (LMICs). Yet, few LMICs have scaled-up lay-counselor-delivered therapies for HIV+ patients, and few studies have shown that such therapies can improve the HIV care cascade. The present study examined the scale-up of a lay-counselor-delivered psychological therapy (CETA) delivered in routine HIV care and its effect on mental health symptoms and HIV care cascade outcomes in Mozambique.

DESCRIPTION: CETA was integrated into routine public HIV care in five high-flow urban facilities in Beira City, Sofala, Mozambique. Beginning in May 2019, all newly-diagnosed adult (18+) HIV+ patients were screened for common mental illness and those with clinically-significant symptoms were offered weekly individual psychological therapy sessions. Mental symptoms were tracked at each visit and HIV care cascade outcomes were collected for CETA patients and compared with facility averages.

LESSONS LEARNED: 59% (148/250) of newly-diagnosed HIV+ patients showed clinically-significant mental symptoms and 16% (20/127) had suicidal ideation. Mental health symptoms of CETA-enrolled patients decreased 56% after 4 sessions and 90% after 6 sessions; suicidal ideation decreased to 0% after 4 sessions. The combined rate of ART initiation among CETA participants was 98%. Among CETA patients attending 2 or more sessions, the ART initiation rate was 100%. One-month retention among CETA participants was 69%, compared to the combined one-month retention rate of 60% for all HIV+ patients (those offered CETA + those not offered CETA). Three-month retention among CETA patients was 83%, compared to 64% among all HIV+ patients.

CONCLUSIONS/NEXT STEPS: Over 50% of newly-diagnosed HIV+ patients in Mozambique suffer from clinically-significant mental health symptoms and over 15% experience suicidal ideation. After 4 CETA sessions, mental health symptoms decreased over 50% and suicidal ideation decreased 100%. Compared to all HIV+ patients, CETA-enrolled patients had 9% higher one-month retention in HIV care (69%) and 19% higher three-month HIV retention (83%). CETA is a promising approach to reduce symptoms of common mental illness among HIV+ patients and improve HIV care cascade outcomes in areas with high HIV prevalence.

OAE0804

NURSE PRACTITIONER-LED MDR-TB/HIV TREATMENT MAY OFFER A SAFE APPROACH TO IMPROVE ACCESS TO CARE: RESULTS FROM A LONGITUDINAL COHORT IN KWA ZULU-NATAL, SOUTH AFRICA

J.E. Farley[1], O. Heidari[1], P.D. Stamper[1], K. Lowensen[1], C. Budhathoki[1], N. Ndjeka[2]
[1]Johns Hopkins University School of Nursing, The REACH Initiative, Baltimore, United States, [2]National Department of Health South Africa, Drug Resistant TB Program, Pretoria, South Africa

BACKGROUND: Tuberculosis (TB) remains the leading cause of death among people living with HIV, with multidrug resistant (MDR) TB worsening outcomes. Delays in linkage to treatment and availability of a competent clinician are contributing factors. Nurse-led models are proven effective in both TB and HIV programs, yet evidence of safety and treatment outcomes are limited in MDR-TB/HIV populations.

METHODS: We evaluated a longitudinal cohort treated by clinical nurse practitioners (CNPs) between 2016 and 2018 from two MDR-TB outpatient clinics in Kwa Zulu-Natal, South Africa. The cohort was nested within a cluster randomized trial evaluating case management for MDR-TB patients. The CNPs were experienced in HIV management before hire and received a nationally accredited,

one-week, MDR-TB training plus a one-month supervised treatment period. After training, medical officers were available for consultation and referral, but did not complete routine audits. A standardized, five-drug, weight-based, MDR-TB regimen was utilized per South African guidelines. Descriptive and univariate statistics were used to compare treatment success to a composite negative outcome (loss to follow-up, death or treatment failure).

RESULTS: CNPs treated 120 (22%) of the 546 participants enrolled at the two sites. These participants were male (55.8%) with a median age of 35.3 years (IQR: 28.9-42.1) and a median BMI of 20.1 (IQR 17.9-23.0). The majority were living with HIV (75.8%) with a median CD4 count of 233 (IQR=111.5-409), with 55% on ART at baseline. MDR-TB treatment success occurred in 70% of CNP (84/120) patients. A negative outcome was associated with being: male (41.8% vs 15.4%, p=0.002); older (39.6 years vs 33.2 years, p=0.003); and having a lower BMI (18.8 vs 20.8, p=0.004). HIV status did not significantly impact outcome. A drug-by-drug prescription review demonstrated excellent guideline adherence. A single drug was documented to be under the recommended dose in 49/1200 (4.1%) prescriptions and only one patient had a single drug (<1%) prescribed over the recommended dosing.

CONCLUSIONS: Treatment success in this cohort was better than both South African and WHO estimates for the same period. CNP adherence to weight-based dosing was high. CNP-led treatment programs may offer a safe approach to improve access to care without compromising outcomes.

OAE0805

NURSES AND OUTREACH WORKERS ARE IMPORTANT BUT UNDERVALUED CARE PROVIDERS IN HIV CARE AND HARM REDUCTION PROGRAMS IN KAZAKHSTAN

S. Primbetova[1], T. Hunt[2], T. McCrimmon[2], M. Darisheva[1], A. Terlikbayeva[1], P. Gulyaev[1], A. Kuskulov[1], Y. Rozental[1], D. Bekishev[1], L. Gilbert[2], E. Wu[2], G. Mergenova[1], D.A. Goddard-Eckrich[2], N. El-Bassel[2]
[1]Global Health Research Center of Central Asia, Almaty, Kazakhstan, [2]Columbia University, School of Social Work, New York, United States

BACKGROUND: In Kazakhstan nurses and outreach workers in primary health care are one of the largest providers of HIV services and harm reduction programs to key populations. For this NIDA-funded Implementation research study (Bridge), we examined syringe exchange program (SEP) workers' roles in HIV care, job climate, level of job demands and satisfaction, training needs, and ability to perform their job on HIV care in SEPs.

METHODS: Structured surveys were conducted with 24 nurses and 44 outreach workers (OW) employed in 24 trust points - SEPs in 4 cities of Kazakhstan: Almaty (n=25), Shymkent (n=21), Karaganda (n=12), Temirtau (n=10). Surveys included sociodemographics, organizational readiness to change assessment (ORCA) RAPHIS and TCU Survey of Organizational Functioning. Descriptive analyses were conducted and data was collected using a tablet assigned to respondents.

RESULTS: Results indicate that the major motivation to work was to help people who use drugs (80.88%); however, 32.84% felt like they weren't making any differences and 19.41% felt organizational structure and procedures at work were a barrier. Respondents complained on limited resources: lack of computers (58.21%), human resources (28.36%), inadequate office and supplies (35.82%), staff turnover (31.35%). Participants expressed a tremendous need for training in assessing clients' needs (67.16%), increasing clients' participation in treatment (77.61%), and improving rapport with clients (62.68%). Respondents perceived they were not efficient enough due to security (22.39%), too slow in making changes (34.33%), stress and strain (23.89%), pressure (29.85%) and heavy workload (32.83%) that reduces program effectiveness.

CONCLUSIONS: In order to improve HIV testing and treatment cascade among PWID, nurses and outreach workers in SEPs need to be engaged in HIV linkage to care and treatment adherence services. There are two main issues they face at the trust points: organizational and individual. Staff reported that they are undervalued for their demanding and important job, underpaid, experience lack of training on how to work with PWID living with HIV, rapid HIV testing, linkage to care and HIV treatment. Additional training on HIV care, institutional changes and better funding will improve nurses and outreach workers level of job satisfaction and decrease job demands and improve treatment outcomes among PWID.

OAE0806

INFORMAL PROVIDERS CAN INCREASE UPTAKE OF HIV TESTING AMONG ADULTS OF UNKNOWN SEROSTATUS: RESULTS FROM A CLUSTER RANDOMIZED PILOT STUDY IN SOUTHWESTERN UGANDA

R. Sundararajan[1], D. Nabukalu[2], R. King[3], J. Mwanga-Amumpaire[2]
[1]Weill Cornell Medicine, New York, United States, [2]Mbarara University of Science and Technology, Mbarara, Uganda, [3]University of California, San Francisco, United States

BACKGROUND: Human immunodeficiency virus (HIV) infection and transmission continue unabated, despite biomedical advances in prevention, diagnosis, and treatment. In low resource settings, such as rural Uganda, a major barrier to epidemic control is poor engagement with HIV testing. Lack of HIV testing uptake has been attributed to frequent use of informal healthcare providers, such as traditional healers, who do not routinely discuss or offer HIV testing.

METHODS: We conducted a cluster randomized trial in southwestern Uganda in August 2019-January 2020. Traditional healers were randomized to offer point-of-care HIV testing (Oraquick©) with pre- and post-test counseling (n = 9 clusters) versus protocolized usual care (n = 8 clusters). Usual care entailed offering HIV education with referral to existing clinic-based testing services. Adults receiving care from participating healers were eligible for participation if sexually active and reported not receiving an HIV test within the prior 12 months. The primary outcome was receipt of an HIV test within 90 days of study enrollment. We conducted qualitative interviews with key informants at 90 days follow-up to gather contextual information regarding outcomes.

RESULTS: 433 participants were enrolled (intervention = 250, control = 183). Participant age, income and gender were similar among study arms. HIV testing was received significantly more often among participants treated by traditional healers randomized to the intervention group (100% vs 17%, adjusted risk ratio 5.90, 95% CI 4.3-8.1, p<0.01).

Ten (4%) participants in the intervention arm were newly diagnosed as HIV-infected, compared to no participants in the control arm (p=0.02). Four of these 10 HIV-positive participants linked to HIV care within 90 days of enrollment. Intervention participants

described the testing program as highly acceptable. Participants in the control arm reported lack of funds and time to travel to the biomedical clinic as primary barriers to HIV testing.

CONCLUSIONS: Informal providers, such as traditional healers, can effectively increase uptake of HIV testing in endemic regions. Our novel approach holds promise to identify HIV-infected adults in communities where conventional biomedical outreach has limited impact. Further work is needed to understand low rates of linkage to care among newly diagnosed HIV-infected participants.

OAF01 DEMYSTIFYING DATA: METHODOLOGIES AND MONITORING FOR EVIDENCE-BASED APPROACHES

OAF0102

MAINTAINING EPIDEMIC CONTROL IN NAMIBIA: DESIGNING THE OPTIMAL PACKAGE. LESSONS FROM ACS SUPPORT TO THE NAMIBIAN GOVERNMENT

E. Owino[1], C. Jones[2]
[1]University of Nairobi, Nairobi, Kenya, [2]University of Nambia, Windhoek, Namibia

BACKGROUND: Namibia has achieved 94% of people living with HIV knowing their status, 96% of those HIV-positive persons were on ART and 95% of those have achieved viral suppression (by 2019). The Namibian Government wanted to develop a priority package of services for epidemic control, the process was driven by the reducing donor funding.

DESCRIPTION: From August to December 2019, the African Collaborative for Health Financing Solutions' (ACS) supported the Ministry of Health to work through the 10-step process suggested by Glassman et al (2016) to devise a package of HIV/AIDS services for epidemic control. Semi-structured interviews were conducted with 40 stakeholders critical to the HIV/AIDS response in Namibia to map existing HIV/AIDS-related interventions and identify the services needed to maintain epidemic control. Through a very collaborative process, ACS facilitated the agreement of the goal of the package of services, the definition of selection criteria, the shaping of package options based on the country epidemiological profile, and the determination of priority services.

LESSONS LEARNED: By the end of the process, we identified that:

1) A political economy analysis is critical to understand the role of all stakeholders involved in HIV/AIDS interventions to ensure a balanced consensus on the priority services.

2) Openness and regular communication among civil society, academia, government agencies and development partners were the critical catalyzers of the process.

3) Clarification and country-specific adaptation of the terminologies (such as epidemic control, fast tracking, critical vs noncritical) is essential at the outset of the process given the sensitivity regarding the Namibian context.

4) The engagement of local political networks and technical stakeholders from the beginning was instrumental to mobilize necessary resources to sustain the prioritization process.

CONCLUSIONS/NEXT STEPS: An inclusive stakeholders' engagement not only provides sound knowledge, critical thinking and hand-on-experience, but it serves as a vital ingredient to secure country ownership and therefore improving sustainability. As Namibia is one of the pioneers in developing an HIV epidemic-maintenance package, the lessons learned on its experience, especially those related to the drivers of an effective process, should be of inspiration for countries that have similar context or want to go through similar approach.

OAF0103

PROGRAMS SHAPING POLICIES: HOW PARTNERSHIPS AND PROGRAM DATA WERE USED TO TRANSFORM THE POLICY ENVIRONMENT FOR KEY POPULATIONS

R. Wilcher[1], R. Dayton[1], H. Mahler[1]
[1]FHI 360, HIV, Durham, United States

BACKGROUND: Since 2014, the USAID/PEPFAR-supported LINKAGES project led by FHI 360 has delivered HIV services to key populations (KPs)—female sex workers, men who have sex with men, people who inject drugs, and transgender people—in more than 30 countries. Throughout the project, LINKAGES forged partnerships and used program data to advocate for policy changes that increase KPs' access to HIV services.

DESCRIPTION: LINKAGES was characterized by strategic partnerships with host-country governments and funders, a focus on KP community-led services, and the use of data to understand and improve program performance. This approach created meaningful opportunities for KP members to have their voices heard, and for project staff and local partners to advocate with government stakeholders and country representatives from Global Fund and PEPFAR for supportive policies to engage KPs in services across the cascade.

LESSONS LEARNED: LINKAGES contributed to enabling policy environments in 22 countries. In each, LINKAGES facilitated updates to national HIV and/or STI policies and guidelines to better address the needs of, and incorporate evidence-based recommendations for, KPs. In 20 countries, LINKAGES program data showing the effectiveness of interventions, including the enhanced peer outreach approach, HIV self-testing, index testing, and peer navigation, led to endorsement of these approaches in government strategies, PEPFAR country operational plans, or Global Fund grants. In 13 countries, LINKAGES removed policy barriers to KP service uptake. For example, in Botswana, Kenya, Malawi, and Lesotho, LINKAGES increased treatment initiation by gaining government approval for antiretroviral therapy provision at KP-led drop-in-centers. LINKAGES also influenced policy-level processes by forming national KP technical working groups (nine countries), strengthening national data systems to include KP-specific data (19 countries), and mobilizing domestic resources for KP services (six countries). In Angola, Botswana, and Malawi, LINKAGES contributed to successful KP decriminalization efforts.

CONCLUSIONS/NEXT STEPS: By leveraging the project's routine data, working closely with local decision-makers, and amplifying KP voices, LINKAGES contributed to policy environments that enabled successful HIV programming, including in criminalized settings. These policy changes not only resulted in immediate improvements in service uptake but are also likely to have a sustained impact on epidemic control efforts and KP individuals' quality of life.

OAF0104

GREATER INVOLVEMENT OF PEOPLE LIVING WITH HIV IN RESEARCH: THE EXPERIENCE OF THE REGIONAL STUDY ON VIOLENCE AND WOMEN LIVING WITH HIV IN LATIN AMERICA

M. Negrete[1], D. Luciano[2], A. Cano[3], M. Iacono[4], M.J. Vazquez[5], F. Hale[6], J. Salas[7], M. Alvarez[8], M. Arends[9], N. Sanchez[4], M. Cabezas[10], B. Chete[11], G. Flores[12], F. Garcia[13], M.L. Herreira[14], L. Lopez[15], B. Ramirez[16]
[1]Development Connections, Research, Asuncion, Paraguay, [2]Development Connections, Washington, United States, [3]ICW Latina, General Secretariat, Managua, Nicaragua, [4]ICW Latina, Regional Coordination, Managua, Nicaragua, [5]Salamander Trust, Research, Barcelona, Spain, [6]Salamander Trust, London, United Kingdom, [7]HIVOS, Monitoring and Evaluation, Mexico DF, Mexico, [8]HIVOS, Advocacy, San Jose, Costa Rica, [9]HIVOS, Program Development, San Jose, Costa Rica, [10]ICW Latina, Country Representative, Cochabamba, Bolivia, [11]ICW Latina, Country Representative, Guatemala, Guatemala, [12]ICW Latina, Country Representative, Lima, Peru, [13]ICW Latina, Country Representative, Santo Domingo, Dominican Republic, [14]ICW Latina, Country Representative, Asunción, Paraguay, [15]ICW Latina, Country Representative, Cali, Colombia, [16]ICW Latina, Country Representative, Tegucigalpa, Honduras

BACKGROUND: The Regional Study on Violence and Women Living with HIV (WLHIV) in Latin America carried out by ICW Latina, Hivos, Development Connections and Salamander Trust in 2018, followed the GIPA principle. We documented WLHIV participation using the following criteria: knowledge and skills used, skills development, autonomy of decision-making, and ownership.

DESCRIPTION: 1) Design and preparation of the Study. The Study methodology and data collection tools were discussed with ICW Latina representatives from 15 countries in a regional meeting. Using their insights, concepts and operational definitions were revised including types of intimate partner relationships, partners' controlling behaviours and types of violence: emotional, economic, related to activism, perpetrated by State agents and organized crime.

2) Implementation. The representatives of ICW Latina in the 7 selected countries (Bolivia, Colombia, Dominican Republic, Guatemala, Honduras, Paraguay and Peru) participated in a five-week online course on research protocol and piloting the questionnaire. They coordinated the country study including: selecting and training the research team, budget management, interinstitutional planning for participants' recruitment, submitting the protocol to Ethical Committees (Dominican Republic, Guatemala), planning and supervising field work, and overseeing the adherence to ethical guidelines. The regional research team provided technical support throughout this phase.

LESSONS LEARNED: a) The involvement of 37 WLHIV ensured the quality of the study's, developed their skills for conducting research and strengthened interinstitutional alliances. The findings were used to design Regional Guidelines for Addressing Violence Against WLHIV; b) Fostering ownership led to a greater use of the findings for policy/program development, advocacy, and capacity building at country level. The study and guidelines are being disseminated through webinars, conferences, social media, websites, @bulletins. Advocacy materials and local adaptation of the regional guidelines were developed in Guatemala, and a proposal for capacity building in Paraguay; c) It is critical to include emotional support and referrals to services for the field researchers.

CONCLUSIONS/NEXT STEPS: Advocacy, dissemination and interinstitutional collaboration will continue aiming to translate the study into action. Activities will be integrated into the national plans of the 3-year (2019-2022) regional project ALEP coordinated by Hivos.

OAF0105

IS PRE-EXPOSURE PROPHYLAXIS SUITABLE FOR FILIPINO CIS-WOMEN? A REVIEW OF LITERATURE, POLICIES, AND CLINICAL GUIDELINES TO INTRODUCE PREP AS A REPRODUCTIVE HEALTH SERVICE FOR CIS-WOMEN IN THE PHILIPPINES

R.S. Regner[1], P. Eustaquio[1], J.D. Rosadiño[2], R. Llauderes[2], L. Yarcia[3], A. Bandola[4]
[1]Love Yourself Inc., Mandaluyong, Philippines, [2]Love Yourself, Mandaluyong, Philippines, [3]HIV-AIDS Support House, Quezon, Philippines, [4]University of the Philippines, General Hospital, Obstetrics and Gynecology Infectious Diseases, Manila, Philippines

BACKGROUND: There has been a focus on HIV prevention for men who have sex with men (MSM) and transgender women (TGW) in the Philippines notwithstanding the three-fold increase in new infection among cis-women in the past 5 years. Among all the cis-women cases, 90% are of reproductive-age upon diagnosis. Cis-women are less likely considered for HIV prevention measures considering that present epidemiologic data reflect TGW and MSM as priority populations for HIV and AIDS interventions. Thus, prevention opportunities for cis-women are limited. The objective of this study was to appraise policies and guidelines that would provide more options for prevention for cis-women.

METHODS: The legal and medical framework for reproductive health services cis-women was appraised through law and policy review and medical literature search to determine availability and accessibility to PrEP for Filipino cis-women.

RESULTS: Only the Reproductive Health Act of 2012 and HIV/AIDS Policy of 2018 ensure HIV-prevention services. Among currently available RH services, only screening and male-condoms function as HIV prevention. Surveys done among sexually active, reproductive-aged, unmarried cis-women consistently show majority (52-62%) knew that male-condoms decrease HIV-transmission yet there is low-uptake (3-9%). 62-72% of female sex workers (FSW) do not use male-condom due to partner objection. Aside from FSW to whom HIV screening is encouraged, studies show low uptake of HIV screening among cis-women (3%). Neither PrEP nor PEP is included in the local STI guidelines for pregnant women. These are consistent with one systematic review of literature on HIV prevention strategies in Filipino cis-women which revealed fixation of literature to no other biomedical strategy but male-condom usage.

CONCLUSIONS: A concentrated epidemic may lead to lapses in service delivery, neglecting those who are not considered high-risk. Given acceptable knowledge yet low uptake of male-condom and HIV screening demands further studies to analyze this disparity and efforts to increase the uptake. In addition, the inclusion of PrEP as another option is both promising and empowering. Although WHO recommendation suggests PrEP provision among high-risk groups, it also emphasized provision to those who desire it. Its integration into RH-service may ensure government-stewardship, financial-sustainability, and access through the community-based service delivery model.

OAF0106

HARMONIZATION OF THE LEGAL ENVIRONMENT ON ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH AND RIGHTS IN EAST AND SOUTHERN AFRICA

R. Tallarico[1]
[1]*UNFPA, East and Southern Africa Regional Office, Johannesburg, South Africa*

BACKGROUND: The aim of the study commissioned by UNFPA and condcuted by the University of Pretoria was to assess the progress in laws, policies and other related sources that directly or indirectly either impede or enable ASRHR. The study measures the legal provisions of the East and Southern Africa countries against the international, continental and regional treaties and commitments.

METHODS: The legal review was conducted through a detailed perusal of various laws and policies in 23 ESA countries, as well as through the study of other sources that set out the legal environment for ASRHR in the relevant countries. The legislative and policy provisions that impact on ASRHR are varied and the desktop review identified 10 themes of relevant laws and policies to guide the assessment.

RESULTS: The study captured a number of relevant findings negatively impacting on ASRHR. To mention a few:

- All ESA countries do not have clear provisions that set the minimum age of consent to sexual activity in legislation.
- All 23 countries have set ages of consent to marriage. However, there is disharmony between the legislative provisions and the international standards; and between statutory and customary law provisions.
- The ages of consent to access HIV services are in the majority of the countries not provided for in laws; in some countries, however, the ages are provided for in policies.
- Sexual diversity is not recognized in the majority of the ESA countries and this is evident from legislative provisions that still criminalize sexual activity between men (variously referred to as acts against the order of nature, or unnatural acts).
- Although the majority of the ESA countries have provisions in their diverse policies indicating that CSE is key and should be implemented, only a handful appear to have CSE curricula in schools aligned to the international standards.

CONCLUSIONS: A particular challenge in the region is the coexistence of customary law, religious law and civil law. The harmonization of provisions directly influencing ASRHR must ensure that contradictions between laws and policies are removed, and that the amended law is infused with the rights-based approach evident in the many of the policies.

OAF02: EQUAL BEFORE THE LAW: EFFECTIVE STRATEGIES TO PROTECT HUMAN RIGHTS

OAF0202

PROGRESS TOWARDS 90-90-90 TARGETS IN CANADIAN CORRECTIONAL FACILITIES, 2019

J. Smith[1], K. Meghnath[1], O. Varsaneux[1], E. Kom[1]
[1]*Correctional Services Canada, Ottawa, Canada*

BACKGROUND: In support of global targets established by the Joint United Nations Programme on HIV/AIDS (UNAIDS), Correctional Service of Canada (CSC) has compiled 90-90-90 estimates for the federal inmate population for 2019.

METHODS: Federal inmates are offered voluntary HIV testing on admission and throughout incarceration. Data collected from CSC's enhanced surveillance system were analyzed to estimate the proportion of inmates in federal custody as of December 2019 that were aware of their HIV status, on treatment, and virally suppressed (< 250 copies/ml). Results were stratified by Indigenous status and gender.

RESULTS: In 2019, the HIV prevalence amongst federal inmates was estimated to be 0.95%, and 88% of inmates were aware of their status. Overall, ninety-eight percent were on treatment and of those, 93% had achieved viral suppression. The majority of inmates (84%) living with HIV were diagnosed in the community prior to incarceration. Over one-quarter of inmates living with HIV (28%) were diagnosed within the past 5 years.

Indigenous persons and women account for a disproportionately high number of HIV cases. Eleven percent of inmates living with HIV were women, and half (50%) self-identified as Indigenous.

These subgroups account for 5% and 30% of the overall inmate population respectively.

Ninety-two percent of Indigenous inmates and 94% of women offenders were aware of their status. All Indigenous inmates known to be living with HIV were on treatment (100%) and 92% had achieved viral suppression. Of the female inmates known to be living with HIV, 92% were on treatment and 87% had achieved viral suppression.

CONCLUSIONS: This analysis shows that a high proportion of inmates with HIV are on treatment and have achieved viral suppression. Almost 90% of inmates were aware of their HIV status. Women offenders and inmates of Indigenous ancestry were disproportionately affected by HIV. CSC is committed to continuing to monitor these indicators and working towards increasing testing uptake in order to achieve the UNAIDS 90-90-90 targets for the federal inmate population.

OAF0203

SUPPORTING THE JUDICIAL RESPONSE TO HIV AND TB IN AFRICA: THE AFRICA REGIONAL JUDGES' FORUM

L. Ferguson[1], M. Lambert-Peck[1], K. Zacharias[1], D. Owolabi[2], D. Patel[2], A. Saha[2], S. Gruskin[1]
[1]*University of Southern California, Institute on Inequalities in Global Health, Los Angeles, United States,* [2]*UNDP RSCA, Istanbul, Turkey*

BACKGROUND: Building on the work of the Global Commission on HIV and the Law, UNDP Regional Service Centre for Africa (UNDP RSCA) initiated regional work to address HIV- and TB-related legal

barriers. The Africa Regional Judges' Forum, now in its sixth year, is a response to judges' requests for capacity building on issues surrounding HIV, TB and the law across the region. Judges have full ownership of fora proceedings, while UNDP RSCA acts as its Secretariat, providing technical and financial support.

DESCRIPTION: The forum convenes judges and magistrates representing 16 sub-Saharan countries to share successes, challenges, and advancements in human-rights based responses to HIV and TB. The goal is to support a new generation of judicial leaders able to preside over legal cases relating to HIV, TB, and human rights. Medical experts, scientists, civil society, representatives of key populations, TB survivors, and other community groups are invited to participate in the fora to maximise understanding of the issues being discussed. An evaluation was recently conducted comprising a review of relevant documents and key informant interviews with stakeholders including participating judges, UNDP staff and consultants.

LESSONS LEARNED: Judges are uniquely positioned to ensure that law is used appropriately in HIV responses. The forum acts as a safe space for peer discussion among judges, for judges to learn directly from key populations about the impact of the law on their lives, and for discussing the latest advancements in science and medicine. Cases addressing exclusion and inequalities, human rights and HIV/TB are shared to promote cross-country learning. Recently, Kenyan judges who participated ruled that the overbroad criminalization of HIV transmission was unconstitutional and that the imprisonment of patients with TB was unlawful and beyond the parameters of public health legislation, and Botswanan judges ruled on the need to provide HIV treatment to foreign prisoners with HIV.

CONCLUSIONS/NEXT STEPS: The sustained demand from the judges for the continuation of this forum demonstrates its relevance and acceptability for bringing HIV science and lived experience into the legal sphere. This is a replicable model for cultivating regional, cross-country knowledge transfers through engendering peer-to-peer collaboration, thereby supporting positive change in HIV-related legal environments.

OAF0204

INVOLVEMENT OF LAW ENFORCEMENT AGENCIES IN RESPONDING TO GBV AGAINST LGBTI PEOPLE AND IN REDUCING THEIR VULNERABILITY FOR BETTER ACCESS TO HEALTHCARE FOR KEY POPULATIONS IN THE CITY OF DOUALA

J. Mandeng[1], J. Ngando[2]
[1]Alternatives-Cameroun, Management, Douala, Cameroon, [2]Alternatives-Cameroun, Genre te Droits Humains, Douala, Cameroon

BACKGROUND: In 2018, a national report indicated 1,134 cases of violence and violations of rights against LGBTI people in Cameroon, an increasing number. The impunity that surrounds this violence has the effect of legitimizing it, and of creating a psychosis among the victims, as well as consequences for their physical and mental health. Alternatives Cameroon decided to work with law enforcement forces to better respond to cases of violence against LGBTI people, and to reduce their vulnerability.

DESCRIPTION: We started by listing some cases of documented violence which did not receive any response. We targeted two police stations in which we had already sensitized the officers during the workshops on human rights and HIV. Then we went to the commissioners of these establishments to submit these cases to them and organize a response. They provided us with inspectors who coached our clients on how to file a complaint, avoiding the use of words which could incriminate them, and then they recorded the complaints, thus allowing the opening of legal proceedings.

LESSONS LEARNED: The collaboration with the police has allowed some of our beneficiaries to have the courage to file a complaint, and better still, to succeed, which strengthens their courage to resort to the police. in the event of violence against them. On the other hand, we were able to team up with fifteen police and gendarmes for the management of future cases of violence. The latter recently referred us to an MSM who was brought into their services. We tested positive for HIV and put him in care.

CONCLUSIONS/NEXT STEPS: In a win-win logic, we have successfully offered to the police forces with whom we collaborate, to often visit their posts to carry out HIV testing campaigns in their favor and in favor of those who may be detained there. . In return, we can always count on these police forces to accompany us in certain night activities, in order to ensure our safety and that of the beneficiaries. We also intend to involve them in a collective complaint procedure in favor of victims of violence without any procedure having been initiated.

OAF0205

THE BATTLE OF DEFEATING HIV STIGMA AND DISCRIMINATION CONTINUES: LESSONS FROM THE SOUTH AFRICAN HUMAN RIGHTS COMMISSION'S USE OF LITIGATION STRATEGY IN THE PROTECTION OF HUMAN RIGHTS

L. Lotz[1]
[1]South African Human Rights Commission, Durban, South Africa

BACKGROUND: According to Statistics South Africa (Stats SA) 2019, approximately 7,97 million people are HIV positive. Evidence is overwhelming on the importance, impact on society, link to systemic discrimination on the grounds of positive HIV status, clearly stringent measures need to be taken to ensure that HIV positive people are able to be productively employed and that their basic human rights are at all times respected. The South African Human Rights Commission (SAHRC) used the litigation strategy in challenges discriminatory practices and policies of the South African National Defence Force (SANDF) In respect of the right to equal treatment of HIV-positive individuals.

DESCRIPTION: In promoting the protection of human rights the SAHRC used the litigation strategy against the SANDF in the Western Cape High Court by seeking redress under the Promotion of Equality and Prevention of Unfair Discrimination Act 52 of 2002 in that a reservist was unfairly and unlawfully discriminated against on the basis of his HIV-positive status. The SANDF had failed to deploy the reservist on naval vessels on account of his status, contrary to its own policy in respect of members who are HIV positive. He complained to the SAHRC that the discrimination has been ongoing.

LESSONS LEARNED: Lessons were learned on how to use different strategies for using rights to impact on HIV stigma and discrimination, and to achieve social change. In order to achieve maximum success in advancing social change, litigation and other strategies can be used. The SAHRC successfully used the litigation strategy in combination with other strategies (i.e. public information; ad-

vice and assistance; and social mobilisation and advocacy), as empowered by its constitutional mandate, to secure redress and to enforce the protection of human rights.

CONCLUSIONS/NEXT STEPS: By litigating the SAHRC impacted on social change by holding government institutions accountable and in protecting the human dignity and right to equality of all who are or may be affected by HIV. The outcome of the litigation strategy found that the SANDF's implementation of its policies relating to HIV-positive members is inadequate. Accordingly, the court found that SANDF had unfairly, unlawfully and unjustifiably discriminated against the reservist.

OAF0206

SCALING UP PUBLIC HEALTH APPROACH TO LAW ENFORCEMENT TO REMOVE HUMAN RIGHTS-RELATED ABUSES AGAINST KEY POPULATIONS IN GHANA

J. Blantari[1], M. Salifu[1], E. Awotwi[2]
[1]Ghana Police Hospital, Ghana Police AIDS Control Programme, Accra, Ghana, [2]United Nations Population Fund, Accra, Ghana

BACKGROUND: Police are a critical sector in determining the risk environment for HIV in most key affected populations (PAPs), especially Sex Workers, Men who Have Sex with Men; People who inject Drugs, and other marginalized communities. In the global response to HIV, the key importance of the police's role has been recognized. In most developing countries however, police continue to serve as barriers to effective HIV responses and their role in human rights violations against KAPs Targeted programs with the Ghana Police seeks to change most of these situations.

DESCRIPTION: A three prongs approach was adopted for this intervention:

Buy-in from the Police Hierarchy

In service training and sensitization for serving personnel

Pre-service training for recruits/students

LESSONS LEARNED: Three meetings with the top hierarchy of the Ghana Police Service were held to solicit their buy-in. These were: one on one with the Inspector-General of police and two separate meetings with the Police Management Board (POMAB).

Intense in-service sensitization meetings were held across 22 Global Fund Implementation Districts spread across 9 out of the 16 Political Regions. Topics treated in these sessions include Human Rights abuses, arrest procedures, SGBV, and the review of a video which highlights HR abuses. 100 master trainers from the Police Team including personnel who serve as UN trainers have also been sensitized to undertake step down trainings in the affected Regions across the country.

Curriculum drawing from the key sectors has been produced to serve as a textbook for all 7 police training institutions in Ghana to equip all personnel who would pass through them.

CONCLUSIONS/NEXT STEPS: It is expected that by the end of the 3-year program, 70% of those trained would become champions of the Public Health Approach to law enforcement, particularly in relation to protecting the rights of key populations. It is also expected that there is sustained change in Police policies, culture and practice with peer education (combined with law and policy reform) and increased partnerships with partners such as the Global Fund/WAPCAS and other key stakeholders to promote the Public Health Approach to Law Enforcement.

OAF03 LIVING IN THE SHADOW: STIGMA, SOCIAL JUSTICE AND SEXUAL VIOLENCE

OAF0302

EFFECT OF HOMOPHOBIC ATTACK TO ATTAINMENT OF 90-90-90 GOALS IN UGANDA: EXPERIENCES FROM TASO JINJA CLINIC

L. Oucul[1], D. Kagimu[2], H. Amongin[3], B.M. Etukoit[4], K. Mugisha[1]
[1]The AIDS Support Organization (TASO), Program and Capacity Development, Kampala, Uganda, [2]The AIDS Support Organization (TASO), Medical, Kampala, Uganda, [3]The AIDS Support Organization, Psycho-Social, Jinja, Uganda, [4]The AIDS Support Organization (TASO), Advocacy, Kampala, Uganda

BACKGROUND: In Uganda, the prevalence of HIV is 6.2% (UPHIA, 2017) and key populations are disproportionately affected. Men who have sex with Men HIV prevalence is double at 12.7% (Crane Survey 2017). MSM continue to face stigma and discrimination due to social, legal and policy environment. Cases of homophobic attack seem to be on resurgence after the repeal of anti homosexual act. We share experience of an attack on one MSM that is likely to affect the attainment of 90-90-90 targets at one of our centers of excellence offering HIV/AIDS services to key populations through the Deeper Engagement Grant (DEG).

DESCRIPTION: TASO began implementing the DEG project in June 2018. The goal of the project is universal access to health for all: Health and empowered LGBT communities. To reach the LGBT, the center uses the peer model, moonlight clinics to offer HTS and combination of other services, monthly adherence club meetings for HIV positive LGBT.

On 5th October 2019, the LBGT peer attached to TASO Jinja clinic was attacked and murdered in his residential room by un -known assailant. This murder left the entire LGBT community and health workers in fear. To mitigate the impact of loss, TASO organized a grief and bereavement counseling session for close peers to the deceased. Staff and peers were trained on security and safety.

LESSONS LEARNED: By November 2019, TASO Jinja clinic had registered 388 LGBT, 231 were reached with HIV Testing Services, 17 diagnosed positive, and 14 were initiated on ART. After the attack, 2 HIV positive LGBT were relocated, 02 who were on intensive adherence counseling due to high viral load went into hiding, and 05 missed their appointments. Only 05 of 14 HIV positive LGBT on ART are still active. No LGBT has since turned up for their routine monthly adherence meetings following the death of their fellow peer.

CONCLUSIONS/NEXT STEPS: Resurgence of homophobic attacks in Uganda is likely to dent the attainment of 90-90-90. Programs providing services to marginalized communities like LGBT in repressive environment should offer training on security and safety for LGBT groups and health workers to mitigate the effects of such attacks.

OAF0303

RE-ENVISIONING THE SOCIAL ENABLERS OF THE GLOBAL RESPONSE: AN EVIDENCE-BASED FRAMEWORK TO INFORM INVESTMENTS AND TARGETS FOR HIV-RELATED STIGMA AND DISCRIMINATION, LEGAL ENVIRONMENT AND SOCIAL JUSTICE, AND GENDER EQUALITY

J.A. Izazola Licea[1], A. Stangl[2,3], T. Pliakas[4]
[1]UNAIDS, Strategic Information, Geneva, Switzerland, [2]Hera Solutions, Baltimore, United States, [3]Johns Hopkins Bloomberg School of Public Health, International Health Department, Baltimore, United States, [4]LSHTM, London, United Kingdom

BACKGROUND: There is consensus that social enablers, like reducing HIV-related stigma and discrimination, modify the effectiveness of HIV prevention, care and treatment services and are important for achieving global HIV goals. While several social enablers were included in the 2011 HIV Investment Framework, it was not possible to set evidence-based funding and programmatic targets for countries to pursue due to the paucity of evidence on what interventions constituted social enablers, and for those interventions that were defined, their effects on HIV outcomes. Over the past decade, significant progress has been made to develop and test interventions to address structural impediments to HIV services, including seven widely promoted human rights programs. Based on this evidence, UNAIDS has been leading a process since June 2019 to re-envision the social enablers and more accurately include them in HIV modelling.

DESCRIPTION: The process began with a broad, multi-stakeholder technical consultation which identified evidence and elements to be highlighted as social enablers of the HIV response. Following the consultation, an in-depth review of the literature was conducted to gather the latest evidence on each social enabler to inform the updated framework and allow estimation of impact on HIV outcomes and resource needs. The resulting framework differentiates enablers based on the 3 S's of the HIV response: services, systems and society. The social context can greatly influence how well countries are able to implement HIV systems and services. We propose that national governments invest in four social enablers to strengthen their HIV responses: (1) HIV-related stigma and discrimination, (2) the legal environment and access to social justice, (3) gender equality, and (4) links with other SDGs.

LESSONS LEARNED: While there is increased evidence documenting direct and indirect effects of social enablers on HIV outcomes, there are still gaps that limit quantitative analyses. The wide consultations allowed for the inclusion of key social enablers regardless of data availability. Better modelling is now expected to predict the impact of scaling up social enabling interventions on HIV services.

CONCLUSIONS/NEXT STEPS: The new framework for social enablers may galvanize advocacy to increase program effectiveness, and improve quantitative statistical or modelling efforts documenting or estimating impact.

OAF0304

MEDICAL MISTRUST, DISCRIMINATION, AND SEXUAL VIOLENCE AMONG A SAMPLE OF WOMEN AT RISK FOR HIV

J.K. Stockman[1], K.M. Anderson[1], A. Fernandez DeSoto[1], M. Young Karris[1]
[1]University of California, Department of Medicine, Division of Infectious Diseases and Global Public Health, La Jolla, United States

BACKGROUND: Women of color are disproportionately affected by HIV, representing the majority of new diagnoses among women. Medical mistrust and discrimination are barriers to accessing HIV prevention methods. These barriers may be further heightened for survivors of sexual violence. We sought to understand medical mistrust and discrimination in the context of sexual violence and HIV risk among racial/ethnic groups in San Diego, California, USA.

METHODS: The THRIVE Study is a case-control study with follow-up, of racially and ethnically diverse girls and women aged 14-45. Eligible participants are consensually sexually active or have experienced recent sexual violence. At study visits, participants complete an interviewer-administered survey with measures on demographics, medical mistrust and suspicion, discrimination, and lack of support subscales, everyday discrimination, and history of sexual violence (ever/never forced/threatened sex). Using baseline data for 48 participants, descriptive statistics examine differences in medical mistrust and experience of discrimination by racial/ethnic group and history of sexual violence.

RESULTS: Women identifying as Black or African American (AA) had higher levels of medical mistrust compared to their non-Black/AA counterparts (34.07+/-9.96 vs. 24.03+/-7.47; p<0.001). Black/AA women also had higher levels of suspicion (12.71+/-2.9 vs. 8.1+/-3.5; p<0.01) and lack of support (9.1+/-2.6 vs. 6.0+/-2.2; p<0.001) compared to non-Black/AA women. Compared to women in all other racial/ethnic groups, non-significantly lower medical mistrust was observed among Hispanic/Latina, Asian, and White women. Survivors of forced or threatened sex had higher medical mistrust than non-survivors (30.9+/-9.9 vs. 24.8+/-8.4; p<0.05), and marginally significantly higher levels of suspicion (11.1+/-4.4 vs. 8.6+/-4.2; p=0.063) and lack of support (7.8+/-3.1 vs. 6.4+/-2.3; p=0.10). Among Black/AA women, survivorship did not significantly impact medical mistrust or sub-scales. Compared to non-survivors, Hispanic/Latina survivors had higher medical mistrust (34.0+/-11.1 vs. 21.9+/-5.2; p<0.01), suspicion (12.2+/-4.7 vs. 7.2+/-2.0; p<0.01), and discrimination (10.0+/-2.7 vs. 6.9+/-2.1; p<0.05) while Asian survivors and White survivors had non-significantly higher medical mistrust.

CONCLUSIONS: Our study findings highlight the need to account for racial/ethnic differences and sexual violence history as relates to medical mistrust and aspects of discrimination. This is imperative in the development of structural interventions for HIV prevention as we address the HIV epidemic in the United States.

UNDETECTABLE = UNTRANSMITTABLE (U=U) TO DRIVE STIGMA REDUCTION AND EPIDEMIC CONTROL IN VIETNAM: A GLOBAL MODEL FOR POLITICAL AND PROGRAM INNOVATION

A. Nguyen[1], J. Blandford[1], C.D. Hoang[2], L.H. Nguyen[2], H.T.T. Phan[2], N.T. Do[2], T.H. Do[2], T. Pollack[3], D.D. Do[4], P.A. Nguyen[5], T.D. Thanh[6], G.M. Le[7], L.H. Tong[8], N. Thi Tuyet Vo[3], H.B. Tran[3], P.T. Nguyen[3]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Hanoi, Vietnam, [2]Ministry of Health, Vietnam Authority on AIDS Control, Hanoi, Vietnam, [3]The Partnership for Health Advancement in Vietnam, Beth Israel Deaconess Medical Center, Hanoi, Vietnam, [4]Vietnam Network of People Living With HIV, Hanoi, Vietnam, [5]Vietnam Network of People Living with HIV, Ho Chi Minh City, Vietnam, [6]Lighthouse Social Enterprise, Hanoi, Vietnam, [7]Hanoi Medical University, Hanoi, Vietnam, [8]The Lab Saigon, Ho Chi Minh City, Vietnam

BACKGROUND: Effective ART with sustained viral load (VL) suppression provides complete protection against sexual transmission of HIV. In Vietnam, the Ministry of Health (MOH), Vietnam Network of People Living with HIV (PLHIV), and community leaders have rapidly and comprehensively leveraged Undetectable = Untransmittable (U=U), K=K in Vietnamese, as a program catalyst and driver for stigma and discrimination reduction and meeting epidemic control goals. K=K is a versatile concept beyond reducing stigma and drives our Vietnam program priorities for case finding and ART initiation.

DESCRIPTION: Since its 2017 inception, the K=K movement ushered in MOH policies to document VL suppression <200 ml/copies as treatment success and mandate integration of K=K messaging into health practice to support 95-95-95 goals. Following two successful municipal campaigns in Hanoi and Ho Chi Minh City, the current national campaign celebrates K=K as transformative for individuals, couples, and communities – directly confronting established public perceptions around HIV. Grants to community-based organizations ensured widespread dissemination of the K=K message to key population and PLHIV networks, especially young urban men who have sex with men.

LESSONS LEARNED: Coordinated MOH and community commitment is critical to mainstream K=K into HIV program strategy. Despite global endorsements, healthcare providers were reluctant to inform patients of the benefits of K=K. Simple, visually impactful materials clarified K=K messaging, addressing concerns vis-a-vis PMTCT and blood transmission and STI prevention. Initial campaigns were conducted first in cities where success would influence broader commitment and leveraged Vietnam's impressive viral suppression rates. In response to these developments, MOH officially endorsed K=K and issued national implementation guidelines. Community fora confirmed regionally nuanced messaging and preferred platforms for effective dissemination, as well as the national campaign design.

CONCLUSIONS/NEXT STEPS: K=K revolutionized the HIV response in health and community settings. As of September 2019, Vietnam is the first PEPFAR country to disseminate official K=K guidance and to document 95% VL suppression <200 ml/copies among ART patients. In the next phase, Vietnam will unite messages of effective ART for those living with HIV and pre-exposure prophylaxis for those at substantial risk so that the preventive use of ARVs offers a clear path to HIV epidemic control in Vietnam.

OAF0306

CUMULATIVE EFFECT OF FEAR OF STIGMA FROM HEALTH PROFESSIONALS AND FAMILY/NEIGHBORS AND HEALTH CARE AVOIDANCE AMONG PLHIV IN MOROCCO: RESULTS FROM THE STIGMA INDEX SURVEY MOROCCO (2016)

R.M. Delabre[1], A. Ben Moussa[1,2], V. Villes[1], M. Elkhammas[1,2], L. Ouarsas[1,2], D. Rojas Castro[1,3], M. Karkouri[1,2]
[1]Coalition PLUS, Community-Based Research Laboratory, Pantin, France, [2]Association de Lutte Contre le Sida (ALCS), Casablanca, Morocco, [3]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France

BACKGROUND: Since 2015, entry into the HIV care cascade in Morocco has been facilitated by community screening and the "test and treat" strategy. However, experience and/or fear of stigma among people living with HIV (PLHIV) can hinder entry into the care system. Through the Stigma Index Morocco survey, we identified factors associated with having avoided health services for fear of stigma.

METHODS: ALCS, Coalition PLUS member, in collaboration with the Ministry of Health, UNAIDS and the Global Fund, conducted the Stigma Index survey in Morocco (March-June 2016) among PLHIV using temporal cluster sampling. The questionnaire addressed several themes, including experiences of stigma and discrimination and health-seeking behavior. Factors associated with avoiding HIV testing and treatment services for fear of stigma were assessed using multinomial logistic regression models. We compared people who did not avoid health services for fear of stigma (reference) to people who avoided health services for fear of stigma from (A) health personnel or family/neighbors and (B) health personnel and family/neighbors (cumulative effect).

RESULTS: Among 583 participants, 280 (48.0%) were women and median age was 36[IQR 29-43]. Half avoided health services for fear of stigma by health personnel and/or family/neighbors: (A) n=228, 39.1% and (B) n=68, 11.7%. After adjustments, having been excluded from social activities ((A) aOR[95% CI]=1.70[1.10; 2.61]; (B) 2.63[1.39; 5.00]), having been discriminated against by PLHIV ((A) 1.87[1.12; 3.13]; (B) 3.35[1.63; 6.88]) and not having had access to antiretroviral treatment ((A) 1.76[1.16; 2.68]; (B) 2.18[1.11; 4.27]) were associated with having avoided health services for fear of stigma by health personnel and/or family/neighbors. Being female (2.85[1.48; 5.47]) and having discussed sexual and reproductive health with a health professional (4.56[2.38; 8.71]) were associated with having avoided health services for fear of the two sources of stigma.

CONCLUSIONS: Results demonstrate a cumulative effect of fear of stigma and discrimination at the community and health service levels among PLHIV in Morocco. PLHIV who have experienced discrimination seek to avoid reproducing the experience at the expense of their health. These findings have informed ongoing implemented actions within the community and the health sector to improve entry and retention in care among PLHIV in Morocco.

OAF0402

BREAKING DOWN HUMAN-RIGHTS RELATED BARRIERS TO HIV AND TB SERVICES IN 20 COUNTRIES. SOON EVERYWHERE?

R. Jurgens[1], A. Iovita[1], H. Lim[1], G. Arustamyan[1], J. Csete[2], S. Timberlake[3]
[1]The Global Fund to Fight AIDS, TB and Malaria, Community, Rights and Gender Department, Le Grand Saconnex, Switzerland, [2]Columbia University, School of Public Health, New York, United States, [3]Consultant, Geneva, Switzerland

BACKGROUND: The six-year Breaking Down Barriers (BDB) initiative of the Global Fund to Fight AIDS, TB and Malaria seeks to vastly scale up programs to reduce stigma, discrimination, gender inequality and other human rights-related barriers to HIV, TB and malaria services. Many programs to address these barriers have been small-scale and unsustainable. Twenty countries from all Global Fund regions were chosen for intensive BDB support to create the conditions for comprehensive responses to these barriers.

DESCRIPTION: In 2018-19, independent research teams conducted desk reviews followed by in-country rapid assessments of existing human rights-related barriers in the 20 BDB countries and of existing programs aiming to reduce them. Barriers to HIV services were assessed in all countries, those related to TB in 13 countries and to malaria in two countries. These largely qualitative baseline assessments included focus group discussions and in-depth interviews with key populations and their organizations, other NGOs, policy-makers and other stakeholders. Local experts were part of the research teams. The researchers also assessed the cost of existing programs and outlined a costed comprehensive response to the barriers identified. Baseline assessments were used to design country-owned multi-year plans for achieving a comprehensive response, funded in part by catalytic funding from the Global Fund.

LESSONS LEARNED: In all countries these barriers were found to be numerous and severe. Key populations face marginalization by undue criminalization and have inadequate access to justice, the stigma of HIV and TB continues to hamper access to care, and gender inequality remains profound. Many programs to address these barriers were poorly funded, not brought to scale, not strategically coordinated, and generally not understood to be central to successful disease programs. Key population organizations were often found to need technical and management support. But the $78 million in catalytic funding and matched funds from governments represents a quantum jump in support for scaled-up programs to reduce human rights-related barriers.

CONCLUSIONS/NEXT STEPS: For the first time in the history of the HIV epidemic, 20 countries, with support from the Global Fund, are seeking to comprehensively address human rights-related barriers. Discussions are starting on how to break down barriers, everywhere.

OAF0403

UTILIZING INDIVIDUAL LEVEL DATA TO ASSESS THE RELATIONSHIP BETWEEN PREVALENT HIV INFECTION AND PUNITIVE SAME SEX POLICIES AND LEGAL BARRIERS ACROSS 10 COUNTRIES IN SUB-SAHARAN AFRICA

C. Lyons[1], D. Diouf[2], J.O. Twahirwa Rwema[1], S. Kouanda[3], A. Simplice[4], A. Kouame[5], Z. Mnisi[6], U. Tamoufe[7], B. Cham[8], I. Ba[2], M.A. Djaló[9], T. Mothopeng[10], I.M. Njindam[11], J. Loum[8], S. Matse[12], J.P. Enama[13], E.-P. Obodou[14], E. Karita[15], R. Nowak[16], T. Crowell[17], O. Ky-Zerbo[18], C. Beyrer[1], S. Baral[1]
[1]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [2]Enda Sante, Dakar, Senegal, [3]Institut de Recherche en Sciences de la Santé, Ouagadougou, Burkina Faso, [4]ONG Arc-en-Ciel, Lome, Togo, [5]Ministère de la Sante et de l'Hygiène Publique, Abidjan, Cote D'Ivoire, [6]Ministry of Health, Health Research Department, Strategic Information Division, Mbabane, Eswatini, [7]Metabiota, Yaoundé, Cameroon, [8]ActionAid, Banjul, Gambia, [9]Enda Santé, Bissau, Guinea-Bissau, [10]People's Matrix Association, Maseru, Lesotho, [11]Johns Hopkins School of Public Health, Yaounde, Cameroon, [12]Health Research Department, Mbabane, Eswatini, [13]The Pact, Yaounde, Cameroon, [14]Enda Sante, Abidjan, Cote D'Ivoire, [15]Project San Fancisco, Kigali, Rwanda, [16]University of Maryland, Institute of Human Virology, Baltimore, United States, [17]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [18]Programme d'Appui au Monde Associatif et Communautaire, Ouagadougou, Burkina Faso

BACKGROUND: Gay men other men who have sex with men(MSM) have consistently been shown to be disproportionately affected by HIV across epidemic settings in Sub-Saharan Africa. Evidence from systematic reviews suggests the association of legislation and engagement in HIV services, however empiric, individual-level data, to assess this relationship remains limited. In response, the aims of this study are to use individual data from MSM from ten different countries across Sub-Saharan Africa to examine the relationship between HIV and legal environments.

METHODS: Respondent driven sampling was used to recruit 8,113 MSM over the period of 2011-2018 across 10 countries: Burkina Faso, Cameroon, Côte d'Ivoire, Gambia, Guinea-Bissau, Nigeria, Senegal, eSwatini, Rwanda, and Togo. Interviewer-administered socio-behavioral questionnaires and biological testing for HIV were conducted. Same-sex policy categorization was based on ILGA defined legal approach: Not criminalized and not protected; criminalized (< 8 years imprisonment); and severe criminalization (>10 years imprisonment).

Legal barriers to civil-society-organizations(CSO) is defined as legal barriers to the registration or operation of sexual orientation-related CSOs. Individual-level data were pooled across countries and multivariable logistic regression models used to measure the association between legal status and HIV.

RESULTS: HIV prevalence among MSM in contexts without criminalization was 8.4% (567/3170); 19.7% (341/1729) in criminalized settings; and 51.8% (422/815) in severely criminalized setting (Table 1).

	Living with HIV							
Policies and Legal Barriers	n/N	%	OR	P value	95% CI	aOR*	P value	95% CI
Legal status of same sex behaviours								
Not criminalized and no protective laws	567/3170	8.4	Ref	Ref	Ref	Ref	Ref	Ref
Criminalized	341/1729	19.7	2.35	0.023	1.12, 4.92	2.31	0.036	1.06, 5.03
Criminalized Severe	422/815	51.8	10.28	<0.001	6.46, 16.37	8.10	<0.001	5.31, 12.34
Legal Barriers to CSO engagement								
No	608/4899	12.4	Ref	Ref	Ref	Ref	Ref	Ref
Yes	422/815	51.8	6.68	<0.001	3.85, 12.3	5.59	<0.001	3.41, 9.17

[Table 1. Prevalent HIV infection and same sex policies]

Same sex policies was associated with HIV (p-value <0.001). When compared to non-criminalized settings, criminalized (aOR:2.31; 95% CI:1.06, 5.03), and severely criminalized settings (aOR:8.10; 95% CI:5.3112.34) were associated with increased odds of HIV. Legal barriers to CSO engagement was associated with increased odds of HIV (aOR:5.59; 95% CI:3.41, 9.17).

CONCLUSIONS: Consistently, same-sex policies was associated with prevalent individual HIV infection MSM with the magnitude of this relationship the strongest in the most punitive settings. These results provide empiric data of how laws potentiate suboptimal individual HIV outcomes among MSM across Sub-Saharan Africa and the potential for decriminalization to optimize HIV prevention efforts.

OAF0404

EARLY WARNING SIGNS: ASSESSING THE IMPACT OF THE EXPANDED MEXICO CITY POLICY ON COMMUNITIES MOST AFFECTED BY HIV

L. Orza[1], L. Stackpool-Moore[2], S. Tuot[3]
[1]Frontline AIDS, Brighton, United Kingdom, [2]Watipa, Geneva, Switzerland, [3]KHANA, Phnom Penh, Cambodia

BACKGROUND: On 23rd January 2017 President Trump signed an Executive Order to re-instate the Mexico City Policy – or Global Gag Rule (GGR) -- with unprecedented application to all US global health assistance, including PEPFAR funds; an approximately 16-fold expansion on previous iterations of the policy. The HIV community mobilised to express concern for what the expanded Global Gag Rule (GGR) could mean for the health and rights of people most affected by HIV, to ensure that negative impacts of the policy are documented, to support advocacy for its permanent rescindment. Frontline AIDS and Watipa, with support from Sida, conducted a study in Malawi and Cambodia to explore the impact of the GGR on HIV and key population services, and on HIV-SRHR integration.

DESCRIPTION: The study combined desk research, service data analysis and community engagement for qualitative data collection. In Malawi 16 organizations were engaged through 10 one-to-one interviews and one focus group discussion. Quantitative data was analysed from two service sites, provided by organisations that work with sex workers and men who have sex with men. In Cambodia, three focus group discussions took place with a mixed group of health care facility workers and civil society organizations; representatives from civil society organisations only; and, entertainment workers. Eight one-to-one qualitative interviews were also undertaken.

LESSONS LEARNED: Findings from both countries suggest that:

1. The policy has created some disruption to HIV programmes, outreach services, and referrals to safe, tailored, integrated services for marginalised people, including sex workers, transgender people and men who have sex with men.
2. The policy has created an environment of mistrust, confusion, and isolation among civil society actors, and tightened the space for advocacy on comprehensive SRHR.
3. These changes have compromised access to HIV prevention, testing and treatment services for marginalised people.

CONCLUSIONS/NEXT STEPS: While quantifying the effect of the GGR on the HIV response remains challenging, findings from this study by Frontline AIDS and partners is consistent with others' research documenting the impact of the policy on HIV programmes and communities most affected by HIV. These findings contribute to the building of a collective advocacy agenda to mitigate and ultimately permanently rescind the policy

OAF0405

ASSESSING THE STATUS OF DRUG REHABILITATION PRACTICES IN SELECTED DISTRICTS OF NEPAL, FROM A HEALTH AND HUMAN RIGHTS PERSPECTIVE BY MOHA, GON IN PARTNERSHIP WITH YV FDDR AND MAINLINE FOUNDATION

R. Thapa[1], M. Ghimire[1]
[1]Youth Vision, Health and Rights for the Key Population, Kathmandu, Nepal

BACKGROUND: In Nepal, PWUD are often marginalized groups who lack access to rights-based and evidence-based treatment. As a result of stigmatization of health care providers, social exclusion and criminalizing laws, many human rights violations have reported in treatment centers. This is the first study assessing health and rights-based treatment in an unique collaboration with Ministry of Home Affairs, the umbrella organisation for Rehabilitation centres (FDDR), a local organisation Youth Vision and an international NGO (Mainline).

METHODS: 85 Drug treatment and Rehabilitation centers were assessed on 9 areas - Adequate water, Enough Toilets, Living Cleanliness Hygiene; Cafeteria/Kitchen Cleanliness Hygiene; Nutrition and full to eat Meal System; Free and Open space Main Area; Playground/ Physical Fitness Provision; 1 person 1 bed full accommodation and Proper Assembly Hall; through a standardized checklist, based on a likert scale of 1-5 with a score of 1 being 'unacceptable' quality and a score of 5 being an appropriate feature of excellent quality.

85 FGDs, 38 KII, 85 interviews with treatment providers and 8 stakeholder interviews, quality and rights-based treatment services was assessed.

RESULTS: 3.5% had serious water supply problems; 16.5% had inadequate Toilet Facilities Vs. number of clients housed. 21.2% had unacceptable living conditions, residential, living cleanliness and general hygiene; 17.6% had unacceptable kitchen cleanliness and hygiene. 17.6% had poor nutrition and meal systems, 13% were congested and badly laid out for a rehab. 20.0% had no playground or provision for physical exercise. 36.5% did not always provide 1 person-1 bed full accommodation and instead, a roll-out mattress. 25.9% did not have appropriate space to gather as a group with little drug treatment program materials. 44.7% were in bad physical condition, some were make-shift huts with tin walls and roofs, others ad-hoc structures.

CONCLUSIONS: Despite improvements in access to rights-based treatment- there are still human rights violations. Only around 10% of the overall rehabs are actually able to comply with SOP's, guidelines and succeeding amendments. The Government of Nepal is currently interested to review current national guidelines and should be regularly monitored and followed-up with close scrutiny by involved civil society organizations.

ASSESSING A HUMAN RIGHTS-BASED APPROACH TO HIV IN KENYA

N. Sircar[1], A. Maleche[2], T. Saoyo[2]
[1]University of California, Center for Tobacco Control Research and Education, San Francisco, United States, [2]Kenya Legal and Ethical Issues Network, Nairobi, Kenya

BACKGROUND: Kenya's health authorities expanded HIV testing and notification services through increased capacity and training to reach vulnerable populations that are under-testing and experiencing stigma and/or discrimination: young women, men who have sex with men (MSM), female sex workers (FSW), and persons who inject drugs (PWID). While Kenya promotes a human rights-based approach (HRBA) to HIV services to help build trust and encourage testing, little was known about program, policy, and practice implementation with respect to privacy, confidentiality, and dignity. This exploratory, qualitative study evaluated Kenya's implementation of a HRBA to HIV through assessing perspectives on human rights and health care interactions.

METHODS: This study included 4 focus group discussions and 16 in-depth interviews with individuals from Key and Affected Populations (KAP), and HIV care providers or policy experts (HPs). Data were collected from four sites (Nairobi, Mombasa, Homa Bay, and Kisumu counties) from May to July 2019. We analyzed data using grounded theory, and applied a rights analysis to the data codes and themes to evaluate Kenya's approach in their HRBA.

RESULTS: A majority of 52 total participants identified female (58%); 36% as male, and 6% were not identified by sex. Most participants self-identified as from KAPs: MSM (21%), FSW (20%), young women (21%), and PWID (23%), with 15% being non-KAP HPs. The KAP participants conveyed mixed perspectives about interacting with providers regarding privacy and confidentiality, with mistrust and fears of disrespect being expressed for government-related facilities. Community-based organizations with health services were highly regarded and KAPs acknowledged improvement in some provider interactions. HPs acknowledge their need to better engage with KAPs and undergo improved, consistent training on the HRBA to overcome known trust and confidence barriers.

CONCLUSIONS: Kenya is increasing the rate of HIV testing and notification among KAPs with community partnerships. Challenges remain in building KAP trust and confidence for HPs and the health care system generally. By identifying opportunities for KAPs to collaborate with HPs, expanding community-based organizations' reach, and raising legal literacy to better recognize human rights and effectuate the HRBA to HIV programs, policies, and practices, more KAPs may utilize HIV services and help identify other at-risk individuals.

PD-1 EXPRESSION IS LINKED TO NK CELL DYSFUNCTION AND ADVANCED LIVER FIBROSIS IN HIV/HCV-COINFECTED INDIVIDUALS

M.L. Polo[1], A. Urioste[1], V. Gonzalez Polo[1], G. Poblete[2], A. Martinez[2], A. Sisto[2], M.J. Rolon[2], G. Turk[1], N. Laufer[1,2]
[1]INBIRS-UBA-CONICET, Ciudad de Buenos Aires, Argentina, [2]Hospital Fernandez, Buenos Aires, Argentina

BACKGROUND: Liver disease is one of the leading causes of morbi-mortality in people living with HIV/HCV. Response to HCV therapy and fibrosis regression after HCV clearance is diminished in cirrhotic patients, together with increased risk of hepatocellular carcinoma. Natural killer cells (NK) are associated with tumoral and viral control, and also amelioration of liver fibrosis; however, frequency and degranulation of NK cells are reduced in cirrhotic HIV/HCV-coinfected individuals. Here, we aim to further study NK cell activation and exhaustion in progressive stages of hepatic fibrosis secondary to HIV/HCV coinfection.

METHODS: Blood samples from ART-treated HCV/HIV-coinfected participants with different liver fibrosis levels (mild: METAVIR F0/F1 n=16; advanced: F4 n=18, assessed by transient elastography) were collected and PBMCs purified. Immunophenotyping (CD25, CD69, NKp46, NKG2D, and PD-1 expression) and degranulation capacity (CD107a assay) of NK cells were studied by flow cytometry. Clinical and experimental data were analyzed using non-parametric statistics.

RESULTS: All participants had undetectable HIV viral load (VL) with a median LT-CD4 count of 646 cells/µl (IQR 394-849). Overall, 47% were female, median age: 49 years (IQR 46.75-53), time of known HIV infection: 20 years (IQR 17.5-23), HCV infection: 14 years (IQR 10.5-20), time on ART: 11.5 years (IQR 7.75-18.35). HCV genotype was predominantly 1a, HCV VL: 6.96 log10 copies (IQR 5.91-16). None of the above parameters differed between groups. Frequency of NK/PD-1+ cells (p=0.006) as well as PD-1 expression per NK cell (p=0.002) were upregulated in F4 participants. In both groups, PD-1 was confined to CD56dim subset (F0/F1: p=0.002; F4: p=0.015) and was associated with higher CD69 and CD25 expression. PD-1 expression on NK cells inversely correlated with NK cell frequency (r=-0.50; p=0.01) and degranulation capacity (r=-0.63; p=0.002). Additionally, PD-1 expression positively correlated with APRI score (r=0.53; p=0.02), liver stiffness (r=0.51; p=0.01), and AST levels (r=0.52; p=0.02), and negatively with albumin (r=-0.6; p=0.01) and prothrombin time (r=-0.57; p=0.01).

CONCLUSIONS: Cirrhosis is associated to NK cell exhaustion in HIV/HCV-coinfected individuals. Potential interventions to improve NK cell function may have relevant implications to boost HCV treatment success in cirrhotic individuals, as well as potential NK cell-based immunotherapies targeted to modulate liver fibrosis or counteract malignant transformation.

THE CARD8 RS2043211 GENETIC VARIANT AND IL-33 PLASMA LEVELS ARE ASSOCIATED WITH TB-HIV/IRIS ONSET IN BRAZILIAN INDIVIDUALS

N.B.R. De Sá[1], N.C.S. De Sousa[1], M. Ribeiro-Alves[2], T.P. Da Silva[1], J.H. Pilotto[1], V.C. Rolla[3], C.B.W. Giacoia-Gripp[1], L.M. De-Oliveira-Pinto[4], D. Scott-Algara[5], M.G. Morgado[1], S.L.M. Teixeira[1]
[1]FIOCRUZ, Oswaldo Cruz Institute - Laboratory of AIDS and Molecular Immunology, Rio de Janeiro, Brazil, [2]FIOCRUZ, National Institute of Infectious Diseases Evandro Chagas - Laboratory of Clinical Research on STD/AIDS, Rio de Janeiro, Brazil, [3]FIOCRUZ, National Institute of Infectious Diseases Evandro Chagas - Clinical Research Laboratory on Mycobacteria, Rio de Janeiro, Brazil, [4]FIOCRUZ, Oswaldo Cruz Institute - Laboratory of Viral Immunology, Rio de Janeiro, Brazil, [5]Institut Pasteur, Unité de Biologie Cellulaire des Lymphocytes, Paris, France

BACKGROUND: Inflammasomes are multi-protein complexes of receptors and sensors that mediate innate immune responses and induce inflammation. Tuberculosis (TB) and aids are the leading causes of infectious disease death worldwide in which inflammation plays a major role in disease progression. In some TB-HIV-infected individuals, treated simultaneously for both diseases, a pathological inflammatory reaction, named immune reconstitution inflammatory syndrome (IRIS), may occur. The search of risk factors for IRIS is of relevance for clinical management. We investigated the role of single-base polymorphisms (SNPs) of the NLRP3, CARD8, and IL-1 β inflammasomes genes, as well as the profile of their related proinflammatory cytokines (IL-1β, IL-18, IL-33, and IL-6) in the susceptibility/resistance to TB-HIV coinfection outcomes.

METHODS: Patients were divided into four groups: TB-HIV (n=88; 11 of them with IRIS), HIV (n=20), TB (n=24) and healthy controls (n=24). These patients were followed-up at INI/FIOCRUZ and HGNI, Rio de Janeiro, Brazil, from 2006 to 2016. SNPs genotyping of the cellular inflammasomes were determined by Real-Time PCR, and plasma concentrations of cytokines were measured by ELISA kits. Protection/risk estimations were performed by unconditional logistic regression models.

RESULTS: Significant differences in the plasma cytokine levels and their relationships with the SNPs were observed among the groups. Regarding the TB-HIV individuals, the A/T genotype (P=0.034), allele T (P=0.030) and carrier-T (P=0.030) in the CARD8 rs2043211 polymorphism were associated with non-IRIS, while IL-33 plasma levels tended to be slightly higher among the TB-HIV/IRIS individuals (P=0.055).

CONCLUSIONS: These results provide new insights into the role of innate immunity in the physiopathology of TB-HIV/IRIS, and as of our knowledge, this is the first study demonstrating an association between the CARD8 rs2043211 polymorphism and plasma levels of IL-33 with IRIS in TB-HIV coinfected individuals. The functional role of such molecules in IRIS pathogenesis is still to be demonstrated. These results, associated with previous data of HLA and KIR polymorphisms in this study group, contribute to the discussion of the impact of host genes in TB-HIV individuals and the IRIS outcome.

PDA0104

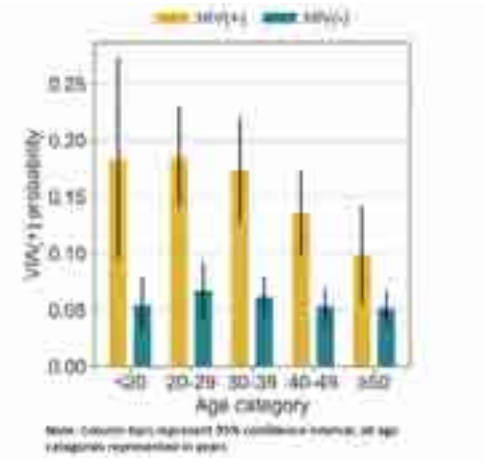
ASSOCIATION OF AGE AND CERVICAL CANCER SCREENING RESULTS IN 11 URBAN HEALTH CENTERS IN LUSAKA, ZAMBIA

J. Pry[1,2], M. Duran-Frigola[3,4], J. Matambo[3], K. Taghavi[5], J. Mubita[3], O. Chituwo[6], I. Sikazwe[3], C. Bolton-Moore[3,7], A. Manasyan[3,7]
[1]Washington University, School of Medicine, St. Louis, United States, [2]Centre for Infectious Disease Research Zambia, Implementation Science Unit, Lusaka, Zambia, [3]Centre for Infectious Disease Research Zambia, Lusaka, Zambia, [4]Institute for Research in Biomedicine, Structural Bioinformatics & Network Biology Lab, Barcelona, Spain, [5]University of Bern, Bern, Switzerland, [6]Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV and TB, Lusaka, Zambia, [7]University of Alabama, School of Medicine, Birmingham, United States

BACKGROUND: Cervical cancer is the leading cancer-related cause of death among women in Zambia and poses an even greater threat to HIV-positive women. The World Health Organization global strategy towards the elimination of cervical cancer requires 70% of women aged 35–45 years to be screened of which 90% should receive treatment by 2030. To identify screening gaps to achieving this goal we evaluated the effect of age on visual inspection with acetic acid (VIA) screening results in Zambia.

METHODS: We abstracted VIA screening data from the Cervical Cancer Prevention Program in Zambia registers (January 1, 2010–June 30, 2019) at 11 clinics in Lusaka Province. We conducted a mixed-effects logistic regression analysis to assess VIA results allowing random effects at the clinic and individual level. Post-estimation modeling was used to calculate adjusted predictive probabilities of VIA-positive results by HIV status and age.

RESULTS: We included 204,225 VIA screening results from 183,194 women. Of 204,225 VIA screenings, 21,326 (10.4%) were positive, and median patient age was 34 years (interquartile range, 28–42 years). The predictive probability of screening positive was highest among HIV-positive patients aged 20–29 years (18.6%; 95% confidence interval [CI]: 14.2%–22.9%) followed by those younger than 20 years (18.4%; 95% CI: 9.6%–27.3%; Figure 1).



[Figure 1: Predictive probability of screening VIA positive by HIV status and age category in Lusaka, Zambia]

CONCLUSIONS: Almost one in five HIV-positive women aged ≤29 years screened VIA positive in Lusaka. To optimize progress toward cervical cancer elimination, in Zambia, a differentiated model that focuses on HIV-positive women, especially younger women (≤29 years), as a high-risk group could be considered.

PDA0105

MODELLING ENDOTHELIAL FUNCTION IN VITRO AND VIA BLOOD SAMPLING TO ASSESS CARDIOVASCULAR RISK IN PEOPLE LIVING WITH HIV

A.A. Khawaja[1], R.T. Maughan[1], K.E. Paschalaki[1], K.A. Taylor[1], A.O. Lovell[2], C. Pericleous[1], J.C. Mason[1], A.M. Randi[1], M. Boffito[2,3], M. Emerson[1]
[1]Imperial College London, National Heart and Lung Institute, London, United Kingdom, [2]Imperial College London, Department of Infectious Disease, London, United Kingdom, [3]Chelsea and Westminster NHS Trust, London, United Kingdom

BACKGROUND: Cardiovascular (CV) disease, which is driven by endothelial and platelet dysfunction, is more prevalent among people living with HIV (PLWH) and has been associated with some antiretroviral (ARV) use. Determining effects of ARVs upon platelet function via blood sampling is commonplace, however examining the impact on endothelial cells, without using invasive sampling methods, is more complex. We therefore evaluated in vitro models of endothelial dysfunction and developed methods to isolate and phenotype endothelial-derived microparticles (EMP) and endothelial 'progenitor' cells (endothelial colony-forming cells, ECFCs), both of which may be isolated from blood and allow for detailed analysis of endothelial function in patients or clinical trial participants.

METHODS: Human coronary artery endothelial cells (HCAECs) were treated with plasma Cmax concentrations of ABC or tenofovir disoproxil fumarate (TDF), stimulated with TNF-alpha to mimic inflammation, and inflammatory and pro-thrombotic properties assessed by flow cytometry. EMP were isolated from cell culture supernatants and plasma from human subjects, and characterised using flow cytometry. ECFCs were isolated in the presence of ARVs using whole blood of healthy subjects taking PrEP in order to establish protocols in a relevant population exposed to daily ARVs. Statistical significance was determined by one-way ANOVA with Tukey's multiple comparison test.

RESULTS: ABC treatment enhanced levels of TNF-alpha-induced inflammatory ICAM-1 and pro-thrombotic TF expression compared to TDF (+1.9- and +1.2-fold, $p<0.05$) in HCAECs. ABC treatment led to greater numbers of ICAM-1+ and TF+ EMP compared to TAF (+2.1- and +3.3-fold, $p<0.05$) in HCAECs and EMP from the blood of human subjects taking ARVs at therapeutic doses were successfully isolated and their inflammatory and thrombotic properties determined. We were able to isolate viable ECFCs from PrEP users in similar numbers to those obtained from ARV-naïve donors in earlier studies.

CONCLUSIONS: ABC enhanced the inflammatory and thrombotic properties of cultured HCAEC suggesting that this model may be used predictively to evaluate the cardiovascular risk profile or ARVs. In the context of clinical studies, EMPs and ECFCs are suggested as useful tools for determining the effects of ARVs and HIV infection per se upon vascular endothelial thrombo-inflammatory properties and therefore cardiovascular health.

PDA0106

INNATE LYMPHOID CELLS ARE REDUCED IN PREGNANT HIV POSITIVE WOMEN AND ARE ASSOCIATED WITH PRETERM BIRTH

C. Akoto[1], C. Chan[1], C. Tshivuila-Matala[1], K. Ravi[1], W. Zhang[1], M. Vatish[1], S. Norris[2], J. Hemelaar[1]
[1]University of Oxford, Nuffield Department of Women's & Reproductive Health, Oxford, United Kingdom, [2]University of the Witwatersrand, South African Medical Research Council Developmental Pathways for Health Research Unit, Department of Paediatrics, School of Clinical Medicine, Johannesburg, South Africa

BACKGROUND: Preterm birth is the leading cause of neonatal and child mortality worldwide. Globally, 1.4 million pregnant women are estimated to be living with HIV/AIDS, the majority of whom live in sub-Saharan Africa. Maternal HIV infection and antiretroviral treatment (ART) have been associated with increased rates of preterm birth, but the underlying mechanisms remain unknown. Acute HIV infection is associated with a rapid depletion of all three subsets of innate lymphoid cells (ILCs), ILC1s, ILC2s and ILC3s, which is not reversed by ART. ILCs have been found at the maternal-fetal interface and we therefore investigated the potential association between maternal HIV infection, peripheral ILC frequencies and preterm birth.
METHODS: We conducted flow-cytometric analysis of peripheral blood samples from 46 HIV-positive (HIV+) and 45 HIV-negative (HIV-) pregnant women enrolled in a prospective pregnancy cohort study in Soweto, South Africa. Frequencies of ILC1s, ILC2s and ILC3s were compared between women with and without HIV infection, and between women with and without PTB or spontaneous preterm labour (Sp-PTL).
RESULTS: We show that maternal HIV infection is associated with reduced levels of all three ILC subsets. Preterm birth was also associated with lower levels of all three ILC subsets in early pregnancy. ILC frequencies were lowest in HIV positive women who experienced preterm birth. Moreover, ILC levels were reduced in pregnancies resulting in spontaneous onset of preterm labour and in extreme preterm birth (<28 weeks gestation).
CONCLUSIONS: Our findings suggest that reduced ILC frequencies may be a link between maternal HIV infection and preterm birth. In addition, ILC frequencies in early pregnancy may serve as predictive biomarkers for women who are at risk of delivering preterm.

PDA0107

YOUTH PERINATAL HIV-ASSOCIATED COGNITIVE IMPAIRMENT: ASSOCIATIONS WITH CHILDHOOD TRAUMA

N. Phillips[1], D. Stein[1], L. Myer[2], H. Zar[3], J. Hoare[1]
[1]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [2]University of Cape Town, Public Health and Family Medicine, Cape Town, South Africa, [3]University of Cape Town, Child Health, Cape Town, South Africa

BACKGROUND: Exposure to childhood trauma is associated with cognitive impairment in non-clinical populations. The association between childhood trauma and cognitive impairment in the context of perinatal HIV-infection has not been published to-date. This study was nested within the Cape Town Adolescent Antiretroviral Cohort (CTAAC) neuro sub-study, a longitudinal cohort of perinatally ARV-treated HIV-infected youth from public healthcare facilities across Cape Town, South Africa. The purpose was to examine the association between childhood trauma and HIV-associated cognitive impairment among perinatally HIV-infected youth.
METHODS: HIV-infected youth and HIV-uninfected controls completed a comprehensive neuropsychological battery and the Childhood Trauma Questionnaire(CTQ). We then assessed associations between cognitive impairment in various domains and CTQ scores by means of a simple bivariate correlation.
RESULTS: Results represent data from 36-month CTAAC follow-ups, which includes 122 HIV-infected and 35 HIV-uninfected controls between 12-15 years old. Independent samples t-test show no statistically significant differences in self-reported childhood trauma between HIV-infected youth and controls (i.e.: both groups showed low – moderate levels of trauma). Within the HIV-infected group CTQ total scores were significantly correlated with impaired working memory (r=.228, p=.023) and processing speed (r=.238, p=.016). The CTQ subscale of emotional abuse was significantly correlated with the domains of attention, working memory and processing speed, yet the CTQ subscale of emotional neglect was only correlated with impaired processing speed (r=.204, p=.041). The CTQ subscales of physical abuse and neglect and sexual abuse were not significantly correlated with any of the cognitive domains. In the control group childhood trauma on the physical neglect subscale correlated with impaired general intellectual function and emotional abuse correlated with impaired motor coordination.
CONCLUSIONS: The majority of HIV-infected youth in South Africa live in very low socioeconomic environments and are exposed to numerous risk factors, the most significant of which is childhood trauma. Given the association between childhood trauma and cognitive impairment, limiting childhood trauma should be a major public health concern. These findings suggest that low – moderate trauma within the HIV-infected group is associated with more cognitive problems compared to controls. This study provides preliminary data to further investigate the relationship between childhood trauma and HIV-associated cognitive impairment.

PDA02: KILL OR BE KILLED: HIV VS HOST IMMUNE RESPONSES

PDA0202

HIGH Y-CHROMOSOME DNA CONCENTRATIONS ARE ASSOCIATED WITH INCREASED CERVICAL CYTOKINE CONCENTRATIONS AND ACTIVATED CERVICAL HIV TARGET CELL FREQUENCIES

J. Jewanraj[1,2], S. Ngcapu[1,2], V. Ramsuran[1,2,3], A. Mtshali[1,2], L. Mansoor[1], S. Abdool Karim[1,4], Q. Abdool Karim[1,4], J.-A. Passmore[1,5,6], L. Liebenberg[1,2]
[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]School of Laboratory Medicine and Medical Science, College of Health Sciences, University of KwaZulu-Natal, Durban, South Africa, [3]KwaZulu-Natal Research and Innovation Sequencing Platform (KRISP), Durban, South Africa, [4]Department of Epidemiology, Columbia University, New York City, United States, [5]Institute of Infectious Disease and Molecular Medicine (IDM), University of Cape Town, Cape Town, South Africa, [6]National Health Laboratory Service, Cape Town, South Africa

BACKGROUND: Semen is the carrier for spermatozoa and the primary vector for heterosexual transmission of HIV to women during intercourse. Semen induces cytokine production and immune cell recruitment at the female genital tract (FGT) in order to facilitate

conception. Since genital inflammation increases HIV susceptibility in women, semen-induced alterations at the FGT may also have implications for HIV risk. Here we investigated the contribution of semen exposure to biomarkers of inflammation associated with HIV acquisition.

METHODS: Genital specimens were collected every 6 months (average 5±1 visits) from 149 HIV-negative women participating in the CAPRISA 008 tenofovir gel open-label extension trial (n=693 specimens). Y-chromosome DNA (YcDNA) was extracted using a Human Y-chromosome DNA detection kit and quantified using the Quantifiler Trio DNA quantification kit in cervicovaginal lavage (CVL) pellet specimens. In matched CVL supernatant specimens, YcDNA concentrations were compared with concentrations of 48 cytokines and 9 matrix metalloproteinases (MMPs; epithelial barrier function proteins) determined by multiplexed enzyme-linked immunosorbent assay (ELISA), and with the frequencies of cervix-derived NK cells and HIV T cell targets determined by flow cytometry.

RESULTS: A total of 175/233 (75%) genital specimens with detectable YcDNA had a yield sufficient for quantitation. In multivariable linear mixed model analyses, higher YcDNA concentrations were associated with elevated concentrations of growth factors (IL-7, IL-9, PDGF-ββ, VEGF, G-CSF), pro-inflammatory/chemotactic (IL-12p70, IL-6, IP-10), anti-inflammatory (IL-10), and adaptive response cytokines (IFN-γ, IL-13, IL-4). Increased concentrations of MMPs (MMP-1, MMP-2, MMP-3, MMP-7, MMP-10, and MMP-13) involved in the degradation and repair of the extracellular matrix were associated with higher YcDNA concentration. Additionally, higher YcDNA concentrations were also associated with significantly increased frequencies of activated HIV target cells (CD4+CCR5+HLA-DR+) at the FGT.

CONCLUSIONS: Higher YcDNA concentrations were associated with raised levels of cytokines and MMPs, and with greater frequencies of HIV target cells at the female genital mucosa. Considering the association between YcDNA and these established biomarkers of genital inflammation and HIV risk, semen-induced alterations at the FGT may, therefore, have implications for HIV susceptibility in women.

PDA0203

CYTOF ANALYSIS REVEALS THAT HIV-1 UPREGULATES EXPRESSION OF MULTIPLE RNA AND DNA SENSORS IN SUBSETS OF PRIMARY CD4+ T CELLS

A. George[1,2], J. Frouard[1,2], T. Ma[1,2], W. Greene[1,3], N. Roan[1,2]
[1]Gladstone Institute of Virology and Immunology, San Francisco, United States, [2]University of California, Department of Urology, San Francisco, United States, [3]University of California, Departments of Medicine, Microbiology, and Immunology, San Francisco, United States

BACKGROUND: While CD4+ T cells are the primary targets of human immunodeficiency virus (HIV), not all are equally susceptible to infection. Cell permissiveness to infection is determined, in part, by innate immune sensing and host restriction of HIV. We set out to determine if cells that fuse to HIV differentially express viral sensors and restriction factors, and whether HIV infection modulates expression of viral sensors and restriction factors in primary CD4+ T cells.

METHODS: We developed and validated a 41-parameter CyTOF panel that includes 23 intracellular viral sensing proteins and restriction factors. Activated human PBMCs from seronegative individuals were exposed to a CCR5-tropic transmitted/founder HIV-1 reporter virus, and then HIV-fused cells, identified using a Blam-vpr-based viral fusion assay, were sorted by flow cytometry and analyzed by CyTOF. Concurrently, cells from the same donor PBMCs were exposed to HIV and productively-infected cells were identified three days later by CyTOF.

RESULTS: Relative to mock-treated CD4+ T cells, HIV-fused CD4+ T cells expressed lower levels of a variety of HIV sensors, including IFI16 and cGAS, as well as restriction factors, including SAMHD1 and IFITM1. Comparison of HIV-fused cells to productively-infected cells revealed that HIV directly upregulated expression of the restriction factors SAMHD1 and IFITM1, the RNA sensors RIGI and TLR7, and the DNA sensors IFI16 and cGAS within infected cells.

CONCLUSIONS: These data suggest that HIV preferentially enters CD4+ T cells expressing low levels of viral sensor and restriction factors, which may facilitate the completion of the viral life cycle. Following entry, HIV upregulates expression levels of many of these factors but this upregulation is insufficient to prevent productive infection. These results suggest that enhancing innate immune recognition of HIV may be necessary to fully restrict replication of the virus.

PDA0205

TILRR MODULATES PRODUCTION OF PROINFLAMMATORY CYTOKINES AND PROMOTE LEUKOCYTES MIGRATION AND MAY BE A NOVEL TARGET TO PREVENT HIV-1 VAGINAL INFECTION

M. Kashem[1,2], X. Ren[3], H. Li[4], F. Lin[3], F. Plummer[1], M. Luo[1,2,4]
[1]University of Manitoba, Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [2]JC Wilt Infectious Diseases Research Center, Winnipeg, Canada, [3]University of Manitoba, Biosystems Engineering, Winnipeg, Canada, [4]National Microbiology Laboratory, Winnipeg, Canada

BACKGROUND: Toll-like Interleukin-1 receptor regulator (TILRR), a splice variant of FREM1, is an IL-1R1 co-receptor and an important modulator of inflammatory responses. Our previous studies showed the minor allele of FREM1 SNP rs1552896 is significantly associated with resistance to HIV-1 infection in the Pumwani sex worker cohort. Women with the minor allele of rs1552896 expressed no or very low TILRR RNA, whereas the major allele of rs1552896 expressed a significant amount of TILRR RNA. Since TILRR modulates many inflammation responsive genes, it could play an important role in modulating immune cell migration in response to infection through its influence on proinflammatory cytokines secretion by epithelial cells. In this study, we investigated the effect of TILRR- overexpressed cervical epithelial cells supernatants on the migration of HIV-1 target cells using two different migration approaches.

METHODS: We conducted the migration experiments using a novel microfluidic real-time migration device and a transwell migration method. THP-1 (monocytes), MOLT-4 (lymphocytes), and primary human T-cells were used as target cells to investigate the effect of TILRR on their migration behavior. Cervico-epithelial cell (HeLa) transfected with either TILRR or vector-only control, and parental cell culture supernatants were used as chemoattractants.

RESULTS: The results showed that TILRR- overexpressed HeLa cell supernatant significantly attracted more monocytes (THP-1) than vector-only control (>20% higher of % relative migration, PRM=59.83±5.00 vs 32.70±4.37, p=0.0021) in transwell assay. Similar to THP-1 cells, significantly higher amount of MOLT-4 (47.72±6.13 vs

14.95±6.68, p=0.0033), and Primary T-cells (72.98±3.08 vs 40.16±2.00, p=0.0001) were also migrated to the TILRR- overexpressed HeLa culture supernatant. Moreover, the microfluidic real-time assay showed that the migration distance of THP-1 and primary T-cells was significantly longer towards TILRR-transfected HeLa culture supernatants than to the vector-only control supernatants.

CONCLUSIONS: Our study, for the first time, demonstrated that TILRR overexpressed cell culture supernatant significantly influences the migration of leukocytes. Thus, TILRR could play an important role in recruiting HIV-1 target cells at mucosal surfaces through its modulation on the production of multiple proinflammatory cytokines that may lead to increased susceptibility to HIV-1 vaginal infection. TILRR may be a novel target to reduce/prevent HIV-1 vaginal infection.

PDA0206

TH17 CELLS ARE EARLY TARGETS OF SIV DURING ACUTE INFECTION IN RHESUS MACAQUE VAGINAL CHALLENGE MODEL

M.S. Arif[1], S. Xiao[1], D. Thakkar[1], G.C. Cianci[1], R. Lorenzo-Redondo[2], M. Halkett[1], K.K. Halavaty[1], M. Becker[1], A.M. Carias[1], D. Maric[1], R. Veazey[3], T. Hope[1]
[1]Feinberg School of Medicine, Northwestern University, Department of Cell and Developmental Biology, Chicago, United States, [2]Feinberg School of Medicine, Northwestern University, Department of Medicine, Chicago, United States, [3]Tulane National Primate Research Center, Tulane University School of Medicine, Covington, United States

BACKGROUND: Identification of infected cells immediately after mucosal HIV/SIV transmission is critical to design effective prevention strategies. Previous studies have identified CD4+ T-cells, especially, Th17s, as early targets of HIV/SIV in the female reproductive tract (FRT). Here we used rhesus macaque (RM) vaginal challenge model to identify early targets of infection and to follow the infected cell phenotype changes over time.

METHODS: 12 female RMs were challenged intravaginally with a non-replicative luciferase reporter, LiCH, and SIVmac239 mixture. Animals were sacrificed 48-, 72-, or 96-hours post-challenge. Macroscopic luciferase signal detected by in vivo imaging system (IVIS) allowed us to identify FRT regions likely containing infected cells. IVIS positive and negative tissues were serially cryosectioned for immunofluorescence staining and RNA isolation. Infected cells were phenotyped microscopically to identify Th17s (CD3+CCR6+), other T-cells (CD3+CCR6-), immature dendritic cells (iDCs)(CD3-CCR6+), and other cells (CD3-CCR6-). RNA was extracted from infected and non-infected adjacent tissue sections for RNA-Seq.

RESULTS: Phenotyping of >5,000 SIV-infected cells in FRT of eight RMs sacrificed at 72hr and 96hr post-challenge identified infection throughout FRT in 3/4 and 4/4 of 72hr and 96hr animals, respectively. Comparing the two time points, proportion of infected Th17s remains constant (85 vs 70%), however, we can detect an increase in infection rate of iDCs (from 10 to 30%) and other T-cells (from 1 to 3%) as infection progressed. The use of serial sectioning allowed us to identify spread of infection across multiple cryosections of the same tissue. Also, plotting the coordinates of infected cells from multiple sections allowed us to visualize the infected cells in three-dimensional space and to follow the infected cells dissemination over the time.

CONCLUSIONS: These findings support our previous data demonstrating the entire FRT is susceptible to infection and that Th17s are the predominant early targets. In our future work, we hope to compare the distribution of infected cells together with the transcriptome profiles between infected and non-infected tissues at different time points to help understand dynamics and kinetics of virus distribution and dissemination during acute infection.

PDA0207

INTERFERON-α MODULATES THE HOST GLYCOSYLATION MACHINERY DURING TREATED HIV INFECTION

L. Giron[1], F. Colomb[1], E. Papasavvas[1], L. Azzoni[1], X. Yin[1], A. Anzurez[1], M. Fair[1], K. Mounzer[2], J. Kostman[2], P. Tebas[3], U. O'Doherty[3], Q. Liu[1], M. Betts[3], L.J. Montaner[1], M. Abdel-Mohsen[1]
[1]The Wistar Institute, Philadelphia, United States, [2]Philadelphia FIGHT, Philadelphia, United States, [3]University of Pennsylvania, Philadelphia, United States

BACKGROUND: A comprehensive understanding of host factors modulated by the key antiviral cytokine interferon-α (IFNα) is imperative for harnessing its beneficial effects while avoiding its detrimental side-effects, during chronic diseases such as HIV infection. Cytokines modulate host glycosylation, and the host glycome (circulating glycans and cell-surface glycans) plays a critical role in mediating several cellular processes and immunological functions. However, the impact of IFNα on host glycosylation machinery has never been characterized.

METHODS: We assessed the impact of pegylated IFNα2a therapy on circulating IgG glycomes and isolated CD8+ T and NK cell-surface glycomes of 18 HIV-mono-infected individuals on suppressive antiretroviral therapy, using capillary electrophoresis and lectin microarrays. Plasma levels of sCD14 and sCD163 were measured by ELISA. CD8+ T cell and K562-stimulated NK cell phenotypes were profiled using flow cytometry. Integrated HIV DNA in CD4+ T cells was measured by qPCR. Wilcoxon test and Spearman's correlations were used for statistical analysis. False discovery rates (FDR) were calculated to account for multiple comparisons.

RESULTS: Interactome analysis highlighted significant interactions that support a model in which a) IFNα increases the proportion of pro-inflammatory, bisected GlcNAc glycans (known to enhance FcγR binding) within the IgG glycome (FDR<0.02), which in turn b) increases inflammation (as measured by sCD14 and sCD163; p<0.03), which c) leads to lower levels of CD8+ T cell functionality (perforin, Eomes, and TNFα expression) but higher degranulation (CD107) (p<0.02, Figure). IFNα-mediated induction of bisected GlcNac associated with a poor reduction of HIV integrated DNA (p=0.02, rho=-0.78). Examining cell-surface glycomes, IFNα increases the levels of T antigen (Gal-GalNAc) on CD8+ T cells (FDR=0.01). This induction is associated with lower CD8+ T degranulation (p<0.02, rho<-0.8). Last, IFNα increases the levels of fucose on NK cells (p<0.05). This induction is associated with higher expression of Eomes, T-bet, and IFNγ upon K562 stimulation (p=0.048, rho>0.8).

CONCLUSIONS: IFNα causes host glycomic alterations that are known to mediate inflammatory responses. These alterations are associated with mainly detrimental, but also beneficial, consequences of IFNα on innate and adaptive immune functions. Manipulating glycan-lectin interactions may represent a strategy to enhance the impact of IFNα on immunity while avoiding its detrimental side-effects.

Chan School of Public Health, Boston, United States, [3]Vanderbilt University Medical Center, Nashville, United States, [4]Whitman Walker Health, Washington, DC, United States, [5]University of Rochester, Rochester, United States, [6]University of Alabama, Birmingham, United States, [7]National Institute of Allergy and Infectious Diseases, Rockville, United States, [8]ACTG Community Scientific Subcommittee, Los Angeles, United States, [9]University of Pittsburgh, Pittsburgh, United States, [10]University of Washington, Seattle, United States, [11]Rush University, Chicago, United States, [12]University of California, San Francisco, San Francisco, United States, [13]Massachusetts General Hospital, Harvard Medical School, Boston, United States, [14]University of California, San Diego, San Diego, United States

BACKGROUND: Strategies for ART-free HIV remission require validation through treatment interruption (TI) studies to confirm a delay in HIV rebound, but there is uncertainty whether modern ART regimens may impact this outcome. We compared HIV rebound timing in A5345 to historic TI studies.

METHODS: A5345 is a prospective study enrolling individuals who initiated ART during chronic or early HIV infection, on suppressive ART for ≥2 years with CD4 count ≥500 cells/mm3 and nadir CD4 count ≥200 cells/mm3. Participants on a non-nucleoside reverse transcriptase inhibitor (NNRTI)-based regimen were switched to a protease inhibitor (PI) or integrase strand transfer inhibitor (INSTI)-based regimen before the TI. During TI, viral loads were monitored twice weekly and participants restarted ART upon two successive viral loads ≥1,000 copies/mL. We compared the chronic-treated participants of A5345 with chronic-treated participants on PI regimens from placebo arms of 4 historic ACTG TI studies.

RESULTS: Thirty-three chronic-treated A5345 participants interrupted ART and were compared to 61 participants from historic studies. There were no significant differences between the groups in age (median 46 vs. 43 years), sex (88% vs. 87% male), nadir or baseline CD4 count (median 783 vs. 852 cells/mm3), or pre-ART viral loads (median 4.5 vs. 4.4 log10 copies/mL). All participants of the historic studies were on older PI-based regimens while 94% of A5345 participants were on INSTI-based ART. The median time to viral rebound ≥1,000 copies/mL in A5345 was 22 days. Acute retroviral syndrome was diagnosed in three (9%) participants. There were no differences between A5345 vs. historic studies in the percentage of participants with viral rebound by either TI week 4 (73% vs 79%, P=0.61) or week 8 (97% vs 95%, P=1.0). There was no significant association of ART duration or CD4 count with timing of HIV rebound in A5345; higher pre-ART HIV RNA was associated with shorter time to rebound (Spearman r = -0.37, P=0.09). All participants re-suppressed after ART re-initiation.

CONCLUSIONS: For chronic-treated individuals, virologic suppression by modern ART regimens did not result in a significant delay in the time to HIV rebound after ART interruption. Novel strategies will be needed to achieve ART-free HIV remission.

IS DTG+3TC EFFECTIVE AND SAFE IN CLINICAL PRACTICE? EVIDENCE FROM REAL WORLD DATA

Y. Punekar[1], D. Parks[2], J. van Wyk[1], A. de Ruiter[1]
[1]ViiV Healthcare, Brentford, United Kingdom, [2]GlaxoSmithKline, Philadelphia, United States

BACKGROUND: RCT evidence has shown dolutegravir(DTG)+lamivudine(3TC) is an efficacious and durable regimen with a good safety profile in treatment-naïve and treatment-experienced HIV-infected individuals. Several observational studies have concluded that it is effective in clinical practice. The objective of this meta-analysis was to estimate effectiveness and safety of DTG+3TC in treatment-experienced, virologically suppressed people living with HIV (PLHIV) by combining real-world evidence (RWE) from clinical practice.

METHODS: A systematic literature review of PubMed and Embase along with 24 regional and international conferences was conducted between 2013-Dec 2019 to identify non-RCT studies of DTG+3TC in PLHIV. Eligible published articles presenting outcomes of interest were identified and extracted. Identified studies were included if they had acceptable level of publications bias and heterogeneity determined using funnel plots and I^2 statistics, respectively. One-arm meta-analyses using the Dersimonian and Laird method were conducted to estimate effect sizes for viral failure, viral suppression, and discontinuations for DTG+3TC.

RESULTS: A total of 7 DTG+3TC studies (n=1,800 patients) reported data on treatment experienced virologically suppressed PLHIV on outcomes of interest at different timepoints. Results showed that among patients switching to DTG+3TC treatment ≥90% maintained virological suppression (ITT) with ≤1% viral failures.

	DTG+3TC			
	Viral Failure (n=1800)	Virological suppression ITT (n=1800)	Virological suppression PP (n=1552)	Discontinuations (n=1800)
Week 48 (Mean [95% CI])	0.008 [0.004-0.014]	0.906 [0.849-0.951]	0.990 [0.983-0.995]	0.089 [0.048-0.139]

ITT=Intention to treat; PP=Per protocol; CI=Confidence Interval

[Table 1: Proportion of patients with viral failure, virological suppression and discontinuations at week 48.]

	DTG+3TC			
	Viral Failure (n= 904)	Virological suppresion ITT (n=904)	Virological suppresion PP (n=767)	Discontinuations (n=904)
Week 96 (Mean [95% CI])	0.005 [0.001-0.013]	0.930 [0.831-0.990]	0.995 [0.976-1.000]	0.057 [0.004-0.151]

ITT=Intention to treat; PP=Per protocol; CI=Confidence Interval

[Table 2: Proportion of patients with viral failure, virological suppression and discontinuations at week 96.]

CONCLUSIONS: DTG+3TC is an effective and durable antiretroviral regimen with low rates of discontinuation in treatment experienced patients in clinical practice.

PDB0104

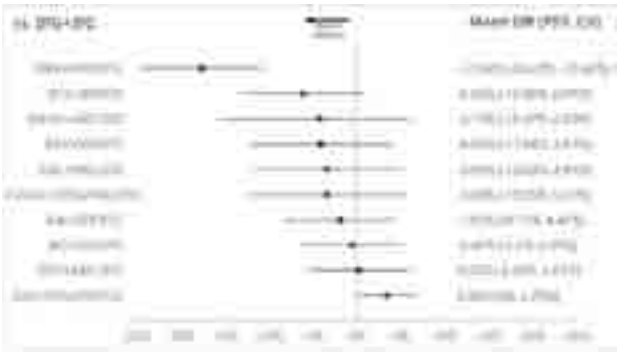
COMPARATIVE EFFICACY AND SAFETY OF A COMBINATION THERAPY OF DOLUTEGRAVIR AND LAMIVUDINE VS 3-DRUG ANTIRETROVIRAL REGIMENS IN TREATMENT-NAÏVE HIV-1 INFECTED PATIENTS AT 96 WEEKS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

K. Nickel[1], N. Halfpenny[2], S. Snedecor[3], Y. Punekar[4]
[1]Pharmerit International, Berlin, Germany, [2]Pharmerit International, Rotterdam, Netherlands, [3]Pharmerit International, Bathesda, United States, [4]ViiV Healthcare, Brentford, United Kingdom

BACKGROUND: Dolutegravir+lamivudine (DTG+3TC) has been shown to be comparable to guideline recommended 3-drug antiretroviral treatments (ARTs) in HIV up to week 48. The objective of this analyses was to compare the efficacy and safety of DTG+3TC to 3-drug ARTs up to 96 weeks (WK96).

METHODS: Randomized controlled trials (RCTs) of treatment-naïve HIV-1 infected patients reporting outcomes at WK96 were identified by systematic review. The proportion of patients achieving virologic suppression (VS) to <50 RNA copies/mL at WK96 for all patients and those with baseline viral load >100,000 RNA copies/mL was compared between DTG+3TC and guideline recommended ARTs using a fixed-effect Bayesian network meta-analysis framework. Other outcomes examined were CD4+ cell count change from baseline, treatment discontinuations and safety (adverse events [AEs], serious AEs [SAEs], and drug-related AEs [DRAEs]).

RESULTS: The network included 11 ARTs from 11 RCTs with 7991 patients. ARTs containing tenofovir disoproxil/emtricitabine (TDF/FTC) and tenofovir alafenamide (TAF)/FTC were combined by their core agent to maintain network connectivity. The treatment difference for viral suppression at WK96 for DTG+3TC compared to the other 10 ARTs ranged from -3% (-7%, 0%) vs DTG+TDF(or)TAF/FTC to 13% (4%, 23%) vs ritonavir-boosted darunavir (DRV/r)+TDF/FTC. On other outcomes DTG+3TC was broadly similar to all 3-drug ARTs with some statistically significant benefits on SAEs and DRAEs.



[Figure 1: Difference in proportions in viral suppression (95% credible intervals) at WK96, 3-drug ARTs versus DTG+3TC.]

CONCLUSIONS: DTG+3TC offers comparable and durable efficacy and safety to guideline recommended 3-drug regimen with reduced exposure to ARTs for naïve patients starting treatment.

PDB0105

SWITCHING TO DOLUTEGRAVIR PLUS LAMIVUDINE (DTG+3TC) IS NON-INFERIOR TO AND AS SAFE AS CONTINUING STANDARD TRIPLE ANTIRETROVIRAL THERAPY (TAR)

J. Rojas[1], J.L. Blanco[1], E. Negredo[2], P. Domingo[3], J. Tiraboschi[4], E. Ribera[5], N. Abdulghani[6], J. Puig[2], G. Mateo[3], D. Podzamczer[4], M. Gutierrez[3], E. de Lazzari[1], R. Paredes[2], E. Martinez[1], DOLAM Study Team
[1]Hospital Clínic, Barcelona, Spain, [2]Hospital Germans Trías i Pujol, Badalona, Spain, [3]Hospital de Sant Pau, Barcelona, Spain, [4]Hospital de Bellvitge, L'Hospitalet, Spain, [5]Hospital Vall d'Hebron, Barcelona, Spain, [6]Hospital Arnau de Vilanova, Lleida, Spain

BACKGROUND: It is uncertain whether virally suppressed patients on standard triple ART can be safely switched to DTG+3TC.

METHODS: HIV-1-infected adults with <50 copies/mL for ≥12 months, no viral failure or resistance mutations to study drugs, CD4 nadir >200 cells/mm^3, and HBsAg negative were randomized 1:1 (stratified by baseline third agent) to continue triple antiretroviral therapy (control) or to switch to DTG+3TC. Primary end-point was the proportion of patients with HIV-1 RNA ≥50 copies/mL at week 48 (FDA Snapshot, 8% non-inferiority margin). Blips, adverse effects, weight and body fat (DXA scan), and sleep quality (PSQI) were secondary end-points.

RESULTS: 265 patients randomized (DTG+3TC: 131; control: 134). Baseline: age 46 years; women 14%; CD4 712 cells/mm^3; weight 75 kg; trunk fat 10134 gr; limbs fat 7615 gr; poor sleep quality (defined by PSQI>5) 40%. At week 48, subjects with HIV-1 RNA ≥50 copies mL 2.4% (3/125) DTG+3TC vs. 0.8% (1/126) control [difference 1.6%; 95% CI -2.3 to 6.1] per-protocol, and 2.3% (3/131) DTG+3TC vs. 0.7% (1/134) control [difference 1.5%; 95% CI -2.1 to 5.8] intention-to-treat demonstrating non-inferiority. There were no differences between DTG+3TC vs. control in incidence of blips or number of patients with ≥1 blip, and overall or serious (none drug-related) adverse events. Weight (kg) change (mean, SD) at week 48 was 1.55 (3.98) DTG+3TC vs. 0.08 (3.95) control (P= 0.005) with no differences among strata; there were no differences in regional fat (gr) (mean, SD): trunk, -115 (4413) vs. 499 (2056) (P= 0.68); limbs, 620 (1308) vs. 1166 (4220) (P= 0.98) or PSQI changes over time (P=0.46).

Snapshot outcomes week 48	DTG/3TC (n=131)	Triple ART (n=134)
VL < 50 copies/mL, n (%)	122 (93.1)	125 (93.3)
VL ≥ 50 copies/mL, n (%)	3 (2.3)*	1 (0.7)
No virologic data, n (%)	6 (4.6)	8 (6.0)
Discontinued therapy	3 (2.3)	4 (3.0)
Lost of follow-up	2 (1.5)	2 (1.5)
Patient's decision	1 (0.8)	2 (1.5)

* No resistance mutations detected in all 3 patients. Two maintained DTG+3TC and had HIV-1 RNA <50 copies mL at week 48.

CONCLUSIONS: Switching to DTG+3TC in virologically suppressed patients was non-inferior to and as safe as continuing triple ART at 48 weeks. Although weight increased with DTG+3TC relative to triple ART, regional fat changes did not differ between arms .

PDB0106

OPTIMIZING THE MANAGEMENT OF PATIENTS WITH VIROLOGIC NON-SUPPRESSION

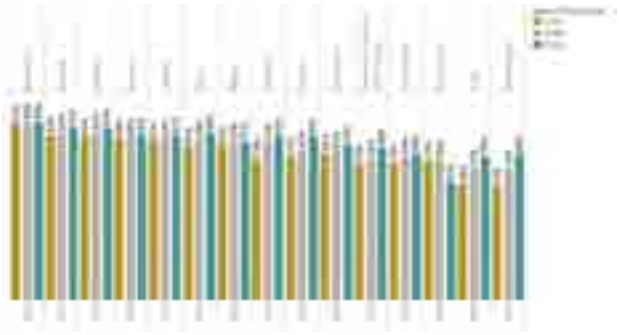
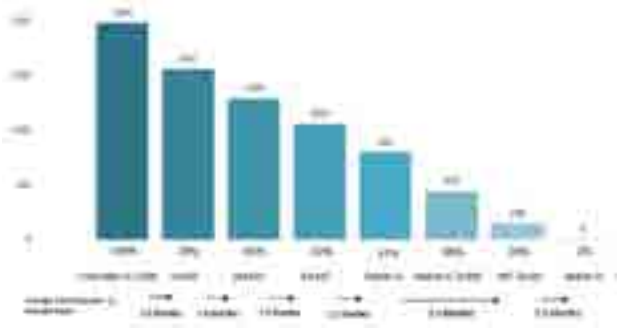
BACKGROUND: Some programs continue to face challenges meeting HIV viral supression targets, with incomplete rates of repeat viral load (VL) testing in patients with virologic non-suppression (PVNS), and persistent VL non-suppresion. Recent data show that interventions such as enhanced adherence counseling (EAC) and the use of Point-of-Care (POC) testing may improve outcomes in PVNS.

METHODS: Significant efforts are underway in PEPFAR-supported countries to improve VL coverage and suppression. Generally, PLHIV on ART for at least 6 months with VL results ≥ 1000 copies/ml receive EAC, with follow-up VL testing. Data from 15 countries were assessed using Wilcoxon-Signed Rank Test for the proportion of individuals with VL suppression over the period 2017-2019, and the average number of PVNS per facility. Site-level high VL cascade were reviewed.

RESULTS:



[Figure 1. Significant improvement in viral suppression rate in PEPFAR 13 supported countries over two year period (FY17-19)]



[Figure 2. High viral load cascade from select sites in South Sudan (2018-2019)]

VL suppression rates improved significantly in 13 of the 15 countries over the three-year period observed (Figure 1, P<0.05). Data from 2, 021 treatment facilities in some selected countries averaged 200 PVNS per facility. Site level high VL cascades highlighted low rates of PVNS EAC receipt, repeat VL testing, and ART switch, with prolonged times between interventions (Figure 2 South Sudan).

CONCLUSIONS: The management of PVNS continues to be a challenge and is critical to achieving epidemic control. There is a continued need for differentiated client-centered models that include interventions for PVNS care, such as the delivery of quality EAC, ART switch, optimized use of both laboratory-based and POC instruments for VL re-testing, and timely results availability and utilization for improved patient and program outcomes.

DARUNAVIR/COBICISTAT/EMTRICITABINE/TENOFOVIR ALAFENAMIDE (D/C/F/TAF) IN TREATMENT-NAÏVE (AMBER) AND VIROLOGICALLY SUPPRESSED (EMERALD) PATIENTS WITH NEUROLOGIC AND/OR PSYCHIATRIC COMORBIDITIES: WEEK 96 SUBGROUP ANALYSIS

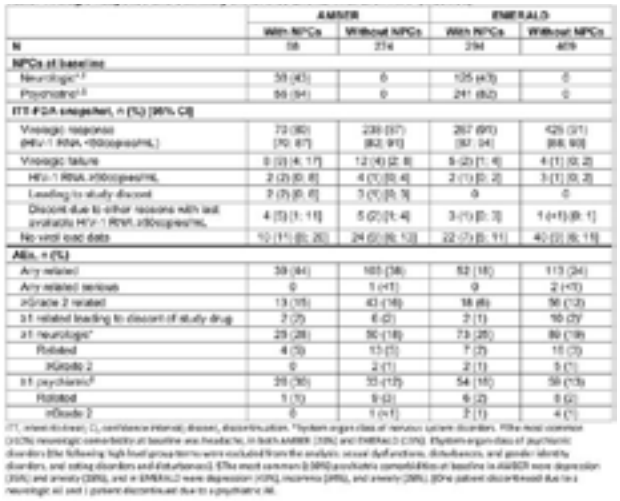
J. Bushen[1], D. Luo[2], R.B. Simonson[1], R. Burress[1], K. Brown[1], D. Anderson[1], K. Dunn[1]
[1]Janssen Scientific Affairs, LLC, Titusville, United States, [2]Janssen Research & Development, LLC, Titusville, United States

BACKGROUND: Patients with HIV-1 and neurologic and/or psychiatric comorbidities (NPCs) face unique challenges including suboptimal adherence and possible exacerbation of NPCs, requiring individualized treatment approaches for optimal health outcomes.

METHODS: This analysis evaluated 96-week efficacy/safety in patients with versus without NPCs at baseline from two trials: AMBER (ClinicalTrials.gov:NCT02431247; treatment-naïve patients randomized to initiate D/C/F/TAF 800/150/200/10mg or control regimen) and EMERALD (ClinicalTrials.gov:NCT02269917; virologically suppressed patients randomized to switch to D/C/F/TAF or continue their boosted protease inhibitor-based regimen). NPCs were based on verbatim medical history terms, coded and defined as those within the MedDRAv22 system organ class Nervous System Disorders or Psychiatric Disorders. In this analysis, efficacy was assessed by virologic response (HIV-1 RNA <50copies/mL) at Week 96 by intent-to-treat FDA snapshot analysis in patients randomized to receive D/C/F/TAF.

RESULTS: Overall, 88/362 (AMBER) and 294/763 (EMERALD) patients receiving D/C/F/TAF had baseline NPCs, with psychiatric comorbidities more common than neurologic (**Table**). High virologic response rates (80-91%) were observed at Week 96, regardless of NPCs (**Table**). Small response rate differences in AMBER patients with versus without NPCs were driven by discontinuation for reasons other than virologic failure with last HIV-1 RNA ≥50copies/mL; notably, no treatment-emergent resistance was detected among AMBER patients with NPCs. Across both studies, most AEs were grade 1 and discontinuation rates due to D/C/F/TAF-related AEs were low and similar for patients with and without NPCs (**Table**). In both studies, patients with NPCs had higher overall rates of neu-

rologic/psychiatric AEs; however, incidences of D/C/F/TAF-related neurologic or psychiatric AEs were similar regardless of NPCs. There were no neurologic or psychiatric D/C/F/TAF-related serious AEs.



[Table. Virologic response and summary of adverse events with D/C/F/TAF (week 96)]

CONCLUSIONS: Patients with and without NPCs receiving D/C/F/TAF over 96 weeks had high virologic response rates and low D/C/F/TAF-related discontinuation rates. Patients with NPCs tolerated D/C/F/TAF well without additional central nervous system-related burden, indicating that D/C/F/TAF may be a suitable option for these patients.

TASK-SHARED, NURSE-DELIVERED, COGNITIVE BEHAVIORAL THERAPY FOR ADHERENCE AND DEPRESSION (CBT-AD) IN HIV CLINICS IN KAYELITSHA, SOUTH AFRICA: A RANDOMIZED CONTROLLED TRIAL

S. Safren[1,2], C. O'Cleirigh[3,4,2], L. Andersen[5], J. Magidson[6], J. Lee[1], S. Bainter[1], N. Musinguzi[7], S.A. Kagee[8], J. Joska[5]
[1]University of Miami, Psychology, Miami, United States, [2]Fenway Health, The Fenway Institute, Boston, United States, [3]Massachusetts General Hospital, Psychiatry / Behavioral Medicine, Boston, United States, [4]Harvard Medical School, Psychiatry / Psychology, Boston, United States, [5]University of Cape Town, Cape Town, South Africa, [6]University of Maryland, College Park, United States, [7]Mbarara University of Science and Technology, Mbarara, Uganda, [8]Stellenbosch University, Stellenbosch, South Africa

BACKGROUND: Depression is a highly prevalent condition among people living with HIV (PLWH) both globally and in Sub-Saharan Africa (SSA), home to the highest number of PLWH. Depression is a consistent and robust predictor of non-adherence to antiretroviral therapy (ART). Yet, there is a significant mental health treatment gap, with insufficient numbers of mental health providers. Task sharing, originally developed in SSA to expand ART availability, may also be a useful solution to increase access to depression treatment (e.g., by nurses who are more available).
METHODS: Methods: This study is a two-arm randomized controlled trial for virally unsuppressed PLWH and clinical depression (N=161) in primary HIV care clinics in Khayelitsha, South Africa. It is comparing a task-shared cognitive behavioral therapy for adherence and depression (CBT-AD) administered by nurses (supervised by a clinical psychologist) with standard of care (SOC) clinic-based adherence counseling and support. Primary outcomes (baseline to acute post-treatment; 4-months) were the Hamilton Depression Rating Scale (HAMD) administered by a blinded independent evaluator, and weekly adherence via real-time monitoring (Wisepill). For the depression analyses, we used linear mixed models using maximum likelihood for missing data. For weekly adherence, we used a generalized estimating equation model (uses all available data) with robust standard errors, censoring Wisepill non-usage.
RESULTS: Results: CBT-AD showed superiority on both outcomes. While both groups improved in depression, there was a significant interaction such that the CBT-AD condition improved by an estimated 4.88 points (CI: -7.86, -1.87, p=.0016) more than SOC. Wisepill usage was variable (non-usage); however, there was also a significant time by condition interaction (est=1.38, CI: .38, 3.60, p=.000) such that the SOC started off lower than CBT-AD, and had a significant decrease in adherence over this time period (est=1.26, CI: -1.79, -.73, p=.000), and the CBT-AD condition maintained their higher adherence. The uncensored adherence (wisepill) analysis yielded a similar pattern of results.
CONCLUSIONS: Conclusions: Nurse-delivered CBT-AD using a task sharing model was effective in improving depression and ART adherence for virally unsuppressed PLWH. Longer term follow-up, with behavioral and biological outcomes are needed, as are future implementation science trials and analysis of cost-effectiveness, to translate findings into clinical practice.

PDB0204

HIGH BURDEN OF DEPRESSION AMONG CLIENTS INITIATING SAME-DAY ANTIRETROVIRAL THERAPY AT THE ANONYMOUS CLINIC, BANGKOK THAILAND

P. Jomja[1], T. Chinbunchorn[1], S. Thitipatarakorn[1], P. Seekaew[2], S. Amatavete[1], M. Avery[3], S. Mills[3], R. Vannakit[4], P. Phanuphak[1], N. Phanuphak[1], R. Ramautarsing[1]
[1]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Columbia University, New York, United States, [3]FHI 360 and LINKAGES, Bangkok, Thailand, [4]USAID Regional Development Mission Asia, Office of Public Health, Bangkok, Thailand

BACKGROUND: Depressive disorders are common, but often underdiagnosed among people living with HIV. We implemented a depression-screening tool into our Same-Day antiretroviral therapy (SDART) service at the Thai Red Cross AIDS Research Centre (TRCARC) to determine the prevalence of depression and its association with clients' decision to accept or reject SDART.
METHODS: Clients at the TRCARC underwent processes for eligibility determination for ART initiation per national guidelines on the same day as HIV diagnosis. As part of the ART initiation process the Thai version of the Patient Health Questionnaire (PHQ-9), a depression screening tool, was implemented, which was completed electronically by the client. A score of 0-4 represents no depression, 5-8 mild depression, 9-14 moderate depression, 15-19 moderately severe depression, and ≥20 represents severe depression.
RESULTS: Between June – November 2019, 879 clients were enrolled in the SDART program, 657 (74.7%) were men who have sex with men, 95 (10.8%) cis-gender women, 82 (9.3%) heterosexual men, and 45 (5.1%) transgender women. Median (interquartile range) age was 29 (24-36). A total of 859 (97.7%) accepted SDART. Of 833 clients who completed the Thai PHQ-9, 471 clients (56.5%)

had no depression, 217 (26.1%) had mild depression, 119 (14.3%) had moderate depression, 22 (2.6%) had moderately severe depression and 4 (0.5%) had severe depression. Among clients with scores indicative of moderate, moderately severe or severe depression, only 2 (1.4%) rejected SDART. There was no relationship between the presence of moderate to severe depression and the decision to accept SDART (p=0.688). The most common reasons for rejecting SDART were: 1) difficulty travelling to healthcare units (33.3%), 2) fear of ART side effects (27.3) and 3) had a job which prohibits taking ART at regular times (21.4%).

CONCLUSIONS: Acceptability of SDART was high, and although the severity of depression did not impact this, we found a high burden of depression among our clients, with almost half of all clients having at least mild depression. HIV diagnosis could be utilized as an opportunity for diagnosis of depression, and routine self-screening for depression during ART initiation using the PHQ-9 can be implemented effectively.

PDB0205

LONGITUDINAL STUDY OF NEUROCOGNITIVE DISORDERS AND ASSOCIATED STRUCTURAL BRAIN CHANGES IN ADOLESCENT HIV

J. Hoare[1], J.-P. Fouche[2], N. Phillips[1], L. Myer[2], S. Heany[1], H. Zar[2], D. Stein[1]
[1]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [2]University of Cape Town, Cape Town, South Africa

BACKGROUND: Neurocognitive disorders (NCD) despite ART are well known in perinatally-infected HIV+ adolescents (PHIV) but there are few data on longitudinal changes in NCD and brain structure in PHIV over time.

METHODS: Within this sub-study of the Cape Town Adolescent Antiretroviral Cohort, PHIV on ART >6m completed baseline and 3-year follow-up assessments including a comprehensive neurocognitive battery assessing function in 10 domains. We applied the youth HIV-associated NCD diagnostic criteriato classify each as having either a major NCD, a minor NCD, or no impairment. Diffusion tensor imaging and structural brain magnetic resonance imaging was done to determine fractional anisotropy (FA), mean diffusivity (MD), grey and white matter volumes, cortical thickness and cortical surface area. In analysis we examined changes over the 3-year period in NCD and neurostructural measures in PHIV compared to age- and sex-matched HIV- controls.

RESULTS: Overall 122 PHIV ages 9-12 years (mean CD4 cell count 953 cells/μL and 85.3% VL<50 copies/mL) and 37 age-matched HIV-controls completed baseline and 3-year follow-up assessments. 48% PHIV had a NCD at baseline and 60% at follow-up: NCD diagnosis was stable over time in 60 (49%) of participants, 22 (18%) improved NCD status and 40 (33%) deteriorated. At baseline, PHIV with major NCD showed the highest whole brain MD (p=.007); at follow-up whole brain grey (p=.004) and white matter volumes (p=.032) were lowest in PHIV, with whole brain MD remaining highest in PHIV with a major NCD (p=.02). Higher MD is suggestive of inflammation and myelin loss. In addition significant regional brain changes were observed at follow-up compared to baseline in PHIV vs controls. Structural changes over time were observed mainly in cortical surface area of the bilateral orbitofrontal, anterior cingulate, medial orbitofrontal, middle frontal, superior temporal, transverse temporal gyri and insula (all p<.05). White matter microstructural changes over time were observed in the internal capsule, cerebral peduncle and the cingulum (all p<.05).

CONCLUSIONS: NCD and brain structural alterations in PHIV increased over the 3 years of follow-up compared to HIV- controls. Studying the participants who improved vs deteriorated over time may provide insight into future interventions for NCD in PHIV.

ASSESSING NEUROCOGNITIVE FUNCTIONING AMONG ADOLESCENTS AND YOUNG ADULTS WITH PERINATALLY ACQUIRED HIV IN THAILAND: SUPPORT FOR THE NEUROSCREEN APP

R.N. Robbins[1], T. Kulvadee[2], T. Puthanakit[3], N. Wipaporn[3], A.F. Santoro[1], C.A. Mellins[1], K.M. Malee[4], R. Paul[5], L. Aurpibul[6]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, New York, United States, [2]Faculty of Humanities, Chiang Mai University, Department of Psychology, Chiang Mai, Thailand, [3]Faculty of Medicine, Chulalongkorn University, Department of Pediatrics, Bangkok, Thailand, [4]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Science, Chicago, United States, [5]Missouri Institute of Mental Health/University of Missouri-St. Louis, Missouri, St. Louis, United States, [6]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand

BACKGROUND: Adolescents and young adults (AYA) living with perinatally acquired HIV (PHIV) often perform worse on selective neurocognitive tests compared to their uninfected peers, including tests of working memory, processing speed and executive functioning. Assessing their neurocognition is challenged in low- and middle-income countries (LMICs), such as Thailand, due to resource constraints (e.g., lack of easy-to-use, validated tools). This study examined if a novel, highly automated (e.g., tests automatically timed and scored), brief (25 minutes), easy-to-use by any staff, tablet-based neurocognitive assessment (NeuroScreen) adapted for Thailand could detect test performance differences between AYA with PHIV and uninfected-AYAs.

METHODS: NeuroScreen underwent translation by bilingual (English and Thai) psychologists, and was reviewed by Thai AYA with and without PHIV, and Thai clinical staff. Thai AYA (50 PHIV, 49 uninfected-AYA) recruited from similar communities were administered the Thai-language version of the NeuroScreen app, consisting of 12 tests of processing speed, working memory, executive functioning, learning, delayed recall, and motor speed. Independent samples *T*-tests were computed examining group differences.

RESULTS: Median age was 18 years (IQR 16-20), 60% were female. Groups did not differ by sex or age. Table 1 presents means and standard deviations and *T*-test results for each NeuroScreen test by HIV-status group. AYA with PHIV performed significantly worse on: five tests of processing speed, one of two tests of working memory, and the one test of executive functioning. AYA with PHIV mean performance was lower on all remaining tests, though not statistically significantly different than uninfected-AYAs.

Domain	Test	PHIV		HIV-		*p*
		Mean	SD	Mean	SD	
Processing Speed	Trail Making 1	21.34	7.04	18.75	4.55	0.04
	Trail Making 2	10.34	11.14	8.42	4.09	0.26
	Visual Discrimination 1	17.92	4.35	22.12	4.39	0.00
	Visual Discrimination 2	30.60	5.16	36.86	6.34	0.00
	Number Speed	28.39	5.26	23.89	6.25	0.00
Executive Functioning	Trail Making 2	22.52	5.97	9.84	4.92	0.03
Working Memory	Number Span Forwards	5.43	0.97	5.68	1.41	0.30
	Number Span Backwards	2.99	1.48	3.67	1.29	0.02
Motor Speed	Tapping (dominant hand)	276.32	38.82	284.00	30.70	0.28
	Tapping (nondominant hand)	250.86	46.07	258.67	29.90	0.32
Learning	Verbal Learning Total	9.38	0.73	9.51	0.65	0.35
Delayed Recall	Verbal Delayed Recall	4.42	0.91	4.65	0.72	0.16

[Table 1. NeuroScreen test performance by HIV status]

CONCLUSIONS: Results indicate that the NeuroScreen app detects performance differences in neurocognitive domains known to be vulnerable to PHIV, including processing speed, executive function, and working memory. NeuroScreen demonstrates potential as an assessment tool for Thai AYA with PHIV and LMICs.

BACKGROUND: High rates of STIs have been reported among MSM on PrEP. Our objective was to assess, within the setting of the ANRS IPERGAY trial, the incidence of bacterial STIs over time and baseline risk factors associated with STIs.

METHODS: Data from all participants enrolled in the ANRS IPERGAY trial were used. Participants were enrolled in February 2012 and switched to open-label PrEP (with TDF/FTC) in November 2014. Study visits were scheduled every 8 weeks.

Participants were screened for STI (syphilis, chlamydia, and gonorrhea) at baseline and at least every 6 months at the physician's discretion. All bacterial STIs reported in the database were analyzed with their location (pharyngeal, rectal, urine). STIs incidence was calculated yearly. Cox proportional hazards model regression was used to explore associations between participant's characteristics at baseline and first STI occurrence.

RESULTS: Between February 2012 and June 2016, 429 participants were enrolled with a median follow-up of 23 months (range: 0-51). At baseline, median age: 35 years, 99% MSM, 91% white, 72% had post-secondary education, 46% used recreational drug, 27% use GHB, 35% use erectile drugs, 27% had STI, median number of sexual partners in prior two months: 8, and 35% had condomless receptive anal sex at last intercourse. Overall STIs incidence was 74, 33, 13, 32 and 30 per 100 PY for all STIs, rectal STIs, syphilis, gonorrhea and chlamydia, respectively. STI incidence significantly increased from February 2012 (55 per 100 PY) to June 2016 (90 per 100 PY) (p<0.001). One hundred and sixty-seven participants (39%) accounted for 557 (86%) of all STIs reported while 170 participants (40%) did not experience any STI during follow-up.

	Univariate analysis			Multivariate analysis	
	N/Ntot	HRCox[IC]	P Cox	HRCox[IC]	P Cox
STI at baseline	115/429	1.46[1.12;1.9]	0.005	1.45[1.11;1.89]	0.007
Number of Partners >=8	240/429	1.45[1.13;1.87]	0.004	1.39[1.07;1.82]	0.015
Sex Party	181/419	1.42[1.11;1.82]	0.005	1.09[0.83;1.43]	0.529
Use of GHB	117/413	1.76[1.35;2.29]	<0.001	1.53[1.15;2.04]	0.004
Use of erectile drugs	151/420	1.62[1.26;2.07]	<0.001	1.32[1.01;1.74]	0.045

[Table. Baseline risk factors associated with STIs occurrence.]

CONCLUSIONS: STI incidence was high and increased during the IPERGAY trial, but most STIs were concentrated in a high-risk group that should be targeted for future interventions.

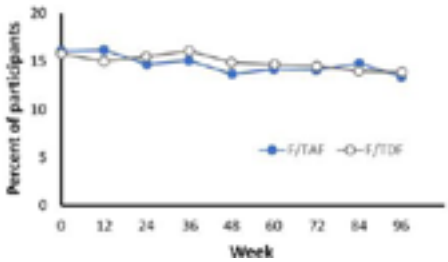
BACKGROUND: In DISCOVER, F/TAF was noninferior to F/TDF for HIV PrEP in MSM and transgender women. Here, we report STI outcomes during the trial through 96 weeks of follow-up.

METHODS: DISCOVER randomized 5387 participants 1:1 to receive blinded daily F/TAF or F/TDF for PrEP. Participation required documented HIV risk, determined by history of rectal STI, syphilis, or sexual behaviors. STI testing (gonorrhea, chlamydia and syphilis) and sexual behavior computer-assisted self-interview (covering the preceding 3 months) occurred at screening and every 12 weeks. Statistical analyses for categorical variables used the CMH test, and comparisons of HIV incidence used a Poisson model.

RESULTS: At baseline, 430 (16.1%) of participants in the F/TAF arm and 421 (15.8%) in the T/TDF arm tested positive for gonorrhea or chlamydia at any anatomic site; 299 (11.3%) and 279 (10.5%) tested positive at the rectum. The proportion of participants positive for gonorrhea and chlamydia by visit is found in the Figure.



[Figure 1. Percent of participants who tested positive for gonorrhea or chlamydia by visit.]

The overall incidence rate of gonorrhea or chlamydia at any anatomic site was 85.7 and 83.1 per 100 person-years (PY) for F/TAF and F/TDF respectively, and for rectal gonorrhea and chlamydia was 47.5 and 46.9 per 100PY. The 96-week prevalence of syphilis was

14.8% and 15.2% in the F/TAF and F/TDF arms, and the incidence rate was 9.9 and 9.3 per 100PY, respectively. The rate of HIV acquisition was higher in participants with a history of rectal gonorrhea, rectal chlamydia or syphilis at screening (0.61 vs 0.12 per 100PY, p<0.001). The mean(SD) number of condomless receptive anal sex partners was 3.6(5.9) vs 3.4(6.2) at screening and 3.8(7.3) vs 3.9(7.8) at week 96 for F/TAF and F/TDF respectively.

CONCLUSIONS: STI acquisition rates, especially rectal gonorrhea and chlamydia, remained stably high through 96 weeks of follow-up. In combination with sexual behavior data, this argues against risk compensation in DISCOVER.

BACKGROUND: In Thailand, *Chlamydia Trachomatis* (CT) and *Neisseria gonorrhoeae* (NG) screening for at-risk populations is not routinely provided. Screening for CT/NG among men who have sex with men (MSM) and transgender women (TGW) must include pharyngeal, rectal and urine samples, leading to high costs (25 dollars per compartment). We integrated Cepheid GeneXpert for CT/NG testing in the Key Population-Led Health Services model. Trained key-population lay-providers performed CT/NG sampling and testing in community-based organizations (CBOs). We present the performance of pooling samples from three compartments for CT/NG detection.

METHODS: Between August-October 2019, 199 MSM or TGW were recruited from 2 CBOs in Bangkok, Thailand. First-catch urine samples were self-collected by participants, KP-lay providers collected pharyngeal and rectal swabs. GeneXpert was used for separate testing of three compartments of 199 participants, and for testing of single participant pooled urine, pharyngeal and rectal samples from a subset of 50 participants. Performance of separate and pooled samples by GeneXpert were compared with the laboratory-based standard of care (SoC – Abbott RealTime).

RESULTS: Compared with SoC, sensitivity and specificity of GeneXpert were 100% and 100% for pharyngeal CT, 100% and 99.4% for rectal CT, 100% and 99% for urethral CT, 93.3% and 98.9% for pharyngeal NG, 100% and 99.5% for rectal NG, and 100% and 100% for urethral NG, respectively. Sensitivity and specificity of pooled samples were 100% and 100% for CT and 88.9% and 100% for NG, respectively, compared with SoC. One pharyngeal NG infection was missed using pooled sampling. Cohen's Kappa agreement for pooled samples was 100% for CT and 98% for NG when compared with SoC.

CONCLUSIONS: Pooled sampling from three compartments among MSM and TGW showed excellent performance for detection of CT. Sensitivity for detection of NG was lower for pooled specimens compared to single-site testing due to a missed infection in the pharynx, where bacterial loads can be lower compared to other compartments. Nonetheless, agreement between pooled sampling, single-site and SoC was good, and pooled sampling significantly reduces costs. Pooled sampling in CBOs by KP-lay providers should be implemented to facilitate access to CT/NG testing services for at-risk populations in Thailand.

CYTOMEGALOVIRUS RETINITIS IN ADVANCED HIV PATIENTS: SCREENING AND CARE IN MOZAMBIQUE

A.G. Gutierrez[1], C.M. Siufi[1], N. Tamayo Antabak[1], G. Muvale[2], H.V. Andela[1], I.C.B. Magaia[2], P. Saranchuk[3], L. Molfino[1], A. Guadarram[1], I. Ciglenecki[4], D. Heiden[3], A. Couto[2], A. Loarec[1]
[1]Médecins Sans Frontières, Maputo, Mozambique, [2]Ministry of Health, Maputo, Mozambique, [3]SEVA Foundation, Berkeley, United States, [4]Médecins Sans Frontières, Geneva, Switzerland

BACKGROUND: AIDS-related cytomegalovirus retinitis (CMVR) is a late-stage opportunistic infection. In Africa, CMVR burden is largely unknown, due to lack of screening and limited access to treatment. In Maputo, Médecins Sans Frontières with the Ministry of Health supports patients with advanced HIV disease (AHD) at the referral centre of Alto Mae (CRAM) and in Jose Macamo hospital (JM). Here we describe CMVR activities as part of the AHD package of care.

METHODS: CMVR screening was introduced for adult HIV-positive patients with CD4 count <100 cells/µl and patients with visual complaints in February 2019.

Retinal examination is performed by trained non-ophthalmologist physicians on fully dilated pupils using indirect ophthalmoscopy. Patients with active CMVR are treated with oral valganciclovir. We analysed routine data, collected between February and November 2019.

RESULTS: Among eligible patients with CD4<100 cells/µl, 120/160 (75%) were screened in CRAM and 245/721 (34%) in JM.

In CRAM, 8/120 patients were diagnosed with CMVR (6.6%; 6 active and 2 inactive CMVR) and 13/245 in JM (5.3%; 11 active and 2 inactive CMVR), with total CMVR prevalence of 5.7% (21/365). Median age was 40 years (IQR 33-49), 76% were women (n:16). At diagnosis time, median CD4 was 21 cells/µl (IQR: 15-45), with 76% of CMVR patients reporting ART history (n:16).

Mortality was high among hospitalized CMVR patients: 7/13 (54%) patients died prior to treatment initiation, and 2 were lost-to-follow-up. Eight patients with active CMVR were treated with oral valganciclovir. At the end of the follow-up period, 6 patients were alive in care (75%) and 2 (25%) died. Overall, 9 (43%) CMVR patients died, some while being treated for co-existent opportunistic infections.

CONCLUSIONS: This first report of AIDS-related CMV retinitis in Mozambique revealed a 5.7% CMVR prevalence among screened patients with AHD. Mortality among patients with CMVR was high. Although CMVR diagnosis with indirect ophthalmoscopy was feasible, we faced limitations to screen all at risk patients. Also, ophthalmic screening doesn't allow for diagnosis of other CMV end-organ disease or viremia. There is urgent need for early and easy diagnosis of CMV infection, such as detection of CMV viremia, and better access to treatment with valganciclovir.

INCIDENCE OF HCV REINFECTION AMONG HIV-POSITIVE MSM AND ITS ASSOCIATION WITH SEXUAL RISK BEHAVIOR: A LONGITUDINAL ANALYSIS

A.M. Newsum[1], A. Matser[1], J. Schinkel[2], M. van der Valk[2], K. Brinkman[3], A. van Eeden[4], F.N. Lauw[5], B.J. Rijnders[6], T.J. van de Laar[7], M. van de Kerkhof[1], C. Smit[8], A. Boyd[1], J.E. Arends[9], M. Prins[1], MSM Observational Study of Acute Infection with hepatitis C (MOSAIC) study group
[1]GGD Amsterdam, Amsterdam, Netherlands, [2]Amsterdam University Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]OLVG, Department of Internal Medicine and Infectious Diseases, Amsterdam, Netherlands, [4]DC Kliniek Lairesse, Amsterdam, Netherlands, [5]Medical Center Jan van Goyen, Department of Internal Medicine, Amsterdam, Netherlands, [6]Erasmus MC, University Medical Center, Department of Internal Medicine and Infectious Diseases, Rotterdam, Netherlands, [7]Laboratory of Medical Microbiology, OLVG, Amsterdam, Netherlands, [8]Stichting HIV Monitoring, Amsterdam, Netherlands, [9]University Medical Center Utrecht, Department of Internal Medicine, Utrecht, Netherlands

BACKGROUND: HIV-positive men who have sex with men (MSM) are at high risk of hepatitis C virus (HCV) reinfection following clearance of HCV. Risk factors for reinfection, which include sexual risk behavior, have yet to be comprehensively assessed.

METHODS: Using data from a prospective observational cohort study among HIV-positive MSM with an acute HCV infection (MOSAIC) in the Netherlands, the incidence of HCV reinfection following spontaneous clearance or successful treatment was assessed. A univariable Bayesian exponential survival model was used to identify risk factors associated with HCV reinfection. Prior distributions of hazards ratios (HR) were based on the anticipated strength of association for a given risk factor and together with the data, were used to estimate the posterior distribution of HR and 95% credible intervals (CrI) for each risk factor with Markov Chain Monte Carlo methods.

RESULTS: Overall, 122 HIV-positive MSM who had a spontaneously cleared or successfully treated HCV infection between 2003 and 2017 were included. During a median follow-up of 1.4 years (interquartile range 0.5-3.8), 34 HCV reinfections were observed in 28 patients. The incidence of HCV reinfection was 11.5/100 person-years and among those with reinfection, median time to reinfection was 1.3 years (interquartile range 0.6-2.7). HCV reinfection was associated with receptive condomless anal intercourse (posterior-HR=4.27, 95% CrI 1.86-9.78), sharing of sex toys (posterior-HR=4.91, 95% CrI 2.27-10.31), group sex (posterior-HR=2.80, 95% CrI 1.33-5.98), anal rinsing before sex (posterior-HR=2.47, 95% CrI 1.14-5.43), ≥10 casual sex partners in the last 6 months (posterior-HR=2.81, 95% CrI 1.26-6.50), nadir CD4 cell count <200 cells/mm3 (posterior-HR=2.22, 95% CrI 1.05-4.81), and recent CD4 cell count <500 cells/mm3 (posterior-HR=3.60, 95% CrI 1.73-7.64).

CONCLUSIONS: Incidence of HCV reinfection was high and strongly associated with sexual risk behavior. These results highlight the need for interventions to reduce risk behavior and prevent HCV reinfections among HIV-positive MSM.

HIV-1 DNA TESTING IN VIREMIC PATIENTS DEMONSTRATES A GREATER ABILITY TO DETECT DRUG RESISTANCE COMPARED TO PLASMA VIRUS TESTING

D. Curanovic[1], S. Martens[1], M. Rodriguez[1], H. Hammill[2], C. Petropoulos[1], C. Walworth[1]
[1]Monogram Biosciences, San Francisco, United States, [2]The Woman's Hospital of Texas, Houston, United States

BACKGROUND: Treatment guidelines recommend drug resistance testing on plasma virus to guide the selection of antiretroviral therapy in patients with HIV-1 viremia >500 copies/mL. However, drug resistance mutations (DRMs) in plasma virus represent only the selective pressure imposed by the failing regimen and may miss DRMs reflective of prior regimens. HIV-1 DNA testing derives drug resistance information from whole blood and offers a resistance testing option when plasma virus is undetectable. HIV-1 DNA testing may also have the ability to capture DRMs in actively replicating virus in viremic patients.

METHODS: Resistance test results derived from paired whole blood (DNA) and plasma (RNA) samples obtained from the same patient on the same day were compared for 89 patients with HIV. DRM and antiretroviral susceptibility concordance was assessed between 103 paired tests. All samples had viral loads (VLs) >500 copies/mL and were stratified to assess the impact of viral load on concordance. Resistance to individual antiretroviral drugs and drug classes was also assessed.

RESULTS: The mean patient age was 38; 88% were female, of whom 19% were pregnant. The mean VL was 132,487 copies/mL. HIV-1 DNA testing captured 505/548 (92%) of all mutations reported by plasma virus testing and identified 128 additional DRMs. HIV-1 DNA testing demonstrated an average 94% concordance in 103 paired comparisons with plasma HIV-1 DRMs. HIV-1 DNA testing also captured 210/240 (88%) of the resistance calls reported by plasma virus testing, and identified 80 additional resistance calls. Plasma virus DRMs identified at VLs >10,000 copies/mL were more likely to be detected in the DNA compartment compared with plasma virus DRMs identified at VLs <10,000 copies/mL. Viral load level did not affect the percentage of DRMs on HIV-1 DNA reports derived from previously archived virus. HIV-1 DNA testing identified more resistance than plasma virus testing across all drug classes, including individual mutations such as M184V and K103N.

CONCLUSIONS: These findings demonstrate that HIV-1 DNA testing largely recaptures plasma virus DRMs, and identifies additional mutations in previously archived virus. HIV-1 DNA testing has clinical utility in viremic patients, especially those who have no or limited prior resistance reports.

[1]Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington, United States, [2]University of Bergen, Center for International Health, Bergen, Norway, [3]Elizabeth Glaser Pediatric AIDS Foundation, TLPO, Washington, United States, [4]Ministry of Health, AIDS Control Program, Kampala, Uganda, [5]University Teaching Hospital, Infectious Disease, Lusaka, Zambia, [6]Elizabeth Glaser Pediatric AIDS Foundation, Research, Nairobi, Kenya, [7]Elizabeth Glaser Pediatric AIDS Foundation, Research, Mbabane, Eswatini, [8]Elizabeth Glaser Pediatric AIDS Foundation, Program, Nairobi, Kenya, [9]Elizabeth Glaser Pediatric AIDS Foundation, Research, Kampala, Uganda, [10]Children's Hospital/George Washington University, Washington, United States

BACKGROUND: Viral load (VL) scale-up has highlighted significant rates of treatment failure among HIV-infected children and adolescents on ART in sub-Saharan Africa. The aim of this study was to describe virologic and immunologic characteristics of children and adolescents with treatment failure on second-line antiretroviral treatment (ART) and to describe their clinical outcomes on third-line ART.

METHODS: This is an observational cohort study collecting prospective data from patients aged 0-24 years on third-line ART in Eswatini, Kenya, Uganda, and Zambia. We collected data from clinical record of patients initiated on darunavir (DRV) and/or etravirine (ETR) as part of third-line ART through the New Horizons drug donation program sponsored by Johnson & Johnson. Baseline demographic, clinical and laboratory data (CD4 cell count, HIV RNA VL, genotypic resistance) were collected at the starting point of initiating third-line ART and summarized using descriptive statistics and median (IQR).

RESULTS: From December 2018 to November 2019, 152 participants were enrolled; 57.2% (87/152) were male; median (min-max) age at initiation of third line was 12.8 (1.3 – 21.8) years. Prior second-line ART was PI-based, including lopinavir/ritonavir in 67.1%(n=102) and atazanavir/ritonavir in 17.8% (n=27). The NRTI backbone included lamivudine plus zidovudine in 20.4%, abacavir in 53.3%, or TDF in 23.0%. Most participants with available VL assessment (85.5%; n=130/152) had elevated VL within six months prior to switching: median (min-max) VL was 4.8 log (1.3 – 6.5). Of the 123 patients with baseline resistance results, 89 (68.5%) had thymidine analog mutations (TAMs), 62.9% (n=56/89) TAM1 and 73.0% (n=65/89) TAM2 pathways. PI resistance mutations were observed in 71 (79.8%), with 70.4% (n=50/71) having accumulated >3 PI mutations. At six months on DRV/ETR based third-line ART, of the 58 participants with VL results, 72.4% (n=42/58) had viral suppression. At twelve months on third-line ART, of 36 participants with VL results, 80.6% (n=29/36) had viral suppression.

CONCLUSIONS: Treatment-experienced pediatric and adolescent patients failing a second-line PI-based ART had high level HIV viremia and high levels of NRTI thymidine analog and PI mutations. Among those patients with VL results available at 6 and 12 months on third-line ART containing DRV and/or ETR, the majority achieved virologic suppression.

PDB0404

DEEP SEQUENCING WITH UNIQUE MOLECULAR IDENTIFIERS FOR EVALUATION OF HIV-1 DRUG RESISTANCE IN THE DISCOVER PRE-EXPOSURE PROPHYLAXIS TRIAL

S. Cox[1], U. Parikh[2], A. Heaps[2], B. Goetz[2], J. Mellors[2], M. Das[1], C. Callebaut[1]
[1]Gilead Sciences, Foster City, United States, [2]University of Pittsburgh, Pittsburgh, United States

BACKGROUND: The DISCOVER study is an ongoing randomized, double-blind study of pre-exposure prophylaxis (PrEP) using daily FTC/TAF (F/TAF; Descovy; DVY) or FTC/TDF (F/TDF; Truvada; TVD) in men or transgender women who have sex with men. Of the 5,335 randomized participants evaluated for HIV-1 infection, 24 (0.4%) became infected through a median of 120 Weeks on study. Here we present standard and ultrasensitive resistance testing from the DISCOVER participants who acquired HIV infection.

METHODS: Plasma samples from participants who became HIV-1 infected and had a viral load of > 400 copies/mL were tested with the Monogram GenoSure™ MG assay, using Sanger sequencing to analyze the protease (PR) and reverse transcriptase (RT) genes for any known resistance mutations (at ≥15-20% of the viral population). Identification of minor variants was evaluated using ultrasensitive resistance testing (at ≥1% of the viral population) that employed unique molecular identifiers for amplification of viral variants followed by next generation sequencing (UMI-NGS) to analyze RT codons 63-131 and 152-211 (University of Pittsburgh).

RESULTS: By standard sequencing, 4/20 HIV positive participants tested had M184V, all in the F/TDF group and all with suspected baseline infection; 2 of these 4 also had M184I present. Six participants had additional mutations conferring resistance to non-study drugs including NRTI, NNRTI, and PI, which were presumed to be transmitted.

By UMI-NGS, 23/24 HIV participants with HIV had samples available and 21/23 were successfully analyzed. The four participants with M184V each had M184I also detected; K65R was detected in 1 participant at very low levels. One participant on F/TAF had the M184V mutation present at 2%. Two out of 3 participants with samples that had viral loads < 400 copies/mL were successfully tested and neither had resistance to study drugs.

CONCLUSIONS: Using standard sequencing, M184V was detected in 4 participants, all in the F/TDF arm. Using ultrasensitive UMI-NGS testing, similar results were observed, with the addition of one participant with M184V in the F/TAF arm. Overall, drug resistance in the DISCOVER study was most commonly seen in participants with suspected baseline infections and in only 1 individual who became infected while on study.

PDB0405

PRETREATMENT LOW-FREQUENCY HIV DRUG RESISTANCE MUTATIONS IN ANTIRETROVIRAL NAIVE INDIVIDUALS IN BOTSWANA

D. Maruapula[1], C. Rowley[2], K. Molebatsi[3], S. Moyo[4], S. Gaseitsiwe[4]
[1]Botswana Harvard AIDS Institute Partnership, Research, Gaborone, Botswana, [2]Harvard T.H Chan School of Public Health, Immunology and Infectious Diseases, Boston, United States, [3]University of Botswana, Statistics, Gaborone, Botswana, [4]Botswana Harvard AIDS Institute, Gaborone, Botswana

BACKGROUND: The commonly used Sanger population based sequencing (SPBS) assay misses low-frequency HIV drug resistance mutations present at less than 20% of the viral population. Detecting and monitoring low-frequency HIV drug resistance mutations at treatment initiation is important for patient management. In this study, we aimed to determine the baseline prevalence of HIV low-frequency drug resistance mutations among antiretroviral naïve individuals in Botswana.

METHODS: Baseline plasma samples from 93 viremic treatment naïve participants were extracted and Pol gene was amplified. The purified PCR product was used for targeted Next Generation Sequencing (NGS) using illumina MiSeq platform. Raw sequences were analysed using Genome Detective platform and Geneious Software where amino acid frequency cut-offs>1% were selected to report low-level HIV-1 drug resistance mutations. Results of NGS were compared with SPBS data for concordance. Mutations were identified and evaluated according to the Stanford HIV-1 Drug Resistance database.

RESULTS: Next-Generation sequencing identified all 9 drug resistance mutations detected by SPBS. However, NGS detected 39 additional low-frequency HIV drug resistance mutations at <20% of the viral quasispecies. Of the 39, 33 low-frequency HIV drug resistance mutations were detected at a frequency of ≥1%; 4 were detected at a frequency of ≥5%; and 2 were detected at a frequency of ≥10%. Among the low-frequency HIV drug resistance mutations, 4 (10%) were to NNRTIs: 17(44%) to NRTIs and 18(46%) to PR inhibitors. Table 1 shows the distribution of the HIV drug resistance mutations detected in baseline samples.

[Table 1. Baseline HIV-1 Drug resistance mutations detected by sanger and NGS from plasma specimens collected from antiretroviral naïve individuals. - means no mutations.]

CONCLUSIONS: This is the fist time in Botswana NGS has been used in a large population to detect HIV pre-treatment low-level drug resistance mutations. Our results revealed the presence of HIV low-frequency drug resistance mutations in baseline samples. The impact of low frequency major DRMs warrants further investigation.

PDB0406

DORAVIRINE RESISTANCE PROFILE IN CLINICAL ISOLATES AND IMPACT OF BASELINE NNRTI RESISTANCE-ASSOCIATED MUTATIONS OBSERVED IN TREATMENT-NAÏVE PARTICIPANTS FROM PHASE 3 CLINICAL TRIALS

E. Asante-Appiah[1], J. Lai[2], Q. Li[1], D. Yang[2], E.A. Martin[1], P. Sklar[1], D. Hazuda[1], C.J. Petropoulos[2], C. Walworth[2], J.A. Grobler[1]
[1]Merck & Co., Inc, Kenilworth, United States, [2]Monogram Biosciences, South San Francisco, United States

BACKGROUND: Doravirine (DOR), a novel NNRTI with activity against viruses bearing common NNRTI resistance-associated mutations (RAMs), is approved for the treatment of HIV-1 infection. This study evaluated the activity of DOR in a large panel of clinical samples submitted for routine drug resistance testing and retrospectively analyzed the impact of baseline RAMs in treatment-naïve (TN) participants from DOR clinical trials to extend our understanding of its resistance profile.

METHODS: Genotype and phenotype data from 4,070 TN and treatment-experienced samples evaluated for DOR susceptibility between August 2018 and August 2019 at Monogram Biosciences were analyzed. RAM prevalence and susceptibility to all FDA-approved NNRTIs was compared. To evaluate clinical significance, the prevalence of baseline RAMs and the proportion of participants achieving HIV-1 RNA <50 copies/mL at weeks 48 and 96 was retrospectively assessed in participants from the Phase 3 clinical trials, DRIVE-FORWARD and DRIVE-AHEAD.

RESULTS: Using established biological and clinical cut-offs for approved NNRTIs and a DOR biological cut-off of 3-fold, the percentage of samples susceptible to DOR, NVP, EFV, RPV and ETR was 92.5%, 77.5%, 81.5%, 89.5% and 91.5%, respectively. A 5-fold DOR cut-off increased susceptible samples to 94.5%. Individual DOR RAMs ranged from 0.02 to 2.29%. Among 228 samples (5%) resistant to NVP, EFV, RPV and ETR, 28.5% remained susceptible to DOR. The prevalence and DOR median fold-change (FC) in samples bearing common NNRTI RAMs (n >50 isolates) were as follows: K103N (14.3%, 1.25), V106I (5.4%, 1.28), Y181C (5.3%, 2.23), V108I (3.1%, 2.15), K101E (3.0%, 1.46), G190A (2.4%, 1.82), E138K (1.4%, 1.64), K103N/Y181C (1.3%, 3.06).

Common NRTI RAMs increased DOR susceptibility by ~2-fold in the absence of NNRTI RAMs; DOR hyper-susceptibility (FC≤0.4) was often observed.

In DRIVE-FORWARD and DRIVE-AHEAD, the most prevalent NNRTI RAM at baseline was V106I, which was detected in 5 TN participants (0.7%); all 5 achieved HIV-1 RNA <50 copies/mL at weeks 48 and 96. Other RAMs were detected in 1 or 2 participants only.

CONCLUSIONS: Clinical samples with common NNRTI RAMs show high susceptibility to DOR. In phase 3 clinical trials, DOR demonstrated high efficacy in a small group of TN participants with common NNRTI RAMs.

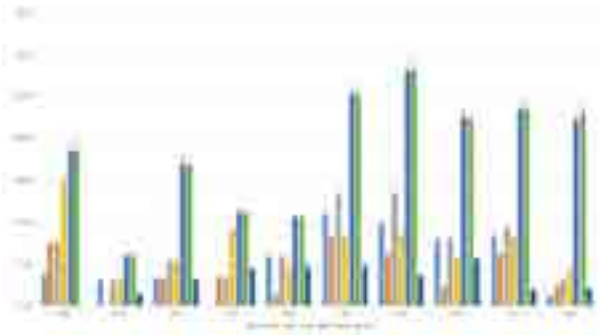
SURVEILLANCE OF TRANSMITTED HIV DRUG RESISTANCE AMONG TREATMENT-NAÏVE CHILDREN UNDER 18 MONTHS IN BRAZIL (2009-2018)

A. Alberto Cunha Mendes Ferreira[1], R. Elisa Gonçalves Gonçalves Pinho[1], R. Castro de Albuquerque[1], T. Cherem Morelli[1], R. Vianna Brizolara[1], A. Francisca Kolling[1], M. Camelo Madeira de Moura[1], A. Sposito Tresse[1], N. Mendonça Collaço Véras[1], L. Martins de Aquino[1], A.R. Pati Pascom[1], T. Dahrug Barros[1], L. Neves da Silveira[1], F. Fernades Fonseca[1], G. Mosimann Júnior[1], G. Fernando Mendes Pereira[1], M. Araújo de Freitas[1], V. Iida Avelino-Silva[2]
[1]Ministry of Health of Brazil, Department of Chronic Disease and Sexually Transmited Infectiouns, Brasilia, Brazil, [2]Faculdade de Medicina USP, São Paulo, Brazil

BACKGROUND: Children living with HIV (CLWHIV) are exposed to antiretroviral drugs antepartum, intrapartum or postpartum, which can lead to HIV drug resistance (HIV-DR). Brazilian guidelines recommend the use of genotyping tests for all CLWHIV before ART initiation, which are fully provided by the national public health system, in order to support the choice of the most adequate ART regimen. The aim of this study is to evaluate the prevalence of HIV-DR in CLWHIV treatment-naïve in Brazil.

METHODS: The national genotyping database from the Ministry of Health of Brazil was used for this analysis. HIV pol sequences from treatment-naïve infants under 18 months from 2009 to 2018 were selected. The Stanford HIVdb Program was used to assess the presence of HIV-DR.

RESULTS: In period of analysis, 838 HIV pol sequences were identified (median age: 5months; IQR:3-9months. The HIV-DR prevalence for Nevirapine (NVP): 18.74% (CI95%: 14.27-22.83), Efavirenz (EFZ): 18.74% (CI95%: 14.2-22.68); Lamivudine (3TC): 5.37% (CI95%: 3.15-7.53), Zidovudine(AZT): 6.92% (CI95%: 4.92-8.92), Abacavir (ABC): 7.16% (CI95%: 4.9-9.44), Lopinavir/ritonavir (LPV/r): 3.34% (CI95%: 2.16-4.24). Only three CLWHIV showed resistance to Darunavir/r. The highest prevalence identified were to NVP and EFZ – Non nucleoside reverse transcriptase inhibitors (NNRTI) (FIGURE 1). In addition, 3.7% (n=31) presented HIV-DR to AZT+ABC, 5.4% (n=45) to ABC+3TC, 2.02% (n=17) to 3TC+AZT, 2.02% (n=17) were resistant to all NRTI (AZT, ABV, TDF), 1.79% (n=15) to AZT+3TC+NVP, 3.7% (n=31) to AZT+ABC+NVP and 4.3% (n=36) to 3TC+ABC+NVP.



[Figure. HIV drug resistance in treatment-naive children under 18 months, Brazil (2009-2018)

CONCLUSIONS: The high prevalence of transmitted HIV-DR to NNTRI in CLWHIV is a matter of concern because there is a limited number of treatment options for this population. The incorporation of new drugs, such as integrase inhibitors, as prophylaxis and treatment, is essential to tackle resistance to NNTRI and improve treatment outcomes in this age group.

HIGH PREP ADHERENCE IN MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN COHORT IN MANILA, PHILIPPINES: EVIDENCE OF HIV PROTECTIVE LEVELS FROM TENOFOVIR BLOOD CONCENTRATIONS IN PROJECT PREPPY

G.-M. Santos[1,2], R. Ditangco[3], C. Lagman[4], D. Rosadiño[4], K. Jonas[5], L. Vi-Le[6], Y.-R.J. Lo[7], F. van Griensven[1,8]
[1]University of California, San Francisco, United States, [2]San Francisco Department of Public Health, San Francisco, United States, [3]AIDS Research Group, Research Institute for Tropical Medicine, Department of Health, Manila, Philippines, [4]LoveYourself Foundation, Manila, Philippines, [5]Maastricht University, Maastricht, United States, [6]World Health Organization, Regional Office for the Western Pacific, Manila, Philippines, [7]World Health Organization, Representative Office for Malaysia, Singapore, and Brunei Darussalam, Kuala Lumpur, Malaysia, [8]Thai Red Cross AIDS Research Center, Bangkok, Thailand

BACKGROUND: Pre-exposure prophylaxis (PrEP) significantly reduces HIV infections. Efforts to increase PrEP access are underway in the Philippines, where an accelerating HIV epidemic disproportionately affects men who have sex with men (MSM) and transgender women (TGW). PrEP's efficacy is contingent on adherence; however, studies on PrEP adherence using objective measures remain limited in the Philippines.

We tested banked human plasma to examine tenofovir concentrations in a cohort of PrEP-using MSM/TGW in Metro Manila, the region with the highest number of new HIV diagnoses in the Philippines.

METHODS: We enrolled 250 participants in a prospective cohort of PrEP-naïve, HIV-uninefected MSM/TGW in "Project PrEPPY." Participants received daily oral PrEP for 12 months. Self-reported PrEP adherence was monitored using daily diaries. Using a computer algorithm, we randomly selected 50 banked plasma samples collected at 6- and 12-month visits for tenofovir concentrations testing using liquid chromatography-electrospray tandem mass spectrometry.

We classified samples as having HIV protective concentrations using previously established cut-offs (tenofovir concentrations>40ng/mL). This cut-off has been estimated to have 88% protective effect against HIV and was demonstrated to be consistent with steady-state daily dosing.

RESULTS: Participants that had their plasma samples randomly selected for testing had similar baseline sociodemographic (age, gender, income, education: p>0.05) characteristics as non-randomly selected participants. The prevalence of HIV protective concentrations from plasma samples was similar (p≥0.99) overtime: 92.9% (95%CI=73.7-98.4%) at 6-month, and 90.9% (95%CI=67.3%-98.0%) at 12-month visits. The proportion of participants who reported taking ≥85% of their PrEP daily doses was 88% during follow-up, whereas 99.6% reported taking 4 pills per week (protective drug-level adherence). There were no HIV seroconversions during the follow-up (187.6 person years).

CONCLUSIONS: This is the first study to demonstrate high prevalence of HIV protective tenofovir blood concentrations levels in a PrEP-using cohort in the Philippines. Data from our objective marker of PrEP adherence demonstrate drug concentrations consistent with high protective effects against HIV during follow-up. Results also corroborate the high levels of self-reported adher-

ence. Taken together, these findings support high acceptability of PrEP among MSM/TGW in Manila and underscore the important role PrEP can play in slowing down the HIV epidemic in the Philippines.

ADHERENCE TO DAILY AND EVENT-DRIVEN PRE-EXPOSURE PROPHYLAXIS AMONG MEN WHO HAVE SEX WITH MEN IN TAIWAN

H.-J. Wu[1], S.W.-W. Ku[2], C.-W. Li[3], Y.-T. Chu[2], Y.-W. Tang[4], A.-C. Chung[5,6], N.-Y. Ko[4,5,6], C. Strong[1]
[1]College of Medicine, National Cheng Kung University, Department of Public Health, Tainan, Taiwan, Province of China, [2]Taipei Veterans General Hospital, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [3]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Division of Infectious Diseases, Department of Medicine, Tainan, Taiwan, Province of China, [4]National Cheng-Kung University Hospital, College of Medicine, National Cheng-Kung University, Department of Nursing, Tainan, Taiwan, Province of China, [5]Taiwan Love and Hope Association, Kaohsiung, Taiwan, Province of China, [6]Healing, Empowerment, Recovery of Chemsex Health Center, Kaohsiung, Taiwan, Province of China

BACKGROUND: WHO has recommended both daily and event-driven (ED) pre-exposure prophylaxis (PrEP) to men who have sex with men (MSM). While switching between two dosing regimens has not been uncommon, real-world data reporting PrEP users' adherence and its correctness related to each regimen were limited.

METHODS: A multi-center, prospective cohort study was conducted at hospital-based clinics in three urban cities in Taiwan between 1st January 2018 and 15th December 2019. At each visit, participants reported their choice of PrEP dosing regimen for the past month and the number of pills taken within five days of the last anal intercourse. We defined correct PrEP use as followed: 1) taking two pills on day X (i.e. the day having sex) or the day X-1, and at least one pill on the day X, X+1 and X+2 for ED regimen 2) at least one pill every day for five days for daily regimen. Missed doses with ED regimen were counted as pre-coital and post-coital respectively.

RESULTS: There were 374 MSM participants with a total of 1,054 visits. ED PrEP was reported in nearly half of the visits (48.7%). There were 53 MSM who reported 81 regimen switches: 46 from daily to ED and 35 from ED to daily. Overall, PrEP were taken correctly in 83.5% visits. The proportion of correct PrEP use was higher with daily use than ED use (92.2% vs 74.3%, p<0.001). Among 132 visits reported incorrect ED use, 65.9% missed pre-coital doses, 20.4% missed post-coital doses, and 13.6% missed both pre-coital and post-coital doses.

CONCLUSIONS: Lower adherence was more likely to be observed in ED than daily PrEP use. Missing pills before sex suggests potential difficulty for MSM to predict sexual acts. Given the high acceptability of ED dosing regimen in Taiwan, understanding barriers to PrEP adherence and developing an effective intervention for both ED and daily PrEP users are urgently needed.

PROJECT MY PREP: RESULTS FROM A PREP DEMONSTRATION PROJECT AMONG HIGH RISK MEN WHO HAVE SEX WITH MEN (MSM) IN KUALA LUMPUR, MALAYSIA

M. Akbar[1], I. Azwa[2], M. Chong[1], O. Hangchen[2], S. Basri[2], A. Yap[3], R. Tai[4], H. Lim[1], J. Ying Ru-Lo[5], F. van Griensven[6,7], A. Kamarulzaman[1,2]
[1]University of Malaya, Center of Excellence for Research in AIDS, Kuala Lumpur, Malaysia, [2]University of Malaya, Infectious Disease Unit, Department of Medicine, Faculty of Medicine, Kuala Lumpur, Malaysia, [3]The Red Clinic, Kuala Lumpur, Philippines, [4]Pink Triangle Foundation, Community Health Care Clinic, Kuala Lumpur, Malaysia, [5]World Health Organization, Representative Office for Malaysia, Singapore, and Brunei Darussalam, Kuala Lumpur, Malaysia, [6]University of California at San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [7]Thai Red Cross AIDS Research Center, Bangkok, Thailand

BACKGROUND: In recent years, HIV prevalence among MSM in Kuala Lumpur has been increasing. Additional HIV prevention measures are urgently necessary. The MyPrEP project aims to evaluate feasibility of daily PrEP among MSM in Kuala Lumpur.

METHODS: Prospective participants were recruited through the internet and social media. Men were eligible if ≥18 years old, Malaysian, HIV uninfected (by 4th Gen HIV Ag/Ab combo and POC HIV VL), had normal renal function, and reported a history of high-risk behavior. Men were seen at three different sites around Kuala Lumpur for a duration of 12 months. Daily generic oral TDF/FTC was provided free of charge. Behavioral and adherence data and STI laboratory test results were collected at baseline and every 3 months thereafter.

RESULTS: From March to October 2018, 381 men were screened of whom 186 (49%) did not meet demographic or behavioral criteria. Of the remaining 195 men, 14 (7%) were HIV infected, 8 (2%) had medical pre-conditions, 23 (12%) declined and 150 (77%) were enrolled. Most participants were >25 years (79%), of Chinese ethnicity (57%) and had at least a university degree (90%). One-year retention was 96% (139/150), daily pill adherence (self-reports and pill counts), 88% (7 doses/wk) and protective drug level adherence (≥4 doses/wk), 99%. Multiple (>1) male sexual partners were reported by 71% at baseline and by 85% at 12 months, inconsistent condom-use by 81% and 86%, and "chemsex" by 51% and 44%. The mean number of anal sex partners increased from 2.5 to 3.6 during the same time period. Prevalence of rectal chlamydia declined from 19% at baseline to 10% at 12 months, of rectal gonorrhea from 10% to 9% and of syphilis from 11% to 9%. None of these differences were statistically significant. No new HIV infections were detected during the course of the project.

CONCLUSIONS: The MyPrEP demonstration project showed feasibility of daily PrEP among MSM in Kuala Lumpur. Adherence and retention were high and no new HIV infections occurred during follow-up. No dramatic changes in HIV risk behaviors were reported. The project provided an excellent opportunity to diagnose and treat asymptomatic STI in a high-risk population.

HIGH PERSISTENCE OF DAILY ORAL PREP AMONG 18-26 YEAR OLD THAI MEN WHO SELL SEX: PRELIMINARY RESULTS OF THE COPE4YMSM STUDY

A. Hickey[1,2], B. Weir[3], C. Dun[3], A. Wirtz[3], S.H.H. Mon[3], T. Chemnasiri[1,2], A. Waraporn mongkholkul[1,2], C. Ungsedhapand[1,2], W. Sukwicha[1,2], S. Pattanasin[1,2], A. Varangrat[1,2], E.F. Dunne[1,2], M. Thigpen[1,2], T. Holtz[1,2], S. Janyam[4], D. Linjongrat[5], A. Adeyeye[6], C. Beyrer[3]
[1]U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]Thailand Ministry of Public Health and U.S. Centers for Disease Control and Prevention Collaboration (TUC), Nonthaburi, Thailand, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [4]Service Workers In Group Foundation (SWING), Bangkok and Pattaya, Thailand, [5]Rainbow Sky Association of Thailand (RSAT), Bangkok, Thailand, [6]National Institute of Allergy and Infectious Diseases (NIAID), Prevention Science Program, Division of AIDS (DAIDS), Bethesda, United States

BACKGROUND: Sustained use of HIV pre-exposure prophylaxis (PrEP) over time (persistence) has been a significant challenge among many populations, including young men who have sex with men (YMSM). PrEP persistence among YMSM who sell sex is unknown.

METHODS: COPE4YMSM, a Thai-US collaborative study, (NIH/NIAID, R01 AI118505) is assessing the effectiveness of an open-label offer of combination HIV prevention with or without daily oral Tenofovir-Emtricitabine (Truvada) for PrEP and mobile phone-based text message adherence support among 18-26 year old MSM who sell or exchange sex. We partner with key population-led service providers, SWING and RSAT, to enable persistence through community mobilization and social media. Participants may choose to take PrEP or not, in combination with regular HIV testing, risk reduction counseling, and condom and lubricant provision. We analyzed PrEP initiation, study retention, and PrEP adherence based on text message self-report of doses of PrEP in the last week. PrEP persistence was defined as self-reported continued use of PrEP 12 months after initiation. A random sample of DBS specimens from those reporting good PrEP adherence in the last 7 days (>4 doses of PrEP in the last week) were analyzed for intracellular tenofovir diphosphate (TFV-DP).

RESULTS: We enrolled 856 HIV-uninfected, at-risk young male sex workers, of whom 590 (68.9%) initiated PrEP within 30 days of enrollment. Among men initiating PrEP at baseline, retention in the study was good, at 75.9% at 12 months. PrEP adherence was also high, with over 98% of participants reporting 4 or more doses of PrEP/week. Self-reported use in the last 7 days had a high positive predictive value relative to intracellular TFV-DP levels; among samples from participants with good self-reported adherence (n = 62), 79.0% had protective levels of TFV-DP in their DBS samples (kappa agreement = 78.3%, chi-square = 79.2, p <0.001).

CONCLUSIONS: Using an open-label combination prevention approach in partnership with key population-led providers can successfully engage and sustain PrEP use among young MSW at risk in Thailand. Over two-thirds of YMSW aged 18-26 years persisted on PrEP at 12 months after initiation, significantly higher than other reports.

YOUTH-FOCUSED STRATEGIES TO PROMOTE ADHERENCE TO PRE-EXPOSURE PROPHYLAXIS AMONG ADOLESCENT MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN AT-RISK FOR HIV IN THAILAND

W.N. Songtaweesin[1], S. Kawichai[1], N. Phanuphak[2], T.R. Cressey[3,4,5], P. Wongharn[1], C. Saisaengjan[1], T. Chinbunchorn[2], S. Janyam[6], D. Linjongrat[7], T. Puthanakit[1,8], CE-PID - TRC Adolescent Study Team
[1]Chulalongkorn University, Center of Excellence for Pediatric Diseases and Vaccines, Faculty of Medicine, Bangkok, Thailand, [2]Thai Red Cross AIDS Research Center, Prevention, Bangkok, Thailand, [3]Chiang Mai University, PHPT/IRD UMI 174, Faculty of Associated Medical Sciences, Chiang Mai, Thailand, [4]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [5]University of Liverpool, Department of Molecular and Clinical Pharmacology, Liverpool, United Kingdom, [6]The Service Workers IN Group Foundation, Bangkok, Thailand, [7]Rainbow Sky Association Thailand, Bangkok, Thailand, [8]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand

BACKGROUND: Strategies are urgently needed to curb the increasing incidence of HIV in young men who have sex with men (YMSM) and transgender women (YTGW) worldwide. We assessed the impact of youth-friendly services and a mobile phone application (app) on adherence to pre-exposure prophylaxis (PrEP) in YMSM and YTGW in Thailand.

METHODS: A randomized control trial was conducted in YMSM and YTGW aged 15-19 years. Participants were provided daily oral TDF/FTC and condoms and randomization to receive either youth-friendly services (standard of care, SOC) or SOC plus a PrEP app (SOC+APP), whose features included self-assessment of HIV acquisition risk activities, point rewards, and reminders for PrEP and clinic appointments. Clinic visits occurred at 0, 1, 3, 6 months and telephone contact at 2, 4, and 5 months. Sexually transmitted infection (STI) screening was performed at baseline and month 6, and HIV testing at all visits. PrEP adherence was evaluated with intracellular tenofovir diphosphate (TFV-DP) concentrations in dried blood spots (DBS) samples at months 3 and 6. The primary endpoint was 'PrEP adherence' defined as a TFV-DP DBS concentrations ≥700fmol/punch [equivalent to ≥ 4 doses of TDF/week at either month 3 and/or 6.

RESULTS: Between March 2018 and June 2019, 489 adolescents were screened, 27 (6%) tested HIV positive and 200 (41%) were enrolled and initiated PrEP. Of these, 147 were YMSM (74%) and 53 YTGW (26%). At baseline, median age was 18 years (IQR 17-19), 84% reported inconsistent condom use in the past month, and prevalence of STIs was 23%. Retention at 6-months was 73%. In the SOC+APP arm, median app time use was 3 months (IQR 1-5). PrEP adherence was 49.1% overall (45.8% in SOC and 52.4% in SOC+APP arm, p value = 0.40). YMSM were 3.6 times (adjusted OR 95% CI 1.41-9.05) more likely to adhere to PrEP than YTGW. No HIV seroconversions occurred during 75 person years of follow-up.

CONCLUSIONS: PrEP implementation in adolescents is feasible through youth friendly services with high retention rates at 6-months. YTGW may require more support for PrEP adherence than YMSM. App use in this trial did not affect PrEP adherence.

PDC0107

ASSESSING THE PERFORMANCE OF INTERNATIONAL PREEXPOSURE PROPHYLAXIS (PREP) ELIGIBILITY GUIDELINES IN A COHORT OF CHINESE MSM, BEIJING, CHINA 2009-2016

E.W. Hall[1], L. Wang[2], X. Huang[3], P.S. Sullivan[1], A.J. Siegler[4]
[1]Emory University, Department of Epidemiology, Atlanta, United States, [2]Emory University/Blued, Beijing, China, [3]Beijing You'An Hospital, Center for Infectious Diseases, Beijing, China, [4]Emory University, Behavioral Sciences and Health Education, Atlanta, United States

BACKGROUND: Evidence is needed for China to design a PrEP eligibility assessment tool to facilitate the development of national guidelines. We assessed performance of international PrEP eligibility criteria to predict future HIV seroconversion among MSM in Beijing, China.

METHODS: Participants were MSM aged ≥ 18 years who enrolled in a cohort study between July 2009 and March 2016. Participants completed HIV testing, syphilis testing, and a questionnaire on recent sexual health behaviors at each follow-up visit and were followed until HIV seroconversion or dropout. We assessed PrEP eligibility at the most recent follow-up visit prior to the final study visit. Participants were classified as either indicated or not indicated for PrEP based on criteria from each of the following guidelines: European AIDS Clinical Society (EACS), Korean Society for AIDS (KSA), Southern African HIV Clinicians Society (SA), Taiwan Centers for Disease Control, British HIV Association (UK), United States Public Health Service clinical (USPHSC) and risk score (USPHSR), and the World Health Organization (WHO). To compare guideline performance, we calculated sensitivity, specificity, Youden's Index (YI), and Matthew's Correlation Coefficient (MCC). For each guideline, performance measures were compared to random allocation of PrEP by randomly selecting a proportion of participants equal to the proportion indicated.

RESULTS: There were 287 (17.3%) incident HIV seroconversions among 1663 MSM. The number of men indicated for PrEP ranged from 556 (33.4%, USPHSC) to 1569 (94.2%, KSA). Compared to random allocation, sensitivity ranged from slightly worse (-4.7%, USPHSR) to 30.2% better than random (USPHSC). Across all guidelines, specificity was not meaningfully better than random allocation. EACS guidelines had the highest binary classification performance measures (YI=0.129, MCC=0.100).

		Sensitivity		Specificity		Matthew's Correlation Coefficient		Youden's Index	
Guidelines	n	Guidelines (95% CI)	Random (95% BI)	Guidelines (95% CI)	Random (95% BI)	Guidelines	Random (95% BI)	Guidelines	Random (95% BI)

WHO	734	0.544 (0.484, 0.602)	0.439 (0.390, 0.495)	0.580 (0.553, 0.606)	0.558 (0.548, 0.570)	0.094	-0.002 (-0.047, 0.049)	0.124	-0.003 (-0.062, 0.065)

CONCLUSIONS: The performance of most international guidelines were slightly better than random PrEP allocation, but none performed well. For settings in which international guidelines perform poorly, alternative indication approaches should be considered.

PDC02 GAPS IN OUR RESPONSE: WHO ARE WE MISSING?

PDC0202

PROGRESS AND CHALLENGES TOWARD REACHING 90-90-90 TARGETS AMONG KEY POPULATIONS IN BOTSWANA

W. Dikobe[1], L. Okui[1], C. Akolo[2], R. Kereng[1], M. Gilbert-Lephodisa[1], O. Komotere[1], D. Kanyenvu[3], K. Kusi[3], B. Nkomo[3], J. Ngidi[4], S. Chishala[4], J. Bolebantswe[3], C. Petlo[3], M. Mine[5], M. Merrigan[2]
[1]FHI360, Gaborone, Botswana, [2]FHI360, Washington, United States, [3]Ministry of Health and Wellness, Dept of HIV/AIDS and Prevention, Gaborone, Botswana, [4]Botswana Harvard, HIV Reference Laboratory, Gaborone, Botswana, [5]Ministry of Health and Wellness, National Health Laboratory, Gaborone, Botswana

BACKGROUND: Botswana has made great strides toward the 90-90-90 goals, however achieving these targets for key populations (KPs) remains a challenge. KPs, such as men who have sex with men (MSM) and female sex workers (FSWs), have limited access to HIV prevention, care, and treatment services due to stigma and discrimination. Using data from the first and second Biological and Behavioral Surveillance Surveys (BBSS1, BBSS2), we analyzed progress toward reaching the targets among KPs in Botswana.

METHODS: To examine progress between 2012 (BBSS1) and 2017 (BBSS2), comparisons were made for the three districts represented in both surveys: Gaborone, Francistown, and Chobe. KP members aged 16–64 years responded to a questionnaire and were tested for sexually transmitted infections, including HIV. HIV testing was done with all participants regardless of documented status.

	First 90(%)	Second 90 (%)		Third 90 (%)	
	% PLHIV who know their HIV status	% PLHIV who know their status who are on treatment *	% PLHIV who are on treatment	% PLHIV who know their status, reporting taking treatment daily *	% PLHIV reporting taking treatment daily*
General Population	85	>85	>81	>89 (with VLS)	>73 (VLS)
FSW (2012)	45.1(35.5-55.1)	24.9(13.8-36)	10.6(6.3-17.2))	not asked	not asked
FSW (2017)	68.4(53.4-80.4)	87.8(81.2-92.2)	60.3(49.5-70.1)	99.2(97.7-99.7)	59.5(49.1-69.1)
MSM (2012)	16.9(9.3-28.9)	13(1.8-27.9)	5.1(1.6-14.9)	not asked	not asked
MSM (2017)	41.0(30.6-52.4)	82.1(66.0-91.4)	37.2(27.1-48.5)	97.2(81.3-99.6)	35.9(25.9-47.3)

[Table 1. Progress toward 90-90-90 targets in Botswana]

RESULTS: HIV prevalence among FSWs remained high from 2012 (61.9%) to 2017 (51.5%), with no significant change (p=0.19). Among MSM, HIV prevalence increased significantly from 13.1% to 19.1% (p=0.016). This may be due to the slightly older sample in 2017 compared to 2012 (28 vs. 23 years). Individuals who self-reported as HIV-positive increased for FSW (68.4% vs. 45.1%, p=0.008) and for MSM (41% vs. 16.9%, p=0.016). Additionally, those living with HIV and on

ART significantly increased from 10.6% to 60.3% (p=0.000) for FSW and from 5.1% to 37.2% (p=0.0000) for MSM. Only 59.5% of all FSWs and 35.9% of MSM, living with HIV who know their status reported taking ART daily in 2017.

CONCLUSIONS: Despite the significant improvements between BBSS1 and BBSS2, KPs continues to be highly affected by HIV and are far from reaching the 90-90-90 goals compared to the general population. FSW are at 68-60-60, while MSM are at 41-37-36 towards targets. For countries to achieve epidemic control, ongoing investments in programs tailored to the needs of KPs are needed.

PDC0203

FOOD INSECURITY HIGHLY PREVALENT AND ASSOCIATED WITH EARLY PREP NON-ADHERENCE AMONG TRANS AND NON-BINARY PEOPLE IN THE SAN FRANCISCO BAY AREA: THE STAY STUDY

A. Liu[1,2], E. Vittinghoff[2], J. Gagliano[1], C. Turner[1], H. Xie[1], J. Rapues[1], S. Pardo[1], P. Anderson[3], C. Rodriguez[1], Z.-J. Eskman[4], E. Palafox[5], R. Lin[6,1], B. Makoni[5], E. Rodriguez[7], P. von Felten[1], S. Buchbinder[1,2], H. Scott[1,2], S. Arayasirikul[1,2], E.C. Wilson[1,2], STAY Study Team
[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of California, San Francisco, United States, [3]University of Colorado, Aurora, United States, [4]San Francisco Community Health Center, San Francisco, United States, [5]Tri City Health Center, Fremont, United States, [6]Tom Waddell Urban Health Center, San Francisco, United States, [7]Castro Mission Health Center, San Francisco, United States

BACKGROUND: Few studies have evaluated real-world PrEP delivery in trans and non-binary populations. We describe baseline characteristics and early adherence in participants enrolled in one of the first PrEP demonstration projects for transgender communities – the STAY Study.

METHODS: The STAY Study enrolled HIV-uninfected trans women, trans men, and non-binary individuals across 5 trans-affirmative clinics in the San Francisco Bay Area and offered participants 48 weeks of PrEP, along with peer navigation, bi-directional SMS support, and panel management. Tenofovir-diphosphate (TFV-DP) levels in dried blood spots (DBS) collected at 4 and 12 weeks were analyzed to assess early adherence. Correlates of early adherence (TFV-DP≥700) were evaluated using multivariable logistic regression.

RESULTS: From August 2017-May 2019, 193 individuals were screened and 159 enrolled. Median age was 35 (IQR 27-46); 26% were Latino/a, 25% White, 14% Black, 8% Asian, and 27% multirace/other. Overall, 86% were transwomen or women, 6% were transmen or men, and 8% were non-binary. Half completed high-school; 92% had a primary care provider/health insurance, and 82% were taking gender-affirming hormones. At baseline, 80% reported food insecurity; 8% were homeless, 15% lived in a motel/hotel/boarding house, and 50% rented a house/apartment/room. In the past year, 68% reported condomless anal/vaginal sex and 22% reported an STI. Retention was 87% at week 4 and 83% at week 12. Among 60 participants with DBS testing at week 12, 55% had levels consistent with 4-7 doses/week, 15% 2-3 doses/week, 25% <2 doses/week, and 5% were undetectable. In a multivariable model, food insecurity (AOR 0.26, 95% CI 0.07-0.94) and those who were multiracial/other (AOR 0.11, 95% CI 0.03-0.45) were less likely to have protective levels, while those living in a motel, hotel, or boarding house (compared with those who were homeless/in a shelter) were more likely to have protective levels (AOR 8.47, 1.56-45.85). Use of gender-affirming hormones was not associated with TFV-DP.

CONCLUSIONS: Over half of STAY participants with DBS tested during early follow-up had protective PrEP levels. Food insecurity was highly prevalent and associated with lower PrEP adherence, while relative housing stability was associated with higher protection, highlighting the impact of structural factors on PrEP adherence in this population.

PDC0204

RATES AND TRENDS OF HIV DIAGNOSES AMONG INDIGENOUS PEOPLES IN CANADA, AUSTRALIA, NEW ZEALAND, AND THE UNITED STATES FROM 2009-2017

K. Koehn[1,2], C. Cassidy-Matthews[3,2], M. Pearce[4,5], C. Aspin[6], H. Pruden[4], J. Ward[7], R. Hogg[2,1], V. Nicholson[2]
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [4]BC Centre for Disease Control, Vancouver, Canada, [5]First Nations Health Authority, Vancouver, Canada, [6]Health Quality and Safety Commission, Wellington, New Zealand, [7]University of Queensland, School of Public Health, Brisbane, Australia

BACKGROUND: While Indigenous peoples of the Anglo-settler states of Canada, Australia, the USA, and New Zealand have experienced similar histories of colonization and resistance to the health impacts of ongoing oppression, few cross-national comparisons of HIV diagnoses have been conducted. The objective of this study is to compare rates and trends of HIV diagnoses among Indigenous peoples in Canada (First Nations, Métis, Inuit, and Other Non-Specified), Australia (Torres Strait Islanders and Aboriginal), the USA (American Indian, Alaska Native, Native Hawaiian, and Other Pacific Islanders), and New Zealand (Māori).

METHODS: We employed publicly available surveillance data from 2009-2017 to estimate the rate per 100,000 of HIV diagnoses. Estimated annual percent change (EAPC) in diagnosis rates was calculated using Poisson regression. The four countries have passive population-based HIV surveillance programs. Population estimates from respective census programs were used as rate denominators. Estimated annual HIV diagnosis rate per 100,000 and EAPC were calculated for total Indigenous peoples, women, and men.

RESULTS: As of 2017, rates of HIV were highest in Canada (16.22, 95% CI: 14.30, 18.33) and lowest in New Zealand (1.36, 95% CI: 0.65, 2.50). Australia had a rate of 3.81 (95% CI: 2.59, 5.40) and the USA had a rate of 3.22 (95% CI: 2.85, 3.63). HIV diagnosis rates among the total Indigenous population decreased in Canada (-7.92 EAPC, 95% CI: -9.34, -6.49) and in the USA (-4.25 EAPC, 95% CI: -5.75, -2.73), but increased in Australia (5.10 EAPC, 95% CI: 0.39, 10.08). No significant trends over time were observed in New Zealand (2.23 EAPC, 95% CI: -4.48, 9.47).

CONCLUSIONS: We found elevated but decreasing rates of HIV diagnoses in Canada compared to Australia, the USA, and New Zealand. While there are limitations to conducting cross-national comparisons, there are substantial differences in HIV diagnosis rates in these four countries that may be reflective of divergent country-level policies and systems that affect the health status of Indigenous peoples.

PDC0205

EFFECT OF TARGETED COUNSELING ON RETENTION TO HIV PRE- EXPOSURE PROPHYLAXIS AMONG MEN WHO HAVE SEX WITH MEN WITHIN NAIROBI CITY COUNTY, KENYA

M. Akolo[1], J. Kimani[2], R. Gichuki[3], J. Osero[4], A. Kibera[4], L. Gelmon[2]
[1]PHDA, Clinical, Nairobi, Kenya, [2]PHDA/University of Nairobi/Manitoba, Nairobi, Kenya, [3]AMREF, Nairobi, Kenya, [4]Kenyatta, Nairobi, Kenya

BACKGROUND: In Sub Saharan African countries, MSMs have 19.3 folds higher odds of being HIV infected compared with the general population. Kenya MSM have a HIV prevalence of 18.2. PrEP protects up to 90% of HIV infection in those who adhere well. However retention of high risk MSM on PrEP in Kenya has proved to be a challenge.

METHODS: Experimental design was used. The two facilities within Nairobi serving Men having sex with Men were purposely selected. Eligible Men who have Sex with Men and had just enrolled into PrEP within one week were selected through simple random sampling and randomized to either arm using computer generated randomization table During the study participants in the intervention arm received targeted counseling as an intervention which included assessment and counseling on depression, PrEP adherence, alcohol consumption and Short message reminder to come to the facility. The control arm followed the government prescription of issuing PrEP in reliance to oral self report on adherence with no other intervention. The two groups were followed for six months; month one after PrEP initiation, month three and month six and retention calculated and compared among the two groups.

RESULTS: 84 study participants were enrolled on each arm. At month one intervention arm had retained 82(97.6%) of its initial study participants compared to 68(81.0%) control group with a significance difference (p <0.001). At month three retention gap widened; intervention arm had retained 77(91.7%) compared to 26(31.0%) control group with a clear significant difference (p < 0.001) At month six the intervention arm retention reduced to 58(69.0%) and the control arm dropped farther to 16(19.0%) with still a significant difference (p<0.001). Each intervention indicator was considered in relation to its effect on MSM retention to PrEP as follows; Depression assessment counseling showed significant association with MSM retention to PrEP at p value of 0.004. Alcohol consumption counseling also showed significant association with PrEP retention (p =0.002), while pill adherence counseling showed a significant association with MSM retention on PrEP (p < 0.001)

CONCLUSIONS: Targeted counseling sessions should be incorporated into ministry of Health PrEP dissemination package among MSM to improve on retention

PDC0206

CLOSING THE HIV IDENTIFICATION GAP FOR MEN: THE IMPACT OF ASSISTED PARTNER NOTIFICATION SERVICES IN A REAL-WORLD SETTING IN KENYA

F. Odhiambo[1], C. Dande[1], R. Onyango[1], G. Nyanaro[1], E. Mulwa[1], M. Aluda[1], M. Agallo[1], F. Miruka[2], A. Aoko[2], E.A. Bukusi[1], C.R. Cohen[3]
[1]Kenya Medical Research Institute, Center for Microbiology Research-Research Care and Training Program, Nairobi, Kenya, [2]Centre for Disease Control and Prevention, Division of Global HIV and TB, Kisumu, Kenya, [3]University of California, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States

BACKGROUND: Globally in 2018, 23.3 million persons living with HIV were receiving antiretroviral treatment. Despite this, progress in identification and linkage of HIV-infected men has lagged behind. We compared the impact of assisted Partner Notification Services (aPNS) in improving identification and linkage of men with undiagnosed HIV infection with facility testing strategies.

METHODS: We conducted a retrospective analysis of routine program data collected from 61 health facilities in Kisumu County, Kenya between October 2018 and September 2019. Records of male clients >15 years of age who received HIV testing services through either aPNS or facility testing approaches, were included in the analysis. We compared the proportions of yield in the aPNS vs facility testing using risk ratios (RR) with confidence intervals (CIs) computed by Traditional (log-transformation) method and linkage to treatment using Chi-square method.

RESULTS: A total of 12,220 men underwent HIV testing through aPNS and 90,127 through facility testing giving HIV-positive yields of 12.3% (n=1503) and 0.6% (n=540), respectively. Most of the HIV-positive males were aged >25 years in both aPNS (92%) and facility testing (77%) groups. The overall HIV positive yield was 20.6-fold (95% CI,18.74-22.73) higher in aPNS compared to facility testing and highest among men aged 20-24 years (Table 1). Similarly, overall linkage to HIV treatment was 84% vs 78%, (p = 0.001) in aPNS compared to facility testing respectively and highest among men aged 20-24 years.

Table 1: Comparison of HIV positive yield and linkage to treatment between aPNS and facility testing among men by age category—Kisumu, Kenya.

Age Categories	HIV testing Modality	Total Tested	Total HIV Positive	% yield (95% CI)	RR (95% CI)	%Linkage to treatment (95%CI)	p-Value
Overall	aPNS	12220	1503	12.30 (11.72-12.89)	20.53 (18.64-22.61)	83.70 (81.77-85.50)	P=0.001
	Facility testing	90127	540	0.60 (0.55-0.65)		77.8 (74.1-81.1)	
15-19 Years	aPNS	594	12	2.02 (1.10-3.41)	20.37 (9.94-41.78)	100.00 (77.91-100.00)	P=0.034
	Facility Testing	19165	19	0.10 (0.06-0.15)		73.68 (50.94-89.66)	
20-24 Years	aPNS	1032	92	8.91 (7.29-10.77)	42.64 (28.92-62.87)	93.48 (86.93-97.31)	P<0.001
	Facility Testing	16261	34	0.21 (0.15-0.29)		5.88 (1.00-18.10)	
25+ Years	aPNS	10594	1399	13.21 (12.57-13.86)	14.83 (13.41-16.41)	82.92 (80.88-84.85)	P=0.492
	Facility Testing	54701	487	0.89 (0.81-0.97)		82.96 (79.32-86.19)	

CONCLUSIONS: Our data suggests that aPNS implemented in a real-world setting identified more HIV-infected men and led to greater linkage to treatment. Thus, scaling up aPNS may be an ac-

ceptable and efficient model to achieve near universal uptake of HIV testing amongst men at high risk of HIV infection and linking them to HIV treatment.

PDC0207

UNEVEN PROGRESS IN EUROPE AND CENTRAL ASIA TOWARDS THE 90-90-90 GOALS

T. Noori[1], A. Brown[2], R. Hayes[3], C. Gowar[3], D. Gold[3], V. Delpech[2], A. Pharris[1], Dublin Declaration monitoring group
[1]European Centre for Disease Prevention and Control, Solna, Sweden, [2]Public Health England, London, United Kingdom, [3]National AIDS Trust, London, United Kingdom

BACKGROUND: The objective of this study was to assess how countries in Europe and Central Asia (ECA) are progressing toward the UNAIDS 90-90-90 targets by 2020: 90% of all people living with HIV (PLHIV) know their status; 90% of those diagnosed are receiving antiretroviral treatment (ART); 90% of those on ART are virally suppressed.

METHODS: National data for the most recent year available were submitted in 2019 to the European Centre for Disease Prevention and Control by national focal points from 52 countries in ECA. Estimates followed standard definitions on these measures. Longitudinal data for the period 2015-2018 were extracted from UNAIDS Global AIDS Monitoring database.

RESULTS: Eighty percent of PLHIV were diagnosed in the 43 countries reporting data (country range: 46%-98%), totalling 438,000 people living with undiagnosed HIV in ECA. Sixty-five percent of those diagnosed in the region are on ART (country range: 40%-100%), while 86% of those on ART are virally supressed (country range: 42%-99%). In the 36 countries in the region able to report data on all measures, 44% of the estimated PLHIV were virally supressed (country range: 22%-87%), totalling 1.2 million people living with unsuppressed viral load in ECA (Fig 1). From 2015 to 2018, the number of undiagnosed PLHIV in the region declined from 580,000 to 480,000, the number not on treatment declined from 1,230,600 to 1,096,000 and the number not virally supressed declined from 1,387,000 to 1,303,000.

CONCLUSIONS: There is considerable diversity in progress toward reaching the 90-90-90 targets across ECA, with a few countries exceeding the targets while others lag far behind. Overall, one in five PLHIV in the region are unaware of their HIV infection and nearly two in five diagnosed are not on treatment. These individuals are at risk of ill health and passing on the virus. Currently ECA are not on track to reach the 90-90-90 targets. There has been progress on reducing the proportion of undiagnosed in the region, but significant challenges regarding treatment and viral suppression remain.

PDC03 MORTALITY AND TUBERCULOSIS: WHAT ARE WE DOING TO PREVENT THEM?

PDC0302

HIV REMAINS THE LEADING CAUSE OF DEATH AMONG ADULTS IN ZAMBIA

S. Kamocha[1], P. Minchella[1], A. Wolkon[1]
[1]Centers for Disease Control and Prevention, Lusaka, Zambia

BACKGROUND: HIV is thought to be a leading cause of death in Zambia despite improved access to treatment and palliative care. Nationally representative data on mortality are not available due to an inadequate vital statistics system. Using population-based mortality data, we describe HIV/AIDS cause-specific mortality.

METHODS: Stratified cluster sampling methodology was used to select 350 rural and urban clusters in Zambia and baseline censuses were implemented in each cluster in 2011 and 2016 to gather information on deaths. VA interviews were conducted at households where deaths occurred during the prior 12 months and where they were identified prospectively for 12 months following the censuses. Probable cause of death was determined by two physicians who independently reviewed each VA questionnaire.

RESULTS: The census covered 136,834 households and identified 193,534 deaths. HIV/AIDS was the leading cause of death among adults; 29,403 (19.7%) of all deaths were due to HIV/AIDS. Nearly 60% of all deaths (17,483, 59.5%) were among men. Deaths due to HIV/AIDS have declined from 20.3% to 15.2% among all ages. Among adults, deaths due to HIV/AIDS have declined from 28.4% in 2011 to 19.7% in 2016. In 2016, there were more deaths due to HIV/AIDS among adult males (17,020, 60.0%) compared to females (11,340, 40.0%).

	Deaths due to HIV				Deaths due to other causes			
	Males		Females		Males		Females	
	n	%	n	%	n	%	n	%
0-4	386	51.3	366	48.7	20,196	55.9	15,959	44.1
5-14	78	26.6	214	73.4	6,866	54.8	5,672	45.2
15+	17,020	60.0	11340	40.0	68,681	59.5	46,757	40.5
Total	17,483	59.5	11920	40.5	95,743	58.3	68,389	41.7

CONCLUSIONS: Despite a decline of deaths due to HIV/AIDS from 28.4% in 2011 to 19.7% in 2016, the leading cause of death among Zambian adults is HIV/AIDS. Adult males appear to be more affected by deaths due to HIV/AIDS compared to their female counterparts (60.0% vs 40.0%). Overall, the decline in deaths due to HIV/AIDS shows that progress has been made. However, there is need to accelerate efforts to improve access to ARVs and to improve retention. Interventions to improve linkage to care for adult males need to continue to receive support.

PDC0303

USE OF VERBAL AUTOPSY TO DETERMINE HIV AND TB CO-MORBIDITY: FINDINGS FROM THE SOUTH AFRICAN NATIONAL CAUSE-OF-DEATH VALIDATION PROJECT

P. Groenewald[1], D. Bradshaw[1], M. Maqungo[1], N. Nannan[1], R. Laubscher[1], D. Morof[2], M. Cheyip[3], E. Nichols[4], C. Rao[5], J. Price[6], J. Joubert[1], NCODV Team
[1]South African Medical Research Council, Burden of Disease Research Unit, Cape Town, South Africa, [2]Centers for Disease Control and Prevention, Division of Global HIV/AID and TB, Pretoria, South Africa, [3]Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Pretoria, South Africa, [4]Centers for Disease Control and Prevention, National Center for Health Statistics, Hyattsville, United States, [5]Australian National University, Department of Global Health, Research School of Population Health, Canberra, Australia, [6]Oxford University, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom

BACKGROUND: In South Africa, despite death registration of 90%, HIV deaths are under-reported, or misclassified to immediate causes of death such as TB. Vital statistics for 2016 reported that 4.9% of deaths were due to HIV, and 6.7% were due to TB. HIV and TB co-morbidity rates are unknown because reporting is limited to 3-character International Classification of Disease (ICD) codes. We assessed the use of verbal autopsies to more accurately ascertain the proportion of deaths caused by HIV and TB.

METHODS: We analyzed data from the 2017/2018 National Cause-Of-Death validation project. Interviewers conducted verbal autopsies with next-of-kin using 2016 World Health Organization (WHO) standardized instruments. Physicians completed the WHO standard medical certificate of cause of death. These were coded to ICD-10, and the underlying cause of death was selected using Iris automated software.

RESULTS: HIV was the underlying cause of death for 22.7% of deaths and TB for 7.0%. Proportions of HIV deaths were similar for men and women; however, there were more TB deaths among men than women. HIV disease resulting in TB (B20.0) accounted for 49.3% of all HIV-related deaths (604/1224) and 61.5% of all TB-related deaths (604/982; Table 1). Verbal autopsies indicated that of the 1224 HIV deaths, 125 (10.2%) individuals had received antiretroviral therapy but had discontinued treatment at some point.

Sex	All Deaths	Median age, years	HIV UCOD				TB UCOD	
			HIV no TB (B20.1-B24)*		HIV with TB (B20.0)*		(A15-A19, B90)*	
	n (%)		n	% (95% CI)	n	% (95% CI)	n	% (95% CI)
Male	2808 (52.1)	51.6	303	10.8 (9.7–12.0)	350	12.5 (11.3–13.7)	247	8.8 (7.8–9.9)
Female	2580 (47.9)	56.4	317	12.3 (11.0–13.6)	254	9.8 (8.7–11.1)	131	5.1 (4.3–6.0)
Total	5388 (100)	53.7	620	11.5 (10.7–12.4)	604	11.2 (10.4–12.1)	378	7.0 (6.3–7.7)

*ICD Code
Abbreviations: CI, confidence interval; UCOD, underlying cause of death; HIV, human immunodeficiency virus; TB, tuberculosis, ICD, International Classification of Disease.

[Table 1. Characteristics of deaths and proportions with HIV and TB as underlying cause, South Africa National Cause-of-Death Validation Project (2017–2018)]

CONCLUSIONS: In South Africa, implementing verbal autopsy may help identify misclassified HIV-related deaths (22.7% vs 4.9%) and HIV and TB co-morbidity deaths that are not otherwise reported in official statistics. If integrated into routine vital registration systems, verbal autopsies have the potential to improve cause-of-death statistics.

PDC0304

THE BURDEN OF ADVANCED HIV DISEASE IN A CONCENTRATED HIV EPIDEMIC: A HISTORICAL ANALYSIS OF THE MEDECINS SANS FRONTIERES HIV COHORT IN MYANMAR

T. Homan[1], P. Thit[1], H. They Mar[1], M.P. Thandar[1], M. Sangma[1], T.T. Thwe[1], A. Spina[2], R. Kremer[3], A. Lenglet[3], A. Mesic[3]
[1]Médecins Sans Frontières, Medical, Yangon, Myanmar, [2]Medecins Sans Frontieres UK, Medical, London, United Kingdom, [3]Medecins Sans Frontieres Amsterdam, Medical, Amsterdam, Netherlands

BACKGROUND: Globally, one-third of those enrolled on HIV treatment, present with advanced HIV disease (AHD). AHD is associated with increased morbidity, mortality, risk of onward transmission and public health costs. Médécins Sans Frontières (MSF) has delivered 15 years of HIV care in Myanmar and has extensive experience in the treatment of AHD patients. We describe burden of AHD in MSF Myanmar cohort and the main risk factors for mortality.

METHODS: We conducted a retrospective cohort analysis, using routinely collected patient-level data. The study population included patients presenting with AHD (CD4 <=200 cells/mL and/or WHO-stage 3/4) in MSF Myanmar cohort from 2003 to 2018). We included antiretroviral treatment (ART)-naïve patients that initiated ART at MSF and patients returning to care after being lost-to-follow-up (LTFU) from MSF HIV cohort. For both groups we compared patients with AHD to those without. We performed mortality and a risk factor analyses using Cox regression.

RESULTS: 34,242 ART naïve patients were enrolled during the study period and 25,435 (74.3%) presented with AHD. In this group 33.9% presented with tuberculosis, 1.6% with cryptococcal menigitis, 1% with ocular cytomegalovirus infection and 0.1 % had penicilliosis at enrolment. ART naïve patients presenting with AHD at enrolment were at 3.4 higher risk of death than ART naïve patients who did not present with AHD at enrolment. The main risk factors for death were documented users of injecting drugs and sex work, while age 40-65 was a protective factor. There were 7811 patients who returned to care after being LTFU; 4707 (60.3%) patients presented with AHD. Those with AHD were at a 2.16 higher risk of death than those without AHD when returning to care. Sex work, male gender and tuberculosis were risk factors for death.

CONCLUSIONS: In Myanmar, there was a high proportion of advanced HIV disease among ART naïve and people returning to care after being LTFU. Patients with AHD had a higher risk of death during treatment and mortality risk factors were associated with vulnerable key populations. Our findings advocate for the introduction of AHD packages of care in models of care designed for concentrated HIV epidemics that target key populations.

PDC0305

IMPACT OF HIV TEST-AND-TREAT POLICY ON THE INCIDENCE OF TB AMONG HIV POPULATIONS IN EAST-CENTRAL UGANDA

R. Nyinoburyo[1], A. Muhwezi[2], N. Tumwesigye[3]
[1]University Research Co., LLC, TB/HIV, Jinja, Uganda, [2]University Research Co., LLC, Health Systems Strengthening, Jinja, Uganda, [3]University Research Co., LLC, Jinja, Uganda

BACKGROUND: Early initiation of antiretroviral therapy (ART) is known to reduce the risk of Tuberculosis by up to 67%. Uganda adopted the test-and -treat policy for HIV in 2016 as a strategy for early ART initiation. However, the impact of this policy on TB incidence in program settings has not been studied in the Ugandan setting. This study aimed to determine the incidence of TB in the test-and-treat era compared to the pre-test-and-treat era.

METHODS: A cross-sectional analysis of retrospective data of adult (>15 years) HIV/AIDS patients receiving ART at a large hospital in East-Central Uganda between 01.01.2005 and 31.12.2018. Data on TB status and the year of starting ART were collected. Patients who had TB before starting ART were excluded. Year of starting ART was categorized into; era1-before 2009 (ART eligibility; CD4 ≤350 cells/μL), era2-2009 to 2015 (ART eligibility; CD4 ≤500 cells/μL) and the test-and-treat era (ART start irrespective of CD4 count). Incident TB was calculated for each of the 3 eras. Odds ratios were determined for association of ART start era and TB incidence.

RESULTS: 3,941 patients were enrolled in this study; 70% were female, the median age was 38 years (IQR 29-46). 648 patients started ART in era1, 2,247 started in era2 while 1,046 started in the test-and-treat era. A total of 383 participants developed TB while receiving ART; 242 (63%) male and 141 (37%) female. Sixteen 16%(104/648) of era1 ART patients developed TB compared to 9.5%(213/2247) in era2 and 6.3% (66/1046) in the test-and-treat era. Chi-square=44, p<0.0001 showing a significant association between TB incidence and era of starting ART. The odds of TB during era1 were 2.5 times those of the test-and-treat era (95% CI; 1.6-3.9), while the odds of TB in era2 were 1.6 times those of the test-and-treat era (95% CI; 1.02-2.24).

CONCLUSIONS: Tuberculosis is still incident in the test-and-treat era for HIV. However, the incidence has decreased with subsequent eras of early ART initiation and was lowest in the era of test-and-treat HIV policy. The test and treat policy has had a positive impact on reducing the incidence of TB among PLHIV in program settings in Uganda.

PDC0306

REDUCING TB/HIV CO-INFECTIONS: TRENDS IN TPT AND HIV TESTING IN PEPFAR-SUPPORTED COUNTRIES IN AFRICA

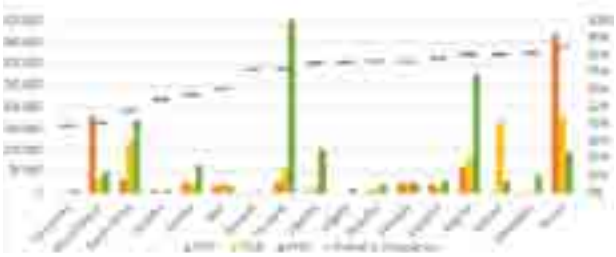
T. Al-Samarrai[1], E. Wong[1], M. Peterson[2], C. Nichols[3], P. Vinayak[1], S. Cavanaugh[1]
[1]US Department of State, Office of the Global AIDS Coordinator, Washington, United States, [2]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Atlanta, United States, [3]US Agency for International Development, Washington, United States

BACKGROUND: Tuberculosis (TB) and HIV co-infection continues to be a major global health concern. TB is the leading cause of death among people living with HIV (PLHIV), while HIV also greatly increases the risk of latent TB advancing to active disease. The President's Emergency Program for AIDS Relief (PEPFAR) is committed to reducing TB/HIV co-infections, setting ambitious targets to treat all PLHIV with TB preventive therapy (TPT) by 2021. In PEPFAR supported countries, HIV testing among presumptive or confirmed TB patients is also critical for HIV case finding and linkage to treatment.

METHODS: We analyzed programmatic data from PEPFAR-supported countries in Africa. We conducted a descriptive analysis of TPT completion data from October 2016 – September 2019 of 18 African countries; one country reported less than 150 completions overall and was excluded from further analysis. To assess HIV testing among confirmed and presumptive TB patients (TB patients), we analyzed data reported from 21 African countries between October 2017– September 2019.

RESULTS: Between fiscal years FY17-FY19, 4,459,397 PLHIV on ART were initiated and 2,947,724 (66%) completed TPT in 17 PEPFAR-supported African countries. TPT completion rates ranged from 0 to 101% (average country completion 50%) in FY17, 14-89% in FY18 (average 62%), and 29-91% in FY19 (average 70%). In FY17, 4/17 countries achieved completion rates of ≥70% while in FY19, 10/17 countries achieved completion rates ≥70%. In Kenya and Tanzania >90% of PLHIV on ART have completed a course of TPT. In FY2019, 93% of TB patients had documented HIV tests across 21 African PEPFAR countries (range: 70-99%). Five of 21 (24%) countries analyzed had HIV testing coverage < 90% in 9/21 (42%) countries. Of those tested, an average 35% of TB patients were HIV-positive across countries (range: 10-81%), with 9% (range: 2.6-18.6%) of those tested newly identified as HIV-positive.

CONCLUSIONS: These results indicate high frequencies of TB/HIV co-infection persist in these countries. While HIV testing among suspected and confirmed TB patients should be routine in PEPFAR countries, there are persistent gaps which need to be addressed, particularly for children <15 years of age. TPT for PLHIV should be scaled up across all PEPFAR-supported countries yet there continues to be significant variation in coverage. Further analyses should be performed to characterize context specific reasons for poor TPT completion and HIV testing among TB patients.



[Figure. Number of TPT Completions Over Time and Overall Percent Completion in African PEPFAR-Supported Countries, FY17-FY2019.]

PREVENTING HIV AND ACHIEVING PREGNANCY AMONG HIV-DISCORDANT COUPLES USING SAFER CONCEPTION STRATEGIES IN ZIMBABWE

J. Brown[1,2,3], S. Gitome[4], B. Mateveke[5], T. Chirenda[5], G. Chareka[5], C. Chasakara[5], C. Murombedzi[5], A. Matubu[5], N. Mgodi[5], P. Musara[5], T. Makurumure[6], C. Smith-Hughes[3], Z.M. Chirenje[2,5], F. Mhlanga[5], SAFER Study Group

[1]University of California, Epidemiology and Biostatistics, San Francisco, United States, [2]University of California, Obstetrics, Gynecology, and Reproductive Sciences, San Francisco, United States, [3]University of California, Global Health Sciences, San Francisco, United States, [4]Kenya Medical Research Institute, Centre for Microbiology Research, Nairobi, Kenya, [5]University of Zimbabwe, Obstetrics and Gynecology, Clinical Trials Research Centre, Harare, Zimbabwe, [6]Mercy-Care Fertility Centre, Harare, Zimbabwe

BACKGROUND: Safer conception strategies are needed to minimize HIV transmission risk among HIV-discordant couples desiring pregnancy. Few studies have evaluated the use and effectiveness of safer conception strategies among HIV-discordant couples. We measured the uptake and clinical outcomes of four safer conception strategies among discordant couples in Zimbabwe planning to get pregnant.

METHODS: We enrolled HIV-discordant couples desiring conception into a prospective, non-randomized pilot study. Couples were given a choice of one or more safer conception strategies: antiretroviral therapy with viral load monitoring (ART/VL), oral pre-exposure prophylaxis (PrEP) with tenofovir disoproxil fumarate/emtricitabine, home-based vaginal insemination (VI) for couples with an HIV-positive female, and semen washing (SW) for couples with an HIV-positive male. Couples were taught to identify the fertile period and counselled to always use condoms, except for those using ART/VL or PrEP, who had condomless sex during the fertile period. Participants were followed monthly for up to 12 months of pregnancy attempts, quarterly during pregnancy, and 12 weeks post-delivery. At each visit self-reported data on strategy use, urine for pregnancy testing, and blood for HIV antibody testing, or viral load if HIV-positive were obtained. Newborns from HIV-positive females were tested for HIV using DNA PCR at 6 and 12 weeks.

RESULTS: Twenty-three discordant couples were followed from April 2017-June 2019 with no loss-to-follow-up. Twelve couples had an HIV-positive female partner. Median age was 31 years for females, 34 years for males. At enrolment, all couples chose ART/VL, and all couples chose at least one additional strategy: (PrEP [n=17/23;74%; 8/17 were female]), VI (n=3/12;25%), SW (n=4/11;36%). During follow-up, three couples switched from ART/VL+SW to ART/VL+PrEP, and one from ART/VL+PrEP+VI to ART/VL+PrEP. One female discontinued PrEP due to an adverse reaction. Half (n=12/23;52%) of the couples achieved pregnancy, with 10 pregnancies reaching term. All participants were virally suppressed prior to pregnancy attempts, and two participants (9%) had detectable viral load during follow-up. There were no cases of horizontal or vertical transmission.

CONCLUSIONS: All four safer conception strategies appear safe and effective. When offered a choice, discordant couples desiring pregnancy seek a combination of HIV prevention strategies, with ART/VL plus PrEP being the most frequently selected.

PDC0403

HIV AND SYPHILIS PREVALENCE AND SEXUAL RISK-TAKING BEHAVIOURS AMONG IN- AND OUT-OF-SCHOOL ADOLESCENT GIRLS AND YOUNG WOMEN IN UGANDA: RESULTS FROM A NATIONAL SURVEY

J.K. Matovu[1,2], J. Bukenya[3], L. Mugenyi[3], A. Nyabigambo[3], D. Lubogo[3], R. Kisa[3], S. Kisaka[3], D. Kasozi[3], D. Serwadda[3], I. Murungi[4], R.K. Wanyenze[3]

[1]Makerere University School of Public Health, Disease Control and Environmental Health, Kampala, Uganda, [2]Busitema University Faculty of Health Sciences, Community and Public Health, Mbale, Uganda, [3]Makerere University School of Public Health, Kampala, Uganda, [4]The AIDS Support Organization, Kampala, Uganda

BACKGROUND: Studies suggest that in-school girls may be at a less risk of HIV infection than their out-of-school counterparts. However, few studies have examined HIV and syphilis prevalence or sexual risk-taking behaviours of in- and out-of-school AGYW as part of the same study. To address this gap, we assessed sexual risk-behaviours and HIV and syphilis prevalence among in- and out-of-school adolescent girls and young women (AGYW) aged 10-24 years to inform the design of age-appropriate HIV prevention interventions.

METHODS: This was a cross-sectional study conducted in 233 villages and 80 schools in 20 districts between July and August 2018. Districts were selected from ten geographically demarcated regions based on background HIV prevalence and presence/absence of HIV interventions. We collected data on socio-demographic, sexual, health and behavioural characteristics and diagnosed HIV and syphilis using rapid diagnostic test kits. Data were entered into EpiData (version 3.1) and analysed using STATA (version 14.1).

RESULTS: Of 8,236 (97.2%) AGYW enrolled into the study, 50.3% (n=4,139) were in-school. In-school AGYW were significantly less likely to have ever had sex (35.2% vs. 73.1%, Risk Ratio [RR]=0.48; 95% Confidence Interval [95%CI]: 0.46, 0.50); or to have initiated sex before age 15 (17.5% vs. 30.3%, RR=0.58; 95%CI: 0.51, 0.65). In-school AGYW were significantly more likely to report that they used a condom or other contraceptive methods to prevent pregnancy at first sex (65.1% vs. 41.1%, RR=1.58; 95%CI: 1.50, 1.68) and to report that they used a condom at last sex (55.3% vs. 20.7%, RR=2.67; 95%CI: 2.46, 2.91) than their out-of-school counterparts. Overall, 1.0% (n=106) had HIV while 1.2% (n=105) had syphilis. HIV and syphilis prevalence increased with age, and were higher among out-of-school than in-school AGYW (HIV prevalence: 1.6% vs. 0.6%; syphilis prevalence: 1.9% vs. 0.6%).

CONCLUSIONS: We found low overall HIV and syphilis prevalence among AGYW. However, both HIV and syphilis prevalence were higher among out-of-school than in-school AGYW, possibly due to the very high-risk behaviours reported by out-of-school AGYW compared to their in-school counterparts. Targeted risk reduction programs including interventions aimed at keeping girls in school may help to tame the HIV tide among AGYW in Uganda.

PDC0404

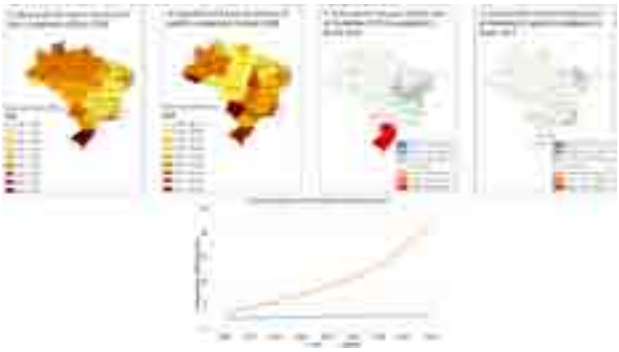
ARE HIV AND SYPHILIS SYNDEMIC IN PREGNANT WOMEN IN BRAZIL? HOT-SPOT ANALYSIS OF THE TWO EPIDEMICS

M.C. Cambou[1], E. Saad[2], K. McBride[3], K. Nielsen-Saines[2]
[1]UCLA, Infectious Diseases, Los Angeles, United States, [2]UCLA David Geffen School of Medicine, Pediatric Infectious Diseases, Los Angeles, United States, [3]UCLA Fielding School of Public Health, Health Policy and Management, Los Angeles, United States

BACKGROUND: Despite enhanced public health efforts to eradicate HIV and syphilis mother-to-child transmission (MTCT), rates of congenital syphilis have quadrupled in Brazil in the past decade. Geographic information system (GIS) and hot-spot analysis, often underutilized research techniques, may provide better understandings of epidemic patterns.

METHODS: Aggregate data provided by the Brazilian Ministry of Health/SINAN for all pregnant women diagnosed with HIV or syphilis between January 1, 2010 to December 31, 2018 was analyzed. ArcGIS software was used to map the annual incidence of HIV and syphilis diagnosed in pregnancy by state. Hot-spot analysis was performed to identify state-specific clusters.

RESULTS: From 2010 to 2018, 66,632 pregnant women were diagnosed with HIV, 271,209 were diagnosed with syphilis, and 150,414 infants were diagnosed with congenital syphilis. While the annual, national incidence of HIV diagnosis in pregnancy remained stable, syphilis incidence increased six-fold, from 3.5 per 1,000 live births in 2010, to 21.4 per 1,000 live births in 2018 (r = 0.97). Rio Grande do Sul had the highest incidence of HIV in 2018 (9.2 per 1,000 live births), and hot-spots of HIV incidence were identified in three Southern states (p <0.01). The incidence of syphilis was significantly higher than HIV, and there was little overlap between HIV and syphilis incidence by state (r = 0.25). While syphilis incidence exceeded 30 per 1,000 live births in 2018 in Acre, Mato Grosso do Sul, Rio de Janeiro, and Espirito Santo, only the last two states in Southeastern Brazil were spatial clusters in hot-spot analysis.



[Figure 1. Spatiotemporal maps and trends of the annual incidence of HIV and syphilis in pregnancy in Brazil]

CONCLUSIONS: HIV and syphilis epidemics in Brazil are not syndemic in pregnant women. There is a spatial cluster of HIV in the South, while syphilis is increasing throughout the country, particularly in the Southeastern coast. Combating HIV hot-spots alone is not sufficient to curtail syphilis MTCT. Monitoring geographic variation allows for improved targeted efforts.

PDC0405

HIV, STIS AND PREGNANCY AMONG WOMEN OF REPRODUCTIVE AGE IN A LAKE VICTORIA FISHING COMMUNITY: A POPULATION-BASED STUDY

A.D. Peer[1], J. Kagaayi[2], R. Ssekubugu[2], J. Jackson[1], G. Kigozi[2], S. Kalibala[2], R.H. Gray[3], M.J. Wawer[3], J. Mpagazi[2], S. Kiboneka[2], S.J. Reynolds[4], A.A. Tobian[1], C.A. Gaydos[1], T.C. Quinn[4], M.K. Grabowski[1]
[1]Johns Hopkins University School of Medicine, Baltimore, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States, [4]National Institute for Allergy and Infectious Diseases, Laboratory of Immunoregulation, Division of Intramural Research, Bethesda, United States

BACKGROUND: Despite sequelae including miscarriage and neonatal death, population-based data on sexually transmitted infections (STI) during pregnancy are limited in sub-Saharan Africa. The prevalence of HIV and four curable STIs (*Chlamydia trachomatis* (CT), *Neisseria gonorrhoeae* (NG), *Trichomonas vaginalis* (TV), and *Treponema pallidum* (syphilis)) were measured among women in a Lake Victoria fishing community in southern Uganda.

METHODS: We compared population-level prevalence of NG, CT, TV, and syphilis among pregnant and non-pregnant sexually active women of childbearing age (15-49) who participated in the Rakai Community Cohort Study May-July 2019. CT and NG testing were conducted by nucleic acid amplification testing (Abbott RealTime CT/NG m2000). Point-of-care testing was performed for TV (OSOM Trichomonas) and syphilis (Anti-TP SDBioline syphilis 3.0), with confirmatory rapid plasma reagin (RPR) titers (Cypress Diagnostics). RPR titers ≥1:8 were classified as active syphilis. All participants received treatment when indicated. Associations between STIs, pregnancy, and HIV status were assessed with multivariable modified Poisson regression and reported as age adjusted prevalence risk ratios (adjPRR) with 95% confidence intervals (CI).

RESULTS: 432 women met inclusion criteria, with 11% (n=47) pregnant. Among pregnant women, HIV prevalence was 32% (n=15), NG 13% (n=6), CT 13% (n=6), and TV 26% (n=12). Syphilis reactivity was 17% (n=8), and 6.4% (n=3) had titers indicative of active infection. Prevalence of ≥1 active STI infection (NG, CT, TV, or active syphilis) was 34% (n=16). Among non-pregnant women (n=385), HIV prevalence was 49% (n=189), NG 9.6% (n=37), CT 10% (n=40), and TV 18% (n=68). Syphilis reactivity was 27% (n=108), and 9.6% (n=37) had active infection. The age-adjusted relative risks of active STI in pregnant versus non-pregnant and HIV-positive versus HIV-negative women were 1.31 (95%CI: 0.74-2.12) and 1.64 (95%CI: 1.12-2.40), respectively. Pregnant women with HIV were 62% more likely to have ≥1 STIs compared to pregnant women without HIV (adjPRR=1.62; 95%CI: 1.11-2.39).

CONCLUSIONS: These data highlight the very high burden of STIs among women in Lake Victoria fishing communities, particularly among pregnant women. There is an urgent need for effective integrated STI screening and treatment in antenatal care and HIV treatment programs in this population.

PDC0406

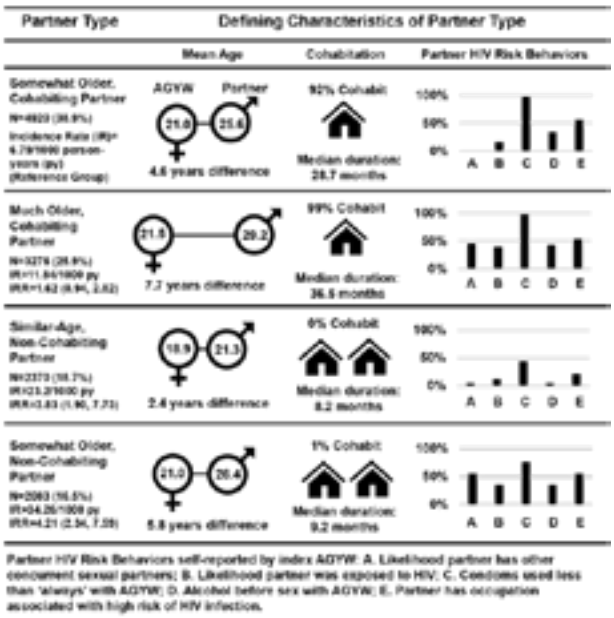
SEXUAL PARTNER TYPES OF ADOLESCENT GIRLS AND YOUNG WOMEN IDENTIFIED FROM LATENT CLASS ANALYSIS (LCA) AND INCIDENT HIV-INFECTION IN RAKAI, UGANDA

N. Nguyen[1], R. Tsong[2], T. Lutalo[3], A. Zhang[2], Y. Wei[2], I. Chen[2], J. Li[2], F. Nalugoda[3], C. Kennedy[4], M.K. Grabowski[5,6], J. Santelli[7], S. Hoffman[1]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, New York, United States, [2]Columbia University Mailman School of Public Health, Department of Biostatistics, New York, United States, [3]Rakai Health Sciences Program, Kalisizo, Uganda, [4]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [5]Johns Hopkins School of Medicine, Baltimore, United States, [6]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [7]Heilbrunn Department of Population and Family Health, Columbia University Mailman School of Public Health, New York, United States

BACKGROUND: Sexual partners play a critical role in HIV acquisition among adolescent girls and young women (AGYW). We identified sexual partner types and associations with incident HIV infection among AGYW ages 15-24 during years 2005-2013 of the Rakai Community Cohort Study.

METHODS: At each survey round, AGYW reported the following partner (age, concurrency, likelihood of HIV-infection, high-risk occupation) and partnership characteristics (cohabitation, condom use, and alcohol before sex with AGYW) and offered HIV testing. Characteristics were used to identify sexual partner types using Latent Class Analysis (LCA). Among HIV-negative AGYW, we estimated incident rate ratios (IRR) and 95% confidence intervals (CI) for each LCA-identified partner type and incident HIV infection using a Poisson GEE model, controlling for other partner types, sexual behavior and demographic risk factors, and repeated observations.

RESULTS: In total 7742 AGYW reported 12,649 sexual partners. Of those AGYW, 2691 were eligible for the HIV-incidence analysis, contributing 7262 total person-years of follow up. Overall, 90 AGYW became newly HIV infected, for an incidence rate of 12.38 per 1000 person-years (95% CI: 6.56, 23.37). We identified four sexual partner types (Figure).



[Figure. Defining characteristics of sexual partner types among adolescent girls and young women in Rakai, Uganda]

Compared to the reference group (AGYW with 'somewhat older cohabiting' partners), AGYW with 'somewhat older non-cohabiting' partners had 4.21 times the rate of HIV infection (95% CI: 2.34, 7.59), while AGYW with 'similar-age non-cohabiting' partners had 3.83 times the rate (95% CI: 1.90, 7.73), and AGYW with 'much older cohabiting' partners had 1.62 times the rate (95% CI: 0.94, 2.82).

CONCLUSIONS: Partner types derived from LCA were strongly associated with incident HIV-infection among AGYW, though some partner types were associated with lower than expected HIV-infection rates given reported risk behaviors, while others were higher. These findings highlight the importance of examining partner characteristics together in the context of sexual partnerships to understand HIV risk in this vulnerable population.

PDC0407

CHARACTERISTICS OF OLDER MALE PARTNERS OF ADOLESCENT GIRLS AND YOUNG WOMEN (AGYW) IN FOUR EASTERN AND SOUTHERN AFRICAN COUNTRIES, PHIA 2015-2017

S. Hoffman[1,2], J. Mantell[2], C. Wang[3], I. Mushamiri[1], A. Low[1,3]
[1]Mailman School of Public Health, Columbia University, Epidemiology, New York, United States, [2]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, Psychiatry, New York, United States, [3]Mailman School of Public Health, Columbia University, ICAP, New York, United States

BACKGROUND: Accumulating evidence indicates that sexual partnerships between older men and adolescent girls and young women (AGYW aged 15-24) contribute to ongoing high HIV incidence among AGYW in Eastern and Southern Africa. However, little is known about characteristics of older men who partner with AGYW.

METHODS: Participants were from Population-based HIV Impact Assessment (PHIA) household surveys in Eswatini, Tanzania, Zambia, Malawi. Past-year sexually active men aged 25-59 with known age of their three most recent female partners were included. HIV status was obtained via rapid test; HIV-1 RNA with real-time PCR. We constructed separate logistic regression models by male partner age-group (25-34 years, 35-44 years, 45-59 years) adjusted by continuous age to compare characteristics of men partnering with AGYW versus those partnering only with same age-group or older women. Analyses were adjusted for survey design; Taylor Series method was used for variance estimation. We tested for interactions by country in a pooled model.

RESULTS: Of 17,110 sexually-active men, 32.3% reported ≥1 past-year AGYW partner: this was highest among men aged 25-34 (58.5%). HIV prevalence was highest in those over age 45 (12.0%). Viral load suppression among those HIV-positive increased with age. Men who were not married/living together, had >1 partner, and bought/sold sex in the past year had higher odds of partnering with an AGYW. HIV-positive men did not have higher odds of partnering with an AGYW (OR=0.81; 95%CI: 0.67-0.99), but among HIV-positive men, virally-unsuppressed men had higher odds of doing so than those virally-suppressed (OR=1.89; 95%CI: 1.42-2.52) (Table 1). Patterns were consistent across age-group, but heterogeneity by country was observed (not shown).

CONCLUSIONS: Older partners may present an HIV-risk to AGYW not only because they have higher HIV prevalence, but also because those who partner with AGYW (versus those who do not) engage in more risk behaviors and are more likely to be virally-unsuppressed.

Characteristic associated with odds of partnering with AGYW	All men aged 25-59 OR (95% CI)		Men aged 25-34 OR (95% CI)		Men aged 35-44 OR (95% CI)		Men aged 45-59 OR (95% CI)	
Marital status (reference = married/living together)								
Never married	**2.15**	**(1.72-2.7)**	**1.67**	**(1.31-2.13)**	**3.49**	**(2.1-5.79)**	0.72	(0.21-2.43)

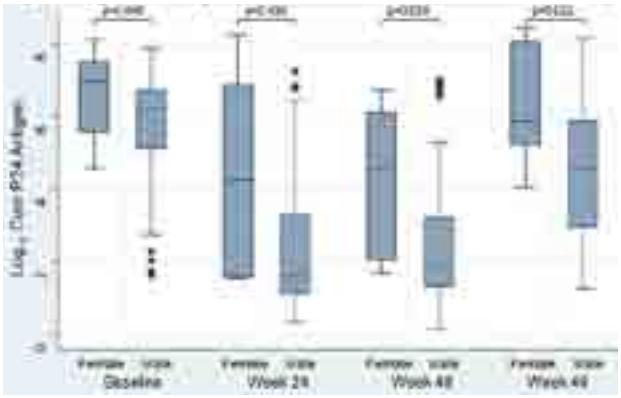
HIGHER COLON TISSUE INFECTIVITY IN HIV SERONEGATIVE CISGENDER WOMEN COMPARED TO CISGENDER MEN ON CANDIDATE ORAL ANTIRETROVIRAL (ARV) PRE-EXPOSURE PROPHYLAXIS (PREP) REGIMENS IN HPTN 069

R. Sekabira[1], K. Yuhas[2], I. McGowan[3], R. Metter Brand[3], M. Marzinke[4], K. Mayer[5], R. J. Landovitz[6], T. Wilkin[7], K.R. Amico[8], Y. Manabe[4], I. Frank[9], A. R. Kekitiinwa[10], R. M. Gulick[7], C. W. Hendrix[4]
[1]Baylor, Research Pharmacy, Kampala, Uganda, [2]Fred Hutchinson Cancer Research Center, Seattle, United States, [3]University of Pittsburgh, Medical School, Pittsburgh, United States, [4]Johns Hopkins University School of Medicine, Baltimore, United States, [5]Fenway Health/Harvard Medical School, Boston, United States, [6]University of California, Center for Clinical AIDS Research and Education, Los Angeles, United States, [7]Weill Cornell Medicine, New York, United States, [8]University of Michigan, School of Public Health, Ann Arbor, United States, [9]University of Pennsylvania, Infectious Disease Division, Philadelphia, United States, [10]Baylor, Kampala, Uganda

BACKGROUND: HPTN 069 randomized HIV-negative men and women to one of four candidate daily oral PrEP regimens for 48 weeks: tenofovir disoproxil fumarate (TDF) + emtricitabine (FTC), maraviroc (MVC) only, MVC+FTC, and MVC+TDF. In this tissue substudy, we compare susceptibility of colon tissue to HIV infection ex vivo between men and women.

METHODS: Plasma, peripheral blood mononuclear cells (PBMC), and colon tissue were collected for drug concentrations. Colon biopsy "explants" were challenged with HIV ex vivo followed by tissue culture supernatant collection over two weeks for p24 antigen measurement; results were summarized as cumulative biopsy-weight adjusted p24 (Cum p24 pg/mL/mg). Assessments were made at baseline (no drug), week 24 and 48 (on study drugs), and week 49 (one week after the last dose). Comparisons used Wilcoxon with exact significance.

RESULTS: This substudy included 12 women and 59 men. Compared to men, women's median week 24 and 48 colon tissue MVC concentrations were 42% lower (p=0.08) and 57% lower for FTC (p=0.004), but higher for TFV diphosphate (p=0.002). Blood ARV concentrations and recent daily adherence (90% overall based on PBMC drug concentration benchmarks) did not differ by sex. Women had higher explant p24 expression at all visits (Figure) compared to men, which ranged from 2-fold (p=0.046) to 16-fold (p=0.016). Two-fold male-female differences existed before any drugs were taken and were largest (10- to 16-fold) when participants were taking the drug daily (week 24 and 48). The male-female p24 differences were not statistically significant in the MVC only arm (minimal, variable p24 suppression) or the TDF+FTC arm (near maximal p24 suppression).



[Figure. Log_{10} median weight adjusted Cum P24 antigens in MSM and women by visits]

CONCLUSIONS: Colon explants from women have higher HIV replication after ex vivo HIV challenge compared to men - with and without the PrEP study drugs. This is not due to adherence differences. Male-female differences in tissue concentrations may partly provide an explanation

PDD01 FROM WITHIN: EFFECTIVE STRATEGIES FOR COMMUNITY MOBILIZATION AND DEMAND CREATION

PDD0102

SAVINGS AND LOANS GROUPS AS A POTENTIAL COMMUNITY TOOL FOR VIRAL LOAD SUPPRESSION IN RESOURCE-LIMITED SETTINGS: AN INTERVENTION STUDY FROM MOZAMBIQUE

M. Lisboa[1], S. Culuze[2], A. Cambule[2], S. Greenberg[1]
[1]United States Agency for International Development (USAID), Integrated Health Office, Maputo, Mozambique, [2]World Vision Mozambique, Health and Wellbeing - SCIP Ogumaniha, USAID Funded Project, Quelimane, Mozambique

BACKGROUND: Village savings and loans groups (VSLGs) are a sustainable community-based intervention, comprised of HIV-positive and -negative participants, that improve resilience at the household and community levels. Evidence supports that VSLG members report heightened awareness levels of health problems and healthy behaviors as well as enhanced social cohesion, community support systems, and solidarity. We aimed to assess the impact of VSLG membership on continuous retention to HIV treatment and viral load suppression (VLS) among HIV-positive members over a 12-month period.

METHODS: A randomized, two-arm, unblinded, non-inferiority design with 12-months follow-up (from January to December 2018) of newly enrolled HIV treatment and previously lost to follow up

clients was conducted in Zambézia, Mozambique. The control arm received a standard facility-based package of HIV care while the intervention arm received the same package coupled with VSLG participation. In addition to financial activities, VSLG meetings included facilitated sessions on various health-related topics, including HIV-related stigma and discrimination, social support and solidarity, and HIV treatment retention and VLS. Patient-level assessments of continuous retention over a 12-month period and VLS were performed. Associations between VSLG status and retention and VLS were calculated using logistic regression.

RESULTS: Among 677 patients included in the study, 47% (321) were in the intervention arm, from which 57% were female and 49% were aged 25-34 years. Within the analyzed 12-month period, 93% of VSLG members had not experienced any treatment interruptions as compared to 47% in the control arm. VSLG members were far more likely than the control group to have a documented viral load test (78% vs. 40%) and to experience VLS (94% vs. 55%). Patients in the intervention arm were nearly six times more likely to achieve VLS (aOR= 5.6; 95% CI: 2.6-11.8) when compared to the control arm, adjusting for socio-demographic and clinical factors.

CONCLUSIONS: These results suggest that promoting VSLGs among people living with HIV may be an effective way to reaching HIV epidemic control. Scaling-up VSLGs should be considered not only as a sustainable community tool for economic and social support strengthening, but also as a platform for better communication for improved HIV outcomes and stigma and discrimination reduction.

PDD0103

#MENOFPREP: ENGAGEMENT OF ONLINE COMMUNITY INFLUENCERS AND THE USE OF SEX-POSITIVE MESSAGING IN CREATING AWARENESS OF HIV PRE-EXPOSURE PROPHYLAXIS AMONG MEN WHO HAVE SEX WITH MEN IN THE PHILIPPINES

J.D. Rosadiño[1], P.V. Junio[1], J.O. Corciega[1], R. Pagtakhan[1], C. Lagman[1]
[1]*LoveYourself, Inc., Manila, Philippines*

BACKGROUND: The WHO recommended the use of antiretroviral pre-exposure prophylaxis (PrEP) in addition to other prevention methods may be an option to halt and reverse this epidemic in the Philippines. However, PrEP awareness is low among Filipino MSMs. The project aims to bring PrEP awareness to MSMs in the Philippines by engaging online community influencers and using sex-positive messaging.

DESCRIPTION: A communications plan was designed to determine the tone and feel of the campaign, together with its accompanying key messages. The messages focused on PrEP information, access, and its impact on the lifestyle of prospective clients. The visual theme and the key messages developed are sex-positive, with a motivational tone of espousing self-empowerment. The developed plan was then cascaded to people who have the following qualifications: a known member of the MSM community and has an established online presence. The following were then shared with the influencer as part of the campaign development: A PrEP 101 briefer, the photoshoot, and an "influencer package" containing FAQs should they receive inquiries regarding PrEP on their personal accounts. After the campaign development, the materials (together with its appropriate captions/key messages) were then posted on LoveYourself's social media channels (Facebook, Twitter, and Instagram), and shared by the influencers. All posts contain the registration link for PrEP access in LoveYourself community centers and its affiliates.

LESSONS LEARNED: A total of 20 MSM community influencers agreed to participate in the campaign, even without monetary compensation. Each post has received unique engagements ranging from 8,000 to 30,000. These numbers are organic, and no advertising/boosting funds were spent. The sign-up link for PrEP registration was accessed 25,000 times. Inquiries regarding PrEP in LoveYourself's social media channels increased by 2000%. The campaign has helped increase the number of PrEP enrollees under LoveYourself's care from 50 to 750 in 4 months.

CONCLUSIONS/NEXT STEPS: It was seen that a sex-positive campaign powered by the community is effective in bringing awareness of PrEP. Population-specific variants of the campaign (#WomenOfPrEP for cisgender and transgender women, for instance) are recommended in order to create PrEP campaigns that are targeted and diverse.

PDD0104

EMPLOYING SYNDEMIC THEORY IN PRE-EXPOSURE PROPHYLAXIS (PREP) ACCESS AMONG TRANSGENDER WOMEN OF COLOR IN SOUTH FLORIDA

S. Kiplagat[1], Y. Mariano[1], J. Dévieux[1], M. Jean-Gilles[1], S. Johnson[1], M.J. Trepka[1], M. Padilla[1], D. Stephens[1], A. Lint[2], Y. Ocon[3], F. Duberli[3], C. Lewis[4], E. Cyrus[1]
[1]*Florida International University, Miami, United States,* [2]*Arianna's Center, Miami, United States,* [3]*Survivor's Pathway, Miami, United States,* [4]*Empower U Community Center, Miami, United States*

BACKGROUND: Although transgender women of color (TWOC) are disproportionately at high risk of acquiring HIV, they remain underrepresented in HIV screening and engagement in HIV prevention including pre-exposure prophylaxis (PrEP). Syndemics of poverty, substance use, violence and mental health further restrict engagement in HIV prevention. Therefore, the objective of this study was to employ a syndemic theoretical framework to identify barriers and facilitators of PrEP among TWOC in South Florida.

METHODS: In September-January 2020, eight in-depth interviews and two focus groups were conducted among transgender adult women living in Miami-Dade and Broward counties in South Florida. Participants were recruited through convenience sampling, active recruitment, print advertisements and emails to transgender organizations listservs. Content analysis approaches were developed for coding categories and themes. The codes were developed independently using NVivo before comparison, discussion, and differences were reconciled to identify and analyze themes.

RESULTS: The mean age of participants was 42.2 years old; 82.4% were transgender Latinas and 17.6% were African American. Discrimination and stigma by providers and the wider society, and limited economic opportunities were identified as primary barriers to accessing HIV screening and PrEP healthcare services. Lack of employment opportunities, due to prejudice, stigma and discrimination was a recurring theme. As a result, many participants were vulnerable to economic insecurity. The high cost of PrEP medication as well as stigma and discrimination by healthcare

providers limiting engagement in HIV prevention also emerged as a theme. The participants also noted that under-representation of transgender women in clinical trials has led to inadequate data on side effects including dermatological side effects forcing them to discontinue PrEP. Emerging themes also included physical violence, psychological violence and sexual abuse from peers, partners, and systems from early childhood. Effects of violence were compounded by the syndemics of poverty, substance misuse, mental health issues, and engagement in transactional sex work. Consequently, HIV screening and engagement in HIV prevention is often a low health priority among TWOC.

CONCLUSIONS: Economic constraints, stigma, discrimination, and violence are associated with systematic marginalization of TWOC in their local communities, inhibiting HIV screening use of PrEP. The development of tailored interventions should consider these syndemic factors.

PDD0105

COMMUNITY INFLUENCERS ARE KEY TO HIV PREVENTION FOR LATINO HOMELESS POPULATIONS: A STRATEGY FOR GETTING TO ZERO AMONG IMMIGRANTS

J. Zepeda[1], R. Melendez[2], M.G. Alaniz[1]
[1]San Francisco AIDS Foundation, San Francisco, United States, [2]San Francisco State University, Sociology and Sexuality Studies, San Francisco, United States

BACKGROUND: In San Francisco, 20% of new HIV diagnoses in 2018 were among people without housing, with the proportion growing in recent years. Nearly a quarter (24%) of HIV cases from 2009 - 2018 were Latinx. To reduce HIV transmission in San Francisco and "Get to Zero", we must invest in developing effective ways to reach these populations, since they may not be aware of or may be distrustful of available services. Instead of relying on individuals to access services, community-based recruitment strategies may successfully bring services to individuals.

DESCRIPTION: In 2018, San Francisco AIDS Foundation's Latino Programs piloted the Todos Somos Familiaproject with the support of a Kaiser Permanente Community Benefit Grant. The project trained 16 formerly and currently homeless Latino immigrants as community HIV influencers, or promotores de salud, to share information about navigating drug use programs and mental health services, overdose prevention, applying for housing, and accessing legal assistance and HIV services. During outreach, influencers also shared HIV prevention information including how to access HIV testing, advantages of routine sexual health screenings, and the benefits of PrEP, PEP, and condoms. Influencers were each paid $494; clients receiving case management were provided $120 for completing 8 contacts with influencers. Over 6 months, 16 influencers made 376 health education contacts with Latino homeless individuals; 175 of those individuals made a second contact with project staff and HIV screening referrals. Of those 175 who made a second contact with SFAF: 25 accessed case management, 19 accessed legal services, 7 entered methamphetamine treatment, 10 entered psychiatric treatment, 2 re-connected with HIV care, 2 clients were diagnosed with cancer and sought treatment, 8 took a PrEP orientation class, and 1 received an overdose reversal.

LESSONS LEARNED: Paying formerly and currently homeless immigrant individuals to reach their communities with health information and services is an effective way to share HIV and health services. Formerly and currently homeless Latino individuals successfully engage with other Latino homeless individuals organically and are social influencers--securing survival for themselves and communicating skills to others.

CONCLUSIONS/NEXT STEPS: SFAF, in collaboration with other Latino organizations, seeks to replicate and expand the project.

PDD0106

THE CEDAR PROJECT: INTERGENERATIONAL CHILD APPREHENSION AND HIV HEALTH AND WELLNESS AMONG YOUNG INDIGENOUS PEOPLE WHO HAVE USED DRUGS IN TWO CANADIAN CITIES - A MIXED METHODS STUDY

K. Jongbloed[1], S. Pooyak[2], M.E. Pearce[1], A. Mazzuca[1], R. Sharma[1], W.M. Christian[3], M. Teegee[4], L. Demerais[5], R.T. Lester[1], M.T. Schechter[1], P.M. Spittal[1], For the Cedar Project Partnership
[1]University of British Columbia, Vancouver, Canada, [2]Aboriginal HIV/AIDS Community-Based Research Collaborative Centre (AHA Centre), Victoria, Canada, [3]Splatsin te Secwepemc, Enderby, Canada, [4]Carrier Sekani Family Services, Prince George, Canada, [5]The Cedar Project, Vancouver, Canada

BACKGROUND: Wellbeing is eroded when Indigenous children are forcefully removed from families and communities, as they have been through Canada's residential school and child apprehension systems. Despite prevalence of intergenerational child apprehensions among Indigenous people involved in substance use, there is a paucity of research on child apprehension as a determinant of HIV-related health. We explored how child apprehension experiences shaped HIV health and wellness among young Indigenous people who have used drugs in two Canadian cities.

METHODS: This exploratory sequential mixed-methods study took place within the Cedar Project cohort involving young Indigenous people who have used drugs in British Columbia, Canada. In-depth interviews addressing HIV cascade of care experiences involved 12 participants living with HIV in 2016. Interpretive description identified themes. Based on qualitative findings, longitudinal generalized linear mixed effects models involving 52 participants tested for relationships between intergenerational child apprehension and HIV viral suppression using data collected between 2011-2014.

RESULTS: Child apprehension experiences were a central concern for participants; 78.8% had been apprehended as children and, among parents, 60.5% had experienced their own child(ren) being apprehended. Themes highlighting intersections with HIV included: (1) impact of removal from families on long-term health and wellbeing; (2) re/connecting with family; (3) intersections of substance use, apprehension, and HIV; (4) stress and demands of maintaining/regaining custody; and (5) traditional wellness practices being valued but complicated. Being apprehended (aOR: 0.23; 95%CI: 0.06-0.82) and having a child apprehended (aOR: 0.24; 95%CI: 0.07-0.77) were significantly associated with reduced odds of HIV treatment success (viral suppression).

CONCLUSIONS: Young Indigenous people who have used drugs were over 75% less likely to be virally suppressed if they were apprehended from their parents as children, or their own children had been apprehended. To our knowledge, this is the first study to demonstrate statistical links between intergenerational child apprehensions and negative HIV outcomes among young Indigenous people with HIV. Respecting Indigenous rights to self-determination over child welfare processes is urgent. HIV care for young Indigenous people who have used drugs must acknowledge and

address ongoing impacts of intergenerational child apprehension experiences. Supporting parenting and family connections are essential to culturally-safe, healing-centered HIV care.

PDD0107

PATIENT-CENTERED, PATIENT-PROVIDER ENGAGEMENT AS MEDIATOR OF EFFECTS OF HEALTHCARE DISCRIMINATION, DEPRESSION AND PAIN ON LATER PAIN-RELATED OUTCOMES AND QUALITY-OF-LIFE AMONG AFRICAN AMERICANS WITH HIV WHO USE DRUGS

T.-Y. Tseng[1], M. Mitchell[2], M.C. Beach[3], G. Chander[3], A. Knowlton[1]
[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]Friends Research Institute, Baltimore, United States, [3]Johns Hopkins School of Medicine, Baltimore, United States

BACKGROUND: Chronic pain is a prevalent, under-addressed co-morbidity among people living with HIV (PLHIV) that adversely impacts their quality-of-life (QOL). Because pain may compound discrimination in healthcare and problematic (self-medicating) coping , racial/ethnic minority PLHIV who use drugs experience particular disparities in pain and treatment access. Patient-centered patient-provider engagement (PCE), characterized by provider respect and shared treatment decision making, is associated with patients' improved well-being, and is a metric of healthcare quality. We examined whether PCE mediates the effects of discrimination, depression, and pain on later mental health-related QOL (MHRQOL) and other pain-related outcomes among African American PLHIV who use drugs.
METHODS: 331 PLHIV (95.8% African American, 42.6% female) with current or former drug use recruited from HIV clinics and community venues in Baltimore, Maryland, USA completed 3 semi-annual surveys. In structural equation modeling, PLHIV's 12-month pain-related outcomes (MHRQOL, fear of doctor's disbelief that they are in pain, and substance use for unrelieved pain) were regressed on PCE (a latent mediator assessed at 6-months) and baseline depression, pain intensity and healthcare discrimination experiences. Analysis adjusted for baseline assessment of outcomes and changes in HIV care provider between baseline and 6-month.

*[Figure 1. Structural equation modeling analysis showing standardized path coefficients, adjusting for reported change of HIV care provider between baseline and 6-month (N=331). CFI=1.00, TLI=1.01, RMSEA<.01 (.00, .03), *p<.05, **p<.01, ***p<.001]*

RESULTS: Baseline depression, discrimination, substance use for pain, and fear of doctor's disbelief of their pain were all associated with reduced PCE at 6-months. There were significant indirect paths from baseline discrimination to higher chances of substance use for pain and lower MHRQOL at 12-month, and from baseline depression to lower MHRQOL and higher chances of reporting fear of doctor's disbelief in their pain at 12-month, mediated through reduced PCE.
CONCLUSIONS: Findings highlight the important role of patient-centered engagement in chronic pain management to enhance mental health and quality-of-life for PLHIV. Integrative interventions are needed to address co-occurring pain and behavioral health problems, and to improve quality of patient-clinician relationships.

PDD02 HARNESSING THE POWER OF TECHNOLOGY AND INNOVATIVE METHODOLOGY

PDD0202

ONLINE DATING PATTERNS, SEXUAL BEHAVIORS, AND RELATIONSHIP CHARACTERISTICS AMONG SINGLE YOUNG MEN WHO HAVE SEX WITH MEN: LATENT PROFILE ANALYSIS

S.K. Choi[1], J.A. Bauermeister[1]
[1]University of Pennsylvania, Family and Community Health, Philadelphia, United States

BACKGROUND: Geosocial networking applications (GNA) are a popular way to find dates and hookups among young men who have sex with men (YMSM; ages 18-24). Despite the increased use of GNA and its purported association with HIV risk behaviors in the literature, few studies have examined whether YMSM can be classified into different GNA use patterns. This person-centered approach may unmask heterogeneity of GNA using patterns among YMSM, and examine whether these GNA patterns are differentially associated with HIV risk correlates.
METHODS: 180 YMSM (mean age 21.67) who completed the baseline survey of an online HIV intervention trial delivering dating and partner-seeking behavior contents. Latent Profile Analysis (LPA) was used to identify the number of online dating usage profiles based on the distribution of four variables: frequency of GNA use for dating and hookups, respectively, and perceptions of the usefulness of GNA for dating and hookups. Using LPA, multinomial logistic regression (MLR) was used to assess associations with sexual behaviors and relationship characteristics. Mplus was used for LPA and SAS was used for MLR.
RESULTS: Based on fit indices, a 3-latent-profile solution was selected. Profile1 (Low Utility Users; 50.8%) spent the least amount of time in GNA and did not consider GNA as useful to meeting partners. Profile2 (Hookup Seeker; 11.8%) used GNA almost everyday for hookups and found GNAs useful to meet partners. Profile 3 (Dates; 37.4%) spent more time in GNAs seeking dates over hookups, yet acknowledged that GNA were useful to hookup. In MLR, Hookup Seekers (profile 2) were more likely than Low Utility Users (profile 1) to report higher scores in sexual sensation seeking and lower relationship commitment. They also reported a greater number of recent sexual partners, receptive/insertive anal intercourse, and a greater likelihood of having sex with a partner met online (ps<0.05).
CONCLUSIONS: YMSM reported different GNA use profiles and, in turn, reported differences in HIV risk correlates. Interventions using technology to reduce HIV risk among YMSM who meet part-

ners online may explore tailoring based on GNA profiles and offer risk reduction strategies that align with users' frequency and perceived usefulness of GNA when seeking partners online.

PDD0204

USING MIXED METHODS IN DISCRETE CHOICE EXPERIMENTS TO DETERMINE PATIENTS' PREFERENCES FOR HIV AND TB SERVICES

Y. Hirsch-Moverman[1], J.E. Mantell[2], J.M. Zech[1], M. Strauss[3], G. George[3], T. Masvawure[4], M. Rabkin[1,2]
[1]ICAP at Columbia University, New York, United States, [2]Columbia University Irving Medical Center and the New York State Psychiatric Institute, Division of Gender, Sexuality and Health, Psychiatry, New York, United States, [3]Heatlh Economics and HIV and AIDS Research Division (HEARD), University of KwaZulu-Natal, Durban, South Africa, [4]College of the Holy Cross, Health Studies Program, Center for Interdisciplinary Studies, Worcester, United States

BACKGROUND: The discrete choice experiment (DCE) is a quantitative method increasingly used to understand patient preferences in healthcare. Participants make choices in a series of hypothetical scenarios that force trade-offs to reveal how patients prioritize different attributes (e.g. cost, location, clinic hours) and attribute levels (e.g., $1 vs. $3 vs. $5 for cost). Aggregate ranked preferences are useful for formulating patient-centered policies and designing programs that maximize uptake. However, there is limited guidance on developing attributes/levels used in DCE scenarios.
DESCRIPTION: We used qualitative and quantitative methods to refine DCE designs exploring HIV services in Zimbabwe and TB services in Eswatini. For each, we developed an initial list of literature-derived attributes/levels. For the HIV-related DCE, we then conducted eight focus group discussions (FGD) with adults on antiretroviral therapy (ART) to identify key attributes/levels of ART service delivery. Participants also placed stickers on a list alongside attributes they felt most important; attributes with more stickers were selected for inclusion. Choice card content and design were validated in two follow-up FGDs. The TB-related DCE examined preferences for TB preventive treatment in children in Eswatini. The initial list of literature-derived attributes/levels was explored via 80 in-depth interviews with children, caregivers and healthcare providers. Using participatory ranking methods (PRM), we asked participants to select the three most important attributes. Scores were tallied and the highest ranked attributes included in the DCE.
LESSONS LEARNED: Using mixed methods ensured inclusion of the most important context-specific attributes/levels in each DCE. Qualitative data enabled assessment of content validity and validation of DCE results; PRM allowed systematic reduction, refinement and validation of attributes/levels. Qualitative analysis also allowed us to combine some attributes, such as number of pills and pill size in Eswatini. In both DCEs, participant preferences were consistent in qualitative interviews, DCEs and surveys: HIV – provider interactions, individual- versus group-based models, clinic visit cost, visit frequency, and wait time; TB – clinic visit cost, wait time, pill formulation/size, pill taste, dosing frequency, treatment duration and visit frequency, and clinic hours.
CONCLUSIONS/NEXT STEPS: A rigorous mixed-methods process for developing attributes can improve the validity of DCEs, reducing the chances of excluding important variables.

PDD0205

EXPANDING THE USE OF THE ECHO MODEL TO IMPROVE ACCESS TO HIGH-QUALITY CARE AND TREATMENT FOR PEOPLE LIVING WITH HIV IN MALAWI

M. Phoso[1], T. Maphosa[1], K. Ashburn[2], R. Kanyenda[1], H. Nkhoma[1], M. Chilombe[1], K. Kwashie[1], S. Hrapcak[3], N. Buono[4], S. Phiri[5], R. Nyirenda[6], A. Auld[4], E. Kim[4], A. Maida[4]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Lilongwe, Malawi, [2]Elizabeth Glaser Pediatric AIDS Foundation, Washington DC, United States, [3]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Center for Global Health, Atlanta, United States, [4]Centers for Disease Control and Prevention, Lilongwe, Malawi, [5]Lighthouse Trust, Lilongwe, Malawi, [6]Ministry of Health, Department of HIV, Lilongwe, Malawi

BACKGROUND: Despite task-shifting for antiretroviral treatment (ART) initiation and follow-up to improve access to treatment at the primary care level, targeted capacity building activities to optimize clinical management have limited reach in Malawi. We implemented the project 'Extension for Community Healthcare Outcomes' (ECHO) to assess acceptability and improvement in clinical knowledge and capability among providers caring for people living with HIV (PLHIV) in Malawi.
DESCRIPTION: Project ECHO used proven adult learning techniques and interactive video technology connecting ART service providers in five high-volume facilities in Malawi (one 'hub' and four 'spokes'). From November 2018—September 2019, weekly, hour-long sessions covering 25 didactic topics and collaborative case presentations were conducted. The sessions utilized case-based learning and mentorship to increase the expertise of local health-care workers to manage PLHIV. The evaluation consisted of a pre- and post-intervention assessment; 29 clinical providers completed paper questionnaires and surveys before and after the project period, assessing HIV knowledge, perceived behavioral capability, and acceptability of ECHO. Change in knowledge was defined as (post-evaluation/pre-evaluation) knowledge scores * 100 across subject areas.
LESSONS LEARNED: Improvements in overall knowledge were noted, with a mean post-test score of 67% compared to the pre-test score of 59%, though this was not statistically significant. Knowledge gains were highest in the topics 1st and 2nd line ART failure (+41.1%), contraception and family planning (+31.6%) and pulmonary tuberculosis (+31.2%). Negative knowledge efficacy was observed in topics covering HIV and Hepatitis B (-50.1%), HIV and neurology (-19.0%), and HIV and the heart (-16.7%). Topic areas with negative knowledge efficacy had lower participation (attendance rates ≤50%). Participants reported improved perceived behavioral capability in all topics, with an increase in the number considering themselves experts. Most (86%) felt ECHO has improved the quality of care in their clinics. Participants were motivated to use innovative technology to expand communication for health providers.
CONCLUSIONS/NEXT STEPS: Project ECHO proved acceptable and showed overall positive gains in knowledge efficacy and capacity of clinical HIV providers. The model can be adopted nationally to increase real-time, cost-effective, high-quality training in HIV services in Malawi. Strategies to increase attendance are key in implementing successful ECHO.

PDD0206

EMPOWER" A TECHNOLOGY SOLUTION TO SOCIAL PROBLEM: A TOOL IN HANDS OF GRASSROOTS WORKERS TO INCREASE EFFICIENCY

V. Arumugam[1], H. Rosenara[1], S. Kandaswamy[1], R. Prasad[1]
[1]India HIV/AIDS Alliance, New Delhi, India

BACKGROUND: In India, 2.1 million PLHIVs are estimated of which 1.4 million are taking regular treatment from the national ART program. With the support of Global fund, India HIV/AIDS Alliance implements Vihaan Care and Support program since 2018 through 310 care and support centres(CSCs) across India through differentiated care service model. Vihaan programme registered 85% of 1.3 million PLHIV and provide services through 1822 outreach workers and peer counsellors. With the huge clients load (Average ORW client load is 992), outreach workers were facing challenge to identify the needy clients and provide required services using hard copy data sheets. User friendly eMpower application (android based mobile/tablet application) has been developed to resolve this issue.

DESCRIPTION: eMpower tablet based IT application has been designed and provided to 1822 community ORWs/peer counsellors across India with client's prioritisation, GIS, evidence collection, pop-up reminders, in-built validation and offline entry options. Priority clients were allotted to ORWs as per their geographical area coverage through regular synchronisation between tablets and CMIS.ORWs provided needed services to their clients and updated the data in tablet which further synchronises once in fortnight with CMIS. Tablets were managed centrally using MDM(mobile device management) system.

LESSONS LEARNED: eMpower tablet based application, has increased the efficiency of outreach workers in providing need based services and capture quality data in a timely manner as the follow up rate has increased from 42%(n=10,80,031) before tablet implementation to 52%(n=12,29,665) after tablet implementation as per September 2019. There is an evident increase in achievements between December 2017 to September 2019 related to TB screening(13,318/month to 149,035 clients/month), and HIV testing of partner/family members(453/month to 4,311/month) and lost to follow clients brought back to the treatment(10,550/month to 16,779/month).

CONCLUSIONS/NEXT STEPS: eMpower tablet application utilisation provided clear evidence that user friendly technology solution is important to prioritise and provide needful services to the PLHIV community in the high load setting. It increases the efficiency of the work of the field workers in the community. This application can be scaled up in different regions in HIV and associated service provision and data collection.

PDD0207

LEVERAGING LOW-COST MOBILE TECHNOLOGIES TO INCREASE COMMUNITY PARTICIPATION AND SUSTAINABILITY OF THE HIV RESPONSE: THE CASE OF OVC CARE IN EASTERN AND NORTHERN UGANDA

E. Kazibwe[1], N. Kamwesigye[1], J. Barry[2], D. Kaufa[1], A. Mugume[1]
[1]World Education, Inc., The Bantwana Initiative, Kampala, Uganda, [2]World Education, Inc., The Bantwana Initiative, Boston, United States

BACKGROUND: Government spending on the HIV response in Uganda remains below the recommendations of the WHO ($84 USD per capita) and Abuja Declaration (15% of GDP). The bulk of the deficit in healthcare financing is shouldered by donor agencies that emphasize country ownership and sustainable interventions. This paradigm requires innovative approaches to reach priority populations with quality healthcare using fewer resources while inculcating elements of sustainability.

DESCRIPTION: Since 2016, under USAID/Uganda Better Outcomes for Children and Youth in Eastern and Northern Uganda, the Bantwana Initiative of World Education, Inc. has leveraged its commercial partnership with MTN Uganda to create a Closed User Group (CUG), an in-service network connecting health, social welfare, and child protection actors as part of an integrated referral network to ensure rapid response to child protection issues and comprehensive access to core services.

The monthly CUG subscription cost of $1.74 USD per user (paid by the project) allows users to communicate at no cost using voice and text messages within the group. The initiative has been scaled up to 22 districts, connecting more than 3,600 actors.

LESSONS LEARNED: Program evidence suggests that the majority of CUG-registered users were utilising the service to consult on child abuse cases (92%), coordinate critical child protection activities (88%), report child abuse cases (87%), mobilise community actors for case conferences (84%), follow up on reported cases (76%), and refer of cases to tertiary care providers (73%).

A 2019 study indicated that by improving communication and coordination among the multiple actors, the CUG has enabled quick identification of cases of child neglect and HIV-exposed children and youth, mobilisation, and referral to support services like HIV screening, ART referral, and adherence and viral load tracking -- providing evidence that the CUG improves coordination between communities and health service providers.

Referrals for cases of HIV and child abuse and neglect have improved, with a completion rate of 95% across the continuum of response.

CONCLUSIONS/NEXT STEPS: Leveraging low-cost mobile technologies that link multilateral stakeholder efforts in national HIV response mechanisms can be part of a strategic support package to sustain and expand gains towards Uganda's epidemic control and social development goals.

PDD03 SEXUAL CONCURRENCY AND SEXUAL NETWORKS

PDD0302

LEVERAGING SOCIAL NETWORKS AND TECHNOLOGY FOR HIV PREVENTION AND TREATMENT WITH TRANSGENDER WOMEN

I.W. Holloway[1], S. Jordan[1], S. Dunlap[1], A. Ritterbusch[1], C.J. Reback[2]
[1]University of California, Social Welfare, Los Angeles, United States, [2]Friends Research Institute, Los Angeles, United States

BACKGROUND: Transgender women ("trans women") are disproportionately impacted by HIV; yet there are few interventions tailored to trans women. There has been increasing interest in how social networks may influence health behaviors. This study employed qualitative methods to better understand how trans women's social networks and technology-based networking platforms may be leveraged in developing health promotion strategies for this high-priority population.

METHODS: Five 60-minute, audio-recorded focus groups were conducted with 39 trans women. Participants were eligible if they identified as a trans woman; were assigned male at birth; were at least 18 years of age; and used either alcohol or illicit substance or engaged in condomless anal sex in the past 12 months. Four of the focus groups were comprised of community members and consumers of social services (N=31) and one of the focus groups were comprised of trans women service providers (N=8). . During the focus groups, open-ended questions focused on social network composition and use of technology for socialization, partner seeking, and health information. Audio recordings were transcribed, coded using an iterative, open coding process and analyzed.

RESULTS: Participants were racially and ethnically diverse with majority (74.4%) identifying as Black/African American and Latinx, ranging from ages 20 to 72, with a mean age of 37 (SD=11.90). [CJR1] Most participants were connected to other trans women online where they exchanged health information. Qualitative data supports the crucial role of these social networks for social support and health seeking information. Participants used technology to break isolation and to exchange health-related information and advice. Participants' described their social networks as stratified across class, racial, and generational differences.

CONCLUSIONS: Technology served as a crucial resource for collectively organizing resources and establishing relationships with other trans women. The strength of existing networks supports the development of network-driven HIV prevention intervention strategies for trans women. Policymakers and practitioners should invest in the knowledge and expertise of trans women in using technology to organize health resources in the development of technology-based HIV prevention and care interventions.

PDD0303

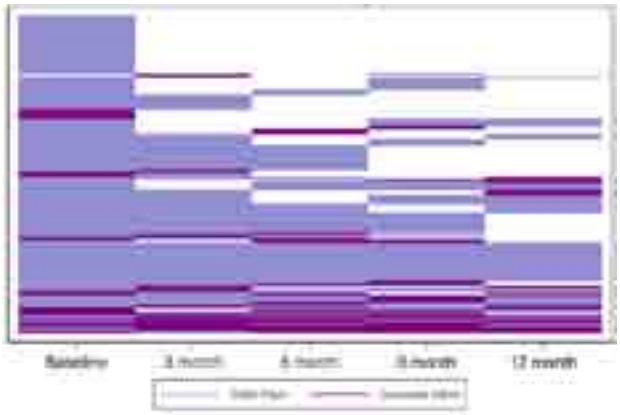
LONGITUDINAL ASSOCIATIONS BETWEEN PLACE OF SEX WORK, DEPRESSION AND HIV VULNERABILITIES AMONG SEX WORKERS IN BALTIMORE, MARYLAND: A SOCIAL GEOGRAPHY OF SEX WORK APPROACH TO GUIDE HIV PREVENTION CASCADE OPTIMIZATION

C. Logie[1], R. Hamilton White[2], N. Galai[2], C. Tomko[2], S.G. Sherman[2]
[1]University of Toronto, Social Work, Toronto, Canada, [2]Johns Hopkins University, Baltimore, United States

BACKGROUND: Sex workers' work environments influence sex worker-client dynamics and HIV vulnerabilities. Cross-sectional studies have documented violence, HIV risks, and depression associated with sex work in public compared to indoor spaces. In exploring where women reported sex with clients, we examined longitudinal associations between public place of sex work (PPSW) and health outcomes (HIV vulnerabilities, depression) among sex workers.

METHODS: This cohort study involved five data collection points over one year among cisgender women sex workers (N=246) in Baltimore, Maryland. We conducted bivariate analyses to examine associations between currently conducting any sex work in a public place (PPSW, e.g., car, abandoned house, street, park/forest, public bathroom) vs. exclusively indoor sex work (ISW, e.g., house, motel, dance club) with sociodemographic, substance use (e.g., injection drug use [IDU], crack use), past 3-month condom coercion (e.g., client condom refusal/removal), and baseline clinically-significant depression (CES-D-10; cut off of 10). We used logistic regressions with generalized estimating equations and exchangeable correlation structure to examine longitudinal associations between PPSW and subsequent condom coercion or depression adjusting for sociodemographics and substance use.

RESULTS: Among participants (race/ethnicity: White: 67.5%; Black/African American: 22.8%; Latina/other ethnicity: n=9.8%), most reported daily IDU (58.5%), daily crack use (62.2%), and homelessness (62.2%). Over three-quarters (88.6%) reported any PPSW at baseline. PPSW was associated with increased odds of past 3-month condom coercion (AOR: 1.85, 95%CI: 1.16-2.94, p=0.01) and depression (AOR: 1.41, 95%CI: 1.02-1.97, p=0.04) compared to ISW. PPSW was dynamic, reported by n=218 at baseline, 3-month (n=133/155), 6-month (n=103/130), 9-month (n=93/119), 12-month (n=77/99), and was associated with not completing all study visits (see lasagne plot).



[Figure. Public place of sex work vs. exclusively indoor place of sex work]

CONCLUSIONS: Public environments of sex work were associated with sexual (condom coercion) and mental (depression) health disparities. Public sex work confers additional health risks in contexts of illegality. Interventions to optimize HIV prevention cascade engagement can address these social geographies of sex work.

PDD0304

CREATING COMMUNITIES OF EMERGENCY RESPONDERS TO REDUCE VIOLENCE AGAINST SEX WORKERS AND INCREASE ACCESS TO JUSTICE AND HIV SERVICES: LESSONS LEARNED FROM THE HANDS OFF PROGRAMME

S. Bouwmeester[1], P. Chakuvinga[2], M. Mogale[3], A. Mashumba[4], I. van Beekum[1]
[1]Aidsfonds, International Sex Work Programme, Amsterdam, Netherlands, [2]Sisonke, Cape Town, South Africa, [3]North Star Alliance, Durban, South Africa, [4]BONELA, Gaborone, Botswana

BACKGROUND: Gender-based violence is a key risk factor increasing sex workers' vulnerability to HIV. Violence impedes sex workers' access to services. Despite evidence showing that a reduction of 25% of HIV infections among sex workers may be achieved when violence is reduced, there remains a lack of investment in programmes directly addressing violence as a structural barrier to HIV prevention. Under the Aidsfonds' Hands Off programme (2014-2019) sex worker-led organisations and service providers implemented various strategies to reduce violence against sex workers and increase access to services in Southern Africa.

DESCRIPTION: As a distinctive component of the programme, 65 different community-led crisis response systems were set up, among which drop-in centres and helplines. Trained sex worker paralegals escorted their peers to report cases, and provided court support, information and counselling. Crisis response teams consisting of sex workers, healthcare workers, police and influential community members ensured efficient referral and follow-up to HIV, psychosocial and legal services. Litigation lawyers supported in bringing case before court.

LESSONS LEARNED: An independent evaluation of the programme showed that innovative crisis response systems such as helplines directly operated by police and multidisciplinary local response teams have increased access to services for sex workers. Over 81.000 sex workers have accessed healthcare, psychosocial and legal services. Partners learned that using decentralised systems leads to more effective referrals and follow-up. In places where paralegals were responsible for supporting sex workers, sex workers received rapid assistance far more than they had in the past. Paralegals documented 1.500 cases of violence, contributing to an evidence-informed advocacy strategy for sex workers' rights. Over 235 cases were brought before court, illegal arrests have decreased and perpetrators have faced consequences for violence. However, to significantly reduce individual and structural violence, community-led crisis response needs to be implemented parallel to interventions strengthening a rights-based sex worker movement and supporting police engagement.

CONCLUSIONS/NEXT STEPS: Coupled with movement building and police engagement, community-led response systems are a powerful strategy to reduce sex workers' vulnerability to HIV. Substantially larger investment in programmes that focus on addressing violence as a structural barrier to HIV prevention is needed.

PDD0305

ROLL OUT OF INNOVATIVE "SOCIAL NETWORK MODEL" INTEGRATED WITH INDEX TESTING CONTRIBUTED TO REACHING "HARD-TO-REACH", HIV CASE DETECTION AND LINKAGE TO ART AMONG PWID IN NORTHEAST INDIA

P. Goswami[1], N. Singh[2], B. George[2], G. Shreenivas[2], P. Choudhury[2]
[1]FHI 360, Research and M&E, New Delhi, India, [2]FHI 360, New Delhi, India

BACKGROUND: Reaching, testing and treating "hard-to-reach" individuals at risk of HIV infection is vital for achieving UNAIDS' 90-90-90 goals. Northeast India, which has poor roads, uneven topography and inadequate facilities, has a large population of people who inject drugs (PWID), but traditional government-run interventions in this difficult environment have achieved low case finding (0.4%). FHI 360 implemented an innovative "Social Network Model" under the CDC- and PEPFAR-funded Project Sunrise to reach, test and treat hard-to-reach PWID.

DESCRIPTION: The Social Network Model used respondent-driven chain referral to reach, test and treat PWID not already covered by government-supported Targeted Interventions (TI). PWID who self-reported large injecting networks were selected as seeds to recruit clients from their networks and refer them for HIV screening. Seeds, and any subsequently recruited clients, were given four coupons to distribute among injecting partners not covered by TI. For each new client tested, the recruiter received US $1, and clients were compensated for travel to HIV testing. Clients confirmed positive were linked to ART. HIV positive clients were also given index testing coupons to recruit their sexual partners, spouses and children, who were offered motivational counseling and HIV testing.

LESSONS LEARNED: 42 initial seeds from two districts in northeast India generated contact with 1,476 previously unreached PWID, all of whom were tested. 13.8% were confirmed HIV positive, a case-finding rate 35 times higher than under the TI model. 72% positive clients were linked to ART, while 24% positive and negative clients were linked to prevention services including OST. Index testing carried out with all PLHIV contributed to 16.7% positivity. Focusing on the high-risk population led to higher reach, case detection and treatment.

Parameters	Churachandpur	Aizawl	Total
Initial seeds	14	28	42
Recruited and tested for HIV	810	666	1,476
PLHIV newly diagnosed	82 (10.1%)	121 (18.2%)	203 (13.8%)
PLHIV initiated on ART	72 (88%)	74 (61%)	146 (72%)
Contacts of PLHIV tested for HIV	132 (1:1.6)	119 (1:1)	251 (1:1.2)
Contacts of PLHIV diagnosed HIV positive	22 (16.7%)	20 (16.8%)	42 (16.7%)

CONCLUSIONS/NEXT STEPS: SNM integrated with index testing identified HIV-positive PWID at a much higher rates than traditional programs, though challenges remain linking all positive clients to ART. This model has been adopted by National AIDS Control Program and is now being scaled up across India.

PDD0306

PREVALENCE OF DEPRESSION AND KEY ASSOCIATED FACTORS AMONG FEMALE SEX WORKERS LIVING WITH HIV IN DURBAN, SOUTH AFRICA

A. Bhardwaj[1], C. Comins[2], V. Guddera[3], M. Mcingana[3], K. Young[3], R. Phetlhu[3], N. Mulumba[3], S. Mishra[4], H. Hausler[3], S. Schwartz[2], S. Baral[2]
[1]Johns Hopkins Bloomberg School of Public Health, Population, Family and Reproductive Health, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [3]TB HIV Care, Durban, South Africa, [4]University of Toronto, Toronto, Canada

BACKGROUND: More than half of all female sex workers (FSW) in South Africa are estimated to be living with HIV, however, emerging data have demonstrated that up to 80% of FSW in KwaZulu Natal also are clinically depressed. The syndemic framing of HIV and depression among FSW has been described, but there are limited data characterizing the upstream structural determinants of depression among FSW who are living with HIV.

METHODS: Non-pregnant, cisgender women (>18 years), enrolled in the Siyaphambili study in Durban, South Africa reporting sex work as their primary source of income and diagnosed with HIV for ≥6 months, were eligible for enrollment. Analyses was guided using an adaptation of stress-diathesis model. Robust Poisson regression models were used to asses univariate associations with depression (PHQ 10). Variables aligned with the conceptual framework and significantly associated with depression in bivariate analyses (p<0.1) were included in the multivariate robust Poisson regression model.

RESULTS: Of the 1,207 FSW enrolled, nearly all were South African, 27% were homeless (n=326) the median age was 31 years [IQR27-37]. A total of 387(32%) participants reported symptoms of depression defined as a PHQ9 score greater than or equal to 10. Age, education, housing, viral suppression, experiences of sexual and physical violence, alcohol use, anticipated and internalized stigmas were associated with depression and included in multivariate analyses. In the multivariate regression, significant increases in the prevalence of depression were observed for participants who were homeless(PR=1.25,95%CI 1.03–1.52), had ever experienced sexual violence(PR=1.54, 95%CI 1.28-1.85) and reported internalized stigma(PR=1.08, 95%CI 1.00–1.16).

CONCLUSIONS: Taken together, these results reinforce the structural foundation of syndemics of HIV and depression among FSW in South Africa and depression with independent predictors including unstable housing, violence, and stigmas. Given the relationship between depression and adherence among PLWH, these results suggest the need to integrate mental health and HIV programs to optimize outcomes for both.

PDD0307

SEEING REGULARS ASSOCIATED WITH LOWER ODDS OF SEXUAL VIOLENCE AND CLIENT CONDOM REFUSAL AMONGST SEX WORKERS IN METRO VANCOUVER, CANADA (2010-2019): IMPLICATIONS FOR HIV PREVENTION AND REMOVAL OF 'END-DEMAND' CRIMINALIZATION

B. McBride[1], S.M. Goldenberg[1], K. Shannon[1], M. Braschel[1], S. Moreheart[1], AESHA Project
[1]Centre for Gender and Sexual Health Equity, Vancouver, Canada

BACKGROUND: Globally, individuals who purchase sex services (i.e., clients) are commonly misrepresented as violent and exploitative, and are criminalized under 'end-demand' legislation in 50+ countries. While qualitative research has documented heterogeneous relationships between clients and sex workers, there remain significant gaps in quantitative evidence examining the impacts of seeing different types of clients (i.e., regulars vs. one-time) on sex workers' safety and HIV/STI risks.

METHODS: Analyses drew on longitudinal data (2010-2019) from a community-based open cohort of 900+ indoor, street-based, and online sex workers in Vancouver (AESHA; An Evaluation of Sex Workers' Health Access) which has included experiential staff (e.g., interviewers, nurses, coordinators) since the project's inception in 2010. Our objectives were to (1) describe characteristics of women seeing mostly regulars (defined as 75%-100% of clients are repeat clients) in the past 6 months, and (2) identify independent effects of seeing mostly regulars on odds of experiencing sexual violence and client condom refusal over a 9-year period.

RESULTS: Among 942 sex workers, 58.5% (n=551) saw mostly regulars at some point over the 9-year study. HIV prevalence was 14.1% at baseline. Women who reported inconsistent condom use for vaginal/anal sex with clients had lower odds of seeing mostly regulars (OR 0.80, 95%CI 0.67-0.96). In multivariable analysis, recent and longterm immigrants and those in in-call venues (e.g., massage parlours) had lower odds of seeing regulars, while those soliciting independently and working in informal indoor settings (i.e., apartments) had higher odds of seeing regulars. In separate multivariable confounder models, seeing mostly regulars was independently associated with reduced odds of experiencing sexual violence (AOR 0.71, 95%CI 0.52-0.97) and client condom refusal (AOR 0.73, 95%CI 0.60-0.88), after adjusting for key confounders.

CONCLUSIONS: Our results disrupt common stereotypes of clients as inherently violent or 'risky' and suggest that within criminalized environments, sex workers may see mostly regulars as a strategy for enhancing safety and reducing HIV risk. Full decriminalization of sex work, including removal of 'end-demand' client criminalization, is needed to enable sex workers to choose clients and organize their work according to their needs, towards HIV prevention and the full achievement of sex workers' labour and human rights.

PDD04 STILL A LONG WAY TO GO: HIV CARE FOR MOTHERS AND CHILDREN

PDD0402

BUILDING RESILIENCE FOR CHILDREN AFFECTED BY PARENTAL HIV IN CHINA: EFFICACY OF THE MULTI-LEVEL CHILDCARE INTERVENTION AT 18-, 24-, 30-, AND 36-MONTHS

S. Harrison[1], X. Li[2], C. Cai[3], J. Zhao[4], G. Zhao[5]
[1]University of South Carolina, Department of Psychology, Columbia, United States, [2]University of South Carolina, Department of Health Promotion, Education, and Behavior, Columbia, United States, [3]University of South Carolina, College of Pharmacy, Department of Clinical Pharmacy and Outcomes Sciences, Columbia, United States, [4]Henan University, College of Educational Sciences, Kaifeng, China, [5]Henan Normal University, Department of Psychology, Xinxiang, China

BACKGROUND: Global literature indicates that children affected by parental HIV are at risk for a range of negative developmental outcomes, including psychosocial, behavioral, educational, and health-related challenges. Yet despite these hardships, many youth with parents who are living with HIV or who have died from AIDS-related causes go on to experience positive later life outcomes. Building on four decades of theory and empirical research on resilience, the Child-Caregiver-Advocacy Resilience (ChildCARE) was developed to enhance the resilience of children affected by HIV in rural central China. Notably, the ChildCARE intervention provides psychosocial intervention at three levels, including the child-level (i.e., peer-group sessions), caregiver-level (i.e., positive parenting training, caregiver support), and community-level (i.e., local advocacy, stigma reduction efforts).

METHODS: Efficacy of the ChildCARE intervention was evaluated through a four-arm cluster-based randomized controlled trial in Henan, China. In total, 790 child and caregiver dyads were assigned to one of four intervention conditions: control, child-only intervention, child+caregiver intervention, and child+caregiver+community intervention. The current study utilized difference score modeling to compare resilience-related outcomes between children assigned to the control condition and those who received the full intervention package (i.e., child+caregiver+community intervention). Specifically, we evaluated whether children who received the multi-level intervention displayed increases in psychosocial wellbeing and resilience-related outcomes at 18-, 24-, 30-, and 36-months.

RESULTS: Children assigned to the intervention group displayed higher resilience and enhanced psychosocial functioning when compared to children assigned to the control group at multiple time points after the ChildCARE intervention concluded. Notably, change scores from baseline to the final study assessment point (i.e., 36-months) indicated that youth assigned to the child+caregiver+community intervention displayed increased resilience (p=0.010), higher levels of post-traumatic growth (p=0.033), and better emotional regulation skills (p=0.049) than those in the control group. Positive trends were noted for other constructs, including self-esteem and use of positive coping skills.

CONCLUSIONS: There is increasing support for psychosocial HIV interventions that target not only vulnerable individuals, but also their social support systems and broader community networks. Current findings provide support for the efficacy of one such intervention--ChildCARE--in enhancing the resilience of children made vulnerable by parental HIV in China.

PDD0403

THE NATIONAL PREVALENCE OF VIRAL LOAD SUPPRESSION AND ASSOCIATED FACTORS AMONG CHILDREN RECEIVING ART IN MALAWI

A. Ahimbisibwe[1], T. Maphosa[1], G. Woelk[2], H. Nkhoma[1], S. Zimba[1], J. Sunguti[1], R. Kanyenda[1], V. Sampathkumar[1], E. Kim[3], A. Maida[3], N. Wandonda[3], T. Mekonnen[3], T. Kalua[4], B. Bighnoli[5], B. Mvula[5], M. Kagoli[6], G. Bello[6,7]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Lilongwe, Malawi, [2]Elizabeth Glaser Pediatric AIDS Foundation HQ, Washington, United States, [3]Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV & TB, Lilongwe, Malawi, [4]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [5]Ministry of Health, National Reference Laboratory, Lilongwe, Malawi, [6]Ministry of Health, Epidemiology Unit, Lilongwe, Malawi, [7]I-Tech, Lilongwe, Malawi

BACKGROUND: Impressive gains have been made in expanding access to antiretroviral therapy (ART) in Malawi. However, challenges remain in viral load suppression (VLS) among children. We assessed national VLS among HIV-positive children aged <18 years on ART for at least 6 months.

METHODS: Between June 2018 and January 2019, we conducted a cross-sectional survey that employed a two-stage, cluster-sampling design where 36 study health facilities providing ART were selected nationally using probability proportion to size. Blood samples were collected through heel or finger prick or venipuncture for viral load (VL) analysis at the National Reference Laboratory on the Abbott m2000 platform. VL>1000 copies/ml was considered high VL. Demographic data were abstracted from routine facility-based medical records. Counts and proportions were used for the descriptive analysis while bivariate analysis was conducted using the Chi square test.

RESULTS: Of 806 children with VL results, (median age 10 years, interquartile range 7-13), 516 (64%) had suppressed VL. The majority (73%) of children with high VL were aged between 6-14 years old, with the age group of 10-14 years contributing 60% of high VL cases. Similar to children with suppressed VL, the majority (70%) of children with high VL had been on ART >=3 years. Of the children with high VL, 94% were on non-nucleoside reverse transcriptase inhibitor (NNRTI)-based regimens (98% nevirapine, 2% efavirenz as a tail), while 80% were on zidovudine (AZT) as nucleoside reverse transcriptase inhibitor (NRTI) backbone. The majority of children with no ART exposure for prevention of mother-to-child transmission (PMTCT) (66%) had high VL compared to those with PMTCT exposure (52%; p= 0.03). A higher proportion of children on abacavir (ABC)-based regimens were virally suppressed compared to children on any other NRTI-based regimen (53% vs. 30%, respectively; p=0.02). The proportions of children on NNRTI and protease inhibitor (PI)-based regimens with suppressed VL were 37% and 38%, respectively.

CONCLUSIONS: VLS among children was suboptimal. The study showed no difference in suppression rates between children on NNRTI- and PI-based regimens, while a higher proportion of children on ABC-based regimens were virally suppressed compared to children on any other NRTI-based regimens.

PDD0404

PATHWAYS TO HIV DISCLOSURE AND OPTIMAL PMTCT OUTCOMES AMONG PREGNANT AND POSTPARTUM WOMEN LIVING WITH HIV IN THE DEMOCRATIC REPUBLIC OF CONGO

A. Adedimeji[1], C. Mpody[2,3], N. Ravelomanana[4], M. Tabala[4], F. Malongo[4], B. Kawende[4], P. Babakazo[4], M. Yotebieng[1], CQI-PMTCT Study Group
[1]Albert Einstein College of Medicine, Epidemiology and Population Health, Bronx, United States, [2]Ohio State University, Epidemiology, Columbus, United States, [3]Ohio State University, Columbus, United States, [4]The University of Kinshasa, School of Public Health, Kinshasa, Congo, Democratic Republic of the

BACKGROUND: Disclosure of HIV status in the context of PMTCT may increase social support and adherence to ART and thus, contribute to improved outcomes for women living with HIV (WLWH) and their infants. We examined factors associated with and the pathways mediating HIV disclosure among pregnant and postpartum WLWH receiving routine PMTCT care.

METHODS: We performed a cross-sectional analysis, utilizing baseline data from a cluster-randomized trial to evaluate the effect of continuous quality interventions on long-term ART outcomes among pregnant and postpartum WLWH. We enrolled all pregnant and postpartum (≤1-year post-delivery) WLWH receiving ART in the 3 clinics with the highest caseload within each of the 35 provincial health zones in Kinshasa, from November 2016 to July 2019. For our outcome, we derived 3 binary indicators of HIV status disclosure to (i) anyone, (ii) a sexual partner, and (iii) family or friends that are important sources of social support. We performed logistic regression to estimate the association of disclosure of HIV status with demographic and clinical characteristics, using a general estimating equation to account for clustering at the health facility and health zone level.

RESULTS: Of the 2775 WLWH enrolled, 2754 who provided information on HIV disclosure were retained in the analysis. Participants' ages range from <=24 (16%), 25-34 (53%) and >35 (31%). The majority were married (69%), had secondary education (87%), no income (90%) and multiparous (95%). About 58% were diagnosed with HIV prior to the most recent pregnancy and 55% initiated ART >=12 months. About one-third (35%) experienced intimate partner violence (IPV). HIV status disclosure ranges from 52% to anyone, 34% to a sexual partner and 35% to family/friend. Factors associated with disclosure included older age, marriage, multiparity, tertiary education, >= 13 months on ART and history of IPV. Participants who exhibited symptoms of depression were less likely to disclose to anyone (OR: 0.98; 95%CI: 0.97, 0.99) or sexual partner (OR:0.98, 95%CI: 0.96, 1.00).

CONCLUSIONS: Pregnant and postpartum WLWH face difficult decisions regarding disclosure of HIV status. Depression and IPV complicate the disclosure processes, but the pathways through which these limit optimal PMTCT outcomes are less understood and warrants further investigation.

PDD0405

CAREGIVER CHARACTERISTICS AND PREDICTORS OF VIRAL SUPPRESSION AMONG CHILDREN LIVING WITH HIV ON ART IN KENYA

B. Odeny[1], R. Patel[1], L. Abuogi[2], I. Mukui[3], E. Kinywa[4], P. Oyaro[5]
[1]University of Washington, Seattle, United States, [2]University of Colorado, Denver, Denver, United States, [3]Ministry of Health, Nairobi, Kenya, [4]Department of Health, Kisumu, Kenya, [5]Health Innovations Kenya, Kisumu, Kenya

BACKGROUND: Caregivers play a vital role in ensuring antiretroviral therapy (ART) adherence, retention in care, and viral suppression among children living with HIV (CLHIV). Caregiver characteristics may strongly predict viral suppression among CLHIV.

METHODS: We analyzed pre-enrollment data for caregivers and children (<15 years old) enrolled from March to December 2019 in an on-going randomized controlled trial, Opt4Kids, which assesses the impact of point-of-care viral load (VL) testing on VL suppression among CLHIV on ART and conducted in five facilities located in Kisumu County, Kenya. Clinical and sociodemographic characteristics were obtained through self-report, standardized questionnaires, and clinical records.

We used multivariable logistic regression models adjusting for various characteristics to assess associations between caregiver characteristics and the children's viral suppression (defined as VL <1000copies/ml).

RESULTS: Overall, 704 children were enrolled with a median age of children of 9 years (interquartile range [IQR] 6-11) and caregivers of 36 years (IQR 31-43). A majority of caregivers (69%) had attained at least primary education. The biological mother was the most common primary caregiver (68%) while 23% had someone other than their biological parent as their caregiver. A total of 568 caregivers (81%) were living with HIV and among these, 45% reported being virologically suppressed. Most children (78%) were virologically suppressed. Children with virologically suppressed caregivers were more likely to achieve viral suppression than children who had caregivers without viral suppression (adjusted odds ratio [AOR] = 7.53, 95% confidence interval [CI] 1.32-43.03, $p<0.017$). Compared to children who had their biological mother as the primary caregiver, children with other caregivers were less likely to achieve viral suppression (AOR=0.26, 95% CI 0.08-0.82, $p=0.016$).

CONCLUSIONS: Our results indicate viral suppression of caregivers living with HIV and type of caregiver are associated with viral suppression in CLHIV. Targeted support of specific groups of caregivers may help improve viral suppression in CLHIV.

PDD0406

UNDERSTANDING EMOTIONAL DISTRESS AMONG PERINATALLY ACQUIRED HIV INFECTED ADOLESCENTS IN PUNE, INDIA: EXAMINING MEDIATING AND MODERATING EFFECTS

A. Verma[1], K.K. Kota[2], S. Bangar[3], G. Rahane[1], N. Yenbhar[1], S. Sahay[1]
[1]ICMR-National AIDS Research Institute, Division of Social and Behavioural Research Sciences, Pune, India, [2]Georgia State University, Department of Health Policy & Behavioural Sciences, Atlanta, United States, [3]ICMR-National AIDS Research Institute, Division of Epidemiology, Pune, India

BACKGROUND: Development of emotional distress (ED) among adolescents living with HIV (ALHIV) affects their adherence behavior, social and psychological functioning. Data on stressors among

ALHIV demonstrates the gap pertaining to the predictors of ED experienced by 'adolescents living with perinatal HIV (ALPH)' in the socio-cultural milieu of India. This study aimed to examine the underlying mechanisms leading towards ED among Indian ALPH through mediation and moderation analysis.

METHODS: This mixed-method study was conducted (2014-17) to explore the psycho-social issues and predictors of ED among Indian ALPH. Forty-three qualitative interviews with ALPH, parents/guardians and health care providers were followed by a cross-sectional survey among 100 ALPH (10-19 years). Distress sub-scale of Weinberger's Adjustment Inventory was used to measure ED. Qualitative data were analyzed using grounded theory in QSR NUD*IST Version 6.0 and survey data in SPSS 25.0. Mediation and moderation models were tested using Hayes PROCESS macros v3.0. The study was approved by the institutional ethics committee.

RESULTS: Strong parental control, compulsive asexuality, internalized stigma by ALPH, and anger on parents were the major themes emerged from qualitative component. These themes led to survey tool constructs viz., HIV awareness, parental control (PC), hypervigilance, adolescent-parent relationship (APR), adolescent-parent communication (APC), body image and perceived negatively different from peers (PNDP). ED was found to be high among ALPH and significantly associated with PNDP (B=3.91; 95% CI: 0.43-7.40; p=0.03), anger (B=0.22; 95% CI: 0.04-0.41; p=0.02), body image (B=0.37; 95% CI: 0.06-0.68; p=0.02), and hypervigilance (B=0.57; 95% CI: 0.17-0.96; p=0.006). Anger was partially mediating the pathway between PNDP and ED while body image and hypervigilance had moderating effects on the relationship between PNDP and ED. The findings emphasize the need for mental health interventions for Indian ALPH.

CONCLUSIONS: The study provides empirical evidence that negative self-perception, anger, body image issues and hypervigilance by primary caregivers are the predictors of ED among ALPH. It is critical to intervene early before an ALPH develops ED. Focused counseling on body image issues and self-perception is critical for living a 'normal' life by ALPH. Primary caregivers need to build skills to draw a line between protection and over protection.

PDD0407

INDIVIDUAL AND FACILITY-LEVEL FACTORS ASSOCIATED WITH INTERRUPTION IN HIV CARE AND TREATMENT AMONG PREGNANT AND POSTPARTUM WOMEN IN THE KABEHO STUDY IN KIGALI, RWANDA

E. Nawar[1], K. Andrinopoulos[2], T. Carton[3], R. Machekano[1], E. Bobrow[4], A. Asiimwe[5], P. Mugwaneza[6]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Washington DC, United States, [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, United States, [3]Louisiana Public Health Institute, New Orleans, United States, [4]Mathematica, Washington DC, United States, [5]National Early Childhood Development Program, Kigali, Rwanda, [6]Rwanda Ministry of Health, Kigali, Rwanda

BACKGROUND: Pregnancy and postpartum are challenging periods where interruptions in HIV care and treatment (starting, stopping, and returning to care over time) are common. The absence of ART is strongly associated with high viral load and vertical transmission. Understanding determinants for interruptions in care could inform interventions aimed at continuous retention to prevent negative health outcomes related to high viral load.

METHODS: The Kigali Antiretroviral and Breastfeeding Assessment for the Elimination of HIV (Kabeho) study was an observational, prospective cohort of 608 HIV-positive women enrolled in their third trimester of pregnancy or within two weeks post-delivery between April 2013 and May 2014. Multivariate logistic models adjusted for clustering by facility were used to examine the odds of an interruption (one or more missed visits followed by returning to care). Models included the following individual characteristics ascertained from interviews at enrollment: age, marital status, travel time to facility, education, CD4 results, disclosure of HIV status to partner, and household size. Facility characteristics captured during site assessments such as frequency and types of services offered were also included.

RESULTS: Women who attended facilities that offered select services had much lower odds of having an interruption as compared to women who attended facilities that did not offer those services (Table 1). None of the individual characteristics examined were associated with interruptions.

Facility level characteristics [individual characteristics not shown]	OR (95% CI)
ANC, PMTCT, and ART services offered all 5 days per week	0.54 (0.32, 0.92)
Services not offered all 5 days	Reference
Retention support (telephone reminders, transportation reimbursement/support, or defaulter tracing system)	0.30 (0.12, 0.76)
No retention support	Reference
Peer counseling	0.31 (0.23, 0.42)
No peer counseling	Reference
Infant feeding counseling	0.20 (0.15, 0.26)
No infant feeding counseling	Reference

[Table 1. Adjusted odds ratios and 95% confidence intervals from logistic models examining individual and facility-level characteristics among women enrolled in the Kabeho Study; Kigali, Rwanda; 2015-2017.]

CONCLUSIONS: Our study suggests that health facilities may be more effective targets for interventions to improve retention than individuals. The lack of services offered was strongly associated with interruptions. Studies aimed at assessing health care utilization and motivation may be an effective means to identify the services that most encourage continuous engagement of pregnant and postpartum women to reduce the likelihood of vertical transmission.

PDD05: THE BIG CS: CIRCUMCISION, CONDOMS AND CONTRACEPTION

PDD0502

IMPROVING POST-OPERATIVE FOLLOW-UP OF VOLUNTARY MEDICAL MALE CIRCUMCISION CLIENTS USING A TOLL-FREE LINE: LESSONS FROM RWENZORI REGION-UGANDA

F.F. Tendo[1], P. Elyanu[2], N. Mukiza[1], J. Balungi[1], A. Kekitinwa[3]
[1]Baylor College of Medicine Children's Foundation, Medical and Psychosocial, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Research and Knowledge Management, Kampala, Uganda, [3]Baylor College of Medicine Children's Foundation, Executive Director, Kampala, Uganda

BACKGROUND: Voluntary Medical Male Circumcision (VMMC) is one of the effective biomedical HIV prevention interventions implemented in Uganda. Mobile outreaches have been used to increase uptake of VMMC. However, there are challenges managing post-operative complications for clients circumcised during the outreaches since the VMMC teams are mobile, and client's homes may be far from health facilities which may lead to inadequate post-operative follow-up and management of the adverse events. Baylor-Uganda implemented a VMMC call center to aid in post-operative follow-up and link clients to care in rwenzori Region. We describe the implementation and impact of the toll-free on follow-up of client's post-operation from July 2018 to June 2019.

DESCRIPTION: A VMMC toll-free line was set-up in July 2018, marketing of the line was done through radio talk shows, posters and engraved wristbands given to males after circumcision. The line is manned by a trained doctor, communication experts and counsel, who on receiving a call, give advice and depending on the query, link the client to the responsible follow-up officer in specific VMMC camps. The project provided a standby vehicle to pick clients who required urgent medical attention then a follow-up call is made 24-hours after the initial call to monitor progress. Data from calls was recorded, descriptive statistics generated and shared monthly. We used proportions to analyse adverse events reported by the callers.

LESSONS LEARNED: Between July 2018 to June 2019, we received 2001 VMMC calls, 87% of the callers were males and the median age 16years (IQR:12,22). Of the 2001, 1181(59%) were given advise online especially on wound care and did not need linking to a VMMC officer while 820(41%) had adverse events and were linked. Of the clients linked, 96% successfully received care within 24 hours.
Mild adverse events (AEs) reported were pain(10%) and swelling of the penis (15%) whereas moderate AEs included; wound disruption (40%),Abscess formation (11%),wound infection (10%),inability to urinate (9%), excessive bleeding (3%) and sexual dysfunction(2%).

CONCLUSIONS/NEXT STEPS: The toll-free line service is effective in follow-up of VMMC clients post-operation. Other VMMC partners and the Ministry of Health should consider adopting this approach nationally.

PDD0503

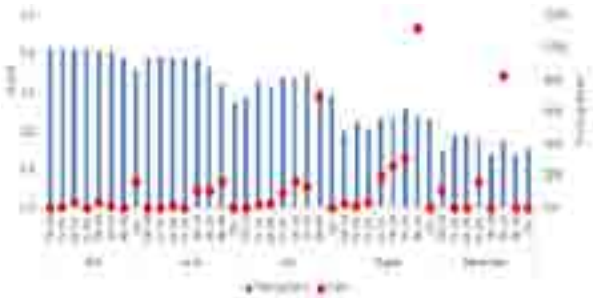
INCREASED YIELD IN VOLUNTARY MEDICAL MALE CIRCUMCISION (VMMC) USING HIV TESTING SERVICE SCREENING TOOL IN ZAMBIA

J. Masiye[1], G. Sishekanu Liche[1], L. Aladesanmi[1], J. Banda[1], K. Asiedu[1], O. Chituwo[2], R. Kamboyi[3], J. Siachobe[1]
[1]Jhpiego, Affiliate of Johns Hopkins University, Jhpiego, Lusaka, Zambia, [2]Centers for Disease Prevention and Control, CDC/DDPHSIS/CGH/DGHT, Lusaka, Zambia, [3]Ministry of Health, Health Services, Lusaka, Zambia

BACKGROUND: VMMC prevalence in Zambia is 21% and HIV prevalence among males is 9.3%. The VMMC package includes HIV Testing Services (HTS) and has been touted as a unique opportunity to reach men thus contributing towards the UNAIDS 95-95-95 target. Universal testing for VMMC clients remains the gold standard, yield among VMMC clients is consistently low, suggesting opportunities for better targeting and resource optimization. Ministry of Health developed an HIV risk screening tool to identify and test clients most at risk. The screening tools has been primarily used in other HTS service points but newly introduced in VMMC.

DESCRIPTION: Since April 2015, Jhpiego implemented a 5-year PEPFAR/CDC funded project that aims to increase VMMC coverage to 80%. The national HTS screening tool was rolled out in 58 VMMC facilities in 5 provinces in May 2019. Facility staff were trained before implementation. We assessed changes in HIV testing rates and yield among VMMC clients during 5 months of implementation (May – September 2019).

LESSONS LEARNED:



[Table. HIV testing rate and yield in VMMC in Zambia (May to Sep, 2019)]

Testing rate declined and yield increased; a 64% reduction in testing rates (100% to 36%) in the 10-14 age-group and minimal increase in yield (0.2%), the 40-49 age-group equally recorded a 60% drop in testing with more increase in yield (2.3%). The yield improvements are prominent in age-groups older than 15-29, suggesting the tool helps target HTS for higher risk men, and decreases testing rates for men less likely to be HIV-positive. These low yield rates below 3% are the highest recorded in the last 2 years.

CONCLUSIONS/NEXT STEPS: The tool has resulted in reduced testing and increased yield among VMMC clients, it appears to be an effective approach for targeting HTS to the highest risk clients, particularly older age groups. The use of the tool should be expanded and monitored closely to ensure we are not turning away high risk clients.

PDD0504

BEHAVIOR DESIGN METHODOLOGY FOR UPTAKE OF VOLUNTARY MEDICAL MALE CIRCUMCISION AMONG FISHERFOLKS IN THE LAKE ZONE OF TANZANIA

C. Mejia[1], M. Swai[2], E. Zimmerman[3], E. McElwee[3], L. Mphuru[2], Z. Lweno[2]
[1]IntraHealth International, Chapel Hill, United States, [2]IntraHealth International, Dar es Salaam, Tanzania, United Republic of, [3]Ideas42, New York, United States

BACKGROUND: Voluntary medical male circumcision (VMMC) is highly effective and among PEPFAR's highest HIV prevention priorities. HIV prevalence among fisherfolks in Tanzania's Lake Zone Region is estimated at 14%, three times higher than national HIV prevalence; 26% - 54% of adult men from the general population in the Lake Zone Regions are uncircumcised. VMMC outreach approaches that have succeeded among the general population have not been as effective among fisherfolks in Lake Victoria islands; thus, nonconventional multidisciplinary solutions are needed to reach this segment of the population. Behavioral design (BD) leverages insights from social psychology, economics, and neuroscience to understand individuals' decisions and actions. IntraHealth International, in collaboration with ideas42, used BD to create tools to increase VMMC uptake among fisherfolks.

DESCRIPTION: BD occurred in four-phases: problem definition, diagnosis, design, and testing. We generated over 100 hypotheses about behavioral drivers of VMMC uptake, which were investigated through interviews with providers, clients, and community members. Confirmed common behavioral drivers included:

- Time inconsistent preferences: immediate costs of VMMC related to lost wages and wait times outweigh longer-term benefits.
- Zero risk bias: men's motivation to avoid any risk of jeopardizing sexual performance, even if they perceive that risk to be remote.
- Descriptive social norms: men perceive circumcision to be uncommon among peers and conform to this norm.
- Availability heuristic: vivid stories of fears or complications related to VMMC come easily to mind, leading men to overestimate risks.

We designed protypes (job aids) for community health workers to support them in addressing these and other behavioral drivers through outreach and sensitization activities.

LESSONS LEARNED: BD can be employed to address cognitive biases and other behavioral tendencies contributing to low uptake of VMMC among priority populations. Solutions can reframe choices to allay fears about sexual performance, provide identity cues that show accessing VMMC as consistent with strength and masculinity, reduce immediate costs, and connect VMMC to salient, immediate benefits.

CONCLUSIONS/NEXT STEPS: Implementers and researchers must understand the context of service provision and learn directly from priority populations what drives their behavior so that behaviorally informed interventions can be harnessed to achieve HIV prevention goals.

PDD0505

CONDOM USE AMONG MEN WHO HAVE SEX WITH MEN WITHIN METRO MANILA, PHILIPPINES: ASSOCIATIONS WITH ATTITUDE TOWARDS ITS USE AND SEXUAL HEALTH OUTCOMES

J. Cadelina[1,2]
[1]LoveYourself, Inc., Administration, Mandaluyong City, Philippines, [2]De La Salle University, Behavioural Science Department, Manila, Philippines

BACKGROUND: The purpose of this study was to determine and explain the level of condom use among men who have sex with men (MSM) within Metro Manila. It also intended to determine the associations between the level of attitude on condoms towards their level of condom use and the association of the direction of condom use attitude, level of sexual health knowledge, level of condom access and the associations of their level of condom use and sexual health outcomes.

METHODS: The research used a quantitative methodological approach utilizing an online self-administered survey questionnaire as a data collection tool using non-probability sampling of 415 MSM. The data gathered was analyzed using descriptive statistics to find means scores, frequencies and percentages. Meanwhile, a non parametric inferential statistics were used to test the association of variables.

RESULTS: Findings revealed that men who have sex with men have a high level of knowledge, high level of condom access, high level of condom use and good level of sexual health outcomes but with a negative attitude towards condom use. However, only one fourth of the respondents have knowledge on the new concept of undetectable equals unstransmittable, where in a person living with HIV who have undetectable viral load by taking antiretroviral drugs cannot transmit HIV sexually. Findings also revealed that sexual health knowledge and condom access have significant but negative association with condom use attitude while no significant association was found between the level of condom use attitude and condom use implying that attitudes has nothing to do with MSM's condom use practices. However, a significant positive correlation was found between condom use and the level of sexual health outcomes.

CONCLUSIONS: Despite the high level of knowledge, condom access, condom use, and sexual health outcomes among men who have sex with men within Metro Manila, their condom use attitudes were negative and the researcher recommends further investigation to gather insights on the factors affecting their negative attitudes toward condom use. Furthermore, continuation and scaling up of condom distribution programs are recommended while behavioural change communication strategies should focus on changing the negative attitudes of MSM on condom use.

PDD0506

END-USER RESEARCH FOR THE DEVELOPMENT OF AN IMPLANT TO PREVENT UNINTENDED PREGNANCY AND HIV PREVENTION: QUALITATIVE INSIGHTS FROM SOUTH AFRICA AND ZIMBABWE

M.K. Shapley-Quinn[1], W. Makoni[2], E. Luecke[1], E. Mbatsane[3], E. Odoom[1], E. Krogstad[4], L. Johnson[5], A. van der Straten[1,6]
[1]RTI International, Women's Global Health Imperative, San Francisco, United States, [2]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe, [3]Setshaba Research Centre, Soshanguve, South Africa, [4]University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, [5]RTI International, Research Triangle Park, United States, [6]University of California, Center for AIDS Prevention Studies, San Francisco, United States

BACKGROUND: The SCHIELD (Subcutaneous Contraceptive and HIV Implant Engineered for Long-Acting Delivery) program aims to develop a Multipurpose Prevention Technology (MPT) implant for HIV and pregnancy prevention. An assessment was undertaken to provide rapid implant attribute and acceptability feedback to the product development team from potential end-users.

METHODS: Twelve Focus Group Discussions (FGDs) were conducted with women aged 18-34 in Soshanguve, South Africa and Harare, Zimbabwe along with quantitative demographic and preference data collection with each participant. FGDs were stratified by contraceptive implant experience as well as parity and transactional sex. Frequencies were run on quantitative data and debriefing reports of FGDs were analyzed to summarize emerging themes.

RESULTS: 110 women (median age 24) were enrolled, and they overwhelmingly supported the idea of an MPT implant. Preferred duration varied by participant type and country. Women who engaged in transactional sex in Soshanguve and parous women at both sites favored a longer lasting implant (3 years), whereas women who engaged in transactional sex in Harare and nulliparous women generally preferred shorter durations (≤2 years). Participants had mixed reactions to possible menstrual changes related to use of a hormonal contraceptive, citing impact on daily activities and economic considerations (e.g. ability to engage in transactional sex, cost of menstrual products). These were considered possible barriers to future uptake and persistence with an MPT implant. Participants anticipated situations where their desire to conceive could rapidly change, necessitating a quickly reversible contraceptive component, whereas the need for quick reversibility for the HIV prevention indication was not anticipated. This drove preference – especially in Harare – for separate rods for each indication, with easy removability of the contraceptive portion while the HIV prevention portion could be left in place (preference for separate rods: Harare=70%, Soshanguve=48%).

CONCLUSIONS: An MPT implant system for prevention of HIV and unintended pregnancy was highly desirable to potential end-users, and optimal duration may vary by personal and country context. Furthermore, product developers should consider the importance of return to fertility and tolerance for menstrual changes in early stages of product development when it is more feasible to modify attributes of an MPT product containing a hormonal contraceptive.

PDD0507

A CALL TO IMPROVE UNDERSTANDING OF UNDETECTABLE EQUALS UNTRANSMISSIBLE (U=U) SLOGAN IN BRAZIL

T.S. Torres[1], L.M.S. Marins[1], D.R.B. Bezerra[1], V.G. Veloso[1], B. Grinsztejn[1], P.M. Luz[1]
[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

BACKGROUND: The correct understanding of U=U (undetectable equals untransmissible) is key in the fight against the HIV epidemic as it empowers people living with HIV, improving adherence and decreasing self-stigma. We assessed the correct understanding of U=U in Brazil in 2019 by population groups.

METHODS: Adult (age ≥18y) Brazilian residents were recruited to complete a web-based survey through advertisements on a geosocial network dating app (Grindr), Facebook and WhatsApp Groups during October/2019. Participants were grouped as: people living with HIV (PLWH), HIV-negative/unknown gay or bisexual cisgender men (GBM) and other populations (POP). Understanding of U=U was accessed with the question: "With regards to HIV-infected individuals transmitting HIV through sexual contact, how accurate do you believe the slogan U=U (undetectable equals untransmissible) is?" Responses were dichotomized into "correct" (completely correct) and "incorrect" (partially correct, partially incorrect, completely incorrect and I don't know what undetectable means). Logistic regression models were used to assess the factors associated with the correct understanding of U=U by group.

RESULTS: A total of 2311 individuals accessed the questionnaire, 234(10%) did not meet inclusion criteria and 1690(73%) completed the survey. Of these, 347(20%) were PLWH, 785(46%) GBM and 558(33%) POP. More PLWH had a correct understanding of U=U (79%, 274/347), compared to 44%(347/785) GBM and 17%(96/558) POP (Chi-square test p-value <0.01). Among PLWH and GBM, black race and lower income were associated with decreased odds of correct understanding, respectively (Table).

		PLWH aOR (95%CI)	GBM aOR (95%CI)	POP aOR (95%CI)
Gender/ Orientation	Category A (Ref: Category B)[1]	0.74 (0.36-1.49)	**2.16 (1.48-3.18)**	**3.12 (1.18-8.02)**
Age	≤ 35 years (Ref: >35 years)	**2.64 (1.40-5.20)**	**2.00 (1.45-3.18)**	1.15 (0.68-1.92)
Race	Black (Ref. Other[2])	**0.34 (0.16-0.71)**	1.22 (0.76-1.94)	0.79 (0.32-1.74)
Family Income	Middle/High (Ref. Low[3])	1.59 (0.85-2.99)	**1.55 (1.09-2.22)**	0.77 (0.45-1.35)
Schooling	≤ Secondary school (Ref. > Secondary school)	0.94 (0.50-1.78)	0.96 (0.66-1.38)	1.06 (0.62-1.78)
Living in Capital Cities	Yes (Ref. No)	1.35 (0.72-2.49)	**1.44 (1.02-2.04)**	1.26 (0.77-2.11)
Steady Partner	Yes (Ref. No)	**2.58 (1.39-5.01)**	1.11 (0.80-1.56)	1.38 (0.84-2.32)
Ever testing HIV	Yes (Ref. No)	NA	**1.54 (1.00-2.40)**	**2.26 (1.28-4.20)**

[1] For PLWH, Category A= GBM and Category B= other; For GBM, Category A= Gay and Category B= Bisexual; For POP, Category A= Transgender/Non-Binary and Category B= Cisgender;
[2] Other = White, Asian, Native or Pardo (Mixed-black); [3] Low income is equivalent to R$1996.00 or USD468.00 per month; NA: not applicable

[Table]

CONCLUSIONS: There was significant difference in U=U knowledge across population groups, with average and very poor understanding among GBM and the general population, respec-

tively. Correct understanding of the slogan needs to be promoted in more vulnerable populations such as PLWH of black race and GBM of lower income, and more broadly among older individuals and the general population, in an effort to decrease stigma against PLWH.

PDE01 COMMUNITIES AT THE FOREFRONT: INTEGRATING COMMUNITIES IN HIV PROGRAMMING

PDE0102

CAPACITY BUILDING FOR COMMUNITY HEALTH WORKERS IN VIETNAM: RESULTS OF AN INTERVENTION TRIAL

L. Li[1], L.-J. Liang[2], C. Lin[1], L.Q. Pham[1], T.A. Nguyen[3]
[1]University of California, Center for Community Health - Semel Institute, Los Angeles, United States, [2]University of California, Statistics Core, Department of Medicine, Los Angeles, United States, [3]National Institute of Hygiene and Epidemiology, Hanoi, Vietnam

BACKGROUND: Community health workers (CHW) can play an essential role in addressing the needs of people living with HIV (PLH) and people with substance use disorders (PSUD); this is particularly critical in low- and middle-income countries. Coordination and networking among CHW and with providers of other service agencies need to be strengthened so that that CHW can be equipped with relevant knowledge and supported from their professional peers. In this study, we report preliminary outcomes of a capacity-building intervention targeting CHW in Vietnam. The aim was to enhance their networking and collaboration to support HIV and addiction treatment initiation, retention, and adherence.

METHODS: From 2017 to 2019, we conducted a cluster randomized controlled trial in four provinces of Vietnam. Intervention CHW participated in the intervention program for integrated service delivery, including two in-person group sessions followed by online group communications to network and support each other. All the CHW participants completed assessments with an audio computer-assisted self-interview method. The outcome measures include two multi-item scales. Interaction with providers in other service sectors was measured by an eight-item scale developed for this study. Confidence in HIV/drug-related service provision was measured by CHW ratings in confidence in providing services to PLH and PSUD in several service areas. Mixed-effects regressions models were performed to evaluate intervention outcomes based on the data collected at baseline, 3-, 6-, 9-, and 12-month follow-up.

RESULTS: We observed no significant differences in baseline CHW demographic characteristics, work background, and training between the intervention and control conditions. Intervention CHW showed greater improvement in interaction with providers in other service sectors (P=0.004) and confidence in HIV and drug-related service provision (P=0.025) than control CHW at the 6-month follow-up. The intervention effects on both outcome measures remained at the end of the study (12-month, P-values < .05).

CONCLUSIONS: Our study indicated that the intervention focusing on capacity building and networking has the potential to improve cross-agency communication and collaboration among CHW. With the support of a professional network, CHW will be more equipped to provide HIV and drug-related services in community settings.

PDE0103

A COMMUNITY-BASED EXPERIENCE OF A VIRAL LOAD (VL) SAMPLE COLLECTION CAMPAIGN TO ENHANCE DOLUTEGRAVIR (DTG) CONTAINING ANTIRETROVIRAL THERAPY (ART) REGIMEN SWITCH AMONG FEMALE SEX WORKERS (FSWS) IN MALAWI

C. Kwitonda[1], E. Nicco[1], D. Van Laeken[1], E. Chang[1], K. Chawinga[1], D. Muambeta[1], I. Kwamwanza[2], G. Momba[2], R. Chimenya[2], T. Ellman[3], L. O'Connell[3]
[1]MSF OCB, Limbe, Malawi, [2]MOH, Mwanza, Malawi, [3]SAMU, Cape Town, South Africa

BACKGROUND: The MSF FSWs Project provides HIV TB and sexual and reproductive health (SRH) services for Malawian FSWs through a community-based peer-led model. National VL monitoring policy is VL testing for all those on ART at 6 months and yearly. VL coverage among FSWs in the MSF cohort was 45% prior to the campaign. The additional importance of VL in ensuring correct switch at the time of DTG rollout adds urgency to improve VL coverage. We conducted a campaign to reach enrolled FSWs eligible for VL based on peer-led community outreach in Dedza, Mwamza and Zalewa Districts. This descriptive data analysis presents the outcome of the intervention.

DESCRIPTION: From Aug. to Nov. 2019, FSWs eligible for VL sample collection in the 3 districts were mobilized by peers to have dried blood spot (DBS) VL tests according to Malawian guidelines. Tracing was achieved using micro-planning tools and an eligible list was extracted from program database. Data was collected on paper register, encoded into an excel sheet and an analysis was performed using STATA 13.

LESSONS LEARNED: 252 DBS samples were collected during the campaign, reaching 71% of the 355 eligible FSW. . Among those reached, 39% had never previously had a VL and 80% were VL suppressed (<1000 copies/mL). VL suppression rate on DBS was 45,6% (21/46), 86% (123/143) and 83,5% (56/63) in Zalewa, Mwanza, and Dedza. Of 252 FSWs reached by the campaign 220 (87%) returned for results and DTG-based regimen switch, increasing the speed of DTG switch among FSWs.

CONCLUSIONS/NEXT STEPS: A campaign led through peer based community mobilization is an effective method to rapidly increase coverage of VL testing among FSWs on ART in Malawi, increasing VL coverage from 44,7% to 64,4% among FSWs enrolled in the MSF cohort in the 3 sites. All reached during the campaign received a VL. The observed percentage of VL suppression (80%) indicates remaining gaps in achieving the 90-90-90 target for FSWs. While Malawi protocol at the time of the campaign pragmatically recognized that DTG switch should not be delayed by awaiting VL results, our approach demonstrates that VL guided switch can be rapidly achieved in this population.

PDE0104

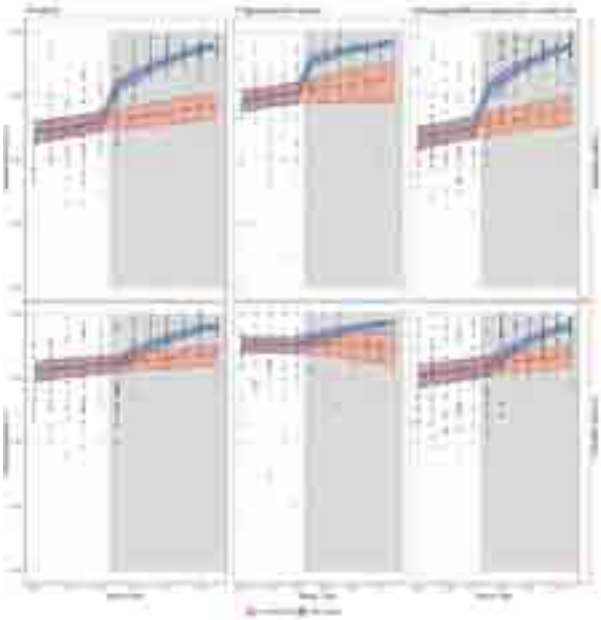
POSITIVE EFFECTS OF INTENSIFIED PREVENTIVE CALLS/HOME VISITS ON EARLY RETENTION AMONG ADULTS NEWLY INITIATED ON ANTIRETROVIRAL THERAPY IN ZAMBÉZIA PROVINCE, MOZAMBIQUE

C. De Schacht[1], G. Amorim[2], S. Van Rompaey[1], J. Matsimbe[3], A. Naftal Fernando[4], J. A. Tique[1], I. Torres[1], L. Dique[5], E. Ntasis[1], C.W. Wester[6,7]
[1]Friends in Global Health, Maputo, Mozambique, [2]Vanderbilt University Medical Center (VUMC), Department of Statistics, Nashville, United States, [3]Friends in Global Health, Quelimane, Quelimane, Mozambique, [4]Provincial Health Directorate, Quelimane, Mozambique, [5]Centers for Disease Control and Prevention (CDC), Maputo, Mozambique, [6]Vanderbilt Institute of Global Health, Nashville, United States, [7]Vanderbilt University Medical Center (VUMC), Department of Medicine, Nashville, United States

BACKGROUND: In Mozambique, early retention rates among antiretroviral therapy (ART)-treated adults remained low in 2018, ranging from 65% to 69% at one and three months, respectively. To bolster rates, patients newly initiated on ART received services in the first three months including phone calls and/or monthly supportive home visits performed (for non-pregnant/lactating adults) by Counselors and Peer Educators, and (for pregnant/lactating women [PLW]) by Mentor Mothers. In February 2019, activities were intensified in 20 health facilities in Zambézia Province, focusing on technical support to counselors and volunteers, data triangulation and weekly process measures monitoring. The effect on early retention was evaluated.

METHODS: Routinely collected aggregated program data extracted from electronic patient database of HIV-positive adults initiating ART between September 2018-August 2019 were evaluated. Retention was defined as returning for ≥1 ART pick-up within 33 days (1-m retention) and 61-120 days (3-m retention) post-initiation. Trend analysis was done using generalized linear mixed effects models to account for site-level clustering, adjusting for covariates (urban/rural, patient volume, district).

RESULTS: Analysis included 19,750 patients. Overall, one- and three-month retention rates increased with the intervention from 61% to 93%, and 76% to 91%, respectively (Figure 1).



[Figure 1. Fitted model of effect of the intervention on one-month and three-month retention (September 2018 - August 2019)]

In observation period, odds of being retained at one-month increased by 1.92 (95%CI: 1.67-2.20) and we predicted a continuous retention rate increase of 1.23 (95%CI: 1.18-1.29) post-observation period. The change was less substantial (OR 1.01, 95%CI: 0.87-1.16) for 3-m retention, but the increased rate was still significantly higher (OR 1.25, 95%CI: 1.19-1.31).

CONCLUSIONS: Improved psychosocial support implementation appeared to have a significant effect on early retention. Counselors and volunteers ensured procedural fidelity through clear identification of roles/responsibilities and creating a feedback loop regarding performance. High quality community support should start as early as possible to prevent lost to follow-up in this critical post-ART initiation window.

PDE0105

COMMUNITY-BASED ANTIRETROVIRAL THERAPY DELIVERY ASSOCIATED WITH VIRAL SUPPRESSION AND RETENTION IN CARE IN SOUTH AFRICA

L. Violette[1], J. Dorward[2], J. Quame-Amaglo[3], N. Garrett[2,4], P. Drain[1,3,5]
[1]University of Washington, Department of Medicine, Seattle, United States, [2]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [3]University of Washington, Department of Global Health, Seattle, United States, [4]University of KwaZulu-Natal, School of Nursing and Public Health, Durban, South Africa, [5]University of Washington, Department of Epidemiology, Seattle, United States

BACKGROUND: We assessed South Africa's differentiated community-based antiretroviral therapy (ART) delivery program (CCMDD) for people living with HIV (PLHIV) for participation rates and to determine the association between CCMDD enrollment and HIV care outcomes.

METHODS: The STREAM trial enrolled PLHIV in Durban who were clinically stable on ART for six months and randomized participants to receive either point-of-care viral load (VL) testing (Xpert® HIV-1 VL, Cepheid) and task-shifting to an enrolled nurse or standard laboratory VL testing. Six months after STREAM enrollment, non-pregnant participants with two consecutive undetectable (<40 copies/mL) VLs were eligible for referral into the CCMDD program. At 12 months after STREAM enrollment, participants were reassessed for eligibility. We used Poisson models with robust standard errors to evaluate the association between CCMDD enrollment and viral suppression (<200 copies/mL) and/or retention in care.

RESULTS:

HIV Care Outcomes	Not enrolled in CCMDD [a] N=264 (68%)	Enrolled in CCMDD [a] N=126 (32%)	RR (95% CI)	p-value	aRR [b] (95% CI)	p-value
HIV viral load <200 copies/mL and retained in care at the clinic	204 (77.3)	119 (94.4)	1.22 (1.13-1.32)	<0.001	1.19 (1.09-1.29)	<0.001
HIV viral load <200 copies/mL	218 (82.6)	126 (100.0)	1.21 (1.15-1.28)	<0.001	1.20 (1.12-1.29)	<0.001
Retained in care at the clinic	226 (85.6)	119 (94.4)	1.10 (1.03-1.18)	0.003	1.08 (1.01-1.16)	0.017
a. Enrollment into CCMDD is defined as first enrollment prior to the study exit visit. b. Adjusted for study randomization arm, continuous age, and gender						

[Table. Centralized Chronic Medication Dispensing and Distribution (CCMDD) Programme enrollment and HIV care outcomes at study exit in the STREAM Study, n=390]

Among 390 participants, 176 (45%) were eligible, 168 (43%) were referred, and 144 (37%) enrolled into CCMDD. Participants obtained their ART within the expected window at 93% (265/286) of scheduled CCMDD visits. Reasons ART was not obtained included missed appointments (9/21, 43%) and ART package not being available at the pick-up point (6/21, 29%). Of 135 participants reassessed for CCMDD consideration six months after initial eligibility, 14 (10%) became CCMDD-ineligible due to pregnancy (n=5), detectable viral loads (n=3), and declined re-referral (n=6). After adjusting for study randomization arm, age, and gender, CCMDD enrollment prior to study exit was significantly associated with viral suppression (<200 copies/mL) and retention in care at the clinic (RR=1.19 p<0.001), viral suppression alone (RR=1.20 p<0.001) and retention in care alone (RR=1.08 p=0.017).

CONCLUSIONS: Among clinically stable participants, those enrolled in the CCMDD program had higher rates of viral suppression and retention in care, indicating that the community-based ART delivery model did not negatively impact HIV care outcomes. The CCMDD program should be promoted for clinically-stable PLHIV in South Africa.

PDE0106

HIGH SATISFACTION WITH KEY POPULATION-LED XPRESS SERVICE DELIVERY FOR FOLLOW-UP OF PRE-EXPOSURE PROPHYLAXIS CLIENTS IN COMMUNITY BASED ORGANIZATIONS IN THAILAND

N. Thammajaruk[1], P. Posita[1], S. Promthong[1], O. Nampaisan[1], T. Sangpasert[2], P. Meekrue[3], T. Pasansai[4], P. Palee[5], P. Brutrat[6], M. Avery[7], S. Mills[7], R. Vannakit[8], P. Phanuphak[1], N. Phanuphak[1], R. Ramautarsing[1]
[1]PREVENTION, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]The Service Workers In Group Foundation, Bangkok, Thailand, [4]Mplus Foundation, Chiang Mai, Thailand, [5]Caremat, Chiang Mai, Thailand, [6]The Service Workers In Group Foundation, Pattaya, Chonburi, Thailand, [7]FHI360 and LINKAGES, Bangkok, Thailand, [8]USAID Regional Development Mission Asia, Office of Public Health, Bangkok, Thailand

BACKGROUND: Thailand has achieved significant scale-up of HIV pre-exposure prophylaxis (PrEP) under a community-based service delivery model with lay providers; however, PrEP retention has been suboptimal. Xpress service flow was implemented to reduce the one-hour wait time for PrEP follow-up visits and potentially improve service retention. Here we report clients' experiences with Xpress services.

METHODS: Xpress service flow was designed by staff of community based organizations (CBOs) working across 6 Thai provinces, and was launched at 6 CBOs in June 2019. Eligibility assessment was performed by counselors, and clients were considered eligible if they had good adherence, no acute HIV symptom and willing to use Xpress service. If eligible, clients skipped post-test counseling during that visit, and received their HIV test result through a channel of their choosing (LINE, SMS, or email), resulting in an average visit duration of 30 minutes. A satisfaction survey using a 5-point Likert scale was conducted among clients using the Xpress service on the day of service utilization.

RESULTS: Between August–December 2019, 898 clients came for PrEP follow-up, all were eligible and used the Xpress service, of whom 341 completed the satisfaction survey. A majority indicated to be satisfied or very satisfied with service accessibility (98.5%), duration (95.9%), and convenience (97.7%). Nearly all clients agreed or strongly agreed that enough attention was paid to them during Xpress services (98.2%), that Xpress services fit their lifestyle better than regular services (98.8%), that they preferred Xpress over regular services (97.1%), and that receiving test results through LINE/SMS/email is private and safe enough (94.4%). Of the 898 clients who used the Xpress flow, one seroconverted. This client was immediately contacted by CBO staff and linked to treatment within one day.

CONCLUSIONS: The Xpress option to optimize the flow and duration of services for PrEP follow-up clients results in very high client satisfaction and should be offered as a service option for eligible clients, and longitudinal clinical outcomes like retention in care and adherence should be assessed in the future to inform service optimization. The Xpress option should also be expanded to other services to improve service utilization.

PDE02 DIFFERENT METHODS, BETTER RESULTS: DIFFERENTIATED SERVICE DELIVERY IN HIV TESTING AND PREVENTION

PDE0202

VARIATIONS IN COMMUNITY-BASED HIV TESTING OUTCOMES BY TESTING APPROACH: AN UPDATED SYSTEMATIC REVIEW OF THE EVIDENCE FOR COMMUNITY-BASED HIV TESTING

P. Stankard[1], A.K. Groves[2], S. Bowler[2], M. Jamil[3], S. Shaw[4], L. Gebrekristos[2], C. Quinn[3], R. Baggaley[3], C. Johnson[3]
[1]Stankard Consulting LLC, Washington DC, United States, [2]Drexel University, Dornsife School of Public Health, Philadelphia, United States, [3]World Health Organization, Global HIV, Hepatitis and STIs Programme, Geneva, Switzerland, [4]Independent Consultant, Washington DC, United States

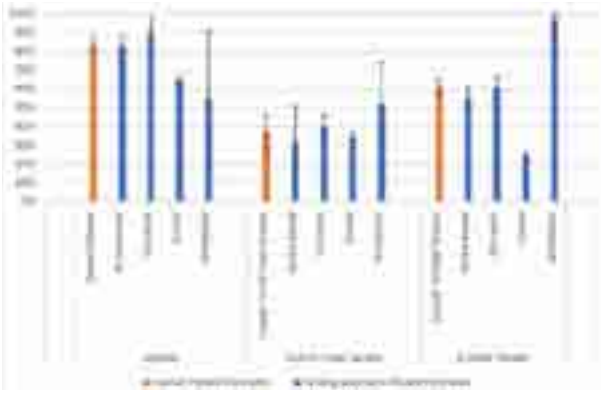
BACKGROUND: Approximately 8.1 million people with HIV (21%) are undiagnosed. Efforts to scale-up HIV testing among those unreached, using efficient and effective approaches, is essential for achieving the 95-95-95 global targets. WHO recommended community-based HIV testing services (CB-HTS) in 2013 and, in 2015, recommended lay provider testing to further support implementation. Here we examine differentiated CB-HTS to guide future implementation.

METHODS: We conducted a global systematic review following PRISMA, searching 8 electronic databases, for studies on CB-HTS published/presented between January 2015 and July 2018. This analysis presents studies reporting on CB-HTS outcomes among the general population. We calculated pooled proportions using random effects models.

RESULTS: 228/13,218 unique studies were included in this review. HIV testing uptake across CB-HTS approaches was 83% (95% CI:78-87%). Over a third were first time testers (37%;CI:28-46%) and over half were male (61%;CI:57-65%). Pooled HIV positivity was 6% (CI:5-7%) and over three-quarters of those diagnosed HIV+ were new diagnoses (78%;CI:67-87%).

Results varied by CB-HTS approach (Figure 1) Compared with home-based testing, outreach had greater uptake (O:90%,CI:77-98% vs H:83%,CI:77-88%), reached more first time (O:40%,CI:34-46% vs H:32%,CI:16-51%) and male testers (O:61%,CI:55-66% vs H:55%,CI:49-61%), and resulted in a greater percentage of new HIV+ diagnoses (O:77%,CI:38-100% vs H:71%,CI:58-83%).

Site-specific approaches varied greatly. School-based testing found lower uptake (65%,CI:63-67%) and reach among first-time (34%,CI:32-37%) and male testers (24%,CI:22-26%). Pooled HIV positivity was also low (0%,CI:0-1%). Workplace models demonstrated similarly low uptake (55%,CI:6-91%), but reached high proportions of men (97%,CI:84-100%) and first-time testers (52%,CI:30-74%). Pooled positivity was 7% (CI:4-11%) and 94%(CI:63-100%) of HIV+ diagnoses were new.



[Figure 1. Update, first time and male testing by CB-HTS approach]

CONCLUSIONS: CB-HTS remains an effective way to reach first-time testers and men, and to identify new HIV infections. There is considerable variability by testing approach. Programmes must consider their context and select a strategic mix of CB-HTS approaches to reach those in need of HIV testing, prevention and treatment services.

PDE0203

AN INNOVATIVE "1+1" HIV SELF-SERVICE TESTING IN COOPERATION WITH COMMUNITY-BASED ORGANIZATIONS OR VOLUNTARY TESTING AND COUNSELLING SITES IN FIVE PROVINCES, CHINA

Y. Lyu[1], M. Chen[2], J. He[3], S. Liang[4], X. Hu[5], Y. Yao[6], J. Yao[1], Y. Jiang[1]
[1]National Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China, [2]Yunnan Center for Disease Control and Prevention, Kunming, China, [3]Hunan Provincial Center for Disease Control and Prevention, Changsha, China, [4]Guangxi Province Centers for Disease Control and Prevention, Nanning, China, [5]Xinjiang Uygur Autonomous Region Center for Disease Control and Prevention, Urumchi, China, [6]Guizhou Center for Disease Control and Prevention, Guiyang, China

BACKGROUND: In order to meet the needs of both fast and accurate testing results in the anonymous state, as well as professional medical service, we developed the "1+1" HIV self-service testing (including finger-prick rapid testing and dried blood spot self-collection testing), and evaluated its acceptability and feasibility in five Province, China.

METHODS: From March to December 2019, in cooperation with local community based organization or voluntary testing and counselling sites, 9868 "1+1" HIV self-service testing packages were distributed to the participants for free . When got the package, according to the instructions, participants performed finger-prick rapid testing, collected their dried blood spot (DBS) in private, completed the questionnaire and mailed the specimen and questionnaire back to the designated laboratory. The DBS specimens were tested with HIV-1 antibody ELISA and the results were uploaded to the web-based platform within five working days.

RESULTS: A total of 4196 (42.5%) urine specimens and questionnaires were mailed back. Of these 4196 participants, 2016 had performed finger-prick rapid testing and the positive rate was 8.4% (169/2016). 416 out of 4196 (9.9%) dried blood spot specimens were determined HIV-1 antibody positive. CDC staff reached 401 of 416 (96.4%) HIV-1 antibody-positive participants, and provided a western blot diagnostic assay kit to test their venous blood specimens. Among them, 100% reported being confirmed HIV antibody positive. 352 out of 401 (87.8%) participants were confirmed as newly diagnosed. 93.3% (388/416) HIV-1 antibody-positive participants and 63.2% (2390/3780) HIV-1 antibody negative participants searched for their test results by logging onto the website with the unique identification code.

CONCLUSIONS: This study showed that "1+1" HIV self-service testing was an efficient approach supplemental to the existing HIV testing and counseling system through eliminating the key barriers of conventional PITC and VCT testing, could help medical professionals to establish a linkage with individuals with high-risk sexual behavior, effectively identify undiagnosed HIV infection, and timely refer and confirm those who screened HIV-positive in private.

PDE0204

COMBINING ENHANCED PEER OUTREACH APPROACH WITH INDEX TESTING: A BETTER STRATEGY FOR REACHING KEY POPULATIONS AT HIGH RISK IN HIV CONCENTRATED SETTINGS IN INDIA

K. Krishnan[1], M.R. Parthasarathy[1], A.K. Paulraj[1], G.S. Shreenivas[1], J. Bhaisya[2], B. George[1]
[1]FHI 360, LINKAGES, New Delhi, India, [2]USAID, Health, New Delhi, India

BACKGROUND: The USAID/PEPFAR funded LINKAGES project led by FHI 360 and implemented in six high- burden districts for HIV in India, explored combining the enhanced peer outreach approach (EPOA) among hidden networks of men who have sex with men (MSM) with index testing to reach spouses and stable sexual partners and achieve India's 90-90-90 goals. HIV prevalence among MSM is reported as 2.69%.

DESCRIPTION: EPOA adapts respondent driven sampling to reach networks of key populations (KPs) beyond the catchment geographies of the National HIV Control Program, while index testing expands HIV testing from HIV diagnosed KP members to undiagnosed high-risk individuals particularly spouses and stable sexual partners. Stakeholders were consulted on locally appropriate and community- friendly strategies for peer- based outreach, HIV screening, accompanied referral for confirmatory testing, and antiretroviral therapy (ART) initiation. HIV testing was performed through community-based approaches either at drop-in centers or community events. Confirmatory tests were conducted at the government testing centers. The WHO Partner Notification Framework was adapted for index testing. A differential package of services for MSM based on risk was developed. Risk assessment targeting high risk MSM and the documentation system were strengthened. Onsite mentorship and supportive supervision were provided.

LESSONS LEARNED: During 2018-2019, 12,896 new MSM clients were reached through EPOA, with a case detection rate of 6.09% (n=786). From the index MSM clients found HIV positive, 334 spouses were notified and tested for HIV with a case detection rate of

51.79% (n= 173). In addition, 1,229 regular partners were notified and tested with a case detection rate of 17.49% (n= 215). ART was initiated among 148 spouses (85.54%) and 190 regular partners (88.37%).
CONCLUSIONS/NEXT STEPS: Results show that combining the hidden peer led network testing approach with index testing enhances the coverage of high risk KP members and improves HIV case detection. The blended approach extends into high risk individuals, specifically spouses and stable sexual partners of MSM, who are otherwise beyond the reach of the National HIV Program, contributing toward the 90-90-90 goals. Adapting locally appropriate and community centric outreach, disclosure and partner notification for HIV concentrated settings are pre-requisites for such combination approaches.

PDE0205

REACHING THE 'FIRST' 95 - UPTAKE AND YIELD OF COMMUNITYBBASED HIV TESTING SERVICE MODALITIES IN SOUTH AFRICA

N. Nyoni[1], C. Magezi[1]
[1]FHI 360, Capacity Development and Support, Pretoria, South Africa

BACKGROUND: Despite high HIV burden in South Africa, testing coverage remains low. Community-based HIV testing services play improves diagnosis and linkage to HIV care for marginalized gaps. The Accelerated-Targeted Community-based HIV Testing Services (ATC-HTS) project, funded by USAID, aimed to increase case-finding of HIV positive individuals to link and retain them in care and treatment. The project focused on priority populations and undiagnosed HIV-positive individuals in targeted communities in Mpumalanga and Free State provinces, Africa.
DESCRIPTION: To achieve high testing coverage, mobile, home-based and index testing modalities were implemented. The results compared HTS uptake and yield according to the modalities implemented. Using routine HTS data, from October 2017 – September 2018, the impact of the different modalities in identifying undiagnosed HIV infections. Index testing targets sexual partners and biological children (off-shoots) of positive index clients identified through TIER.Net registers, mobile testing and home-based testing through door-to-door campaigns.
LESSONS LEARNED: Approximately 100,000 people were tested: 56,026 - home-based HTS (56.1%), 35,692 -mobile (35.7%) and 8,328 - index (8.2%) testing. Home-based testing modality achieved higher uptake, compared to the other two modalities of testing: a higher proportion of <18 were tested through home-based than index testing (91% vs. 9%) and a higher proportion of adult men than index-testing (88% vs. 12%).
Of 8,328 index off-shoots tested for HIV, 1,630 (20%) tested positive while 1,533 tested positive through home-based modality and 1,376 through mobile testing. In comparison, Index testing was the most efficient for case identification with 20% positivity rate, compared to 2% for both mobile and home-based testing.
Of the 4,539 HIV-positive individuals, 92% of clients tested positive through community-based testing and were linked to care, confirmed through TIER.Net.
CONCLUSIONS/NEXT STEPS: Index testing is the most efficient modality for identifying HIV positive individuals. It allows testing for sex partners and biological children of index clients resulting in increased yield. This model reached PLHIV who would not ordinarily access HTS through conventional health facility HTS modalities.

PDE0206

HIV SERVICES CLOSER TO THE COMMUNITIES: COMMUNITY-LEVEL INTERVENTIONS TO OPTIMIZE HIV CASE FINDINGS AND TREATMENT INITIATION IN NEPAL

A. Shrestha[1], H. Subhani[1], K. Bam[1], R. Khanal[1], B. Shrestha[1], R. Didiya[2], A. Bhattachan[3]
[1]FHI 360/LINKAGES Nepal Project, Kathmandu, Nepal, [2]National Association of People Living with HIV in Nepal, Kathmandu, Nepal, [3]National Center for AIDS and STD Control, Kathmandu, Nepal

BACKGROUND: In 2018, 20% of the estimated total number of people living with HIV (PLHIV) in Nepal did not know their status, and 30 percent who knew their status were not enrolled in antiretroviral therapy (ART). We describe the efforts of community lay providers for HIV screening through test-for-triage and peer navigators facilitating ART initiation to increase case finding and treatment in the USAID/PEPFAR-funded LINKAGES Nepal Project.
METHODS: Based on LINKAGES Nepal program data for HIV prevention, care, support, and treatment in 17 high-burden districts, we calculated the case finding through test-for-triage by mobilizing community lay providers (including key populations), and the use of HIV-positive peer navigators to facilitate treatment (October 2018–September 2019). Peer navigators accompanied those identified as positive for ART initiation including adherence support. Test-for-triage is a process where the lay-providers do HIV screening in the community as a part of a cost-effective and targeted approach. Test-for-triage were used for differentiated outreach and index testing. Index testing was offered to trace sexual, injecting partners and risk network referrals, and U=U messages were communicated to discordant couples.
RESULTS: Compared with no test-for-triage approach in FY18, case finding increased from two cases to 549 cases in FY19; also in FY19, case finding through index testing using test-for-triage increased to 18% compared to those from static clinics (2.7%), where beneficiaries need to find time to come for testing. Compared to no peer navigation support in FY18, ART initiation increased by 14% point in FY19 (75% to 89%). This demonstrates human-centered approach for HIV epidemic control where rather than beneficiaries going to services, services go to the beneficiaries.
CONCLUSIONS: Mobilization of community lay providers and peer navigators helps risk groups to know of their HIV status rather than visiting the clinic and helps to initiate ART. Their role is crucial to fill the gap in Nepal's HIV cascade.

PDE03 FROM FAITH TO MTV: EXPANDING THE REACH OF HIV SERVICES

PDE0302

FAITH-ENGAGED COMMUNITY POSTS ASSOCIATED WITH OVER 1200% INCREASE IN NEW HIV CASE ASCERTAINMENT, WITH HIGH LINKAGE AND RETENTION, ZAMBIA

G. Makangila[1], A. Mwango[2], M. Shah[3], N. Kancheya[4], K. Nkwemu[4], I. Zulu[3], I. Essiet-Gibson[3], L. Erickson Mamane[3], S. Agolory[4], S. Hillis[5]
[1]Circle of Hope, Lusaka, Zambia, [2]Catholic Relief Services, Lusaka, Zambia, [3]Centers for Disease Control and Prevention, Atlanta, United States, [4]Centers for Disease Control and Prevention, Lusaka, Zambia, [5]Office of the Global AIDS Coordinator, Washington DC, United States

BACKGROUND: Recent data indicate that gaps in HIV testing uptake and antiretroviral therapy (ART) coverage in Lusaka, particularly for men and children, are related to their being less likely to access health facilities, preferring to receive HIV services from trusted individuals. Catholic Relief Services and Circle of Hope (an Assembly of God affiliate) addressed this by engaging and deploying local faith leaders to de-centralized community posts (CPs). We considered whether this model was associated with increases in case-finding, linkage, and retention, particularly for men and children.

DESCRIPTION: Each of 21 CPs was located in a high-activity setting with minimal branding and served by a multi-disciplinary team of community health workers and a clinician. CRS and COH collaborated in a program to increase case-finding, linkage, and retention. The intervention leveraged trusted relationships of faith leaders to identify individuals at higher risk for HIV infection.

LESSONS LEARNED: During the 19 months following introduction of CPs (March 2018–September 2019), as compared to the 17 months before, the median number of new HIV cases identified per month increased 1087% overall (from 46 to 500), 1494% in men (from 16 to 239), and substantively in children (from 0 to 10). During the program period, testing yield for men was 27.0% and for children, 5.5%. Of the 11,457 clients identified as new HIV cases at CPs, >96% were linked and >92% were retained on ART as of September 2019.

Key program components include:

- Hiring – harnessed social infrastructure, with >90% of staff serving as trusted faith leaders in local congregations;
- Senior Management support - through daily meetings and WhatsApp
- Celebration – quarterly events distribute non-monetary awards
- Leveraging faith leaders' close relationships with those at risk in the community (such as those with marital/partner conflict, familial illness, bereavement, or attendance at healing services)
- Shared core values – training with continuous reinforcement - 'RECIPE' – Responsibility, Empathy, Compassion, Integrity, Passion, Ethics

CONCLUSIONS/NEXT STEPS: We report that implementation of this faith-engaged CP model can result in substantial improvements in case-finding, linkage, and retention. Expanding this model to other contexts may help advance epidemic control in Zambia and beyond.

PDE0303

PILOT EVIDENCE-BASED INTERVENTIONS TO REDUCE METHAMPHETAMINE USE IN VIETNAM: PROMISING OUTCOMES AND LESSONS LEARNED

H.D. Hoe[1], N.H. Anh[1], N.T. Trang[1], S. Larkins[2], S. Shoptaw[3], L.M. Giang[1]
[1]Hanoi Medical University, Center for Research and Training on Substance Abuse and HIV, Hanoi, Vietnam, [2]University of California, Intergrated Substance Abuse Programs, Los Angeles, United States, [3]University of California, Departments of Family Medicine and Psychiatry and Biobehavioral Sciences, Los Angeles, United States

BACKGROUND: Methamphetamine has gradually replaced opioids to be the first drug of abuse in Asia-Pacific. Methamphetamine use is associated with HIV risk behaviors and lower uptake of methadone maintenance treatment. Little evidence exists to guide the effective implementation of evidence-based interventions (EBIs) to reduce methamphetamine use in resource-poor settings like Vietnam.

DESCRIPTION: Between 2018 and 2019, VHATTC at Hanoi Medical University has piloted four combinations of EBIs on methadone patients and people who use drugs (PWUD) not in treatment. The project aims to assess the feasibility of interventions and preliminary treatment outcomes. These EBIs included motivational interviewing, contingency management, Matrix group therapy, SMS messaging and on-site psychiatric treatment. Participants with methamphetamine-positive urinalysis and/or at moderate/high risk with methamphetamine were recruited into intervention programs that lasted between 8 and 16 weeks. Participants were tested for methamphetamine twice every week throughout the interventions.

LESSONS LEARNED: The retention rate of 288 patients receiving interventions remained at 90% in all EBIs combinations, except for MSM who used methamphetamine. The reduction of both methamphetamine and heroin use across EBIs combinations was consistent. Among high-risk methadone patients (n=56), methamphetamine use reduced from 39.3% to 6%, opioid use from 28.6% to 4% after 16 weeks. Among PWUD not in treatment, methamphetamine use reduced from 49.2% to 31% after 8 weeks. Among HIV-positive methadone patients (n=51), methamphetamine use reduced from 54.9% to 12.5% and viral load decreased after 12 weeks. In all combinations, participants' mental health improved after interventions. Findings indicate that EBIs implementation is feasible in Vietnam. Methadone providers were able to adopt intervention techniques with online and on-site assistance. When confidentiality was ensured, all patients agreed to be tested for methamphetamine. SMS messaging might work to sustain participants' achievements in resource-poor settings. Moderate-risk users responded better to all EBIs combinations.

CONCLUSIONS/NEXT STEPS: EBIs have been proved to be effective in Vietnam. We will assist Vietnam's Ministry of Health to develop implementation guidelines for methamphetamine interventions in methadone clinics. Strategies to retain MSM who use methamphetamine in care and other EBIs like family interventions among adolescents using drugs need to be piloted.

PDE0304

VIOLENCE, CONFIDENTIALITY BREACHES, AND HARD TO REACH CLINICS IMPEDE ADOLESCENT TREATMENT ADHERENCE

L. Cluver[1,2], Y. Shenderovich[2], E. Toska[3,2,4], W. Rudgard[2], S. Zhou[3], M. Orkin[2,5], R. Haghighat[2], L. Sherr[6], L. Gulaid[7], A. Armstrong[7]
[1]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa, [4]University of Cape Town, Department of Sociology, Cape Town, South Africa, [5]University of Witwatersrand, MRC-NRF Developmental Pathways to Health Research Unit, School of Clinical Medicine, Johannesburg, South Africa, [6]University College London, Research Department of Global Health, London, United Kingdom, [7]UNICEF Eastern and Southern Africa Regional Office, Nairobi, Kenya

BACKGROUND: We urgently need effective strategies to increase treatment adherence amongst Africa's adolescents living with HIV, but lack evidence of social, structural and clinical factors impacting adherence.

METHODS: A prospective 3-year study of n=1,060 adolescents living with HIV (55% female, mean age 13.6) in one health district of South Africa's Eastern Cape. We traced all adolescents ever initiated on treatment (90% uptake) in all 73 government health facilities, with standardised questionnaires and clinical records. Study retention was 94% (18 months) and 91% (36 months), with 3% mortality. Ethical approvals were received from University of Cape Town, University of Oxford, Provincial government. Analyses used logistic random-effects and fixed-effects models (estimating semi-elasticities) to investigate predictors of adherence.

Outcome: past-week self-reported ART adherence. Potential predictors included: Healthcare: medication stockouts, confidentiality of records, travel time to clinic and clinic waiting time; Structural family factors: orphanhood, changes of primary caregiver, household size and (non)biological relationship to primary caregiver; and Family care factors: physical or emotional violence victimisation, domestic violence, good caregiver supervision and caregiver-adolescent communication. Controls were: age, study round, gender, urban/rural, (in)formal home, poverty, vertical/horizontal infection and recent ART initiation.

RESULTS: Adherence was associated with undetectable viral load (baseline OR 1.45, 95% CI 1.02;2.07; 18-month OR 1.47, CI 1.03;2.11). Rates of consistent adherence from baseline were 45% at 18-month and 37% at 36-month follow-up. Three factors independently predicted changes in individual's adherence from baseline to 18-month follow-up ($p<0.05$): emotional or physical violence (OR 0.46, CI 0.33;0.65), travel time to clinic >1 hour (OR 0.50, CI 0.29;0.86), and perceived non-confidentiality of clinical information (OR 0.64; CI 0.46;0.88). Average probability of adherence was reduced by becoming exposed to violence (by 27%), >1hour travel to clinic (24%), and non-confidentiality (15%).

CONCLUSIONS: Findings highlight three modifiable areas for intervention. Violence victimisation had the greatest impact, suggesting urgent need for effective violence prevention caregiving programmes. ART distribution through adherence clubs or closer to home may be valuable. Modifying patient flow and mentoring health workers may improve confidentiality. Adolescents need access, trust and care to survive, and their voices will need to inform most relevant solutions.

PDE0305

IMPLEMENTATION OF THE "FIRST FRIENDLY PRACTICE FOR TRANS-FEMALE PEOPLE" AT ARZOBISPO LOAYZA NATIONAL HOSPITAL. A PUBLIC-PRIVATE PARTNERSHIP, LIMA, PERU 2019

M. Muñoz[1], E. Matos[2], N. Bravo[1], M. Caballero[1], J.C. Minano[1], R. Carrasco[3], S. Ramirez[1], M. Guevara[1], L. Mestanza[1], J.L. Sebastian[1]
[1]AIDS Healthcare Foundation, Lima, Peru, [2]Arzobispo Loayza Hospital, Lima, Peru, [3]Continental University, Lima, Peru

BACKGROUND: Trans-gender population is considered at high risk for HIV infection due to multiple factors.

AHF Peru works with trans-female population since 2013, and since 2017, has implemented a "friendly" external consultant for Trans-female patients at Arzobispo Loayza National Hospital (HNAL), with a high impact in the attention of the HIV Trans-Female population.

METHODS: A cross-sectional, retrospective and descriptive study, evaluates the impact of this intervention in the quality of the attention of the Trans female population in Peru.

The work was executed through II phases of implementation:

Phase I: Approach of the female trans population to the friendly service considering a trans female hostess , support with diagnosis and timely linkage to HIV positive through a trans linker, provision of hormones, ensuring a comprehensive health system to 100%.

In this first phase, we targeted 100 transgender people.

Phase II: The trans-female population of Phase I, replicated the intervention and expanded the population by adding the approach to the system, HNAL assumed 100% of the cost of the hormonal treatment.

RESULTS: Before the start of this project, only 06 Trans female person were attended in the HNAL in the period of one year.

Since the start of the implementation of consultant, there was an increase of around 3000% (182) in the number of patients. 87 (48%) were detected as reactive to HIV.

After 10 months of starting care at the "First Friendly Practice for Trans-Female People", the MoH made the purchase and delivery of hormones to the HNAL. Currently, the hormone treatment is guaranteed for free for all female transwomen.

CONCLUSIONS: Adapting the offer of a differentiated and friendly practice for the trans-female population, identifying their needs and values their health priorities, generates confidence and approach of female Trans population to the health system.

PDE0306

'MTV SHUGA': CAN MASS MEDIA COMMUNICATION HIV PREVENTION AND SEXUAL HEALTH IN ADOLESCENT GIRLS AND YOUNG WOMEN IN RURAL SOUTH AFRICA?

M. Shahmanesh[1], N. Mthiyane[2], N. Chimbindi[2], T. Zuma[2], J. Dreyer[2], I. Birdthistle[3], S. Floyd[3], N. Kyegombe[3], S. Danaviah[2], T. Smit[2], G. Harling[1], J. Seeley[3], K. Baisley[3]
[1]University College London, London, United Kingdom, [2]Africa Health Research Institute, Durban, South Africa, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: Adolescent girls and young women (AGYW) in South Africa are at high risk of HIV and early pregnancy. MTV-Shuga, a mass-media edu-drama, improved some sexual health outcomes in a randomised trial amongst young people in Nigeria. We used a national free-to-air TV screening of MTV-Shuga (the "Down South" series), concurrent with the roll-out of a large scale-up of combination HIV prevention for AGYW ("DREAMS"), to test the hypothesis that mass-media edu-drama can improve the sexual health of AGYW in a rural and resource-constrained area of KwaZulu-Natal was evaluated.

METHODS: We followed a representative population-based prospective cohort of females aged 13-23 (between May 2017 and September 2019). We measured the relationship between exposure to MTV-Shuga (i.e. reported seeing ≥1 of 24 episodes; able to recall any storyline) and incident HSV-2; incident pregnancy; condom use at last sex; uptake of HIV-testing and contraception; and awareness of HIV Pre-Exposure Prophylaxis (PrEP).

RESULTS: Of 2184 (85.5%) eligible participants that were surveyed at baseline, 2016 (92.3%) had at least one follow-up visit. MTV-Shuga exposure at baseline was low - 308 (14.1%) reported seeing ≥1 episode and 121 (5.5%) recalled any storyline. Teenage pregnancy and incident HSV-2 were high: 9.1 (95%CI: 9.2-11.4) and 15.3 (95%CI: 13.5-17.3) per 100 person-years respectively. MTV-Shuga exposed AGYW were from wealthier households, urban areas, and more likely to have been received DREAMS interventions (all p<0.001). After adjusting for these confounders, watching MTV-Shuga was associated with significantly greater awareness of PrEP (aOR=2.06, 95%CI: 1.57-2.70), contraception uptake (aOR=2.08, 95%CI: 1.45-2.98), consistent condom use (aOR=1.84, 95%CI: 1.24-2.93), and lower probability of early pregnancy (aOR=0.49, 0.26-0.81). Watching MTV-Shuga was not associated with HIV testing (aOR=1.02,95%CI: 0.77-1.21) or acquiring HSV-2 (aOR=1.01, 95%CI: 0.68-1.51).

CONCLUSIONS: In a setting where AGYW remain at high risk for STI, HIV and early pregnancy, the minority who watched the MTV-Shuga edu-drama had better HIV prevention and sexual health outcomes. Further work is needed to explore the pathways through which MTV-Shuga synergises with social norms and interventions on the ground to improve demand and uptake of HIV prevention and sexual health technologies.

PDE0307

A QUALITY IMPROVEMENT COLLABORATIVE (QIC) FOR HIV-POSITIVE ADOLESCENTS TO IMPROVE IMMEDIATE ART INITIATION AT 25 HEALTH FACILITIES (HF) IN LUSAKA, ZAMBIA

G. Dougherty[1], R. Boccanera[2], M.A. Boyd[3], T. Gantt[2], S.C. Kasonka[4], P. Kasonde[4], N. Kaetano[4], C. Madevu-Matson[5], P. Milimo[4], M. Mwamba[4], B. Senyana[5], F. Tsiouris[5], L. Walker[5], N. Zyongwe[6], A. Zulu[4], M. Rabkin[5]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [2]U.S. Health Resources and Services Administration (HRSA), Bethesda, United States, [3]U.S. Centers for Disease Control and Prevention (CDC), Lusaka, Zambia, [4]ICAP Zambia, Lusaka, Zambia, [5]ICAP at Columbia University, New York, United States, [6]Ministry of Health, Quality Assurance, Lusaka, Zambia

BACKGROUND: HIV testing and rapid antiretroviral therapy (ART) initiation are life-saving interventions for adolescents living with HIV (ALWH). In Zambia, the time between HIV diagnosis and ART for ALWH often exceeds the national standard of two weeks, despite rollout of national guidelines, training, and adequate ART supply.

METHODS: In collaboration with the Zambian MOH, HRSA and CDC Zambia, ICAP at Columbia University designed and implemented a QIC to increase the proportion of ALWH (age 10-19) starting ART within two weeks of diagnosis at 25 HF in Lusaka between August 2018 - July 2019. Key indicators were collected at baseline and throughout QIC implementation, which included training on QI methods for 107 HF staff and leaders, monthly QI coaching visits, and quarterly workshops. Each HF QI team identified contextually appropriate interventions; used QI methods and tools to conduct rapid tests of change; and analyzed progress using run charts. QI teams presented their performance and shared best practices at joint quarterly learning sessions.

RESULTS: During the 12-month implementation period, QI teams tested interventions focused on: health worker training, data quality, patient education, workflow processes and community engagement. 205,232 adolescents were tested for HIV during this time: 3,355 (2%) were positive. ART initiation within 2 weeks of diagnosis improved from a median of 24% at baseline to a median of 95% during the final six months of the QIC. Same-day ART initiation improved from a median of 27% at baseline to a median of 94% during the final six months of the QIC.

CONCLUSIONS: The QIC approach improved immediate ART initiation for ALWH by helping QI teams generate local innovations to identify and link ALWH to ART. In addition to building QI capacity

and improving targeted outcomes, the QIC resulted in a "change package" of successful initiatives that will be disseminated within Zambia.

PDE04 HOW DATA IS LEADING INNOVATION: EVIDENCE INFORMED PROGRAMMES

PDE0402

IMPROVING ACCESS TO QUALITY HIV SERVICES IN 11 WEST AFRICAN COUNTRIES: IMPACT OF A REGIONAL COMMUNITY TREATMENT OBSERVATORY

G. Oberth[1], S. Baptiste[2], W. Jallow[3], A. Manouan[4], P. Garcia[4], A. Traore[4], J. Murara[4], R. Boka[5], V. Keïpo[4]
[1]University of Cape Town, Center for Social Science Research, Cape Town, South Africa, [2]International Treatment Preparedness Coalition (ITPC), Johannesburg, South Africa, [3]International Treatment Preparedness Coalition (ITPC), Gaborone, Botswana, [4]International Treatment Preparedness Coalition (ITPC), Abidjan, Cote D'Ivoire, [5]International Treatment Preparedness Coalition - West Africa (ITPC-WA), Abidjan, Cote D'Ivoire

BACKGROUND: In West and Central Africa, 64% of people living with HIV (PLHIV) are aware of their status, 51% are accessing antiretroviral therapy (ART), and 39% are virally suppressed. Progress is stymied by low demand for services, frequent stock-outs, weak health systems and poor quality of care. In 2017, the International Treatment Preparedness Coalition (ITPC) established a Regional Community Treatment Observatory in West Africa to increase accountability for the 90-90-90 targets.

METHODS: ITPC trained and supported national networks of PLHIV to collect and analyze facility-level HIV treatment data from 125 health centers in 11 West African countries. From January 2018-June 2019, the treatment observatory completed 1781 monthly monitoring reports, 1501 interviews and 143 focus group discussions. Feedback was provided to patients, health center staff and government decision-makers through real-time alerts, quarterly reports, and multi-stakeholder dialogues.

RESULTS: At the monitored health centers, the frequency of ART stock-outs decreased from 23.6% (95% CI 19.9-27.2) in the first six-month period, to 16.4% (95% CI 13.6-19.3) in the second, to 15.2% (95% CI 12.3-18.1) in the third. In one country, the average duration of stock-outs fell from 52.9 days (95% CI 33.4-86.3), to 32.9 days (95% CI 24.1-41.8), to 22.5 days (95% CI 9.4-35.6). The number of viral load tests performed more than doubled, from 16,532 in the first period, to 31,472 in the second, to 33,376 in the third. The rate of viral suppression increased dramatically, from 48.3%, to 67.9%, to 77.4%, respectively. In the third period, 30% of viral load results were returned within two weeks, up from 26% in the first period and 27% in the second. While quality of care steadily improved – from 3.8 (out of 5), to 4.0, to 4.2 – young women were twice as likely as the general population to say that unfriendly health workers were a barrier to services.

CONCLUSIONS: When communities of PLHIV are activated to monitor HIV services, access and quality improves. The treatment observatory changed the way that networks of PLHIV were perceived, creating a culture of collective problem-solving among patients, healthcare workers and policy-makers. The approach should be expanded to achieve global targets.

PDE0403

IMPLEMENTING A "LOW DOSE HIGH FREQUENCY" CAPACITY BUILDING APPROACH FOR HIV SERVICE DELIVERY IN UGANDA'S MILITARY HEALTH FACILITIES

D. Bwayo[1]
[1]URC, Program, Kampala, Uganda

BACKGROUND: Evolving evidence indicates that Continuous capacity building (CB) is critical for improving health workers' knowledge and is used to inform HIV care guidelines. The lack of standard appropriately tailored CB content and delivery mechanisms contributes to non-adherence to evidence-based practices with less than optimal HIV care service delivery. The Low Dose High Frequency (LDHF) CB approach has been shown to be comparatively effective and impactful. We describe the URC-Department of Defense HIV/AIDS Prevention Program LDHF approach and its effect on HIV services within the Uganda military health services.

DESCRIPTION: We implemented a LDHF approach that entailed; initial startup training of health workers followed by bi-monthly on-site mentorship, coaching and feedback session at 28 military health facilities over a 6 months period. Using mixed methods, we assessed health workers' response to the approach and adherence to HIV guidelines. Data was abstracted from 541 client records with 12 health workers interviewed.

LESSONS LEARNED: Overall, health workers were positive to the LDHF approach which resulted into improvement in quality of care. Prescriptions for recommended first line ART regimen improved from 82% to 95%; timely due viral load test ordering increased from 45% to 80%; timely initiation of adherence counseling for non- suppressed clients increased from 32% to 55%; and appropriate switching of patients on failing regimes improved from 23% to 51%. Key barriers to adherence to guidelines raised by the health workers were; burdensome reporting requirements, work overload, complex guidelines, lack of capacity in pediatric guidelines, inability to timely follow up of some patients and frequent changes in existing guidelines.

CONCLUSIONS/NEXT STEPS: The LDHF CB model was acceptable to health workers and results in adherence to HIV guidelines. However, comprehensive adherence to the guidelines requires addressing other health system and patient-related factors that cannot be resolved by the LDHF approach alone.

PDE0404

ARE ART PATIENTS WHO MISS APPOINTMENTS REALLY LOST? DETERMINING TRUE PATIENT OUTCOMES THROUGH TRACING IN 7 REGIONS OF NAMIBIA

L. Bikinesi[1], I.C. Pietersen[2], S. Hong[2], T. Negussie[1], B. Seolwane[3], N. Hamunime[1], L. Ashipala[1], E. Dziuban[2], G. Mutandi[2], A. Knutson[4], D. Cockburn[3], A. Besa[3]
[1]Ministry of Health and Social Services, Windhoek, Namibia, [2]Centers for Disease Control and Prevention, Windhoek, Namibia, [3]Development AID from People to People, Windhoek, Namibia, [4]Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: Namibia's standard of care for antiretroviral therapy (ART) includes phone and physical tracing of treatment defaulters. Development Aid from People to People Namibia (DAPP) is a community-based PEPFAR implementing partner providing sup-

port to the Ministry of Health and Social Services with community tracing. DAPP obtains from public health facilities a list of patients who missed their appointments from seven days to a month. Tracing is conducted telephonically and physically. Transfers are verified with the health facilities.

METHODS: Program data were analyzed for DAPP from seven high burden regions for the period of October 2018-September 2019. Key analytic outcomes were traced and untraced; with traced further classified into alive, died, and unable to locate; and with those alive classified into confirmed missing, confirmed active, silent transfer, facility transfer out, and unable to locate; and with those confirmed missing further classified into re-engaged and confirmed active, promised to return to care, and refused.

RESULTS: Results: The graph below shows tracing outcomes.

CONCLUSIONS: Most patients thought to be missing appointments were still active in care in the same ART clinic or at another ART clinic. Of those patients truly missing, most were able to be re-engaged into care through tracing. This model of tracing is being scaled throughout all ART clinics in Namibia.

PDE0405

INTEGRATION OF KEY POPULATION CLASSIFICATION INTO NATIONAL ROUTINE HIV TESTING SERVICES IN MOZAMBIQUE, 2019

J. De Seleme[1], A. Couto[1], N. Chicuecue[1], G. Amane[1], R. Hoek[1], M. Cunha[1], H. Magaia[1], I. Sathane[1]
[1]Ministry of Health of Mozambique, STI and HIV/AIDS Control Program, Maputo Cidade, Mozambique

BACKGROUND: Though over one-quarter of new HIV infections are among key populations (KP), there is a dearth of national-level cascade program data for KP in higher prevalence countries. Expansion of HIV Testing Services (HTS) in Mozambique with provision of KP-specific care has created an opportunity to collect timely national program data on KP, specifically female sex workers (FSW), men who have sex with men (MSM), people who inject drugs (PWID), and prisoners. This information can provide essential, timely information for optimal resource allocation, programmatic decisions, and contribute to the body of knowledge on KP in the region.

DESCRIPTION: In March 2019, the Ministry of Health updated HTS data tools to enable collection of key population status and test result data at all public HTS facilities in Mozambique (n = 1,634). HTS providers were trained using a KP package that included sensitization materials and a risk behavior classification algorithm to identify and record KP status on HTS paper-based forms, which are aggregated at the clinic level and digitized into a national database.

LESSONS LEARNED: We analyzed HTS routine program data from April to December 2019. Of 2,709,331 persons receiving HIV counseling and testing during this time, 37,223 (1.4%) were identified as KP; 503 (0.02%) were PWID and 6,022 (0.22%) were prisoners. Among females tested, 26,471 (1.8%) were FSW. Among males tested, 4,227 (0.4%) were MSM. The proportion testing positive was highest among PWID (18%) and lowest among prisoners (11%). Among MSM, 15% were positive compared to 6% of males not classified as MSM. Among FSW, 13% tested positive for HIV compared to 6% among non-FSW classified women.

CONCLUSIONS/NEXT STEPS: Mozambique is among the first high HIV prevalence countries to collect national program data on KP status at all public HTS sites. Data confirms feasibility of capturing KP status country-wide. The granular level and timely information on KP at facility, district and national level can complement other surveillance data such as KP size estimations and behavioral surveillance surveys to better assess the roll of KP in national and sub-national HIV epidemics, and helps with planning and allocating prevention and treatment resources appropriately.

PDE0406

MODELING DIFFERENTIATED HIV SERVICES FOR TRANSGENDER PEOPLE: EXPERIENCES FROM MAHARASHTRA, INDIA

J. Kirubakaran[1], S. Acharya[2], L. Gabhane[3], S. Katkar[2], M. Setia[4], S. Panyam[5], S. Talwar[6], S. Mathew[7], P. Goswami[8], G. Shreenivas[8], J. Baishya[9], B. George[8], P.S. Keskar[2]
[1]Consultant Public Health Expert, New Delhi, India, [2]Mumbai District AIDS Control Society (MDACS), Mumbai, India, [3]Maharashtra State AIDS Control Society (MSACS), Mumbai, India, [4]Consultant, Epidemiologist, Mumbai, India, [5]Consultant Monitoring and Evaluation Expert, Hyderabad, India, [6]Consultant Program Management Expert, Mumbai, India, [7]Consultant Strategic Information Expert, Bengaluru, India, [8]FHI360, New Delhi, India, [9]USAID/India, New Delhi, India

BACKGROUND: In India, HIV services for key populations are delivered through targeted interventions (TIs) implemented by non-governmental organizations and funded by the National AIDS Control Organization (NACO). To maximize impact, optimized service delivery approaches are needed to meet the differentiated preferences of key population members with elevated risks.

METHODS: In collaboration with Maharashtra/Mumbai AIDS Control Societies and NACO, we developed and validated a model to prioritize service delivery for transgender people under the PEPFAR/USAID-supported and FHI 360-led LINKAGES project. We analyzed routinely collected program data from two transgender TIs in Maharashtra, covering demographics, risk behavior, vulnerabilities, and biological outcomes from April 2016–March 2018. Individuals' behavioral data prior to HIV testing were linked to their test results, generating 3,938 data points. We used penalized regular logistic regression analyses to estimate the odds ratio, 95% confidence intervals of HIV positivity, and prospective explanatory variables; the best model was used for dominance analyses to estimate the weights. The final model was applied prospectively in two transgender TIs to study their efficiency in segmenting transgender people for differentiated prevention services.

RESULTS: In the data set for generating the model, the HIV positivity proportion was 0.94%. The factors associated with HIV positivity were being transgender for less than three years (p<0.001) and ever having missed a condom in the last 10 sex acts (p=0.01), which were assigned the highest weights. We used an optimal

cutoff for identifying high-priority and moderate-priority groups; the sensitivity for HIV positivity was 83.8%, and negative predictive value was 99.8%. At this cutoff, the proportion of HIV positivity in the high-priority group was significantly higher compared with the moderate group (p=0.007). Among the 1,785 transgender people prospectively categorized into priority groups, 1,276 (71.5%) were considered high priority. All 27 HIV cases were from the high-priority group (p<0.001).

CONCLUSIONS: The model demonstrated effective, precise categorization of transgender people at increased HIV risk, supporting the need for differentiated efforts for priority subgroups. Based on this successful experience, a national-level model has been developed as part of NACO's revised/revamped TI strategies.

PDE0407

A NATIONAL ELECTRONIC SYSTEM TO SUPPORT ANTIRETROVIRAL (ART) INITIATION OF PEOPLE LIVING WITH HIV IN BRAZIL AT SITE LEVEL

R. Vianna Brizolara[1], T. Cherem Morelli[2], P. Emília Adamy[1], A. Alberto Cunha Mendes Ferreira[1], R. Castro de Albuquerque[1], A. Francisca Kolling[1], M. Camelo Madeira de Moura[1], A. Sposito Tresse[1], G. Fernando Mendes Pereira[1], M. Araújo de Freitas[1]
[1]Ministry of Health of Brazil, Department of Chronic Diseases and Sexually Transmitted Infections, Brasília, Brazil, [2]Ministry of Health of Brazil, Department of Chronic Disease and Sexually Transmited Infectiouns, Brasília, Brazil

BACKGROUND: After national implementation of Test and Start strategy, Brazilian Ministry of Health (MOH) developed an electronic system to support immediate ART initiation of people living with HIV (PLHIV) in Brazil linked to care at site level. The Clinical Monitoring System of People Living with HIV (SIMC) was launched in 2013 and was made available countrywide.

DESCRIPTION: HIV services of the national health system are granted access electronically through SIMC to on-line lists of HIV-positive individuals older than 12 y.o with at least one VL exam who have not started ART. Lists are automatically generated on a monthly basis by the MOH, with the linkage of the national ART with the laboratory VL database. Lists of patients are specific for each HIV service, so that health care workers have access to information of their own patients only. The situation of each patient in the list is analyzed by HIV services and outreach activities are conducted so that patients have their treatment started. The use of SIMC counts entirely with the existing structure of the National Health System and does not require additional funds. By December 2019, 2,948 health workers from 1,692 health services had access to the system.

LESSONS LEARNED: From December 2013 to December 2019, SIMC identified 209,746 PLHIV who had not started ART: 82,3% (172,526) were analyzed - 73,5% (154,215) started treatment over the period, 2,8% (5,949) were dead, 0,4% (743) were transferred, 2,9% (6,065) were not located, 0,6% (1,274) refusal treatment, 1,2% (2,488) were duplicates and 0,9% (1,792) others. 17,7% (37,220) haven't yet been analyzed. In the same period, time from linkage to care and ART initiation in Brazil decreased from 182 to 33 days.

CONCLUSIONS/NEXT STEPS: SIMC has proven to be useful to support ART initiation at site level and stands as an important national strategy to improve access to care and treatment services and reduce time from diagnosis to ART initiation. Moving forward, in 2020 MOH will include in SIMC individuals below 12 y.o and link other national surveillance systems, in order to include all PLWHIV who were tested positive for HIV but did not have a VL exam.

PDE05 MONEY DOESN'T GROW ON TREES: AFFORDABILITY AND COST-EFFECTIVENESS IN THE HIV RESPONSE

PDE0502

COST-BASED ESTIMATED PRICES FOR KEY HIV, HCV, AND MDR-TB MEDICINES

M. Barber[1], D. Gotham[2], A. Hill[3]
[1]Harvard University, Global Health and Population, Boston, United States, [2]Independent, London, United Kingdom, [3]University of Liverpool, Department of Translational Medicine, Liverpool, United Kingdom

BACKGROUND: Prices for treatments for HIV and coinfections vary substantially between countries, with high prices limiting treatment access in many settings. Scaling up of generic HIV manufacture has enabled massive expansion of global treatment programs. The cost of active pharmaceutical ingredient (API) is a significant determinant of the cost of production. The aim of this analysis was to estimate cost-based prices that could be achieved with robust generic competition for WHO-recommended treatments for key HIV, hepatitis C virus (HCV), and multidrug-resistant tuberculosis (MDR-TB) medicines, and to compare them with current prices.

METHODS: Active pharmaceutical ingredient (API) price and volume data were collected from an online database (Panjiva) of export data from India. Cost-of-production was then calculated using an established algorithm, accounting for API costs, excipients (API x 2 x $2.63), formulation ($0.01/pill), tax obligations on profit assuming manufacture in India (27%), and a 10% profit margin. List prices for key HIV, TB, and HCV drugs were extracted from national drug price databases in 7 countries for comparison.

RESULTS: Table 1 shows current prices of antiretrovirals for HIV (per year), direct-acting antivirals for HCV (per 12 week course), and solid oral formulations for tuberculosis (per month). API costs/kg were $1500 for dolutegravir (DTG), $5000 for tenofovir alafenamide (TAF), $150 for tenofovir disoproxil fumarate (TDF), $900 for darunavir (DRV), $700 for sofosbuvir (SOF), $600 for daclatasvir (DCV), $6000 for velpatasvir (VEL), $250 for moxifloxacin (MFX), and $100 for linezolid (LZD). There was inadequate data to determine glecaprevir+pibrentasvir (G+P) API prices.

	Estimated cost-based price	Argentina	Brazil	India	Russian Federation	Thailand	Ukraine	USA (Veterans Affairs)
DTG	$35	$7,408	$3,687	$574	$1,672	$3,695	$4,467	$12,520
TAF	$25	$3,717	-	$252	-	-	-	$9,026
TDF	$23	$2,807	$1,913	$174	$40	$131	$1,832	$264
DRV	$455	$6,162	$1,955	$841	-	$1,410	-	$6,441
SOF+VEL	$85	$37,499	$13,632	-	-	-	-	$17,965
SOF+DCV	$31	$30,012	$25,732	$41	$8,976	$7,021	$78	$111,659
G+P	-	$24,085	$12,724	-	-	-	-	$19,014
MFX	$4	$93	$62	$6	$43	$91	$33	$70
LZD	$5	$9	$45	$2	$3	$11	$12	$5,260

[HIV (yearly), HCV (per course), TB (monthly). USD.]

CONCLUSIONS: Current prices for medicines are up to 1000 times more than cost-based estimated generic prices. Originator prices are often incongruous with country income level, with implications for access and scale-up of treatment programs.

PDE0503

HEALTHCARE RESOURCE USE AND RELATED COST OF NON-HIV COMORBIDITIES MANAGEMENT IN PEOPLE LIVING WITH HIV IN A SPANISH COHORT FROM 2007 TO 2017

Y. Milanes Guisado[1], F. Jodar[2], D. Sánchez Pardo[3], J. Moreno[3], P. Viciana[1], C. Roca[1]
[1]Institute of Biomedicine of Seville/Virgen del Rocio Hospital, Infectious Diseases, Seville, Spain, [2]Institute of Biomedicine of Seville, Medical Informatics and Health Economics, Seville, Spain, [3]Institute of Biomedicine of Seville/Virgen del Rocio Hospital, Medical Informatics and Health Economics, Seville, Spain

BACKGROUND: Few studies have assessed the economic impact of non-HIV comorbidities in people living with HIV (PLHIV) during a long follow-up period. Our objective was to estimate the cost and healthcare resources use associated to the prevalence of comorbidities in PLHIV in a Spanish cohort along 11 years.
METHODS: From 2007 to 2017, patients with at least one follow-up visit were included. PLHIV were categorized into 2 groups according to time of diagnosis: before 2007 (Pre_2007 group) and after 2007 (Post_2007). The cost categories evaluated were Hospitalizations, Ambulatory costs, Emergency visits, Laboratory testing, HIV Antiretroviral therapy (ART), and Other Non-HIV tests. Generalized linear models and cross-validation were used to evaluate predictors of total care cost for overall population and by stratified groups
RESULTS: The study included 2.803 PLHIV (21.385 p-y), 82.9% were men, median age at entry was 39 years (Interquartile Range (IQR): 32-44). 1.660 (59.2%) were included in Pre_2007 Group and 1.143 in Post_2007, 8.9 ± 3.40 and 5.8 ± 2.8 years of follow-up, respectively (p-value < 0.001). Overall, 1.623 (57.9%) presented at least one non-HIV comorbidity, 826 (29.3%) had 3 or more comorbidities during follow-up. The most prevalent non-HIV comorbidities were hypertension (28.5%), Diabetes (13.7%), Bacterial infections (13.4%), and Cardiovascular diseases (12.8%). The presence of comorbidities increases total healthcare cost by 47%. The highest cost increase of 65% was observed in PLHIV with 3 or more comorbidities compared to PLHIV with no comorbidities (over the 11-year period, 115.435 ± 57.870€ vs. 69.795 ± 47.931€, p-value <0.001). The mean annual cost per patient was higher in Pre_2007 group with comorbidities compared to the Post_2007 cohort (14.218 ± 11.117€ vs.12.159 ± 8.207€, p-value < 0.001 for interaction); due to a higher mean age and longer follow-up. Patterns are similar if ART costs are excluded. There was a positive correlation between the presence of comorbidities and healthcare costs in PLHIV, both for the overall population and for stratified groups for adjusted models.
CONCLUSIONS: The presence of comorbidities increases the total healthcare cost of PLHIV, being more relevant in older patients. Both clinical and economic decision-makers should consider and evaluate cost of comorbidities when evaluating HIV treatment guidelines or recommendations

PDE0504

THE CLINICAL AND ECONOMIC IMPACT OF GENOTYPIC RESISTANCE TESTING AFTER VIROLOGIC FAILURE ON FIRST-LINE TENOFOVIR-LAMIVUDINE-DOLUTEGRAVIR IN SOUTH AFRICA

E.P. Hyle[1,2], C.M. Dugdale[1,2], A.C. Bangs[1], L.-G. Bekker[3], M.J. Siedner[1,2], S.M. McCluskey[1,2], P.E. Sax[2,4], A.L. Ciaranello[1,2], J.A. Scott[1], R.T. Gandhi[1,2], M.C. Weinstein[5], K.A. Freedberg[1,2], R. Wood[3], R.P. Walensky[1,2]
[1]Massachusetts General Hospital, Department of Medicine, Boston, United States, [2]Harvard Medical School, Boston, United States, [3]The Desmond Tutu HIV Center, University of Cape Town, Cape Town, South Africa, [4]Brigham and Women's Hospital, Medicine, Boston, United States, [5]Harvard T. H. Chan School of Public Health, Department of Health Policy and Management, Boston, United States

BACKGROUND: Treatment-emergent resistance is rare when tenofovir-lamivudine-dolutegravir (TLD) is used as first-line ART. We examined the clinical and economic impact of genotypic resistance testing (GRT) for adults in South Africa with virologic failure (VF) on first-line TLD despite 3m of enhanced adherence counseling (EAC).
METHODS: We used the CEPAC-International model to compare four strategies among adults with VF on TLD after EAC: 1) "*GRT*" to distinguish people with susceptible virus (VF_S) who continue TLD from people with dolutegravir-resistant virus (VF_R), who switch to second-line ART (LPV/r+AZT/3TC); 2) "*Immediate switch*" to second-line; 3) "*EAC+*," additional EAC while continuing TLD with switch to second-line for anyone with persistent VF at 6m; 4) "*TLD*," remaining on TLD indefinitely. We assumed 1% of VF were VF_R and mean ART adherence was better among VF_R (85%) than VF_S (78%). We estimated 48-wk virologic suppression based on trial data and adherence (Table). Costs included TLD ($70/yr), LPV/r+AZT/3TC ($270/yr), and genotypes (RT and IN, $290/total). Outcomes were life expectancy (LE), HIV-related costs, and incremental cost-effectiveness ratios (ICERs, Δ$/ΔLE). Sensitivity analyses included %VF_R, ART effectiveness (Table), second-line cost ($60-270/yr), and genotype cost ($50-290/total).

Model Input Parameters	VF_R, Base Case (Range)		VF_S, Base Case (Range)		
Prevalence among those with VF	1% (0-20%)		99% (80-100%)		
48-week suppression	TLD: 35% (25-59%) LPV/r+AZT/3TC: 73% (62-85%)		TLD: 68% (50-71%) LPV/r+AZT/3TC: 60% (50-70%)		
Modeled Outcomes	**Undisc. LY**	**Undisc. Costs ($)**	**Disc. LY**	**Disc. Costs ($)**	**ICER ($/YLS)***
TLD	26.13	14,400	15.97	9,000	-
GRT	26.35	14,800	16.08	9,400	3,100
EAC+	26.02	17,500	15.90	10,700	Dominated
Immediate switch	25.52	19,200	15.61	12,000	Dominated

VF_R: virologic failure with resistant virus; VF_S: virologic failure with susceptible virus; GRT: genotypic resistance testing; TLD: tenofovir-lamivudine-dolutegravir; LPV/r+AZT/3TC: lopinavir-ritonavir+zidovudine-lamivudine; Undisc: undiscounted; Disc: discounted; LY: life years; ICER: incremental cost-effectiveness ratio; YLS: year-of-life-saved.
*We calculated ICERs using LYs and costs discounted at 3%/year. We considered strategies to be cost-effective if ICER<$1,175/YLS (Woods et al. 2015) or ‚dominated' if clinical outcomes were worse at higher cost.

[Table. Selected model input parameters and modeled outcomes regarding the clinical and economic impact of genotypic resistance testing after virologic failure on first-line tenofovir-lamivudine-dolutegravir in South Africa.]

RESULTS: *GRT* resulted in longer LE at lower costs than *EAC+* and *Immediate switch* (Table). *GRT* became cost-effective versus *TLD* (ICER<$1,175/YLS) at genotype cost ≤$60 or VF_R prevalence ≥5%. In sensitivity analyses, *GRT* remained clinically preferred unless virologic suppression for VF_S was higher on second-line than TLD; even then, *GRT* remained the most economically efficient strategy, unless second-line also cost less than TLD.

CONCLUSIONS: A strategy offering genotypic resistance testing after virologic failure on TLD resulted in the best clinical outcomes at lower cost than *EAC+* or *Immediate switch* and was cost-effective versus *TLD* at lower genotype cost (≤$60) or ≥5% dolutegravir resistance. Scaling up capacity for genotype in resource-limited settings is a rational addition to TLD rollout.

PDE0505

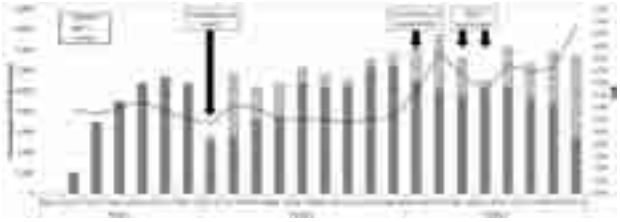
PREPARING FOR SCALE-UP: THE CHANGING COST AND COST-EFFECTIVENESS OF HIV SELF-TESTING INTEGRATION INTO COMMUNITY-BASED MOBILE OUTREACH AND INDEX HIV TESTING MODELS IN LESOTHO

M. d'Elbée[1], M.C. Makhetha[2], M. Jubilee[3], K.M. Maphatsoe-Pule[2], M. Taole[2], S. Nako[2], C. Nkomo[2], A. Machinda[2], M. Tlhomola[4], L. Sande[5,1], L. Corbett[5,6], C.C. Johnson[7], K. Hatzold[8], G. Meyer-Rath[9,10], F. Terris-Prestholt[1]

[1]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [2]Population Services International, Maseru, Lesotho, [3]John Snow, Inc, Lusaka, Zambia, [4]Ministry of Health, Maseru, Lesotho, [5]Malawi Liverpool Wellcome Trust Research Programme, Blantyre, Malawi, [6]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [7]World Health Organisation, Department of HIV, Hepatitis and STIs, Geneva, Switzerland, [8]Population Services International, Johannesburg, South Africa, [9]Health Economics and Epidemiology Research Office - University of the Witwatersrand, Department of Internal Medicine, Johannesburg, South Africa, [10]Boston University, School of Public Health, Boston, United States

BACKGROUND: In Lesotho, 25.6% of adults are living with HIV (PLHIV) with only 81% aware of their status. HIV self-testing (HIVST) was added to existing mobile outreach and index testing (HTS) in five priority districts in 2017. We investigated costs and yield as the programme evolved (Figure 1).

METHODS: We evaluated programme costs before/after HIVST addition (Period 1 and 2: Figure 1), and after encouraging clients to use onsite HIVST booths (Period 3) allowing multiple clients to self-test concurrently and immediately link to confirmatory testing. We estimated full economic costs for mobile HTS, including central costs, and only incremental cost of adding HIVST onto HTS as well as overall cost-effectiveness of all testing.



[Figure 1. Outcomes of the ongoing HIV testing programme between May-2017 and April-2019.]

Yield corresponds to new HIV-positive cases among clients tested with HTS, including confirmatory testing following a reactive self-test

RESULTS: The introduction of onsite HIVST increased HIV yield in all districts (Figure 1). For both HTS and HIVST programmes, the drivers of costs are personnel and testing supplies (Table 1). Costs per new HIV-positive case identified increased between period 1 and period 2 but was the lowest in period 3 when onsite HIVST was introduced.

US$ 2019	Period 1		Period 2				Period 3			
Cost inputs	HTS	%	HTS	%	HIVST	%	HTS	%	HIVST	%
Personnel & Per diems	$546,031	67%	$614,262	65%	$72,445	75%	$781,795	74%	$23,121	33%
Supplies (rapid tests, HIVST kits, consumables)	$115,657	14%	$86,126	9%	$17,396	18%	$75,490	7%	$34,510	49%
Others (start-up and central costs, capital (vehicle), and other recurrent costs: fuel, waste, etc.)	$157,953	19%	$245,824	26%	$7,395	7%	$203,146	19%	$12,941	18%
Total costs – HTS and HIVST programme	$819,641	100%	$946,212	100%	$97,236	100%	$1,060,431	100%	$70,572	100%
Total costs - HIV testing programme	$819,641		$1,043,448				$1,131,003			
Total number of new HIV-positive cases identified	858		836				1,392			
Cost per new HIV-positive case identified	$955		$1,248				$813			

[Table 1. Three-month averages of costs and outcomes of the HTS/HIVST programme by period]

CONCLUSIONS: Continuous programme learning is critical for sustainable scale-up. The introduction of HIVST improved overall programme efficiency and cost-effectiveness once onsite self-testing became available. Additionally, our HIVST incremental costs assume that the existing HTS programme is adequately funded, which should considered when planning for scale-up.

PDE0506

SINGLE VERSUS MULTIPLE TABLET REGIMENS FOR FIRST-LINE ANTIRETROVIRAL TREATMENT OF HIV: A REAL-WORLD COST-EFFECTIVENESS ANALYSIS USING A PATIENT COHORT IN BRAZIL

J. de Oliveira Costa[1,2], W. Botha[1], M.d.G. Braga Ceccato[3], S. Pearson[1], S. Goodall[4], F. de Assis Acurcio[3,2], ECOART Project Group

[1]UNSW Sydney, Centre for Big Data Research in Health, Sydney, Australia, [2]Universidade Federal de Minas Gerais, Post-Graduation Program in Public Health, Belo Horizonte, Brazil, [3]Universidade Federal de Minas Gerais, Department of Social Pharmacy, Belo Horizonte, Brazil, [4]University of Technology Sydney, Centre for Health Economics Research and Evaluation, Sydney, Australia

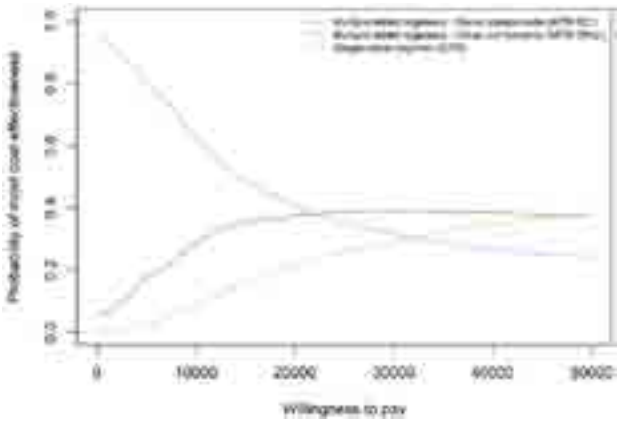
BACKGROUND: Single-tablet regimens (STR) are as effective in improving antiretroviral therapy outcomes and cost-effectivene when compared with multiple-table regimens (MTR) based on clinical trial data. However, there is currently no evidence on the real-world cost-effectiveness of STR in the Brazilian context.

METHODS: Data from 440 people initiating antiretroviral therapy in 2014 and 2015 in Belo Horizonte, Brazil were analysed. We compared the STR containing tenofovir, lamivudine, efavirenz to multiple-tablet regimens with the same components (MTR-SC) or different components (MTR-Other). We assigned effectiveness and costs to the initiating therapy and defined effectiveness as the probability of achieving viral suppression (viral load < 50 copies/ml) after 12 months of therapy. The cost analysis was adjusted for censoring and a public payer perspective was adopted, which included direct medical costs.

RESULTS: A total of 185 (42.0%) patients initiated STR, 189 (43.0%) MTR-SC and 66 MTR-Other. Overall, 64.3% of patients achieved viral suppression and the average annual cost per patient was US$ 1,544 (SD 3,803). STR was as effective but a lower cost option when compared to MTR, hence it dominates MTR (Table). The lower cost of STR was driven by a lower utilization of specialists' visits, laboratory exams, and by the lower cost of antiretroviral therapy, despite no differences in the number of dispensations among groups. STR is the optimal choice for payers with a willingness to pay threshold below US$ 19,500- 21,500 (Figure).

Outcomes after 12 months of follow-up	STR (n = 185)	MTR-SC (n = 189)	MTR-Other (n = 66)	p-value*
Supressed viral load, % (95% CI)	62.7 (55.7; 69.7)	65.1 (58.2; 71.9)	66.6 (55.0; 78.3)	0.812
Total mean cost per patient, US$ (SD)	1,102 (2,776)	1,572 (3,453)	2,706 (6,283)	0.013
Cost per responder ratio (95% IC)	1,757 (1,178; 2,461)	2,415 (1,788; 3,289)	4,059 (2,202; 7,084)	-
Incremental cost-effectiveness ratio, US$/responder	Reference	19,583	41,128	-

CI: Confidence interval, MTR-Other: multi tablet regimen with different components of STR, MTR-SC: multi tablet regimen same components of STR, SD: Standard deviation, STR: Single tablet regimen containing tenofovir disoproxil fumarate, lamivudine, efavirenz, 1 US$ = 1.996 R$
* $\chi 2$ test or Student-t tests, where appropriate



[Figure. Cost-effectiveness acceptibility curve for multiple comparisons]

CONCLUSIONS: We identified that generic STR is the most cost-effective regimen when compared to all other multiple-tablet regimens available in the period analyzed. This regimen should be the standard comparator for future evaluations and the preferred first-line therapy in the Brazilian health system.

PDE0507

THE IMPACT AND COST-EFFECTIVENESS OF EXPANDING CRYPTOCOCCAL ANTIGEN SCREENING TO INCLUDE INDIVIDUALS WITH CD4 100-200 CELLS/µL IN BOTSWANA

C. Muthoga[1,2], M.W. Tenforde[2,3,4], P. Ponatshego[1,2], J. Ngidi[1,5], M. Mine[6], B. Larson[6], J.N. Jarvis[1,7]
[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Botswana-UPenn Partnership, Gaborone, Botswana, [3]University of Washington School of Medicine, Seattle, United States, [4]University of Washington School of Public Health, Seattle, United States, [5]National Health Laboratory, Gaborone, Botswana, [6]Boston University School of Public Health, Boston, United States, [7]London School of Hygiene & Tropical Medicine, London, United Kingdom

BACKGROUND: Cryptococcal antigen (CrAg) screening and pre-emptive fluconazole for CrAg-positives reduces incident cryptococcal meningitis (CM) and all-cause mortality in persons with advanced HIV starting antiretroviral therapy (ART). The WHO conditionally recommended increasing CrAg screening thresholds from CD4<100 to <200 cells/µL in those initiating or re-initiating ART, but the benefit of this increase in CD4 threshold is unknown. We evaluated the marginal impact and cost-effectiveness of reflex CrAg screening among patients with CD4 100-200 cells/µL in Botswana, a country with a mature ART program still performing CD4 count monitoring post-ART initiation.

METHODS: We developed a decision analytic model to evaluate laboratory-based CrAg screening at CD4 counts of 100-200 cells/µL using local CD4 distribution, CrAg prevalence, titer, and ART status data from 2019. We estimated CM cases and deaths averted, and cost per disability-adjusted life year (DALY) averted with nationwide implementation of CrAg screening in this group compared to the current policy of no screening.

RESULTS: An estimated 34,775/650,000 (5.35%) CD4 tests nationwide in 2019 were 100-200 cells/µL; of these, 2.5% were CrAg-positive and eligible for pre-emptive therapy with 20% having a high CrAg titer (>1:160) indicating higher risk of CM progression. Only 15% were ART-naïve; 25% of ART-experienced were classified as defaulters / treatment failures. Without screening, 129 CM cases (36 in ART-naïve) and 77 CM-related deaths (21 in ART-naïve) occur. With screening and pre-emptive fluconazole for ART-naïve patients only, an estimated 6 deaths and 123 DALYs are averted at a cost of US$1385/DALY averted. With treatment extended to ART-naïve and ART-experienced, 43 deaths and 919 DALYs are averted at a cost of US$244/DALY averted.

CONCLUSIONS: In a mature ART program with routine CD4 monitoring, a low proportion of CrAg-positive patients with a CD4 100-200 cells/µL were ART-naïve. Pre-emptive treatment in ART-naïve has only a marginal impact and modest cost per death or DALY averted. Assuming a benefit in treating ART-experienced individuals (a proportion of whom are reinitiating ART), screening and pre-emptive treatment has greater impact and is more cost-effective. CrAg screening in the CD4 100-200 cells/µL group should include ART-experienced individuals, who now make up a majority of CM cases.

PDF01 QUEER EYE: A FOCUS ON GENDER DIMENSIONS IN HIV PROGRAMMING

PDF0102

STRONG IN DIVERSITY: BUILDING INTERSECTIONALITY IN CREATING AN ENABLING ENVIRONMENT FOR HIV WORK IN EAST JAVA, INDONESIA

D. Oetomo[1]
[1]*GAYa NUSANTARA Foundation, Surabaya, Indonesia*

BACKGROUND: In the past three years Indonesia has experienced a politicized moral panic involving homophobia, transphobia, demonization of PLHIV and people who use drugs, and more generally other religious and social minorities. Human Rights Watch summarized the problem for HIV work among sexual minorities in its report: https://www.hrw.org/report/2018/07/01/scared-public-and-now-no-privacy/human-rights-and-public-health-impacts-indonesias.. Civil society has fought back intersectionally to create and maintain equity and equality, including advocating for enabling environment for work on HIV and STIs as well as sexual and reproductive health and rights more generally.

DESCRIPTION: GAYa NUSANTARA Foundation, Surabaya, East Java, Indonesia, has in 2018-2019 collaborated with (inter)faith organizations, media, human rights organizations, AIDS service organizations, academics and politicians to mainstream diversity in SOGIESC to partners in eight key municipalities or districts in East Java Province (total number of municipalities and districts: 38).

The project identifies existing sexual minority communities, often through AIDS service organizations; primes them to intersectionally and strategically work with key stakeholders; and creates local networks to work on issues of diversity in SOGIESC in a proactive and a reactive way (i.e. responding to crises such as negative government policies or disturbances by religious militias). This is done through preliminary work, and follow up workshops.

Particularly on faith issues, a workshop with progressive faith leaders and theologians as well as members of diverse SOGIESC communities in 2018 resulted in a master document on progressive interpretation of Christian and Islamic texts, currently in print. This will be used for campaigns, both offline and online, to create a conducive social environment.

LESSONS LEARNED: 1. Trans women communities are most ready to engage, while in some locations gay men are also ready. People with non-normative SOGIESC find one another and build networks, mostly through internet platforms.

2. Sexual minority communities are not in touch with key stakeholders and vice versa. The project brings them together to build advocacy and crisis response networks.

3. Allies exist in all localities. Knowledge of SOGIESC diversity and commitment to pluralism and human rights, vary.

CONCLUSIONS/NEXT STEPS: The project can be replicated in other localities. A similar project is on the drawing board in Eastern Indonesia and other localities in East Java.

PDF0103

TRANS TASK FORCE TEAM AGAINST VIOLENCE AND HARASSMENT TOWARDS MARGINALIZED TRANSGENDER COMMUNITY ACROSS PAKISTAN, 2019

M.K.A. Choudhry[1], K.A. Khan[1]
[1]*Sub Rang Society, Karachi, Pakistan*

BACKGROUND: Established in 2016 and legally registered in 2018; Sub Rang Society (SRS) is working towards empowering transgender community in Pakistan to get their basic and equal human rights granted in Constitution of Pakistan as well as prescribed in Universal Declaration of Human Rights (UDHR).

DESCRIPTION: In 2019 a total of 11 transgender lost their lives in Pakistan. To fight against the harassment and violence related issues with transgender of Karachi, SRS has formulated TRANS TASK FORCE TEAM (TTFT) which is actively working across 19 towns of Karachi; against the issues faced by TGs and other sexually marginalized community members.

It was decided that two representative from each town will be selected for a point of contact, to build capacity and spread awareness of Trans Rights and legal Procedures within the trans community of their respective districts.

LESSONS LEARNED: TTFT tackles root causes of violence against transgender by working with civil society, local institutions and governments and helps change community attitudes toward transgender, supporting them to realize their potential and advocate for their rights.

TTFT will strive to minimize the cases of violence and harassment within Karachi city with the help of TTFT irrespective of Hijra Culture and their sects; work with unity and also build the capacity of TTFT to raise their voice and report the cases by TGs themselves.

CONCLUSIONS/NEXT STEPS:

1. Support safety, justice and autonomy of all victims and survivors of violence.
2. Work to meet the needs of underserved and marginalized trans community.
3. Create a forum to enhance the response of sexual violence prevention initiatives among TTFT response team.
4. Create social media to empower TTFT with the members of the group for follow up, furthermore to create awareness regarding laws and policies of state.
5. TTFT will engage trans community and their allies to educate masses to reduces violence, stigma, discrimination and bring positive change in society toward marginalized trans community.
6. Efforts are also be made by focusing on policies and efforts to engage trans community by examining and challenging destructive notions of gender and power in post-conflict settings, while being guided by the voices and inputs of community.

PDF0104

SEXUAL VIOLENCE AGAINST WOMEN AND GIRLS FUELING THE SPREAD OF HIV IN URBAN COMMUNITIES THAN RURAL COMMUNITIES IN ONDO STATE, NIGERIA

F. Bamigboye[1], D. Faponle[2]
[1]Kids & Teens Resource Centre, Programmes, Akure, Nigeria, [2]Kids & Teens Resource Centre, M&E, Akure, Nigeria

BACKGROUND: Majority of HIV Prevention Programs in Nigeria promote safe sex through condom use while ignoring the realities of sexual violence and gender inequalities which increases the susceptibility/vulnerability of women and girls to HIV. Victims of Gender Based violence more often suffer sexual and reproductive health consequences including unwanted pregnancies, unsafe abortion, traumatic fistula, sexually transmitted infections that could lead to death or prevent survivors from achieving economic prosperity due to social stigma or physical and psychological trauma caused by the violence. This paper analyzed and reveals the relationship between sexual violence and the spread of HIV in urban settings.

DESCRIPTION: An Adolescent Girls and Young Women Program was carried out in Akure (urban) and Bamikemo (rural) communities of Ondo State between February and August 2019 where SRHR issues were discussed among 52 adolescents (10 -14) and Young Women (15-24).10 In-depth Interviews with parents and community leaders, Focused Group Discussions with 12 adolescents and another one with 15 young women were conducted in both the rural and urban communities. Also, the youth leaders (2) and women leaders (2) and Community heads were interviewed.

LESSONS LEARNED: Focus Group Discussions and interviews revealed gender based violence (structural), male superiority (cultural) and economic disadvantage (financial) as factors increasing the susceptibility of Adolescent Girls and Young Women to HIV. 73% of the women and girls in the Urban areas reported sexual violence as the definite cause of the spread of HIV/STIs while 58% in the rural communities named Poverty, ignorance (63%) and abuse of trust(42%).Interviews with the youth leaders in the Urban revealed male superiority and economic power as major drivers of HIV while the rural area revealed cultural bias. Women leaders were of the opinion that gender inequalities was at the center of problems they experience in life.

CONCLUSIONS/NEXT STEPS: Sexual Violence undermines the health, dignity and autonomy of its victims, yet it remain shrouded in a culture of silence.The power of protection and choice should be placed in the hands of women through women empowerment and female condoms availability/accessibility. The culture of acceptance of rape as something excusable or blame able should be shattered through policy advocacy &value clarification.

PDF0105

INTERNATIONAL GENDER AFFIRMING MEDICAL INTERVENTION TO AVOID PERSECUTION AND VIOLENCE IN EL SALVADOR

A. Montano[1]
[1]ALDES, San Francisco, United States

BACKGROUND: Life expectancy for Central American transwomen is 35 years. They suffer sexual violence, extortion by criminal gangs and police. School bullying forces them to abandon their education. Families force them out of their homes at an early age. They are coerced into sex work or selling drugs. They are hate crime victims which are rarely investigated and criminals go 'scot-free.' Verónica, Trans woman at ASTRANS (Salvadoran human rights NGO), states: *"We know we can be killed. We do not know if we will come back home, or come to work the next day . . ."*
Gender-affirming services are vital; 'passing' as a woman or man protects against violence. Yet, sex change surgeries are not available. Trans Salvadorans must rely on hormones, but access is limited. Many transwomen inject oil into their breasts, leading to severe medical complications. Others purchase hormones, but without medical supervision, it's dangerous.

DESCRIPTION: ASTRANS has the only Non-Surgical Gender Affirmation clinic managed by 'queer' staff. They offer free-hormone therapy and social-psycho support to one hundred (100) trans patients, approx. % are HIV+. ASTRANS teaches interpreting HIV lab results, avoiding self-medication, reproductive options, legal/advocacy issues, the nature of human trafficking to reduce risk, and PrEP.

LESSONS LEARNED:

- Having a gender-affirming clinic avoids dangerous self-inflicted treatments like injecting oil in breasts as a desperate measure to enhance feminization.
- Free hormone treatment helps avoid discrimination and violence.
- HIV treatment and gender-affirming hormones in one location, and staff who reflect the clientele, fosters trust.
- Clients that have a 'safe space' clinic engage and adhere to HIV care.

CONCLUSIONS/NEXT STEPS:

1. HIV care and gender affirming clinics accelerate ending the HIV/AIDS epidemic.
2. The ASTRANS clinic model saves trans lives.
3. The Salvadoran ASTRANS clinic model needs replication.
4. US researchers should collaborate with El Salvador and expand mental health supports, gender enhancing treatment, HIV prevention, evaluation and PrEP.

PDF0106

REASONS WHY YOUNGER QUEER FACE VULNERABILITY AND RISKS WHILE SEEKING ASYLUM IN KENYA: STUDYING THREE SAFE SPACES, AUGUST 2019-JANUARY 2020

T. Mumba[1], T. Muyunga-Mukasa[2], Refugees
[1]*Refugee Independence Support Organisation, Communication Office, Nairobi, Kenya,* [2]*Advocacy Network Africa, Advocacy, Mobilisation and Education, Nairobi, Kenya*

BACKGROUND: Kenya is considered to be a more progressive country than Uganda when it comes to asylum seeking by Queer refugees from other African countries. Younger Queer refugee's face a triple stigma based on age, status conditions of asylum seeking. Kenya bases its refugee reception conditions on her Immigration Act (Cap. 172) and the international instruments. However, younger Queer refugees meet bias and prejudices as they seek asylum. This study aimed at finding out what these biases and prejudices were as they navigated access to social services while awaiting resettlement in Kenya.
METHODS: Through Respondent driven sampling, Questionnaire administering and Focus Group discussion with 74 younger MSM living in Nyeri, Nairobi and Nakuru as refugees from Uganda, Rwanda, Burundi and Tanzania.
RESULTS: All respondents stated that what was on the ground was different from what they expected. 24 (18-25 years) reported they were suspected of being impostors or telling lies; recruited into the vice; and asked questions that were off the script of eligibility Such questions were probing whether they were recruited into homosexuality or trafficked. This led to 22 (18-22 years) being denied registration in time. This caused delays in acquiring National IDs. This raised vulnerability to them.
CONCLUSIONS: Age and status of person impact presentation and case processing for Queer refugees during asylum seeking. When they are younger they are said to be recruited into homosexuality. This study report was based on self reporting, further research using a bigger sample and service providers can throw more light on reasons for delays in refugee status processing, integration in host communities, productivity and awareness levels or cultural sensitivity of providers as far as Sexuality, Orientation, Gender Identity, Gender Expression and Sexual Characteristics (SOGIESC) is concerned.

ENDING DISCRIMINATION IN HIV/TB PROGRAMS: LESSONS LEARNED FROM THE GLOBAL FUND'S BREAKING DOWN BARRIERS INITIATIVE

J. Amon[1], N. Sun[1], R. Jurgens[2], A. Iovita[2], G. Arustamyan[2], O.b.o. BDBI MTA Evaluation Team[1]
[1]*Drexel University, Office of Global Health, Philadelphia, United States,* [2]*Global Fund, CRG, Geneva, Switzerland*

BACKGROUND: The Global Fund's 2017 – 2022 Strategy recognizes that addressing HIV and TB requires scaling-up programs to remove human rights-related barriers to health services and end discrimination. Supporting this goal, the five-year Breaking Down Barriers (BDB) initiative has funded HIV and TB programs in 20 countries focused upon: stigma and discrimination reduction; training for health care providers; sensitization of law-makers and law enforcement agents; reducing HIV-related gender discrimination, harmful gender norms and violence against women and girls in all their diversity; ; legal literacy; legal services; and monitoring and reforming laws, regulations and policies. Additional programs for TB include: mobilizing and empowering patient and community groups; addressing overly-broad policies regarding involuntary isolation or detention for failure to adhere to TB treatment; and making efforts to remove service barriers in prisons.
DESCRIPTION: In 2019-2020, a mid-term evaluation was conducted that assessed efforts under the initiative's 20 countries to identify progress towards a comprehensive response to reduce human rights-related barriers to service access. In addition to a descriptive assessment of barriers and facilitating factors for the implementation of human rights programs, the assessment examined program integration into national plans and existing health services, and identified emerging evidence of increased coverage, access and/or retention of key and vulnerable populations as a result of the BDB Initiative. Key informant interviews with government officials, donors, key populations and their organizations, other NGOs, policy-makers and other stakeholders formed the basis of the assessment.
LESSONS LEARNED: Eliminating discrimination is an often proclaimed goal and a frequently underfunded objective. The Global Fund's $78 million investment in the BDB initiative represents a significant step towards scaling up evidence-based programs to address discrimination and other human rights-related barriers to access HIV and TB services. Innovative programs targeting discrimination, legal services and law reform will be highlighted.
CONCLUSIONS/NEXT STEPS: The BDB initiative has resulted in a sharp increase in funding for human rights-related programs addressing discrimination. Emerging evidence suggests that key populations are increasingly able to access HIV and TB programs and be retained in care.

PDF0203

THE OBLIGATION OF THE STATE TO ENSURE FREEDOM FROM TORTURE AND ABUSE FOR WOMEN WHO USE DRUGS DURING PREGNANCY AND CHILDBIRTH

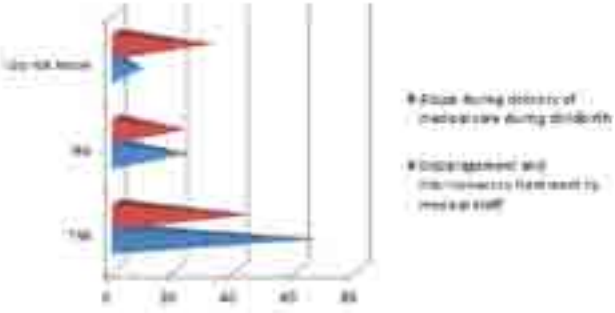
L. Vorontsova[1]
[1]*Central Asian Association of People Living with HIV, Almaty, Kazakhstan*

BACKGROUND: The estimated number of women who use drugs in Kazakhstan is 21,726. 87% of women who use drugs and psychotropic substances are at the fertile age. Drug-addicted pregnant women in Kazakhstan experience pain and suffering that amounted to torture. Because in Kazakhstan there are no separate normative legal acts on the provision of this medical care-doctors do not have clear algorithms for managing such patients. Support methods available in the form of methadone therapy are not available to women in maternity hospitals. Methadone therapy is not available in some regions of the country. Because of the stigma, pregnant women who use drugs do not want to seek medical help. Women do not always have access to medical services, including drug treatment, prenatal and postnatal care.

OBJECTIVE: to obtain information on the realization of the right to freedom from torture and ill-treatment for drug-addicted women during pregnancy and childbirth in Kazakhstan.
Hypothesis: women who use drugs receive necessary and timely medical care during pregnancy and childbirth without discrimination and abuse.
METHODS: To conduct the study, we used a mixed-method approach that combines the use of primarily qualitative data.
Information collection methods:

- Analysis of the laws of the country and international standards
- Focus groups and a survey of women who use drugs
- In-depth interviews with experts (practicing psychotherapists-narcologists, representatives of NGOs)
- Documentation cases of human rights violations

RESULTS:



CONCLUSIONS: Due to the stigma and lack of appropriate medical protocols, pregnant women who use drags in Kazakhstan are not always able to use the necessary medical services, including drug treatment, prenatal and postnatal care. This leads to the fact that women experience pain and suffering. Kazakhstan needs a comprehensive approach that includes working with the medical staff of women's clinics and maternity hospitals on issues of stigma and discrimination against women who use drugs.

PDF0204

BREAKING DOWN BARRIERS: ENGAGING AND TRAINING LAWYERS TO IMPROVE HEALTH RIGHTS AND ACCESS TO CARE FOR PEOPLE LIVING WITH HIV

M. Pedrola[1], A. S. Benzaken[2], F. Rick[2], G. Alaniz Gatius[1,1]
[1]AIDS Healthcare Foundation Argentina, Buenos Aires, Argentina, [2]AIDS Healthcare Foundation, Manaus, Brazil

BACKGROUND: Even though HIV care in Argentina is provided free of charge, the fragmented health system makes it difficult for people living with HIV (PLHIV) to identify which sector is responsible for their healthcare. Therefore, PLHIV need support from lawyers to access HIV care. Beyond stigma and discrimination, the scarcity of lawyers specialized in health rights contributes to increased barriers to healthcare. AIDS Healthcare Foundation (AHF) Argentina, together with Foundation FUNDALEIS (a leading NGO in health rights) began training lawyers countrywide in health rights to help PLHIV access HIV care.
METHODS: In 2018, AHF started this initiative in 16 of 24 Argentine provinces, where AHF partners identified lawyers to attend training sessions. Following the training, a network of specialized lawyers was created, and support was offered free of charge.
RESULTS: After a total of 32 lawyers from 14 provinces completed three courses, the National Network of Lawyers for the Right to Health (NNLRH) (specializing in HIV) was established. It provided 156 free consultations related to HIV care, 149/156 were resolved after the first consultation or by extrajudicial actions. Only seven went to court, which resulted in favorable decisions for all clients. PLHIV still face constrains or unawareness about their rights due to myths, fears, and resistance, which prevents them from searching for lawyers and exercising their rights to submit claims for care.
CONCLUSIONS: This initiative showed an effective method for breaking down barriers and increasing retention by improving access to the health system. It also reinforced the role of lawyers on expanding access to HIV care by promoting health rights. Marketing campaigns on rights and NNLRH support are also required to encourage PLHIV to seek access to improve their wellbeing.
Further training sessions for lawyers on stigma and discrimination, and for PLHIV on health rights, can empower communities to support this initiative, which will further improve and expand access to HIV care.

PDF0205

PROTECTING HEALTH AND BIOMETRIC DATA IS A HUMAN RIGHTS NECESSITY

M. Johnson[1], J. Mukherjee[2,3,4], G. Jerome[5], W. Lambert[6]
[1]Partners In Health, Strategic Information & Systems, Boston, United States, [2]Partners In Health, Chief Medical Officer, Boston, United States, [3]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States, [4]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States, [5]Partners In Health, Boston, United States, [6]Zanmi Lasante, Director of Research, Education, and Strategic Information, Port au Prince, Haiti

BACKGROUND: Partners In Health is a network of 10 international NGOs unified by our work in healthcare delivery, health system strengthening, and global policy advocacy. PIH provides care and advocacy to people living with HIV/AIDS and TB through a partnership with PIH-affiliated INGOs and MOH partners in Haiti, Peru, Rwanda, Lesotho, Malawi, Liberia, Sierra Leone, Kazakhstan, Mexico, and Navajo Nation. PIH has been a pioneer in the use of electronic health records to support clinical care and quality monitoring for PLHIV since 1990, co-founding Open Medical Record System (OpenMRS) in 2004, now in use in 65 countries.
DESCRIPTION: While data security has always been a priority for the health sector, recent expansion in data-sharing requirements and biometric identification have raised questions about the important responsibility INGOs hold in ensuring data protection of personally identifiable health data, especially biometric data which can never be de-identified or anonymized. We have been involved in projects capturing fingerprint biometrics and GPS location of community based activities in multiple countries. The pathways for opting out of this data collection are not clearly communicated to PLHIV, clinicians, or INGOs, and government regulations lack specific guidance.
LESSONS LEARNED: In our partnerships with governments, we have observed sensitive data collection may in some cases undermine the principles of privacy and human rights for all PLHIV, especially those who are most vulnerable. While we recognize the significant potential for longitudinal health records and biometric data to improve access to high-quality HIV treatment, we are concerned that when data are shared without stringent governance

mechanisms and without patient consent PLHIV may be exposed to current and future harms including identity theft, criminal prosecution, harassment, or death. Our experience has been that most discussions and policies regarding data security, sharing, and privacy involve IT, legal, and administrative staff, without involving clinicians and PLHIV to ensure that their rights are protected.

CONCLUSIONS/NEXT STEPS: Upholding the responsibility of healthcare delivery organizations requires protecting the human rights of vulnerable patients. Protection must include development and implementation of practices that safeguard private health data, especially biometrics and facial recognition, empowering PLHIV to make informed decisions regarding the use of their data.

PDF0206

GLOBAL PERSPECTIVES TOWARD A RIGHTS-BASED APPROACH TO SELF-CARE INTERVENTIONS FOR SEXUAL AND REPRODUCTIVE HEALTH AND HIV: IMPLICATIONS FOR ADVANCING UNIVERSAL HEALTH COVERAGE

C. Logie[1], M. Narasimhan[2], A. Gauntley[1], A. Pauchari[3], N. Siegfried[4]
[1]University of Toronto, Social Work, Toronto, Canada, [2]World Health Organization, Geneva, Switzerland, [3]Centre for Human Progress, Delhi, India, [4]South African Medical Research Council, Cape Town, South Africa

BACKGROUND: Across the globe there are 400 million persons without access to essential sexual and reproductive healthcare services, signalling the urgent need for innovative solutions to realize universal health coverage (UHC). Self-care strategies can harness the ability of individuals to manage their health by improving their autonomy and agency. The 2019 World Health Organization's (WHO) consolidated guideline on self-care interventions for sexual and reproductive health and rights (SRHR) provides recommendations regarding self-care interventions alongside good practice statements to guide service delivery. These self care strategies include HPV self-sampling and HIV self testing. Perspectives from healthcare providers and users are key as we move from conceptual development to programmatic implementation.

DESCRIPTION: Three WHO expert consultations to inform the guideline included a survey to explore both healthcare provider and client perspectives on awareness of, access to, preferences and concerns around self-care interventions for SRHR. These data were collected via an online survey hosted on the website of the WHO Department of Sexual and Reproductive Health and Research and shared through a range of global listservs.

LESSONS LEARNED: There were 326 participants who provided qualitative responses to open-ended questions, these included healthcare providers (n=242) and lay persons (n=70) from 77 countries. Participants were mostly women (66.9%) and were from the African Region (34.5%), Region of the Americas (32.5%), South-East Asia Region (5.6%), European Region (19.8%), Eastern Mediterranean Region (4.8%), and the Western Pacific Region (2.8%). Participants perceived multiple benefits of self-care SRHR interventions, including: reduced exposure to stigma, increased confidentiality, reduced access barriers, empowerment, self-confidence, and informed decision-making. Concerns include insufficient knowledge, stigma, affordability, and side-effects. Implementation considerations included innovative approaches to linkages with health services as needed.

CONCLUSIONS/NEXT STEPS: Self-care interventions are especially promising for the area of HIV testing (HIV self-testing), and care management (e.g. mobile apps for ART adherence) as well as elimination of cervical cancer through better screening tools (HPV self-sampling). As many of these strategies do not necessitate direct contact with healthcare professionals, they may be ideal for key populations who face discrimination when accessing sexual and reproductive health services or for communities in which sexual and reproductive health remain highly stigmatized topics.

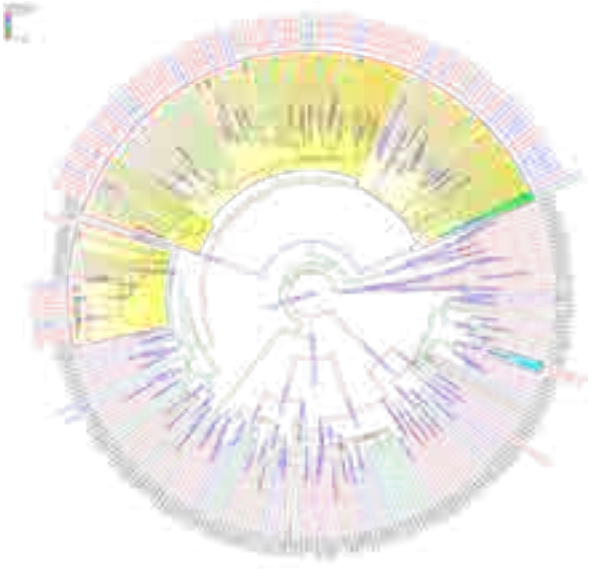
EVOLUTIONARY GENETICS OF HIV-1 STRAIN CAUSING INFECTION IN DIFFERENT COHORT OF PEOPLE LIVING WITH HIV IN NEPAL

S.K. Mishra[1], V. Chimanpure[2], A. Patil[2], V. Nema[2], R. Gangakhedkar[2], S. Kulkarni[2], R. Napit[3], R.K. Mahato[4], K.D. Manandhar[5]
[1]Tribhuvan University / National Public Health Laboratory, National Center for Infectious Diseases, Kathmandu, Nepal, [2]National AIDS Research Institute (NARI), Molecular Virology, Pune, India, [3]Center for Molecular Dynamics, Infectious Diseases, Kathmandu, Nepal, [4]National Public Health Laboratory, HIV/AIDS, Kathmandu, Nepal, [5]Tribhuvan University / Institute of Science and Technology, Central Department of Biotechnology, Kathmandu, Nepal

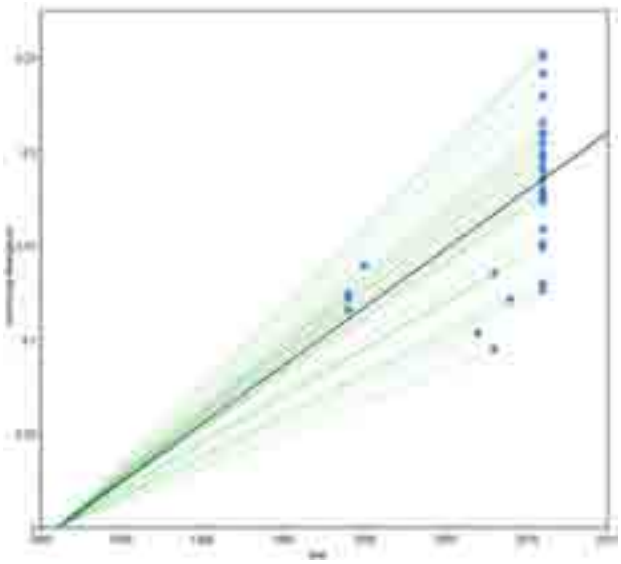
BACKGROUND: Major HIV-1 sub-types documented in South East Asian region are sub-type C . First case of HIV-1 in Nepal was reported in 1988 and till date there is very limited data on HIV-1 genetic diversity from Nepal. This study for the first time reports the genetic diversity of HIV-1 among different cohorts based on analysis of sequences of the viral envelope C2V3C3 region gene.

METHODS: The C2V3C3 region of HIV-1 env was sequenced and DNA sequences were visualized using Aliview software along with MAFFT alignment .The amino acid chain of V3 loop were tested for co-receptors and subjected to the N-linked glycosylation site prediction using the N-GLYCOSITE tool. The tip dates to root date of all the taxa included for MRCA analysis, a Molecular clock analysis was performed for HIV-1 strains.

RESULTS: Among 122 subtype C HIV-1 strains, 84% were CCR5 and 16 % were CXCR4 using strains. Glycosylation sites in the C2 and C3 region revealed that the high mannose glycan bearing sites. Molecular clock analysis for HIV-1 subtype C from Nepal, tMRCA estimated for HIV-1 subtype C Nepal was found to be in 1981.



[Figure 1. Phylogenetic analysis through Bayesian inference method with most recent common ancestral (MRCA) (BEASTv2.5.1) for ancestor determination using HIV database's Ancestor DNA alignment.]



[Figure 2. Tip to root analysis of HIV-1 sub-type C strains]

CONCLUSIONS: The study highlighted the genetic diversity of HIV-1 subtype C from Nepal. Most of the strains showed CCR5 co-receptor usage. Analysis of HIV-1 C envelope sequences indicate their introduction in Nepal in 1981.

PREVALENCE OF DRUG RESISTANCE MUTATIONS AMONG HIV POSITIVE INDIVIDUALS WITH LOW LEVEL VIREMIA ON ANTIRETROVIRAL THERAPY IN BOTSWANA

O. Bareng[1], S. Moyo[1,2], M. Zahralban-Steele[2], D. Maruapula[1,3], B. Mokaleng[1,4], T. Ditlhako[1], P. Mokgethi[1], M. Holmes[2], T. Gaolathe[1], V. Novitsky[1,2], S. Gaseitsiwe[1,2]
[1]Botswana Harvard Partnership, Laboratory, Gaborone, Botswana, [2]T H Chan Harvard School of Public Health, Department of Immunology and Infectious Disease, Boston, United States, [3]University of Botswana, Faculty of Biological Sciences, Gaborone, Botswana, [4]University of Botswana, School of Allied Health Sciences, Gaborone, Botswana

BACKGROUND: Monitoring HIV-1 drug resistance mutations (DRM) in treated patients with a detectable viral load (VL) is important. Currently, there is conflicting data on the impact of low level viremia (LLV) , that is, VL<1000 on development of DRM while there is consensus on the need to investigate DRM in patients with VL of ≥1000copies/ml. The study aimed at determining the prevalence of DRM among HIV positive individuals with varying VL levels whilst on combination Antiretroviral therapy(cART) in Botswana.

METHODS: This was a cross-sectional analysis of 6078 HIV positive individuals enrolled in the Botswana Combination Prevention Project (BCPP) (2013-2018) in 30 communities. LLV was defined as detectable VL between 50copies/ml and 1000copies/ml. LLV was categorized into low and high LLV for ranges of 51-400copies/ml and 401-999copies/ml respectively. Proviral HIV sequences were obtained by long range genotyping. Pol sequences were analyzed for DRM associated with nucleoside reverse transcriptase inhibitors (NRTI), non-nucleoside reverse transcriptase inhibitors (NNRTI), Protease Inhibitors (PI) and integrase strand transfer inhibitors (InSTI) using the Stanford HIV DRM database. We estimated proportions of DRM with 95% confidence intervals using binomial exact method.

RESULTS: Amongst 6078 HIV sequences, 6030 had known ART status. A total of 4748/6030 (78.7%) participants were on cART, 4741 had VL data whom 4385 (92.5%) were virologically suppressed and 354 had detectable VLs; 179 (3.8%) had LLV and 175 (3.7%) had VL ≥1000copies/ml. Stratified by LLV group, 78.8% and 21.2% had low and high LLV, respectively. The prevalence of any DRMs was 34.0% (95% CI 26.3-42.5%) on low LLV, 39.5% (95% CI 24.0-56.6%) on high LLV and 44.6% (95% CI 37.1-52.3%) among VL ≥ 1000 copies/ml group presented in table 1.

Viral load (copies/ml)	N	Any mutation	NRTI mutations	NNRTI mutations	PI mutations	INSTI mutations
All detectable VLs	354	143(40.4%) 95% CI; 35.2-45.7	57 (16.1%)	122 (34.5%)	20 (5.5%)	11 (3.0%)
51- 400	141	48 (34.0%) 95% CI; 26.3-42.5	14 (9.9%)	45 (31.9%)	6 (4.3%)	5 (3.5%)
401-999	38	15((39.5%) 95% CI; 24.0-56.6	5 (13.2%)	11 (28.9%)	2 (5.3%)	2 (5.3%)
≥1000	175	78(44.6%) 95% CI; 37.1-52.3)	38 (21.7%)	66 (37.7%)	12 (6.5%)	4 (2.2%)

[Table 1. Prevalence of HIV DRMs stratified by viral load group].

CONCLUSIONS: There is no statistical difference in the prevalence of DRM amongst LLV subsets suggesting the need for continued investigation into DRMs and comparison between viral RNA and proviral DNA compartments.

PEA0003

IMPACT OF HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 SUBTYPE C (HIV-1C) TRANSMITTED/ FOUNDER (T/F) VIRUSES TAT GENETIC VARIATION ON TRANSACTIVATION ACTIVITY AND DISEASE OUTCOME

Z. Mkhize[1], P. Madlala[1]
[1]*University of KwaZulu-Natal, HIV Pathogenesis Program, Durban, South Africa*

BACKGROUND: The major roadblock to eradication of human immunodeficiency virus type 1 (HIV-1) infection is the early development of latent viral reservoirs. Latent viral reservoirs comprise of cells infected with replication competent and yet transcriptionally silent provirus. However, the mechanisms that govern viral latency at the transcriptional level are not fully understood. The HIV-1 Transactivator of transcription protein (Tat) regulates viral gene transcription and is important for pathogenesis. Interestingly, inter- and intra-subtype variation that translates to differential Tat transactivation activity has been reported during chronic infection suggesting that Tat variation may influence disease outcome. Although it is well established that HIV-1 latency is established early in infection, there is still paucity of data on the effect of HIV-1 transmitter/founder (T/F) virus tat genetic variation latent reservoir development. Therefore, we hypothesized that HIV-1 subtype C T/F viruses tat genetic variation may affect disease outcome.
METHODS: To test this hypothesis, viral RNA was extracted from plasma samples obtained from 30 HIV-1 acutely infected South Africans using QIAmp RNA viral RNA mini kit (Qiagen, Hilden, Germany), reverse transcribed using SuperScript IV and followed by nested PCR using the Platinum Taq DNA polymerase (Invitrogen, Carlsbad, CA, USA). Subsequently, PCR products were sequenced using the BigDye cycle sequencing kit v3.1 (Invitrogen, Carlsbad, CA, USA) and analyzed using phylogenetic tools. The HIV-1 tat sequences harbouring mutations of interest were transfected into TZM-bl cells in order to assess their transactivation activity.
RESULTS: Co-existence of detrimental mutations to Tat activity were associated with significantly lower viral loads compared to co-existence of enhancing mutations ($p < 0.001$). Interestingly, viruses harbouring P21A Tat variant are associated with significantly lower viral loads compared to viruses without P21A mutant ($p = 0.04$). Moreover, transactivation of this mutant was almost completely abrogated. Furthermore, Tat activity positively correlated with viral load ($r = 0.85$, $p = 0.01$).
CONCLUSIONS: Taken together, our data suggest that HIV-1 subtype C T/F viruses tat genetic variation may impact disease outcome. Future studies should investigate the effect of single mutations and protein expression on the disease outcome. Understanding of how HIV-1 gene transcription is regulated, may guide future studies on cure strategies.

PEA0004

EXTENSIVE DISTRIBUTION OF SIV IN TISSUES WITH SECONDARY LYMPHOID ORGANS AS THE MAIN DRIVERS OF VIRAL DYNAMICS

[1]*Université de Paris, Paris, France,* [2]*Unité Bioinformatique Evolutive, Département de Biologie Computationnelle, USR 3756, Institut Pasteur & CNRS, Paris, France,* [3]*Hub Bioinformatique et Biostatistique- Département Biologie Computationnelle, USR 3756, Institut Pasteur & CNRS, Paris, France,* [4]*Institut Pasteur, Unité HIV, Inflammation et Persistance, Paris, France,* [5]*Université Paris-Saclay, Inserm, CEA, Center for Immunology of Viral, Auto-Immune, Hematological and Bacterial Diseases (IDMIT/ IMVA-HB), Fontenay-aux-Roses & Kremlin-Bicêtre, France,* [6]*Institut Cochin – CNRS 8104, INSERM U1016, Université Paris Descartes, Paris, France,* [7]*AP-HP, Laboratoire de Microbiologie clinique, CHU Necker-Enfants Malades, Paris, France*

BACKGROUND: Increasing knowledge concerning the role of anatomical sites in viral dynamics is critical for developing strategies for optimal infection control. We used the model of Simian Immunodeficiency Virus (SIV)mac251 experimental infection of macaques to comprehensively determine tissue viral spread and dynamics.
METHODS: We studied the viral infection and transcriptional activity (SIV-DNA and cell-associated SIV-RNA, respectively, by ultrasensitive PCR) and quasispecies dynamics (env gene - high-throughput sequencing (Illumina)) prospectively in blood and rectal biopsies of six SIVmac251-infected cynomolgus macaques in the absence of antiretroviral therapy and in 23 anatomical sites six months post-infection (axillar/inguinal/iliac/mesenteric/popliteal lymph nodes (LNs), spleen, duodenum, jejunum, ileum, ascending/transverse/descending/sigmoid colon and rectum, bone marrow, thymus, lung, liver, kidney, adipose tissues (axillar, visceral, subcutaneous) and skin). Plasma SIV-RNA loads were then 140,000 copies/mL in median (range: 15,000-1,400,000 copies/mL).
RESULTS: All anatomical sites, including the skin and adipose tissues, showed disseminated and replicative infection. More than 50,000,000 reads were analyzed. From 28 days post-infection on,

viral variants present in the inoculum gradually disappeared, more rapidly in plasma than in PBMCs and were nearly absent after six months post-infection. The genetic distance from the inoculum was time-course dependent. The quasispecies were similar between CD14+ cells and CD4+ T-cells, in the blood and colon. At six months post-infection, LNs and spleen exhibited the highest SIV-DNA and transcriptional levels and the most differentiated and abundant viral quasispecies compared to the inoculum. Interestingly, viral variants in LNs from distinct locations were extremely homogeneous and more closely related to each other than to variants in blood. Variants in LNs were shared to a lesser extent with those of gut-associated lymphoid tissues (GALT). Non-lymphoid tissues and GALT had more variants not shared with other tissues than did LNs and spleen. Despite inter-individual differences, all animals showed the pattern of viral evolution described above.

CONCLUSIONS: In conclusion, LNs and spleen displayed a major role in driving the viral dynamics in untreated animals. Viral variants in LNs from distinct locations were more closely related to each other than to variants in blood, indicating a stronger trafficking of the infected cells (and/or virus) through the lymph than through blood.

PEA0005

IS SOMETHING CHANGING IN THE MOLECULAR EPIDEMIC OF HIV-1 IN KINSHASA, DEMOCRATIC REPUBLIC OF CONGO?

M. Rubio-Garrido[1], J.M. González-Alba[2], G. Reina[3], A. Ndarabu[4], D. Barquín[3], S. Carlos[5], J.C. Galán[2], A. Holguin[1]
[1]Ramón y Cajal Research Institute, HIV-1 Molecular Epidemiology Laboratory, Madrid, Spain, [2]Ramón y Cajal Research Institute, Microbiology Service, Madrid, Spain, [3]Clínica Universidad de Navarra, Navarra Institute for Health Research, Microbiology Department, Pamplona, Spain, [4]Hospital Monkole, Kinshasa, Congo, Democratic Republic of the, [5]Universidad de Navarra, Navarra Institute for Health Research, Department of Preventive Medicine and Public Health, Pamplona, Spain

BACKGROUND: The origin of the HIV-1 epidemic took place in the Democratic Republic of Congo (DRC). HIV-1 diversity is exceptionally high, in continuous evolution, and can impact HIV monitoring and resistance pathways. Our study describes, for the first time, the HIV-1 variants among infected children and adolescents in Kinshasa, the most recent data in adult population, and the temporal trend of HIV-1 in DRC during 1976-2018.

METHODS: From 2016-2018, dried blood specimens were collected in two hospitals in Kinshasa from 340 HIV-infected-subjects: 71 children/adolescents (median age 14) and 269 adults (median age 43). We obtained 165 HIV-1 pol sequences from 55 children/adolescents and 110 adults. For HIV-variant allocation, phylogenetic reconstructions (phy) were done by Maximum Likelihood using GTR+I+G evolutionary model. Recombination events were detected using RDP-program. Genetic diversity (D = 1-∑f2, a measure of variability that takes into account the frequencies of the variants) was calculated. We compared our results with all available HIV-1 sequences from DRC (1976-2012) deposited in Los Alamos.

RESULTS: A huge HIV-1-variants diversification was observed in Kinshasa. The main subtype was A (26.7%), followed by G (9.7%) and C (7.3%); moreover, 36.3% of samples were recombinants (12.7% CRF, 23.6% URF). Among them, we described the first detection of CRF47_BF in the DRC, variant exclusively described in Spain and Brazil. When current surveillance was compared to previous studies, a significant increase of subtype/sub-subtypes A, CRF25_cpx, CRF27_cpx, CRF45_cpx and URF were found and a reduction of subtypes C and D. Surprisingly, a transmission cluster was detected among 4 children/adolescents harboring URF_BG. Genetic diversity was higher in children/adolescents than adults [0.92 vs. 0.88] and in pure-subtypes from Los Alamos sequences (1976-2012) vs. the study cohort (2016-2018) [0.84 vs. 0.76]. CFRs diversity was higher since 2016 [0.78 vs. 0.89], but lower in children/adolescents vs. adults [0.50 vs. 0.88].

CONCLUSIONS: This study provides the most recent data of HIV-1 molecular epidemiology in Kinshasa, including children and adolescents, showing an increase in HIV-1 diversity among recombinants and a transmission cluster involving children/adolescents. The clinical and biological impact of trends of certain HIV-1 variants in DRC is unknown and should be further studied.

PEA0006

ANALYSES OF NEAR FULL-LENGTH HIV-1 GENOME SEQUENCES SHOW INCREASED GENETIC DIVERSITY OF CRF01_AE VIRUSES AND NEW RECOMBINANT VIRUSES IN VIETNAM

Y. Chen[1], B. Hora[1], N.T. Thu[2], V.P. Thao[3], A. Pappas[1], H. Register[1], T. Le[2,3], T.N. Denny[1,2], F. Gao[1,2]
[1]Duke University, Duke Human Vaccine Institute, Durham, United States, [2]Duke University, Department of Medicine, Durham, United States, [3]Oxford University, Oxford University Clinical Reserach Unit, Ho Chi Minh City, Vietnam

BACKGROUND: Many HIV-1 circulating recombinant forms (CRFs) and unique recombinant forms (URFs) have been identified in Vietnam, but the vast majority of those viruses are characterized only by partial viral genome sequences. We aim to better understand the distribution of HIV-1 CRFs and URFs by characterizing HIV-1 whole genome sequences in Vietnam.

METHODS: Viral RNA was extracted from 36 samples from HIV-1-infected individuals in Vietnam and used for cDNA synthesis. Near full-length genome (NFLG) sequences were obtained by amplifying two overlapping half genomes. Subtypes were determined by comparing the newly obtained sequences to the HIV-1 reference sequences. The Vietnam samples were obtained to support the Duke NIAID EQAPOL viral Diversity program.

RESULTS: Phylogenetic tree analysis of NFLG sequences identified 32 CRF01_AEs (88%), one subtype B (3%), and three URFs among CRF01_AE, CRF07_BC, CRF08_BC and subtype B (9%). The diversity of new characterized CRF01_AE sequences was 6.7%, which is 1.4 and 7.4 times higher than the two CRF01_AE NFLG sequence clusters (4.1% and 0.9%) that were reported previously in Vietnam. This suggests that CRF01_AE viruses have continuously diversified to a higher level. Moreover, the new characterized CRF01_AE sequences were as divergent as those from different countries but did not cluster with the previous reported CRF01_AE NFLG sequences. This indicates that the new CRF01_AE viruses have different origins. Small fragment sequences from CRF07_BC and CRF08_BC which are mainly present in China were detected for the first time in the recombinant NFLG sequences, indicating that CRF07_BC and CRF08_BC or their recombinants have recently been introduced into Vietnam.

CONCLUSIONS: Analysis of newly characterized CRF01_AE NFLG sequences showed that they likely originated from different ancestors and have continuously diversified to a higher level. New

CRFs have been introduced into Vietnam in recent years. Continuous monitoring of HIV-1 subtypes by analysis of NFLG sequences may contribute to better control of the HIV-1 epidemic and to the development of broadly reactive vaccines in Vietnam.

PEA0007

PREVALENT SUBTYPES AND OUTCOMES OF A TREATMENT-NAÏVE COHORT FROM AN URBAN PHILIPPINE CENTER

J.A. Bello[1], A.B. Cruz[2], D. Huang[3], A. Danilovic[3], J. Elias[3], J. Bremer[3], C. Abad[1]
[1]The Medical City, Section of Infectious Diseases, Pasig City, Philippines, [2]The Medical City, Pasig City, Philippines, [3]Rush University Medical School, Chicago, United States

BACKGROUND: Circulating HIV subtypes in the Philippines are more diverse as new infections rise exponentially. We enrolled an HIV-treatment-naïve cohort, characterized GAG and POL gene subtype, and describe 1-year treatment outcomes of individuals carrying CRF01_AE, B and CRF01_AE /B recombinants.

DESCRIPTION: Eighty-eight patients at the HIV-IREACT Clinic (The Medical City, Pasig) were enrolled in the Virology Quality Assurance program (RUSH-VQA) from 7/1/2017-6/30/2019. Before initiating anti-retroviral treatment (ART), information about co-infections, AIDS-defining illnesses, CD4 cell count, and viral load (VL) were collected. The ViroSeq™ HIV-1 Genotyping System v.3 and HIV-1 Integrase Genotyping Kit identified drug resistance mutations (DRM). Subtype composition (LTR-VIF) was determined with the jpHMM HIV-1 Tool (University of Göttingen, Department of Bioinformatics) and REGA HIV-1 Subtyping Tool v.3 (Katholieke Universiteit Leuven; HIV Bioinformatics, BioAfrica) after Sanger sequencing. One-year outcomes included virologic suppression, mortality, and physician follow-up.

LESSONS LEARNED: Our cohort included 86 males and 2 females; 61/88 were MSM. Mean age was 30.5 (range 19-65) years. Initial median VL was 168,473 copies/ml with 3 having undetectable VL. Median CD4 count was 94 (0-2296) cells/mm3. Nine had HBV co-infection. 15/85 had DRM; 7/15 had major DRM. Subtyped ViroSeq™-generated sequences included CRF01_AE (58/85), subtype B (12/85), and potential recombinants (12/85). 78/83 patients began ART, 77/83 starting tenofovir/lamivudine/efavirenz. Extensive sequencing (n=70) showed CRF01_AE (50/70), subtype B (7/70), recombinants between CRF01_AE and B (9/70), and recombinants between other subtypes (4/70). Bootstrap analysis identified 7 pairs of strains with high relatedness including 2 from long-term partners. Discordant DRM appeared in 2 pairs, where 1/2 strains displayed DRM. Breakpoint patterns in CRF01_AE/B recombinants were diverse among protease (2/9), RT (5/9) and integrase (3/9) genes. After 1 year, 87 individuals are alive, with 19 lost to care. VL was repeated for 31/77 (40.2%), the majority (24/31,77.4%) being undetectable. Follow-up CD4 testing for 39/77 (50.6%) showed an increase to a median of 327 cells/mm3.

CONCLUSIONS/NEXT STEPS: Our cohort carried subtype CRF01_AE predominantly (~68-70%). Subtype B and CRF01_AE/B recombinants comprised the next largest populations. Overall survival is high after 1 year on ART. The attrition rate warrants concern, with 21.8% lost to care, and 23.6% with possible early virologic failure.

NOVEL HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 INTERGROUP (M/O) RECOMBINATION IN NIGERIA

I. Okonko[1], O. Ogbu[2], J. Bimela[3], M. Tuen[3], R. Duerr[3]
[1]University of Port Harcourt, Virus Research Unit, Department of Microbiology, Port Harcourt, Nigeria, [2]Ebonyi State University, Department of Applied Microbiology, Abakaliki, Nigeria, [3]New York University School of Medicine, Department of Pathology, New York, United States

BACKGROUND: Here we show, for the first time, recombinants between two highly divergent major groups of human immunodeficiency virus type 1 (HIV-1), M and O, within a 38 years old Nigerian woman infected with two diverse HIV-1 strains, a group O virus, and a recently reported URF_A1F2 recombinant virus.

METHODS: Blood specimens were collected from ART-naïve HIV-infected individuals presenting at the University of Port Harcourt Teaching Hospital (UPTH) for voluntary counselling and testing, and routine follow-up from 2016 to 2019. They were sent to the Virus Research Unit of Department of Microbiology, the University of Port Harcourt, Nigeria where the plasma was separated from whole blood and stored at -80 ° C. Furthermore, these plasma samples were shipped to NYUSoM, where the Reverse transcription-Polymerase chain reaction (RT-PCR) and DNA sequencing was performed. Using nested extra-long PCR amplification, we sequenced from the gag to the env region with accessory genes of the viral genome gotten from the patient's plasma and examined them phylogenetically.

RESULTS: The PCR data suggested that this patient was coinfected with a group M virus and a recombinant M/O virus. Compared with reference sequences, there were multiple segmental exchanges between the two HIV-1 strains (group O and URF_A1F2) and, all the recombinants appeared to originate from a common M/O ancestor. Significantly, recombination between groups M and O occurred in the gag, pol, and env regions. Recombination between strains with such distant lineages may contribute substantially to generating new HIV-1 variants. Comparison of the type M sequences shared by the group M and the recombinant M/O viruses showed that these sequences were closely related, with only 3% genetic distance, suggesting that the M virus was one of the parental viruses.

CONCLUSIONS: Recombination between strains with such distant lineages (65% overall homology) may contribute considerably to the emergence of new HIV-1 variants. If such recombinant intergroup viruses derived better viral fitness, prompting variations in their biological properties likened to the parental group O virus, the prevalences of group O sequences could escalate rapidly. Thus, will have significant implications for serological and molecular diagnosis of HIV-1 infections as well as for antiretroviral treatment (ART).

HIV-1 GRAPH REFERENCE GENOME IMPLEMENTATION INFORMED BY CDNA AND NATIVE RNA SEQUENCING OF HIV-1 VIRION

A. Gener[1,2,3], N. Cooley[4], C.S. Kirby[5], Z. Liu[6], R. Sethi[4], Y. Qiu[6], B.S. Chrisman[7], J.P. Buchmann[8], E. Biederstedt[9], C.-S. Chin[10], B. Busby[11]
[1]Baylor College of Medicine, Margaret M. and Albert B. Alkek Department of Medicine, Nephrology, Houston, United States, [2]MD Anderson Cancer Center, Genetics, Houston, United States, [3]Universidad Central del Caribe/School of Medicine, Bayamon, United States, [4]University of Pittsburgh, Department of Biomedical Informatics, Pittsburgh, United States, [5]Johns Hopkins University School of Medicine, Baltimore, United States, [6]Carnegie Mellon University, Computational Biology Department, Pittsburgh, United States, [7]Department of Bioengineering, Stanford University, Stanford, United States, [8]The University of Sydney/School of Life and Environmental Sciences, Charles Perkins Centre, Sydney,, Australia, [9]Memorial Sloan Kettering Cancer Center, Kravis Center for Molecular Oncology, New York, United States, [10]DNAnexus, Mountain View, United States, [11]National Center for Biotechnology Information, Bethesda, United States

BACKGROUND: Current gold-standard approaches to recovering Human Immunodeficiency Virus (HIV) sequences from samples is based on using single linear reference genomes (LRG) for reference-based mapping. This limits recoverable information to sequences resembling the reference(s) used. Nucleobase and approximate k-mer graphs summarize genomic information in different ways. The combination of 10,617 relatively complete HIV LRGs, HIV's high sequence variability, and HIV's tractable genome size (~9kb) provides a unique opportunity for evaluating the suitability of graph reference genomes (GRG) for analyzing HIV genome variability.

METHODS: We evaluated our graph genome construction tool SWIGG (an approximate k-mer graph tool) and VG (a nucleobase graph tool). As input for these tools, we modified HIV-1 single LRGs from the HIV Sequence Database based on information from the first native RNA sequencing of HIV. Data from recent native RNA sequencing was mapped with minimap2, a leading long-read mapper. Public data from HIV-1 virion cDNA-seq (Bioproject: PRJNA320293) was mapped to LRG with with HISAT2, a leading split-read mapper.

RESULTS: We produced approximate k-mer GRGs with SWIGG, and nucleobase GRGs with VG, with k-mers also ranging in size of 16-90 bases and a set of 6 LRGs. We evaluated the resulting nucleobase graphs at well-annotated HIV-1 features. We produced a nucleobase GRG alternative to linear HXB2 or NL4-3 incorporating 6 LRGs including HXB2 for reference-based genomic applications.

CONCLUSIONS: It is possible to make intelligible graph representations of genomic information contained within HIV-1 reference sequences in both approximate k-mer and nucleobase spaces. During our trials, we developed a standardized approach to working with HIV-1 LRGs based on previous models of HIV reverse transcription and native RNA sequencing which reduced artifactually overrepresented k-mers in HIV LTR observed in graphs. This improved approximate k-mer graphs, and facilitated larger nucleobase graphs. Future directions include extending the input of VG graphs to 995 HIV-1 references (all HIV-1, and by subtype), evaluating read mapping compared to standard split and non-split mappers, facilitating nucleobase annotation of k-mer and other feature annotation of approximate k-mer GRGs. The lessons learned from the small yet information-dense HIV genome are extensible to larger genome systems.

HIV BIOLOGY (ENTRY, REPLICATIVE CYCLE, TRANSCRIPTIONAL EXPRESSION AND REGULATION)

HIV GENETIC VARIABILITY AND ISOMIR PRESENCE: EFFECT ON THE EFFECTIVENESS OF ANTI-HIV MICRORNAS

N. Morando[1], M.C. Rosenzvit[2], M.d.l.Á. Pando[1], R.D. Rabinovich[1]
[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, Buenos Aires, Argentina, [2]Instituto de Investigaciones en Microbiología y Parasitología Médica, Buenos Aires, Argentina

BACKGROUND: microRNAs (miRNAs) play an important role in HIV infection. The role of miRNAs that target the *nef* gene is of great interest for HIV latency research. miRNAs can undergo a series of post-transcriptional modifications which yield a set of isoforms of the canonical miRNA sequence (isomiRs), that could differ significantly in terms of complementarity/affinity for the canonical target site. Our objective was to predict *in silico* the potential effect of miRNAs/isomiRs in *nef* gene regulation taking into account:

i) HIV genetic variability, and

ii) variability among canonical miRNAs and isomiRs.

METHODS: Target-miRNA hybridization free energy (ΔG) was calculated for all possible mRNA-miRNA pairs (Two State Melting software, DINAMelt Server) for 43 HIV *nef* sequences from Argentina and Brazil (subtypes B and C and five BF recombinants forms), and miRNAs reported to target nef (miR-1290, miR-196b, miR-223-3p, miR-29a-3p, miR-29b-3p, miR-326). For each miRNA, ΔG obtained with different target sequences were statistically compared using t tests. Additionally, the 10 most abundant isomiR sequences for each miRNA were included (IsomiR Bank). Target RNA secondary structure was predicted (mfold web server software, UNAFold).

RESULTS: *nef* genes from different HIV strains were predicted to bind to the same miRNA with different ΔG, with differences of up to 3.7 kcal/mol. Statistically significant differences between HIV belonging to different subtype/recombinant strains were found for all miRNAs except miR-223-3p (p-values: 0.026 - $7.5x10^{-5}$). Most isomiRs were predicted to bind their target with the same or higher (less favourable) ΔG than the canonical miRNA (maximum difference: 11.2 kcal/mol), whereas for miR-196b and miR-223-3p some isomiRs bound their target with lower (more favourable) ΔG than the canonical miRNA. Analysis of predicted target RNA secondary structures revealed that for almost all miRNAs the canonical sequence can find its target site more accessible, except for miR-29b-3p.

CONCLUSIONS: Our results revealed that HIV strains belonging to different subtypes/recombinants may be differentially susceptible to miRNA-mediated silencing and that isomiRs differ from the canonical miRNA in target binding energy and are not always less effective gene silencers than their canonical counterparts. These results should be taken into consideration for miRNA study in the context of HIV latency research.

INSIGHTS FROM HIV-1 TRANSGENE INSERTIONS IN THE MURINE MODEL OF HIV-ASSOCIATED NEPHROPATHY

A. Gener[1,2,3], Y. Fan[4], G.C. Das[1], W. Zhang[5], D.P. Hyink[1], C. He[5,6], P.E. Klotman[1]
[1]Baylor College of Medicine, Margaret M. and Albert B. Alkek Department of Medicine, Nephrology, Houston, United States, [2]MD Anderson Cancer Center, Genetics, Houston, United States, [3]Universidad Central del Caribe/School of Medicine, Bayamon, United States, [4]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Nephrology, Shanghai, China, [5]Icahn School of Medicine at Mount Sinai, Department of Medicine, Division of Nephrology, New York, United States, [6]James J. Peters VA Medical Center, Kidney Center, Bronx, United States

BACKGROUND: The Tg26 HIV transgenic mouse develops chronic HIV renal disease virtually identical to that seen in humans with HIV-associated nephropathy (HIVAN), but we also noted significant variability in disease phenotype. We wanted to define the context of HIV in this HIVAN model, including transgene copy number and orientation. We used short- and long-read RNA and DNA sequencing to characterize the HIV-1 transgene to better understand the disease variability in the Tg26 mouse.

METHODS: 1) We used RNA-seq to compare the transcriptional profiles of Tg26 mice to immortalized and primary human renal cell lines.

2) As a proof-of-concept to unambiguously cover complete HIV transgenes, we used short- (unpublished) and long-read (Gener, bioRxiv, 2019. https://doi.org/10.1101/611848) PCR DNA-seq to cover the entire HIV-1 reference HXB2 plasmid.

3) We next used short- and long-read PCR-free genomic DNA-seq to define HIV transgenes in a Tg26 mouse.

RESULTS: 1.1) Tg26 HIV mRNA approximated HIV gene expression and splicing seen in human acute infection models.

1.2) Variants in nef and the 3' LTR appeared in subsets of RNA-seq reads after removing PCR duplicates.

2.1) We defined 10 LTR and 10 other variants in pHXB2.

2.2) We sequenced the first complete HIV model proviral reads from PCR and PCR-free methods.

3.1) We defined 6 HIV transgene insertions, and used long reads to evaluate internal structure at individual HIV loci.

3.2) The HIV transgenes occur as concatemers of digested plasmid, exhibiting internal structural variation and plasmid backbone.

3.3) We discovered 46 variants within the HIV transgenes, which may be used to track individual transgene expression with native RNA sequencing.

CONCLUSIONS: Our findings of sense spliced HIV as-seen-in human, defined insertion sites, and neutrally inherited variants at HIV loci support the continued use of the Tg26 mouse as a model of HIV renal disease and extends the view of HIV gene regulation beyond what was possible with previous short-read approaches.

AUTOPHAGY FLUX MODULATING COMPOUNDS INFLUENCE HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 INFECTION

J. Zou[1,2,3], A. Misra[4], K. Song[1,5], W. Li[1], Z. Momin[4], F. Yue[1], J. Kimata[4], L. Liu[1,2]
[1]Texas A&M Health Science Center, Institute of Biosciences and Technology, Houston, United States, [2]The Fifth Affiliated Hospital of Guangzhou Medical University, Guangzhou, China, [3]Central South University, Opthalmology, Changsha, China, [4]Baylor College of Medicine, Molecular Virology & Microbiology, Houston, United States, [5]Central South University, General Surgery, Changsha, China

BACKGROUND: Autophagy is one of the major pathways for degrading dysfunctional organelles, misfolded/aggregated proteins, and infectious microbes including bacteria, parasites, and viruses. HIV-1 replication is significantly impacted by autophagy. In infected cells, early nondegradative stages increase virus production, while maturation stages degrade virus. HIV-1 was reported to inhibit autophagy maturation by interfering with the autophagy regulatory factor Beclin-1, thereby enhancing virus biogenesis. Thus, in this study, we examined if modifiers of autophagy flux could significantly impact HIV-1 infection.

METHODS: To investigate the effects of autophagy flux modifiers on HIV-1 infection and degradation, we examined over time infection of TZM-bl indicator cells with GFP-labeled HIV-1 virions in the presence or absence of the autophagy activator spermidine or inhibitor methamphetamine by confocal microscopy. Localization of GFP-labeled HIV-1 was determined in the presences or absence of bafilomycin A1 (Baf) in cells expressing a RFP-LC3 fusion protein to mark autophagosomes or stained with anti-LAMP2 antibody to identify lysosomes. Modulation of autophagy by methamphetamine or spermidine was confirmed by measuring levels of LC3-II by immunoblot in the presence or absence of Baf. The effect of spermidine on viral replication was further examined in HIV-1 infected primary human peripheral blood T cells costimulated with anti-CD3/anti-CD28 monoclonal antibodies by assaying cell supernatants for HIV p24 by ELISA.

RESULTS: We show that entering HIV-1 viral particles are associated with both autophagosomes and lysosomes. While productive infection of target cells occurs, most viral particles are degraded through the autophagy pathway after they enter host cells. Interestingly, methamphetamine inhibits autophagosomal degradation, thereby increasing the permissiveness of target cells and productive infection. By contrast, the polyamine spermidine promotes autophagy flux and degradation of HIV viral particles, resulting in fewer productively infected cells. Furthermore, in primary T cells cultures, HIV-1 replication was significantly reduced by the addition of spermidine.

CONCLUSIONS: The data suggest that methamphetamine may enhance viral replication by interfering with autophagy. On the other hand, spermidine activates autophagy flux and suppresses viral replication, suggesting its potential for reducing HIV-1 replication in vivo.

EXPRESSION OF CIRCRNAS IN HIV-1 INFECTION

L.P. Iniguez[1], D. Copertino[1], D. Nixon[1], M. de Mulder Rougvie[1]
[1]*Weill Cornell Medicine, Infectious Diseases, New York, United States*

BACKGROUND: HIV-1 infection is still one of the world's most significant infectious diseases, with around 37.9 million people living with HIV-1 at the end of 2018. Since the first case report, 38 years ago, about 32 million people have died of HIV-1 and still there is no accessible cure. The major barrier impeding HIV-1 eradication is a small reservoir of latently infected resting T-cells that persist after ART and can spawn new waves of infection.Circular RNAs (circRNAs) are single stranded covalently closed RNAs which lack the characteristics of linear mRNA such as 5'cap and 3'poly-A tails. CircRNAs are formed as byproduct of post-transcriptional „backsplicing" of coding-genes. Most transcriptomic studies in HIV-1 focus on RNA species, like mRNA or miRNA, while the expression of circRNAs remains to be elucidated. The expression patterns of circRNA have been reported to be sensitive to viral infection and cell division rates, which allow us to hypothesize that circRNAs could be found in HIV-1 latently infected cells.

METHODS: We re-analyzed publicly available total RNA-seq data from in vitro HIV-1 infection of Sup-T1 cells. The dataset consisted of two time points after infection (12 and 24 hours post infection) and its corresponding control (mock infected). The four corresponding samples were sequenced using two different protocols, poly-A enrichment and total RNA-seq. Reads were mapped to identify gene expression with Hisat2 and Stringtie. Additionally, reads were firstly mapped with STAR for chimeric and circular alignments and the resulted alignments were used by CIRCExplorer for circRNA identification.

RESULTS: In total, 52 circRNAs, were found to be differentially expressed in at least one comparison. Most differences, based on gene and circRNA expression, were detected when comparing HIV-1 infection at 24 hpi vs. Uninfected at 24 hpi (41 DE circRNAs).

CONCLUSIONS: The results presented here greater our knowledge of the transcriptional plasticity during H IV-1 infection and the transcriptional state of persistently infected CD4+ T-cells. We have further shown that some circRNAs are differentially expressed during HIV-1 infection and in latent cells from an in vitro HIV-1 latency model. Additional studies on circRNAs in HIV-1 persistence and infection studies are warranted.

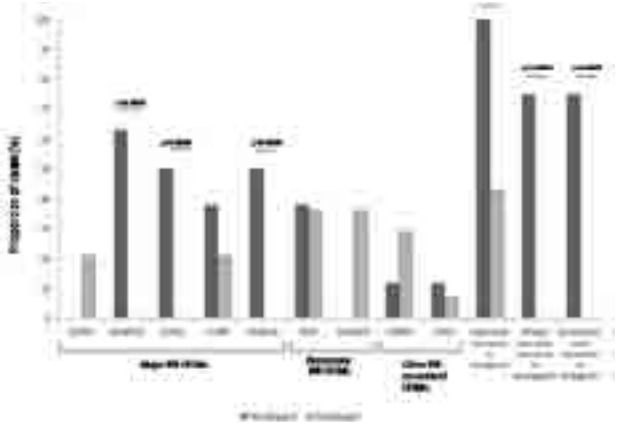
Garrahan", Laboratorio de Biología Celular y Retrovirus, UVEM, Buenos Aires, Argentina,* [2]*Instituto Biológico "Dr. Tomás Perón", Centro Provincial VIH/SIDA y Hepatitis Virales de la Provincia de Buenos Aires, Buenos Aires, Argentina,* [3]*Hospital de Pediatria "Juan P. Garrahan", Servicio de Infectología y Epidemiología, Buenos Aires, Argentina,* [4]*Baylor College of Medicine, Dept. of Molecular Virology and Microbiology, Houston, United States,* [5]*Hospital de Infecciosas "Francisco J. Muñiz", Unidad de Virología, Buenos Aires, Argentina,* [6]*CONICET, Buenos Aires, Argentina*

BACKGROUND: Information on resistance to HIV-1 integrase inhibitors (INIs) is mostly based on subtype B. This contrasts to the increasing use of INIs in LMIC, where non-B subtypes predominate. We aimed to investigate the role of HIV-1 subtype in the development of resistance to INIs (INI-DRMs) among HIV-1 strains circulating in Argentina.

METHODS: INI-DRMs were evaluated in 30 individuals undergoing virologic failure to raltegravir (RAL)-based ART. HIV-1 subtype was characterized by phylogenetic analysis of the integrase (IN) gene. Major INI-DRMs were introduced into infectious molecular clones with subtype B or BF integrases: NL4-3 (B), ARMA159 (BF recombinant), and URTR23 (BF recombinant with 163K polymorphism). Infectious virus stocks were generated by transfection of 293T cells and replication in CEMx174 cells. Virus susceptibility to RAL or dolutegravir (DTG) was determined by TZM-bl assay and IC50s were calculated using PRISM 8 software.

RESULTS: Patterns of INI-DRMs selected by RAL in vivo differed according to HIV-1 subtype in IN (Figure 1). Differences were independent of the median time under RAL therapy (17 versus 22 months), or HIV-1 viral load at the time of genotyping (4.85 versus 4.37 log10 copies/mL) in B or F IN genomes, respectively. In vitro, wild-type BF recombinants were as susceptible to RAL and DTG as NL4-3. As predicted, introduction of N155H (+ G163K) increased the IC50 of URTR23 to RAL (19-fold), but had no effect on susceptibility to DTG. Unlike in NL4-3, where Q148H (+/-G140S) reduced susceptibility to RAL and DTG, but had limited to no effect on viral replication, the introduction of Q148H into URTR23 abolished its ability to replicate.



[Figure 1]

CONCLUSIONS: In BF recombinants with subtype F integrase genes, development of HIV-1 resistance to raltegravir occurs through mutational pathways other than Q148, thereby retaining susceptibility to second generation INIs. Mechanisms involve a severe loss of integrase function of Q148 mutants in BF recombinants.

PHYLOGENY-BASED TRANSMISSION DYNAMICS OF HLA-ASSOCIATED AMINO ACID VARIANTS IN HIV-1 INFECTED INDIVIDUALS IN GHANA

K.A. Fortaleza Kurotani[1,2], P. Kofi Parbie[3,2,4], M. A. Adusei-Poku[4], S. Matsuoka[2], N. I. Nii-Trebi[5], E. Yayra Bonney[4], S. Badu Ofori[6], W. Kwabena Ampofo[4], K. Ishikawa[2], T. Matano[3,2,7], T. Shiino[8]
[1]Tokyo Metropolitan Kokusai High School, Tokyo, Japan, [2]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, [3]Kumamoto University, Joint Research Center for Human Retrovirus Infection, Kumamoto, Japan, [4]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [5]School of Biomedical and Allied Health Sciences, Department of Medical Laboratory Sciences, Accra, Ghana, [6]Regional Hospital Koforidua, Koforidua, Ghana, [7]University of Tokyo, Institute of Medical Science, Tokyo, Japan, [8]National Institute of Infectious Diseases, Infectious Disease Surveillance Center, Tokyo, Japan

BACKGROUND: Suppressive pressure exerted by cytotoxic T lymphocytes (CTLs) leads to viral escape mutations, which are associated with human leukocyte antigen (HLA) variants. As the HLA haplotype of each person differs during an HIV transmission lineage, the virus must adapt at some cost. In West Africa, where the 90-90-90 target has still not been met, we could obtain many cases of virus-CTL interactions that were not affected by anti-retrovirus treatment (ART). Here, we present the phylogenetic-based transmission analysis combined with HLA genotyping of HIV-1 CRF02_AG-infected persons in our Ghanaian cohort that may help assess the effectiveness of CTL-based vaccines in the future.

METHODS: From 2013–2015, plasma samples were obtained from 281 females, 108 males and 1 unknown of ART-naïve individuals through voluntary counseling and testing at the Koforidua Regional Hospital, Ghana. HLA-A, -B, and -C genotypes were determined by next generation sequencing with long-range PCR amplification. Nucleotide sequences of the *gag* and *vif* genes were obtained from plasma viral RNA. Phylogenetic inference and other evolutionary analyses were conducted by maximum likelihood and Bayesian Marcov chain Monte Carlo methods using MAGA10 and BEAST1, respectively.

RESULTS: The *gag* and *vif* phylogenies of the patients revealed that 316 (81.0%) were infected with CRF02_AG, followed by subtypes A1 (10.0%), CRF06_cpx (4.6%), and G (1.5%). We identified 27 and 5 phylogenetic-based transmission clusters in Ghanaian CRF02_AG and subtype A1, respectively. During the transmission links in the clusters, HLA-associated amino acid variants in 19 *gag* and 13 *vif* sites detected in our previous study were primarily selected according to the HLA genotype of the newly infected host. However, a cluster consisting of acute phase individuals showed no associated amino acid site responses to CTLs except for gag-R91K and G357S.

CONCLUSIONS: Our results demonstrated that HIV mostly acquires a CTL epitope adapted to the host HLA genotypes sometime after transmission. The quicker response of some HIV sites in the epitopes may indicate that HLA-associated sites may have priority in the context of CTL escape. Understanding the details of the selection landscape of HLA-viral gene site interactions is necessary for the development of an effective CTL-based vaccine.

BACKGROUND: The low-level viremia and persistence of HIV in reservoir despite antiretroviral therapy (ART) are a challenge for HIV care. We studied the evolution of HIV-DNA level and drug resistance mutations (DRMs) in peripheral blood of patients ART-treated for 25 years.

METHODS: Twenty patients were enrolled in the Immunoco cohort in Paris, France without viral load (VL), CD4, and treatment criteria. HIV-DNA reverse transcriptase was deep sequenced from blood samples at 4 time points, around 1991 (19 samples), 1996 (15 samples), 2012 (20 samples) and 2016 (20 samples). Total HIV-DNA level was measured in leukocytes (Biocentric). DRMs in the latest ANRS algorithm were retained at 5% cut-off. The mutational load was calculated as product of DRMs frequency and HIV-DNA load.

RESULTS: Patients had a median [IQR] zenith VL of 5.06 [4.71-5.71] (log copies/mL), a nadir CD4 count of 138.5 [33.3-239.5] (cells/mm3), HIV infection time of 27.5 [27.0-28.5] (years), time on ART of 24.5 [22.8-26.0] (years), and 10.0 [6.63-12] consecutive years with VL < 200 copies/mL.

The medians [IQR] of HIV-DNA level (log copies/10e6 cells) significantly decayed over 25 years on ART, from 3.56 [3.02-3.84] in 1991 and 3.33 [2.98-3.72] in 1996 to 2.63 [2.32-2.90] in 2012 and 2.25 [2.05-2.61] in 2016 (20-fold reduction from 1991 to 2016, $p < 0.0001$).

From 74 sequenced samples, NRTI-DRMs, T215D/F/I/V/Y and M184V were detected in 57% and 40%, respectively, followed by M41L (35%), D67N (32%), K70R (25%), and L210W (24%), K219E/Q (17%), T69D/N/S/insertion (14%), L74I/V (14%), V179I(7%), E44D (6%). NNRTI-DRMs as K103N/R (8%) and E138A (8%) were less frequently detected.

Interestingly, mutational load reduced over time fastest for K70R and E138A variants (median 144-fold and 93-fold reductions, respectively) while slower for L74I/V, E44D, T69D/N/S, M41L, T215D/F/I/V/Y (10- to 19-fold), and slowest for K103N/R/S, M184V, L210W, K219E/Q, D67N, V179I (nearly 2 to 5-fold). No correlation with CD4 recovery rate and duration of suppressed VL was observed.

CONCLUSIONS: HIV-DNA significantly decayed during 25 years on ART. The different reduction rates of HIV-DNA mutational load for each DRM and no correlation with duration of suppressed VL suggest different kinetics of HIV-infected cell proliferation rather than replenishment of viruses in the reservoir.

PEA0017

COMPARATIVE MOLECULAR CHARACTERIZATION OF CONTEMPORANEOUS AND EARLIER TRANSMITTED HIV-1 VIRUSES FROM TWO UGANDAN COHORTS

S.N. Balinda[1], A. Kapaata[1], Y. Ling[2], F. Kato[1], M.G. Salazar[1], K. Herard[2], J. Hare[3], D. Dilernia[2], M. Price[4], D. Ochiel[5], E. Ruzagira[1], A. Kamali[5], F. Kibengo[1], M. Cotten[1], J. Gilmour[6], E. Hunter[2], P. Kaleebu[1], J.F. Salazar-Gonzalez[1]
[1]Medical Research Council/Uganda Virus Research Institute & London School of Hygiene and Tropical Medicine Uganda Research Unit, Pathogen Genomics Phenotype and Immunity, Entebbe, Uganda, [2]Emory University, Atlanta, United States, [3]Imperial College London, London, United Kingdom, [4]University of California, San Francisco, United States, [5]IAVI-Nairobi, Nairobi, Kenya, [6]IAVI HIL Imperial College London, London, United Kingdom

BACKGROUND: Characterization of the HIV-1 strains being transmitted in Uganda is fundamentally important to inform vaccine design and testing. Previous reports have shown that subtypes A1 and D viruses co-circulate together with inter-subtypes recombinant strains; however accurate data on the proportion and patterns of mosaic recombinants are scarce since most studies have only examined subgenomic fragments. Here we amplified the complete genome and characterized the genetic composition of the most common sexually transmitted HIV-1 strains in Uganda from Dec 2006 to June 2011 and 2015 to 2018.

METHODS: Plasma viral RNA from 40 Ugandan seroconverters from IAVI protocol C 35/40 and Good Health for Women Project (GHWP) 5/40 as examined to infer the transmitted/founder virus (TFV) using single genome amplification and sequencing assays (Sanger/Pacbio). Phylogenetic analysis (Geneious) and LANL tools identified the TFV. Subtyping and recombination tools (RIP) were used to characterize intersubtype recombinant strains.

RESULTS: For Protocol C, an initial analysis of multiple 3'-half genomes from 35 recent sero-converters revealed that like what has been reported for subtype B and C, close to 80% of the infections (28/35) resulted from transmission of a single virus, whereas about 20% (7/35) appeared as multivariant transmissions. Recombination analyses revealed that new HIV-1 infections (61%; 20/33) are established by unique mosaic intersubtype recombinants (17 A1/D, two A1/C/D and one AG_01AE) and 39% were infected by both ‚pure' subtype A (5) and D (8) variants. A very preliminary analyses from 13 GHWP seroconverters identified 5 T/F viruses. Recombination analyses using RIP from 7 full genome sequence data has revealed subtypes, A=2/7, A/D=3/7 and A/C=2/7.

CONCLUSIONS: The high transmission frequency of unique intersubtype recombinants is striking and emphasizes the extraordinary challenge for vaccine design and in particular for the highly variable and recombinogenic envelope gene, which is targeted by rational designs aimed to elicit broadly neutralizing antibodies.

PEA0018

HIV-1 COMPARTMENTALIZATION IN BONE MARROW AND CEREBROSPINAL FLUID

T. Nguyen[1], J. Honeycutt[2], S. Zhou[3], C. Nixon[1], Z. Oksana[4], C. Evans[4], J. Kuruc[4], C. Gay[5], R. Swanstrom[3], J. Garcia[1]
[1]University of North Carolina at Chapel Hill, Center for AIDS Research, Division of Infectious Diseases, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Division of Infectious Diseases, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics and the UNC Center for AIDS Research, Chapel Hill, United States, [4]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States, [5]University of North Carolina at Chapel Hill, Division of Infectious Diseases, Department of Medicine, Chapel Hill, United States

BACKGROUND: Little is known about HIV replication patterns in bone marrow (BM) and the relationship of viruses in BM and cerebrospinal fluid (CSF). We evaluated HIV compartmentalization in the BM and CSF from HIV-infected participants not on antiretroviral therapy (ART) at the time of the study.

METHODS: The HIV *env* gene (V1V3 region, 519 bp) was successfully sequenced from 4/5 peripheral blood (PB), 5/5 BM, and 2/3 CSF plasma samples of 5 participants using the MiSeq sequencing platform with a unique sequence tag (PrimerID). Two participants were previously ART-treated and three were ART-naïve. Phylogenetic trees were computed with FastTree v.2.1.11 and compartmentalization was assessed with ClusterPicker (v1.2.3). Clusters comprising sequences only found in the PB, BM, or CSF within a 3% genetic distance and with a branch support of >70% were defined as compartmentalization. Clusters comprising BM and CSF sequences but not PB were also accessed to compare BM and CSF viruses. Tropism of compartmentalized viruses was predicted using the geno2pheno algorithm and a 2% false positive rate.

RESULTS: The median (IQR) log HIV-RNA (copies/ml) in PB, BM, and CSF samples were 4.85 (4.30-5.09), 4.84 (4.15-5.09), and 3.21 (2.92-3.39), respectively. The two previously ART-treated participants harbored compartmentalized viruses in BM, present at 2.11% and 16.67% of the viral populations. CSF samples were not available for these participants. Viruses from all compartments were successfully sequenced in only one ART-naïve participant. In this participant, 6.45% of viruses in CSF were compartmentalized. Furthermore, 10.3% of viruses in CSF and 4.6% in BM were detected in the same clusters without PB viruses while only 3.2% of viruses in CSF and 2.89% in PB were found in the same clusters without BM viruses (p = 0.0238). One ART-naïve participant had 12.12% of viruses compartmentalized in BM while the other had no compartmentalized viruses. In all participants, the compartmentalized sequences were CCR5-tropic virus.

CONCLUSIONS: We found that viruses in CSF were more similar to those in BM than in PB in one participant and compartmentalized viruses were detected in BM of three participants. Our findings suggest a particular condition in CSF and BM that can favor certain HIV replication patterns in these two compartments.

HIV CONTROLLERS (INCLUDING POST-TREATMENT CONTROLLERS) AND LONG-TERM NON-PROGRESSORS

PEA0019

STRENGTHS AND TRIALS FOR TRANSLATIONAL RESEARCH-TO-POLICY DEVELOPMENTS IN UGANDA

I.S. Miiro[1,2], K. Samuel[3]
[1]Together Alive Youth Link (TAYL), Adminstration, Mbarara, Uganda, [2]Makerere University, Institute of Social Research, Kampala, Uganda, [3]Makerere University, Social Sciences, Kampala, Uganda

BACKGROUND: Research and proof have an influence on policy and practice, leading to helpful results. Nevertheless, translational research is a multifarious, vigorous and non-linear procedure. Even though Makerere universities has participated in producing research evidence, it's planned methodologies to impact health policies and decision making is still fragile.

This study aimed at understanding the procedure of translational research into Policy so as to guide the planned course of Makerere University College of Health Sciences (MakCHS) and related bodies in their mission to impact health results countrywide and internationally.

METHODS: The study engaged stakeholders in HIV prevention projects that is: prevention of mother-to-child transmission (PMTCT) and safe male circumcision (SMC). The study sought to ascertain entry points, strengths and trials for research-to-policy developments by interviewing researcher, policy makers and medical practitioners.

RESULTS: A total of 30 participants was used of which 10 were researchers, 10 policy makers and 10 medical practitioners. Midst the elements that aided PMTCT policy uptake and continued application were: public platforms for knowledge and decision making among stakeholders, operation guides to assess probability of involvement, the developing agencies to commence operations research and the extraordinary prominence of policy benefits to child existence.

Among the elements that aided SMC were: the government's initiative to make SMC free of charge, the public awareness of SMC through the media and the positive consequences of SMC such as cleanness. The policy makers recommended additional research to measure implementation feasibility of SMC within ordinary health system framework.

CONCLUSIONS: This study displays effective translation of PMTCT and SMC research results claimed for a "360 degree" tactic to accumulating additional evidence to inform the enactment viability for these two HIV prevention involvements. MakCHS and related bodies should prioritize operation research to direct the policy procedures about the viability of applying new and effective innovations (e.g. PMTCT or SMC) at a large scale in situations that may be altered from the research atmospheres.

PEA0020

CHARACTERIZATION OF GAG MUTATIONS IN HIV-1 SUBTYPE A LONG-TERM NON-PROGRESSORS

G. Umviligihozo[1], N. Ismail[2], E. Tekirya[3], E. Karita[3], S.A. Allen[3,4,5], E. Hunter[3,6], T. Ndung'u[2], Z.L. Brumme[1,7], M.A. Brockman[1,7]
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]University of KWazulu Natal, HIV Pathogenesis Program, Kwazulu Natal, South Africa, [3]Rwanda Zambia HIV Research Group - Project San Francisco, Kigali, Rwanda, [4]Emory University, Department of Pathology and Laboratory Medicine, Atlanta, United States, [5]Rollins School of Public Health, Department of Global Health, Atlanta, United States, [6]Emory University, Emory Vaccine Center at Yerkes National Primate Research Center, Atlanta, United States, [7]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada

BACKGROUND: Factors associated with control of HIV in the absence of therapy are not completely understood. Protective HLA alleles and robust CD8 T cell responses contribute to immune-mediated mechanisms of control; however, HIV adaptation to immune pressure, which is evident in the accumulation of viral "escape mutations" in targeted epitopes, can result in loss of control. Some escape mutations reduce viral fitness, indicating that functional constraints may play an important role in determining the extent to which HIV can adapt to host immunity.

A better understanding of subtype-specific viral adaptation mechanisms may inform future efforts in HIV vaccine development and cure research.

METHODS: We examined plasma specimens from 20 treatment-naïve long-term non-progressors infected with HIV subtype A who maintained normal CD4 cell counts for over 25 years. The gag coding region was amplified using nested RT-PCR and sequenced using Sanger methods. Viral subtype was confirmed using phylogenetic methods. Mutations in the gag sequence consistent with escape from HLA-mediated immune pressure were identified by comparing aligned sequences to consensus reference strains in regions encoding Gag epitopes, based on the LANL HIV Immunology database.

RESULTS: We observed the following mutations in well-characterized Gag epitopes: B*57/58-KF11 [n=7 (35%) A163G]; B*57/58-TW10 [n=3 (15%) T242N, n=2 (10%) P243T, n=1 (5%) P243V]; B*44-AW11 [n=11 (55%) S310T]; B*57/58-QW9 [n=8 (40%) E312D]; B*57/58-IW9 [n=1 (5%) L147M, n=2 (10%) L147V]. Prior studies demonstrated that many of these mutations reduce in vitro HIV replication capacity, suggesting that viral attenuation is common in this cohort.

CONCLUSIONS: Reduced viral fitness associated with Gag sequence variation may contribute to long-term non-progression in this cohort of HIV subtype A-infected individuals. Future work will confirm this hypothesis by measuring the replication capacity of selected Gag clones.

INNATE IMMUNITY

PEA0021

ESCAPE OF HIV-1 ENVELOPE GLYCOPROTEIN FROM RESTRICTION OF INFECTION BY IFITM3

A. Drouin[1], J. Migraine[1], M.-A. Durand[1], A. Moreau[1], J. Gaillard[2], M. Beretta[1], P. Roingeard[2,1], M. Bouvin-Pley[1], M. Braibant[1]
[1]University of Tours, Inserm U1259- MAVIVH, Tours, France, [2]University of Tours, Plate-Forme IBiSA des Microscopies, PPF ASB, Tours, France

BACKGROUND: Interferon-induced transmembrane protein 3 (IFITM3) is a cellular factor reducing HIV-1 infectivity by an incompletely understood mechanism. In addition to blocking the viral entry into the target cell, IFITM3 may incorporate into virions during viral assembly and thus reduce the infectivity of nascent virions. The aim of our study was to elucidate the role of the HIV-1 envelope glycoprotein (Env) in determining the viral susceptibility to IFITM3.

METHODS: We produced Env-pseudotyped viruses derived from primary and laboratory strains and determined their susceptibility to the inhibition of viral infectivity by IFITM3. To explore whether IFITM3 interact with Env in virions producing cells, co-immunoprecipitation and immunofluorescence experiments were performed. To examine if IFITM3 may induce some Env conformational changes, Env-pseudotyped viruses were tested for their sensitivity to a panel of monoclonal neutralizing antibodies (NAbs).

RESULTS: Infectivity of Env-pseudotyped viruses was decreased by IFITM3 to various levels with a decrease of more than 60% for sensitive viruses but no decrease for resistant viruses. Co-immunoprecipitation experiments showed that IFITM3 interacts with both precursor (gp160) and cleaved (gp120) forms of IFITM3-sensitive Env but only with the precursor (gp160) form of IFITM3-resistant Env. This suggested that the interaction between resistant Env and IFITM3 was inhibited once Env had matured in the Golgi apparatus. This hypothesis was supported by immunofluorescence experiments, which showed that, on the plasma membrane of virus-producing cells, IFITM3 co-localize strongly with sensitive Env but very weakly with resistant Env.

By measuring the sensitivity to NAbs of Env-pseudotyped viruses, we observed that IFITM3 increased the sensitivity of IFITM3-sensitive Env to PG16, which targets the V1V2 loop. This suggested that IFITM3 favored the exposure of the PG16 epitope of sensitive Env. Exchanges of the V1V2 loops between sensitive and resistant Env confirmed that V1V2 in combination with V3 modulate the susceptibility of viruses to IFITM3.

CONCLUSIONS: Together, our results showed that IFITM3 interacts with Env, resulting in conformational changes that may decrease the infectivity of viruses. This antiviral action is nevertheless modulated by the nature of the Env, in particular its V1V2 region, which after maturation may be able to escape this interaction.

PEA0022

WHAT'S SEX GOT TO DO WITH IT? UNDERSTANDING THE POTENTIAL FOR CONFOUNDING AND EXPOSURE MISCLASSIFICATION DUE TO VAGINAL SEX IN STUDIES OF BIOLOGICAL MECHANISMS ASSOCIATED WITH HIV ACQUISITION

J. Deese[1], M. Hobbs[2], D. Lapple[2], M. Wang[3], J. Nelson[2], B. Kuerten[1], M. Steiner[1]
[1]FHI 360, Product Development and Introduction, Durham, United States, [2]University of North Carolina at Chapel Hill, Medicine, Chapel Hill, United States, [3]FHI 360, Biostatistics, Durham, United States

BACKGROUND: Vaginal immune marker concentrations are associated with risk of HIV acquisition in women. However, vaginal specimens may contain both female and male partner biological material following recent sex. Recent vaginal sex may confound immune marker measurement by:

1) attribution of male biomarkers to the female partner (exposure measurement error), and/or,

2) transient modification of female biomarkers due to sex.

METHODS: We enrolled female-male partners aged 18-40 who were HIV and STI negative. We measured pro-inflammatory cytokines, secretory leukocyte protease inhibitor (SLPI) and human beta-defensin (HBD)-2 in vaginal specimens collected immediately after (1-4 hours) sex and in the absence of sex (≥72 hours since last sex) and in male ejaculate samples.

RESULTS: Thirteen female-male partners were enrolled and completed follow-up. Median ages were 24 and 25 for females and males respectively. All vaginal specimens collected 1-4 hours post-sex had detectable prostate specific antigen (PSA) and 78% of specimens collected ≥72 hours post-sex did not have detectable PSA, suggesting high fidelity to protocol-required sample collection timing by participants. All semen specimens had detectable RANTES, IP-10, IL-8, SLPI and HBD-2. The concentration ranges observed in male samples overlapped with the observed female ranges for all markers except HBD-2. RANTES, IP-10 and SLPI concentrations were higher and IL-8 and HB-2 were lower, in female specimens taken immediately after sex vs. those taken in the absence of sex.

CONCLUSIONS: This study suggests that concentrations of vaginal immune markers associated with HIV acquisition vary by sex recency and confirms their presence in male seminal fluid. Therefore, the analysis of female vaginal samples may be biased by contamination of male biomarkers following recent sex. In addition, the observed differences in vaginal biomarkers from samples taken immediately after vs. in the absence of sex suggests sex-induced transient modification of these biomarkers. If true, identification of women with sustained vaginal inflammation may be confounded by frequency of vaginal sex, both of which are associated with HIV risk. While these pilot study results should be confirmed, the results suggest that use of vaginal immune markers in studies of HIV acquisition should identify methods to measure and adjust for sex recency.

PEA0023

RECOMBINANT HUMAN (RH)ERAPS ANTI-HIV EFFECT RELIES ON ACTIVATION OF INNATE IMMUNITY

M. Biasin[1], I. Saulle[2], M. Saresella[3], I. Marventano[3], C. Vanetti[2], D. Trabattoni[2], C. Fenizia[2], M. Clerici[2]
[1]University of Milan, Department of Biomedical and Clinical Science, Milan, Italy, [2]University of Milan, Milan, Italy, [3]Don Gnocchi Foundation IRCCS, Milan, Italy

BACKGROUND: Recombinant human (rh)-ERAP2 (E2)-treated peripheral blood mononuclear cells (PBMCs) are less susceptible to in vitro HIV-1 infection. This antiviral mechanism is partially preserved even when CD8+ T cells are depleted, suggesting that other immunocompetent cells are positively sensitized by E2 treatment. Based on these observations we investigated whether E2 can trigger monocytes and monocyte derived macrophages (MDMs), boosting their antiviral potential. As ERAP1 and ERAP2 share similar functions and a high sequence homology, which allows them to work even as heterodimers, functional analyses were performed on rhERAP1 (E1) and E1+E2 treated cells as well.

METHODS: MDMs differentiated from PBMCs of 15 healthy donors were in vitro HIV-1 infected in presence/absence of 100ng/ml E1, E2 and E1+E2. Six-days post infection mRNA expression and protein production of proinflammatory cytokines were assessed by Real-Time PCR and ELISA, respectively, while viral replication was quantified by p24 viral antigen measurement. We next investigated the molecular mechanism induced by E1, E2 and E1+E2 treatment by analysing:
1) inflammasome activation (FlowSight AMNIS) in monocytes and human THP1 macrophages (hTm);
2) monocyte and Natural Killer (NK) activation (flow cytometry); and
3) phagocytosis in THP and monocytes.

RESULTS: E2 treatment resulted into a 7-fold reduction of HIV-1 replication in MDMs ($p<0,05$). This antiviral activity was associated with an increased mRNA expression of CD80, IL-1b, IL-18, TNF-α, ($p<0.01$ for cytokine) during in vitro ERAPs-treated HIV-1-infected MDMs. This was mirrored by IL-1b, TNF-α,IL-6, IL-8 protein release ($p<0.01$ for each cytokine). Notably, ERAPs addition also induced the functional assembly of inflammasome components (ASC and NLRP3) in monocytes ($p<0,01$) and hTm ($p<0,01$) as well as a rise in the percentage of activated classical monocytes (CD14+CD16-HLADRII+CCR7+CD80+) ($p<0,02$) and NK cells (CD3-CD16+CD56+CD107+) ($p<0,02$). Finally, THP and human monocytes showed an increased phagocytosis following all ERAP treatments.

CONCLUSIONS: ERAPs are able to trigger several antiviral mechanisms in monocyte-macrophagic and NK cells hence their anti-HIV potential is not exclusively dependent on their canonical role in antigen presentation and CD8+ T cell activation. Further investigations on ERAPs' role in both innate and adaptive immunostimulatory pathways and suggests their potential use in novel preventive and therapeutic approaches against HIV-1 infection.

PEA0024

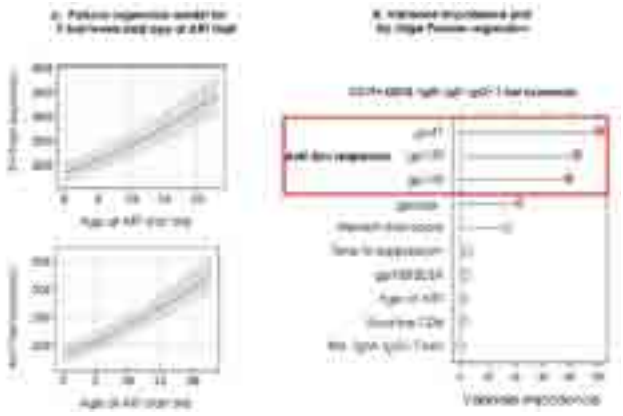
AGING B-CELLS (ABC) AND ANTI-ENV HUMORAL RESPONSES ARE ASSOCIATED WITH T-BET EXPRESSION IN B-CELLS OF PERINATALLY HIV INFECTED CHILDREN (PHIV) TREATED WITHIN 24 MONTHS OF LIFE (THE CARMA COHORT)

A. Ruggiero[1], N. Cotugno[1], S. Dominguez-Rodriguez[2], S. Zicari[1], S. Rinaldi[3], P. Zangari[1], A. Tagarro[2], M. Serna[2], C. Foster[4], A. De Rossi[5], E. Nastouli[6], K. Luzuriaga[7], C. Giaquinto[5], P. Rossi[1], S. Pahwa[3], P. Palma[1], on behalf of the EPIICAL consortium
[1]Ospedale Pediatrico Bambino Gesu', Roma, Italy, [2]Fundación para la Investigación Biomedica del Hospital 12 Octubre, Madrid, Spain, [3]University of Miami, Miami, United States, [4]Imperial College Healthcare NHS Trust, London, United Kingdom, [5]University of Padova, Padova, Italy, [6]Great Ormond Street NHS Foundation Trust, London, United Kingdom, [7]University of Massachusetts Medical School, Worcester, United States

BACKGROUND: The role of T-bet, an immune factor involved in adaptative and innate response, has been poorly explored in B-cells. Previous studies concentrated on HIV+ and HIV- adults and T-bet was found to be associated with ABC. This work characterizes T-bet expression in B-cell (CD19+CD10-) subsets associated with aging (activated memory AM CD21-CD27+, Tissue Like Memory TLM CD21-CD27- and Double Negative DN CD27-IgD-) and with immunological memory (Resting Memory, RM CD27+CD21+IgD-)in PHIV.

METHODS: We studied 40 PHIV starting ART at median 4 months(m) of age (min 0m, max 22m) and ART-suppressed for >5 years (median 14 years (y) (min 5y, max 22y). Flow Cytometry was used to define B-cell phenotype and intracellular T-bet (MFI) in PHIV and in 20 age and gender-matched controls (HC). Anti-HIV serology was measured using Western blot and ELISA. Comparisons were analysed using Mann-Whitney test (MW). Associations were explored using Spearman test (rho, p) and multivariable ridge Poisson Regression model including baseline CD4, gender, and age at ART as confounders.

RESULTS: DN were expanded in PHIV compared with HC ($p=0.01$ MW). T-bet levels were elevated in AM, TLM and marginally DN compared to the others. The models demonstrated a strong association between T-bet levels and time of ART start: for each month without ART T-bet increased by 3% and 2% in DN and AM, respectively (Fig.1a). Anti-Env responses were positively associated and were identified as predictors of T-bet levels in IgG+ B-cells (rho=0.35, $p=0.03$, Fig. 1b), IgM+ B-cells (rho=0.39, $p=0.01$), RM IgM+ (rho=0.33, $p=0.042$).



[Figure 1]

CONCLUSIONS: ABC are expanded in PHIV compared with HC, despite suppressive ART. Earlier ART-start preserves from premature aging of B-cell compartment. Furthermore, elevated levels of T-bet in memory B-cells was associated with anti-Env responses. Our findings add onto the previous literature by suggesting a role of T-bet in the anti-HIV B-cell response that warrant further investigation.

CELLULAR IMMUNITY

PEA0025

LOWER IMMUNE ACTIVATION & EXHAUSTION IN PEOPLE LIVING WITH HIV INFECTED PERINATALLY THAN IN ADULT AGE

L. Taramasso[1,2], D. Fenoglio[3], A. Parodi[3], F. Kalli[3], A. Bandera[1], C. Dentone[4], T. Altosole[3], M. Berruti[5], S. Mora[6], M. Giacomini[6,3], G. Filaci[7,3], A. Di Biagio[5]
[1]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy, [2]MultidisciplinAry ResearCh in Health Science (MACH), Milan, Italy, [3]University of Genoa, Centre of Excellence for Biomedical Research (CEBR), Genoa, Italy, [4]Policlinico San Martino Hospital, Clinica of Infectious Diseases, Genoa, Italy, [5]University of Genoa, Department of Health Sciences (DISSAL), Genoa, Italy, [6]University of Genoa, Department of Informatics, Bioengineering, Robotics and System Engineering (DIBRIS), Genoa, Italy, [7]University of Genoa, Internal Medicine, Genoa, Italy

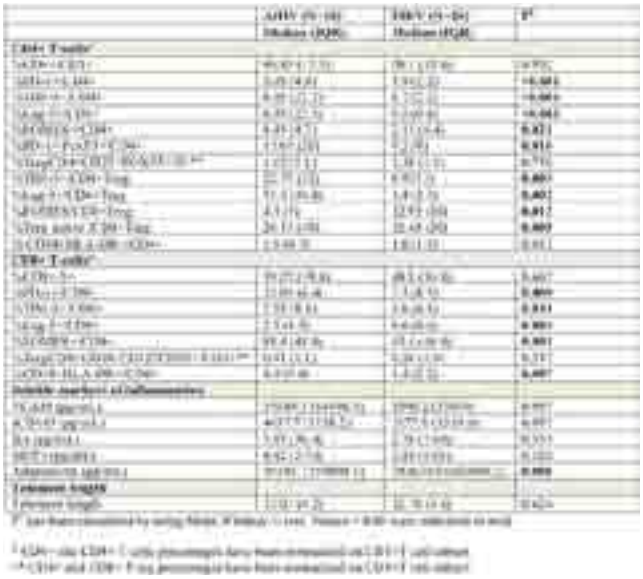
BACKGROUND: The aim of this study was to compare the level of activation, exhaustion and ageing of immune system in perinatally HIV-infected young adults (PHIV) and patients with similar age, but becoming infected in adulthood (AHIV).

METHODS: Cross-sectional study including HIV-infected patients aged 18-40 years and on ART since at least 12 months. Patients with HIV-RNA>50 copies/mL or active AIDS-defining diseases were excluded. We compared the expression of immune exhaustion and activation markers on CD4+ and CD8+T cells, soluble markers of inflammation (VCAM1, sCD163, IL-6, adiponectin) and telomere length in PHIV and AHIV patients. Values were expressed as medians (IQR) and compared by Mann Whitney U test.

RESULTS: We analysed 26 PHIV and 18 AHIV with median age of 26 (8.0) and 28 (6.8) years (p0.080) and history of 20 (9.0) and 2.5 (2.8) years of ART. Percentages of CD4+ and CD8+T lymphocytes on CD3+T subset were similar in PHIV and AHIV, but PHIV showed significant higher percentages of Naïve and lower percentages of Terminal Effector Memory CD4+ and CD8+ cells. AHIV patients consistently exhibited higher expression of exhaustion markers on both CD4+ and CD8+T lymphocytes, as PD-1, TIM-3, Lag-3 and EOMES compared to PHIV (Table).

The percentage of activated CD8+CD38+HLA-DR+T cells resulted higher in AHIV than PHIV. To concern T regulatory arm, the percentages of CD4+CD25+FOXP3+ and CD8+CD28-CD127-CD39+T regulatory cells were similar in the two groups, but the analysis of developmental stages showed a higher percentage of activated CD4+Tregs (CD45RA-FOXP3high) in AHIV (Table).

Among soluble markers of inflammation, only adiponectin showed different concentrations in PHIV than AHIV, while telomere length was similar in the two groups (Table).



[Table. Expression of immune exhaustion and activation markers on regulatory and total CD4+ and CD8+T cells and concentration of soluble markers of inflammation and telomerase length in patients perinatally infected with HIV (PHIV) and in patients infected in adulthood (AHIV).]

CONCLUSIONS: A greater immune-activation was seen in AHIV than PHIV, suggesting that lack of control in recent times, rather than the cumulative time of infection, affects immune-activation and exhaustion of CD4+ and CD8+ T cells.

PEA0026

IMPACT OF EARLY ANTIRETROVIRAL THERAPY ON B AND CD4 T CELL DYNAMICS IN LYMPHOID TISSUES OF SIV INFECTED RHESUS MACAQUES

J. Clain[1], F. Moukambi[1], G. Benmadid-Laktout[1], H. Rabezanahary[1], G. Racine[1], O. Zghidi-Abouzid[1], J. Estaquier[1]
[1]Université Laval, Centre de Recherche du CHU de Québec, Quebec, Canada

BACKGROUND: In SIV-infected rhesus macaques (RMs), previous studies showed an early loss of splenic and mesenteric CD4 T cells. To date, under antiretroviral therapy (ART), HIV-infected patients exhibit low viral load along with restoration of CD4 T cells counts. However, we had recently showed that despite early ART, SIV can persist in the spleen and mesenteric lymph nodes, resulting in viral rebound when treatments are interrupted. Therefore, viral persistence in these tissues may impact on T and B cells in inducing their exhaustion. Thus, we assessed in SIV-infected RMs, treated with early ART, the dynamics and differentiation of B and CD4 T cells.

METHODS: Rhesus macaques (RMs) were infected with SIVmac251 (20 AID50) and treated at day 4 with a cocktail of antiretroviral drugs including Tenofovir (TFV, 20mg/kg, GILEAD) and Emtricitabine (FTC, 40mg/kg, GILEAD) administrated subcutaneously and Raltegravir (RGV, 20mg/kg, MERCK) or Dolutegravir (DTG, 5mg/kg, ViiV) combined with Ritonavir (RTV, 20mg/kg; Abbvie) administrated by oral route. RMs were sacrificed either under ART or after ART interruption (ATi).

In addition to peripheral blood, we recovered the spleen, mesenteric lymph nodes (MLN) and peripheral lymph nodes (PLN) immediately after euthanasia. Cells were isolated and stained with specific monoclonal antibodies and further analyzed by flow cytometry. We also evaluated viral load in ART and ATi RMs.

RESULTS: We provided evidences that early ART restore efficiently CD4 T cells in MLN, PLN, spleen and blood. However, in reservoir tissues (MLN and spleen) in which SIV persists, Tfh cells as well CD4 effector memory cells (TEM) are partially restored compared to the blood and PLN. We also observed that B cells expressed higher levels of CD95 and PD1 under ART compared to healthy RMs. By analyzing specific SIV antibodies in the sera of RMs, we noticed that all RMs under ART displayed SIV-specific IgG antibodies although at lower levels compared to untreated SIV-infected RMs.
CONCLUSIONS: These results indicated that early ART does not fully restore immune system as "naïve" individual suggesting that persistent viral reservoir impairs B and T cell dynamics. Therefore, strategy aims to eliminate viral reservoirs should be essential for adaptive immune responses.

[1]Centro Medico ABC, Medicina Interna, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Departamento de Infectologia, Mexico City, Mexico, [3]Hospital Regional de Alta Especialidad del Bajío, Leon, Mexico, [4]CAPASITS Puebla, Puebla de Zaragoza, Mexico, [5]CAPASITS León, León, Mexico, [6]Hospital General de Tijuana, Tijuana, Mexico, [7]Institut Pasteur, Paris, France, [8]National Institue of Allergy & Infectious Diseases, Maryland, United States, [9]Queen's University, Division of Infectious Diseases, Kingston, Canada

BACKGROUND: CD4+ T-cell recovery after antiretroviral therapy (ART) initiation is variable and difficult to predict. ART administered during acute HIV-infection (AHI) is associated with improved CD4+ T-cell recovery and normalization of the CD4/CD8 ratio. Here we describe different patterns of CD4+ T-cell recovery and their associated T-cell subsets phenotype, according to time from infection to ART initiation.
METHODS: We analyzed two cohorts: The first one was composed of patients with AHI treated within the first 24 hours of HIV diagnosis. The second one was a retrospective cohort of patients with chronic HIV infection (CHI) on their first ART regimen that were identified as Hyperimmune recuperators (Hypers). Hypers were defined as patients with CHI that achieved CD4+ counts >1000 cells/ml before 48 months since ART initiation. We performed Flow-cytometry analysis in fresh whole blood. We defined Naïve-(Nv), central memory (CM), effector memory (EM) and terminally differentiated T-cells (TMRA) with CD3, CD4, CD8, CD45RA, CCR7, CD38, CD31 and HLA-DR markers. We used CD28 and CD57 to identify immunosenescent cells and Fox-P3, CD 25, CD127 and CD45RA to identify Regulatory T-cells and their subsets.
RESULTS: We included 32 patients with AHI and 26 Hypers. After one year of follow-up, AHI patients' median CD4+ T-cell counts increased from 407.28 to 595.5 cells/mm3 (p=0.005), median CD4/CD8 ratio increased from 0.376 to 0.898 (p<0.001). When comparing both patterns of T-cell recovery, AHI patient's CD4+ T cell and CD4/CD8 ratio recoveries closely resembled the pattern shown by the Hypers (p>0.999). AHI patients had more CD8+ EM cells (33.3 vs 27.6, p=0.025), lower total activation (CD4: 0.56 vs 1.16, p<0.001; CD8: 1.42 vs 5.73, p=0.001) and lower CD4+ immunosenesce (1.41 vs 39, p<0.001) with higher CD8 immunosenesce (32.4 vs 22.5, p=0.034), when compared to Hypers.
CONCLUSIONS: ART initiated during acute HIV infection had a marked impact on T CD4+ and CD4/CD8 ratio recovery. Even if the pattern of recovery was similar to Hyper-patients, these had higher immune activation and lower immune senescence, highlighting the importance of early treatment. This suggests the possibility that the superior CD4+ recovery seen in both populations stems from common well-preserved homeostatic mechanisms, and warrants further investigation.

PEA0028

INCREASED FREQUENCY OF NAÏVE T CELL IS A DISTINCTIVE CHARACTERISTIC OF YOUNG ADULTS WITH PERINATAL HIV INFECTION

S. Stöver[1], A. Urioste[2], J. Lattner[1], P. Coll[1], A. Sisto[1], M.J. Rolón[1], Y. Ghiglione[2], G. Turk[2], M.L. Polo[2], N. Laufer[2,1]
[1]Hospital Dr. Juan A. Fernández, Infectious Diseases Division, Buenos Aires, Argentina, [2]INBIRS (UBA-CONICET), Buenos Aires, Argentina

BACKGROUND: Children infected via perinatal transmission at the beginning of the HIV epidemic are now reaching adulthood and data on this population is scarce. HIV infection during the development of the immune system could be associated with irreversible immune damage, once adulthood is reached. Here, we aimed to evaluate the quality of the cellular immune response in perinatally-infected young adults.
METHODS: Three groups were enrolled in 2019 in an Argentinean public hospital: 1-study group (SG): 15 perinatally-HIV-infected young adults (20-30 years); 2-Age control group (CA): 12 young adults with HIV acquisition after 16 years (paired by age to SG); 3-Time-of-infection control group (CT): 14 adults (>40 years) paired to SG, by infection time. Blood samples were obtained at enrollment. Phenotype, immune-activation and senescence markers on NK and T-cells were assayed by flow cytometry. Data was analyzed using non-parametric statistics.
RESULTS:

Characteristic	Young adults non-perinatally infected (CA)	Adults non-perinatally infected (CT)	Perinatally infected young adults (SG)	p-value (CA vs SG)	p-value (CT vs SG)
Female (n, %)	2, 18.2	7, 50	11, 73.3	0.0064	0.2035
Nadir LTCD4+ count -cells/mm3- (median, IQR)	313, 239-562.3	132, 72-407	412, 40-930	0.8558	0.2299
Current LTCD4+ count -cells/mm3- (median, IQR)	672, 608-903	653, 584-912	774, 609-1249	0.6614	0.4082
Current CD4/CD8 (median, IQR)	0.74, 0.58-1.06	0.94, 0.7-1.42	0.8, 0.58-1.26	0.6403	0.4321
ART duration (time since first ART initiation) -months- (median, IQR)	44.3, 33.9-62.9	219.5, 178.72-253.54	208.8, 60.8-262.7	0.0001	0.0160
Time between HIV diagnosis and first undetectable VL -months- (median, IQR)	14.73, 5.62-38.2	104.15, 74.66-190.72	165.73, 144.1-215.57	0.0001	0.0447
Time undetectable -months- (median, IQR)	31.69, 27.02-47.21	170.12, 115.46-230.10	106.45, 65.82-164.55	0.0007	0.0291
Age at time of study enrollment -years- (median, IQR)	28.04, 26.39-30.07	50.91, 47.59-57.6	24.77, 21.92-28.44	0.0734	0.0000

[Table.]

The main characteristics of participants are described in Table-1. Despite similar LTCD4+ count and CD4/CD8 ratio, SG had higher frequency of naive LTCD4+ (44.4%, IQR:33.6-55.8) than CT (13.9%, IQR:3.4-25, p=0.0003) and CA (25.3%, IQR:9.3-37, p=0.01). Regarding naïve LTCD8, the higher frequency was observed in SG (29.3%,

IQR:19.5-46.1) but it was only statistically different to CT (5.9%, IQR:1.9-9.9, p=0.001). LTCD4+, LTCD8+ and NK PD1 expression was lower in SG, being significantly different between LTCD4+PD1+ of SG and CT (27.7%, IQR:20.2-39.1 vs 43.4, IQR:30.4-59.4, p=0.016).

CONCLUSIONS: Young adults,HIV perinatally-infected at the beginning of the epidemic in Argentina, had a history of more difficulties to achieve viral control. Nevertheless, and despite being undetectable for only a median of 8 years, these individuals exhibited a lower frequency of exhausted T-cells and NK-cells, and higher rates of naïve T-cells. These findings could reflect an adaptive response during the development of the immune system in the context of an immunosuppressive virus. Further analyses regarding immune functionality and reservoir composition in this special population are needed.

RESIDENT MEMORY CD8+ T CELLS CONTROL THE HIV RESERVOIR IN CERVIX

N. Massana[1], J. Cantero-Pérez[1], M. Suppi[1], J. Grau-Expósito[1], J. Castellví[2], L. Mañalich-Barrachina[3], C. Centeno-Mediavilla[3], V. Falcó[4], M.J. Buzón[1], M. Genescà[1]

[1]Vall d'Hebron Research Institute (VHIR), Infectious Disease, Barcelona, Spain, [2]Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Pathology, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Obstetrics and Gynecology, Barcelona, Spain, [4]Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Infectious Disease, Barcelona, Spain

BACKGROUND: In tissues, resident memory CD8+T cells (TRM) are most likely necessary to eliminate remaining cellular HIV-1 reservoirs. However, TRM signature includes expression of molecules associated to exhausted phenotypes during chronic viral infections. Here we addressed the functional capacity of CD8+TRM from the cervical mucosa of HIV-infected women on ART to determine the most effective phenotypes at limiting viral persistence.

METHODS: CD8+T cells from cervical tissues were phenotyped based on CD69 expression to determine TRM signature (n=6-9). Frequency and phenotype of CD8+TRM subsets were compared between healthy (n=9) and ART-suppressed HIV+ women (n=18). In a subset of these patients, we determined total vDNA in blood and cervix (n=7). Gag-specific responses and functional assays were assessed to determine suppression of viral reactivation by CD8+TRM in ART-suppressed HIV+ women.

RESULTS: Cervical CD69+CD8+T cells protein profile was compatible with >90% belonging to bona fide CD8+TRM, as determined by CCR7, S1PR1, T-bet, Eomes, Hobit, α1 and PD-1 expression. Cervical samples from ART-suppressed patients were enriched in total CD8+T cells compared to uninfected women, including higher frequencies of non-TRMs ($p<0.01$) and TRM ($p<0.05$), and higher expression of HLA-DR ($p<0.01$). Importantly, the frequency of cervical CD8+TRM correlated with proviral HIV-1 DNA in cervix ($r=-0.82$) and blood ($r=-0.62$). Moreover, tissue CD8+TRM were more efficient at eliminating reactivated HIV-1-infected CD4+T cells than circulating effector CD8+T cells.

CONCLUSIONS: The CD8+T cell compartment from the cervical mucosa of HIV+ women remain disturbed even after several years of effective ART-suppression. The association between higher proportion of CD8+TRM in cervix and less proviral HIV-1 DNA, together with data showing higher control of virally-reactivated infected cells by CD8+TRM, indicates that these cells may be critical to control persisting virus in tissues.

[1]University of Cape Town, Cape Town, South Africa, [2]CAPRISA Centre of Excellence in HIV Prevention, Cape Town, South Africa, [3]Medical Research Centre, Yaoundé, Cameroon, [4]Seattle Children's Research Institute, Seattle, United States, [5]Kenya Medical Research Institute, Kisumu, Kenya, [6]Desmond Tutu HIV Centre, Cape Town, South Africa, [7]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [8]University of Washington, Seattle, United States, [9]National Health Laboratory Service, Cape Town, South Africa

BACKGROUND: Hormonal contraception may influence acquisition of sexually transmitted infections (STIs) including HIV, as may inflammatory cytokines in the lower female genital tract. While the ECHO trial found that intramuscular depo-medroxyprogesterone acetate (DMPA-IM) did not significantly increase HIV risk compared to the levonorgestrel implant nor the copper intrauterine device, the trial was unable to include injectable norethisterone enanthate (NET-EN).

METHODS: We therefore compared the cytokine responses to NET-EN versus DMPA-IM in cervicovaginal secretions collected from menstrual cups of 47 women assigned to DMPA-IM as part of the ECHO trial in three sites: Cape Town and Johannesburg, South Africa and Kisumu, Kenya, and from 43 women assigned to NET-EN as part of the UChoose study in Cape Town, South Africa. Samples were collected at baseline (pre-initiation), and post-initiation after two injections of either NET-EN (given every 2 months) or DMPA-IM (given every 3 months). Concentrations of 27 cytokines were measured by Luminex and analysed in R using descriptive statistics, logistic regressions and non-parametric tests to evaluate differences between groups.

RESULTS: At baseline, genital cytokine levels, STI prevalence, and Nugent scores were similar between women initiating DMPA-IM and those initiating NET-EN. There was no significant increase in genital inflammation, including cytokines related to HIV-risk, in either group post-contraceptive initiation compared to baseline, nor did any cytokine changes differ between women using DMPA-IM or NET-EN. DMPA-IM decreased 20 cytokines up to 1.8-fold, while NET-EN decreased 21 cytokines up to 2.2-fold. However, this fold-decrease was more pronounced for DMPA-IM than NET-EN for 18 cytokines. NET-EN decreased RANTES (1.2-fold), IL-9 (1.1-fold) and IL-10 (1.4-fold), while DMPA-IM did not. Possible confounders including age, marital status, number of partners, number of sexual acts per week, and condom use did not influence the associations between contraceptive type and cytokine concentrations.

CONCLUSIONS: Initiation of DMPA and NET-EN did not increase genital inflammation in sub-Saharan African women, suggesting that their administration is safe in African women at risk for HIV and STIs. A subset of the evaluated cytokines responded differently to NET-EN versus DMPA-IM initiation. As different cytokines have varying biological effects, further investigations are needed to evaluate the clinical relevance of our findings.

PECULIAR PHENOTYPIC AND FUNCTIONAL FEATURES OF PULMONARY MUCOSAL CD8 T-CELLS IN PEOPLE LIVING WITH HIV RECEIVING LONG-TERM ANTIRETROVIRAL THERAPY

O. Meziane[1], Y. Alexandrova[1], R. Olivenstein[2], J.-P. Goulet[3], F. Dupuy[1], E. Thomson[1], M. Orlova[2], E. Schurr[2], P. Ancuta[4], N. Bernard[2], C. Costiniuk[2], M.-A. Jenabian[2]
[1]Research Institute of McGill University Health Centre, and Université du Québec à Montréal, Montreal, Canada, [2]Research Institute of McGill University Health Centre, Montreal, Canada, [3]Caprion Biosciences Inc, Montreal, Canada, [4]Centre de Recherche du CHUM and Department of Microbiology, Infectiology and Immunology, Université de Montréal, Montreal, Canada

BACKGROUND: We recently demonstrated HIV reservoir persistence in the lung mucosa of people living with HIV (PLWH) receiving long-term viral-suppressive antiretroviral therapy (ART). Cytotoxic CD8 T-cells play a pivotal role in controlling chronic viral infections, with CD8 exhaustion/senescence contributing to HIV persistence. Here, we explored the unique phenotypic and functional features of pulmonary versus blood CD8 T-cells in ART-treated PLWH and uninfected controls.

METHODS: Bronchoalveolar lavage (BAL) fluid and matched blood were obtained from participants including ART-treated PLWH smokers (n=10) and non-smokers (n=15) and uninfected smokers (n=12) and non-smokers (n=5) without any active respiratory symptoms. CD8 T-cell immunophenotyping was performed by flow cytometry. *In vitro* CD3/CD28-induced CD8 T-cell degranulation ability (CD107a expression) and functional cytotoxicity to kill autologous Gag-labeled CD4 T-cells (Annexin-V+) were also performed. Transcriptional mRNA profiling was assessed by HiSeq sequencing on FACS-sorted pulmonary CD8 *versus* peripheral memory CD8 T-cells.

RESULTS: In all HIV-infected/uninfected groups, pulmonary CD8 T-cells compared to blood were enriched in cells with an effector memory phenotype to the detriment of naive and terminally differentiated memory T-cell subsets, as well as higher levels of immune pulmonary CD8 T-cell activation (HLA-DR$^+$) and exhaustion (PD1$^+$). Significant reduction in senescent pulmonary CD28$^-$CD57$^+$ CD8 T-cells only in smoking PLWH was observed. Importantly, in all groups pulmonary *versus* blood CD8 T-cells showed reduced Perforin expression *ex vivo*, with Granzyme-B expression being reduced only in non-smoking PLWH. Also, the HIV-specific CD73$^+$ CD8 T-cell subset was significantly reduced in BAL compared to blood. Upon *in vitro* functional assays, pulmonary *versus* blood CD8 T-cells showed a significantly lower capacity to kill autologous Gag-labeled CD4 T-cells, and a lower degranulation capacity (CD107a$^+$) following CD3/CD28 triggering. Finally, genome-wide transcriptional profiling demonstrated overexpression of several metabolic and pro-inflammatory pathways in lung versus blood memory CD8 T-cells.

CONCLUSIONS: Pulmonary mucosal CD8 T-cells differ from blood circulating CD8 T-cells by having a highly differentiated, activated, and exhausted phenotype, along with decreased killing capacity and peculiar metabolic/pro-inflammatory transcriptomic profiles. Such unique features of pulmonary CD8 T-cells may contribute to the establishment and maintenance of HIV reservoirs in the lungs of ART-treated PLWH.

PEA0032

THE IMPACT OF SEMEN EXPOSURE ON CYTOKINE RESPONSE AND BACTERIAL VAGINOSIS IN THE FEMALE GENITAL TRACT

K. Mngomezulu[1], S. Ngcapu[2], C. Baxter[3]
[1]University of KwaZulu-Natal, Department of Medical Microbiology, Durban, South Africa, [2]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Department of Medical Microbiology, Durban, South Africa, [3]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa

BACKGROUND: Diverse microbial communities and inflammatory cytokine responses in the lower female genital tract (FGT) are closely associated with increased human immunodeficiency virus (HIV-1) risk, possibly through increasing mucosal HIV target cell frequency and T-cell activation. The presence of semen in the vagina during unprotected sex has been associated with short-term activation of mucosal immunity. Here, we investigated the extent to which partner semen impacts on cytokine and microbial profiles measured in 248 HIV-uninfected women at high risk for HIV infection.

METHODS: We assessed the semen exposure in SoftCup supernatants by quantifying prostate specific antigen (PSA) levels using enzyme-linked immunosorbent assay (ELISA). Luminex was used to measure 48 cytokines in SoftCup supernatants and the vaginal swabs were used for diagnosis of bacterial vaginosis by Nugent score.

RESULTS: PSA, which denotes semen exposure within 48 hours prior to sampling, was detected in 19% (43/248) of SoftCup supernatants. Of the 43 PSA positive women, 70% (30/43) had self-reported condom use at their last sex act and 84% (36/43) had non-Lactobacillus dominant microbiota (Nugent score >7). In addition, PSA was significantly associated with prevalent bacterial vaginosis (Relative Risk (RR), 2.609; 95% Confidence Interval (CI), 1.104 - 6.165; p = 0.029), after adjusting for potential confounders such as age, STIs, current contraceptive use and condom use.

Furthermore, women with detectable PSA had high median concentrations of Macrophage inflammatory protein- beta (MIP-1β) (p=0.047) compared to those without PSA.

CONCLUSIONS: These findings suggest that the presence of semen has a potential to alter the inflammatory response and microbial communities of the FGT, which may facilitate recruitment of HIV susceptible cells, resulting in increased susceptibility to HIV-1 infection.

HIV TRANSMISSION AND DISSEMINATION

PEA0033

MOTHER TO CHILD TRANSMISSION RATES AND CARE FOR HIV-EXPOSED INFANTS IN UGANDA

L. Nabitaka[1], I. Lukabwe[1], D. Ondo[1], J. Musinguzi[1], W. Kirungi[1], M. Adler[2], P. Namukanja[2], D. Serwadda[3], F. Makumbi[3], J. Kasule[3], F. Nalugoda[3], T. Lutalo[3,4]
[1]Ministry of Health, STD/AIDS Control Program, Kampala, Uganda, [2]CDC Uganda, Care and Treatment, Entebbe, Uganda, [3]Rakai Health Sciences Program, Kampala, Uganda, [4]Uganda Virus Research Institute, Entebbe, Uganda

BACKGROUND: Women of reproductive age (15–49 years) in Uganda have high HIV prevalence (5.7%), and the model-based estimate of early mother to child transmission of HIV (MTCT) rate is 3.9%. We evaluated the effectiveness of the Uganda national prevention of MTCT (PMTCT) program on early MTCT.

METHODS: Our baseline cross-sectional study included a nationally representative sample of 12,627 mother-infant pairs from 152 public and private health facilities. Eligible infants were aged 4–12 weeks, recruited from September 2017 to March 2018. Sociodemographic, behavioral, and health-related data were obtained from interviews with mothers and medical records. We performed virologic polymerase chain reaction tests on infant blood samples to determine early MTCT rates and rapid HIV tests for mothers who did not have documented HIV-positive status. Using STATA 15, multivariate logistic regression was used to determine factors independently associated with MTCT and their corresponding 95% CI.

RESULTS: Median age of mothers was 24 years (interquartile range [IQR], 20–28 years, 10.2% (1290/12,627) were HIV positive, and just over three-quarters (77.7%) reported adherence to antiretroviral therapy. The infant median (IQR) age was 56 days at enrollment, with DPT1 immunization coverage of (91.2%); higher in HIV non-exposed (91.4%) than in HEIs (89.7%; p=0.05). Exclusive breastfeeding was higher among HEIs (89.2%) than HIV non-exposed infants (86.4%; p<0.05).

Receipt of Nevirapine prophylaxis after delivery was 85.3%, but 10.1% of mothers reported skipping Nevirapine for infants, Cotrimoxazole prophylaxis was reported for only 31.9% of infants aged 0–6 weeks. Early MTCT occurred in 28/1216, 2.3%; CI (1.53, 3.33), significantly lower if mother was virally suppressed adj.OR 0.20; 95% CI (0.07 – 0.57).

CONCLUSIONS: Early MTCT in this study was slightly lower than the modelled estimate, but both indicate continuing high levels of transmission. This makes a compelling case for intensive efforts to increase PMTCT programme effectiveness such as addressing the suboptimal infant ART prophylaxis, maternal ART enrolment, adherence and retention, and increasing antenatal care attendance.

PEA0034

AMINO-ACID DELETION IN GAG P6 DOMAIN ALTERS GALECTIN-3 PROMOTING EFFECTS ON VIRUS INFECTION OF HIV-1 CRF07_BC FROM INJECTING DRUG USERS

R.Y. Yuan[1], C.S. Yeh[1], W.H. Wang[2], Z.S. Yang[1], C.P. Pa[1], F.T. Liu[3], Y.M. Chen[4], S.F. Wang[1,2]
[1]Department of Laboratory Science and Biotechnology, Kaohsiung Medical University, Kaohsiung City, Taiwan, Province of China, [2]Center for Tropical Medicine and Infectious Disease, Kaohsiung Medical University, Kaohsiung City, Taiwan, Province of China, [3]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, Province of China, [4]Master Program for Clinical Pharmacogenomics and Pharmacoproteomics, Taipei Medical University, Taipei, Taiwan, Province of China

BACKGROUND: HIV-1 CRF07_BC, a recombination strain, is prevalent in injecting drug users (IDUs) in Taiwan. A sequence alignment of clinical CRF07_BC isolates reveals natural deletions of Gag p6. We previously found that galectin-3 (Gal-3) promotes HIV-1 subtype B viral budding through an association with Alix and Gag p6. However, the role of Gal-3 in HIV-1 CRF07_BC infection is unknown.

METHODS: HIV-1 CRF07_BC infectious clones were constructed using full-length CRF07_BC genes from HIV-1 CRF07_BC-infected IDUs, which contains 7 and 11 a.a. deletions (-7d and -11d) plus a repaired form in the Gag p6 domain. Infectivity assay, replication kinetics, ELISA and immunoblotting were used to evaluate the regulating effects of Gal-3 on CRF07_BC infection, replication, and budding.

RESULTS: Data from co-transfections of pHIV-1 CRF07_BC-7d, -11d, and pGal3 vectors into 293T cells indicate that Gal-3 expression resulted in a slight increase in CRF07_BC viral budding and slower replication kinetics compared to the NL4-3. This phenomenon could be compensated when repairing a.a. deletions in the p6 domain. Immunofluorescent staining and super resolution analyses indicate approximately 20-30% colocalization of Alix and deleted Gag-p6. Gal-3 expression slightly enhanced this colocalization to 30-40%; a significant increase (60-70%) was noted when Alix was colocalized with repaired 07BC-Gag (p<0.01).

Membrane flotation data indicate that:

(a) Alix, Gag-7d or -11d, and flotillin-1 (a lipid raft marker) exhibited reduced co-fractionation toward cell membranes, and;

(b) Gal-3 expression slightly increased the co-fractionation of these proteins,

(c) while significantly increasing the co-fractionation of Alix and repaired Gag-p6 moving toward cell membranes.

Our Co-IP data indicate that IP Alix and Gag-7d or -11d pulled down smaller amounts of Gag-7d or -11d and Alix regardless of the presence of Gal-3 expression. We also detected higher concentrations of Gal-3 in sera collected from patients infected with HIV-1 subtype B compared to patients infected with CRF07_BC.

CONCLUSIONS: This study underscores the integrity of HIV-1 p6 domain and indicates the deletions in the Gag p6 ameliorating the effects of Gal-3 on HIV-1 CRF07_BC replication and budding.

PEA0035

PREVALENCE OF HIV-1 DRUG RESISTANCE MUTATIONS IN NEWLY DIAGNOSED INFANTS IN BOTSWANA

N.O. Moraka[1], S. Moyo[2], D. Setlhare[3], M. Mogwele[2], S. Maphorisa[4], N. Kelentse[5], P.T. Mokgethi[2], J. Ngidi[6], G.U. Van Zyl[1], S. Gaseitsiwe[2]
[1]Stellenbosch University, Pathology, Cape Town, South Africa, [2]Botswana Harvard AIDS Institute Partnership, Research Laboratory, Gaborone, Botswana, [3]Botswana Harvard AIDS Institute Partnership, DNA PCR, Gaborone, Botswana, [4]Botswana Harvard AIDS Institute Partnership, Drug Resistance, Gaborone, Botswana, [5]University of Botswana, Allied Health Proffessions, Gaborone, Botswana, [6]Ministry of Health and Wellness, Gaborone, Botswana

BACKGROUND: Despite a successful prevention of mother-to-child-transmission (PMTCT) and improved antiretroviral regimens in Botswana, there is no data on HIV drug resistance mutations (DRM) prevalence among infants. We describe the prevalence of surveillance HIV DRMs among infants diagnosed with HIV in the Botswana routine early infant diagnosis program.

METHODS: Residual dried blood spots (DBS) from <18-month old HIV positive children who were diagnosed as part of the Botswana public sector HIV early infant diagnosis (EID) program between 2016 and 2018 were available for HIV DRM surveillance (n = 78). The protease and reverse transcriptase regions were amplified and sequenced using the ATCC HIV-1 Drug Resistance Genotyping kits and big dye chemistry. Surveillance drug-resistance mutations were assessed using the Calculated Population Resistance program (http://cpr.stanford.edu/cpr.cgi) from Stanford.

RESULTS: Of the 78 samples available, 32 (41%) were successfully amplified and sequenced and 1 was excluded due to APOBEC-induced mutations. The median age was 2 months (IQR: 2- 4). Three (9.7%) newly diagnosed infants had detectable SDRMs. Although PMTCT coverage is >95% in Botswana, PMTCT exposure data was not available for all infants. Among these infants, one (33%) had a non-nucleoside reverse transcriptase inhibitor (NNRTI) HIV SDRM (K103N) detected and two (67%) had a detectable protease inhibitor (PI) SDRMs (M46L and L23I).nm

CONCLUSIONS: We observe relatively high and regionally comparable rates of SDRMs among newly diagnosed infants with unknown PMTCT exposure in Botswana; which may suggest that most transmissions occurred in mother-baby pairs who did not access PMTCT services.

PEA0036

ENDOGENOUS GALECTIN-3 REGULATES CELL-TO-CELL TRANSMISSION OF HIV-1 CRF07 BC

Z..S. Yang[1]
[1]*Kaohsiung Medical University, Kaohsiung, Taiwan, Province of China*

BACKGROUND: HIV propagation is mainly through cell-to-cell transmission via virological synapse (VS) and budding viruses in the early and late phases, respectively. The formation of VS is known for recruiting several viral and cellular factors engaged at membrane lipid raft. HIV1 CRF07_BC is prevalent among injected drug users(IDUs). CRF07_BC clinical isolates in Taiwan contained 7-13 amino acids naturally deletion in p6Gag domain. Galectin-3 (Gal3) was recently reported to promote HIV-1 NL4-3 budding. However, the effect of Gal3 in CRF07_BC is still unclear. This study aimed to investigate the role of endogenous Gal3 in CRF07_BC infection, mainly focused on HIV cell-cell transmission.
METHODS: The CRF07_BC infectious clones containing 7 and 11 amino acid deletions (7d&11d), and a non-deletion wild type (wt) in p6Gag were constructed. Jurkat cells expressing CCR5 and Gal3 were generated (Jurkat-R5/Jurkat-R5-Gal3). A cell-to-cell transmission assay was established using HIV-1 infected cell (donor cells) co-cultured with HIV-1 uninfected cells (target cells). Transmission efficacy and VS formation were analyzed by flow cytometry and confocal microscope.
RESULTS: Results from cell-to-cell transmission indicate that Gal3 expression in Jurkat significantly promoted CRF07_BC-wt transmission. We noted that this promotion effect regulated by Gal3 was not observed in CRF07_BC-7d and CRF07_BC-11d. Results from confocal microscope and flow cytometry indicate that more Env, Gag and CD4 engaged at cell-cell contact regions and higher amounts of VSs of CRF07_BC-wt-infected Jurkat-Gal3-R5 cells compared to CRF07_BC-wt-Jurkat-R5 cells were observed. The phenomena were not observed in CRF07_BC-7d and CRF07_BC-11d infected Jurkat-R5 or Jurkat-R5-Gal3 groups.
CONCLUSIONS: This study concluded that endogenous Gal3 expression promotes the intercellular transmission of CRF07_BC-wt instead of CRF07_BC-7d or CRF07_BC-11d.

PEA0037

BONE MARROW STROMAL ANTIGEN 2 (BST-2) MRNA EXPRESSION PROFILE MAY MODULATE ANTIBODY-DEPENDENT CELL-MEDIATED CYTOTOXICITY (ADCC) IN HIV-1 CHRONICALLY INFECTED PATIENTS

H. Mlimi[1], P. Madlala[1]
[1]*University of KwaZulu Natal, HIV Pathogenesis Programme, UKZN, Durban, South Africa*

BACKGROUND: Tetherin, bone marrow stromal antigen 2 (BST-2) is an interferon-induced protein that blocks the release of HIV-1 and other enveloped viral particles from the plasma membrane of infected cells. A previous study showed association of BST-2 polymorphisms with protection and disease progression in mother-to-child HIV-1 transmission. An ex vivo study showed that enhancing virion tethering by BST-2 sensitizes HIV-1 infected cells to antibody-dependent cell-mediated cytotoxicity (ADCC).However, the role of endogenous BST2 expression level on ADCC has not been determine. The aim of this study was to characterize the expression profile, frequency of single nucleotide polymorphisms of BST-2 in HIV-1 subtype C chronically infected individuals and associate this with disease outcome and ADCC.
METHODS: To this effect RNA was extracted from cryopreserved PBMCs obtained from 20 HIV-1 negative and 30 positive participants (RNeasy mini Kit (Quigen, Hilden, Germany), reverse transcribed (iScript Synthesis Lit (BIO rad, California, USA), Quantitative PCR was performed using SYBR Green chemistry and analyzed using LightCycler 480 (Roche). Subsequently, TaqMan Assay was used to determine the frequency of SNPs rs919267 and rs9576.
RESULTS: Interestingly, our data demonstrate that HIV-1 of uninfected participants have higher BST2 expression compared to HIV-1 positive participants (p< 0.0001). The SNP rs919267 AG allele was associated with low expression in both infected (p=0.017) and uninfected individuals (p=0.053) this SNP also showed a trend toward lower levels of viral load (p= 0.099). The SNPs rs9576 GT was nominally associated with the trend toward high BST2 expression.
CONCLUSIONS: Ongoing analysis include looking at the CD4 decline overtime from baseline and ADCC activity. Determining the influence of rs919267 and rs9576 on BST2 expression and disease outcome.

PEA0038

IMPACT OF HUMAN HIV- 1 SUBTYPE C (HIV-1C) TRANSMITTED/FOUNDER (T/F) VIRUSES LTR AND TAT CO-VARIATION ON DISEASE OUTCOME

P. Madlala[1], Z. Mkhize[1], S. Naicker[1], T. Ndung'u[1,2]
[1]*University of KwaZulu-Natal, HIV Pathogenesis Program, Durban, South Africa,* [2]*Africa Health Research Institute, Durban, South Africa*

BACKGROUND: The persistent latent viral reservoir which is established early in infection is the greatest barrier to HIV-1 eradication. Latent reservoirs comprise cells infected with replication competent yet transcriptionally silent provirus. However, the mechanisms that govern viral latency at the transcriptional level are not known. Previous studies associated viral latency with cellular factors such as integration sites. While other studies investigated the role of viral factors such HIV-1 LTR and tat during chronic infection. HIV-1 LTR is the promoter that drives viral gene transcription while the tat encodes Transactivator of transcription protein (Tat) that enhances the transcription activity of the LTR. Despite that knowledge that viral latency is established early, the role of the transmitted/founder (T/F) viruses LTR and Tat on latency development has not been extensively investigated. Therefore we hypothesized that covariation of HIV-1 subytpe C (HIV-1C) T/F viruses LTR and Tat may impact disease outcome.
METHODS: To this effect, viral RNA was extracted from plasma samples obtained from 30 South Africans with acute HIV-1 infection, reverse transcribed (SuperScript IV Invitrogen), amplified using nested PCR for LTR and tat, separately (Platinum Taq DNA polymerase, Invitrogen) and sequenced (BigDye cycle sequencing kit v3.1, Invitrogen). Subsequently, HIV-1C LTR and tat sequences either wildtype or variants were co-transfected into Jurkat cells to assess the expression of the reporter gene luciferase, under the HIV-C LTR promoter.

RESULTS: Although wild type Tat increased the LTR activity for most of the LTR variants, the T/F virus LTR containing the TATA box mutation (TATAA à TAAAA) was not induced. Interestingly, our data demonstrate that autologous Tat induced transcription positively correlated with viral load at transmission (p=0.0086, r=0.71). Furthermore, the autologous Tat increased transcription activity of the TATA box mutant LTR, albeit at significantly low levels compared to other LTR variants. On the other hand, P21A Tat variant in combination with other mutants are associated with significantly lower viral loads when was assessed on TZMbl cells.

CONCLUSIONS: Taken together our data suggest that HIV-1C T/F viruses LTR and Tat genetic variation may impact disease outcome. The ongoing experiments includes assessing the effect of these mutants on latent reservoir development and reversal.

SYSTEMIC IMMUNE ACTIVATION AND INFLAMMATION

HIV-1 INDUCED TELOMERE ATTRITION AND ITS EFFECTS IN PI3K/ATM DYNAMICS

S. Khanal[1], Z. Qiang Yao[2,3,4]
[1]East Tennessee State University, Internal Medicine, Johnson City, United States, [2]Center of Excellence in Inflammation, James H. Quillen College of Medicine, East Tennessee State University, Infectious Disease and Immunity, Johnson City, United States, [3]Quillen College of Medicine, ETSU, Division of Infectious, Inflammatory and Immunologic Diseases, Johnson City, United States, [4]Hepatitis (HCV/HBV/HIV) Program, James H. Quillen VA Medical Center, Department of Veterans Affairs, Johnson City, United States

BACKGROUND: Lower CD4 T cell count characterizes the canonical HIV/AIDS conciliated immune deficiency. CD4 T cell depletion is a hallmark of HIV/AIDS however; the underlying mechanism is still unclear. Telomeres are aging markers and HIV infection-induced telomere attrition might instigate T-cell aging and senescence. We have recently reported the deficiency of ataxia-telangiectasia mutated (ATM) in patient-derived CD4 T cells accelerates DNA damage, telomere erosion, and cell apoptosis in HIV-infected individuals on antiretroviral therapy (ART). Whether these alterations in ART-treated HIV subjects occur in vitro in HIV-infected CD4 T cells remains unknown.

METHODS: T-cell isolated from HIV-infected patients from James H. Quillen VA Medical Center and healthy subject, as well as, T-cell line samples are used for this research. Experimental techniques such as flow cytometry, cell culture, RT-PCR, western blotting, microscopy and overexpression/silencing approaches are used to generate the data for this work.

RESULTS: An in-vitro model of HIV-1 infection is established which helped characterize the mechanisms underlying CD4 T cell destruction by analyzing the telomeric DNA damage response (DDR) and cellular apoptosis in highly permissive SupT1 cells. We illustrated complications within telomeric DDR, T-cell apoptosis and PI3K/ATM dynamics in activated primary CD4 T cells with active or drug-suppressed HIV-1 infection. Overall, we were able to mimic the results of ATM dynamics observed from patient samples in an in-vitro infection model. Specifically, we have established an in vitro HIV-1 T cell culture system with viral replication and raltegravir (RAL, an integrase inhibitor) suppression, mimicking active and ART-controlled HIV-1 infection in vivo. We have evidence of HIV-induced telomeric DDR playing a pivotal role in triggering telomere erosion, premature T cell aging, and CD4 T cell apoptosis or depletion via dysregulation of the PI3K/ATM pathways.

CONCLUSIONS: We conclude the deficiency of ATM triggers T-cell senescence dismantling PI3K dynamics resulting in a DDR failure and T-cell senescence. Both patient samples and in vitro model support our conclusion. We believe this in vitro model provides an easier approach to investigate the HIV pathogenesis. We aspire our results shed more light on the molecular mechanisms of telomeric DDR and CD4 T cell homeostasis during HIV-1 infection.

INCREASED PROPORTION OF THE HIGHLY PERMISSIVE TH17 CELL PROFILE DURING HIV-1 INFECTION AFTER MACROPHAGE MIGRATION INHIBITORY FACTOR (MIF)-CD74 AXIS SIGNALING

C.A. Trifone[1], L. Baquero[1], A. Czernikier[1], J. Salido[1], L. Leng[2], H. Salomón[1], F. Quiroga[1], R. Bucala[3], Y. Ghiglione[1], G. Turk[1]
[1]University of Buenos Aires, Microbiology, Buenos Aires, Argentina, [2]Yale University School of Medicine, Department of Medicine, New Haven, United States, [3]Yale University School of Medicine, Medicine, New Heaven, United States

BACKGROUND: MIF plasma levels are increased in people living with HIV/AIDS (PLWHA). In vitro, treatment of HIV-infected primary monocyte-derived-macrophages (MDMs) with MIF generates a pro-inflammatory environment which fosters HIV-1 infection/replication in non-activated CD4+ T-lymphocytes (CD4TLs). However, whether MIF exerts an effect on CD4TL activation and/or profiling during the infection is unknown. Aim: To evaluate the role of MIF in CD4TL function during HIV infection.

METHODS: CD4TLs and MDMs were obtained from healthy donors. MDMs were infected with HIV-1 and allogeneic MDMs-CD4TLs co-cultures plus 25 ng/ml MIF were assayed. Also, stimulation was performed with MIF-neutralizing reagents. Likewise, PBMCs from PLWHA were treated with MIF. Soluble cytokine production was evaluated by ELISA. Intracellular cytokine and transcription factor expression were evaluated by flow cytometry. Data was analyzed by parametric or non-parametric methods.

RESULTS: MIF stimulation induced the expression of IL-6 (p=0.013) and IL-1b (p<0.0001) in HIV-infected MDMs, , whereas IL-10 was diminished (p<0.0001), compared to control. Increased IL-17A-expressing (p=0.02), RORgt-expressing CD4TLs percentages (p=0.038) and soluble IL-17A (non-statistically significant) were found in the MIF-stimulated MDMs/CD4TL co-cultures. A decrease in soluble IFNg but no differences in neither IFNg-producing nor Tbet-expressing CD4TLs were observed. MDM infected with transmitted/founder HIV-1 strains model recapitulated these results. Monoclonal antibody (p=0.00046) or chemical antagonist (MIF098) mediated MIF-neutralization (p=0.025), induced a decrease in IL17+ CD4TLs. Also, a slight decrease in IL-17A+ CD4TLs was observed when neutralizing IL-6 and IL-1b activity (non-statistically significant). Additionally, in samples from PLWHA, higher MIF plasma level were related to higher IL-17+ CD4TLs percentages (p=0.02). In vitro, 24-hour MIF-stimulation of PBMCs from PLWHA led to an increase in the Th17 population (p=0.004), and in IL-6 concentrations in culture supernatant (p=0.04) compared to control.

CONCLUSIONS: These results suggest that CD4TLs exposed to the environment produced by MIF-stimulated HIV-infected MDMs biases responding CD4TLs toward a Th17-like profile. The results ob-

tained using T/F HIV-1 strains and PBMCs from PLWHA further support these findings. Overall, MIF may contribute to viral pathogenesis by generating an immune environment enriched in activating mediators and Th17 CD4TLs, which are reported highly susceptible to HIV-1 infection and relevant to viral persistence.

PEA0041

PLASMA BILE ACID LEVELS PREDICT SERIOUS NON-AIDS EVENTS

N. Utay[1], E. Arning[2], A. Somasunderam[1], M. Martinez[1], T. Bell[1], R. Arduino[1], T. Bottiglieri[2]
[1]University of Texas Health Science Center at Houston, Houston, United States, [2]Baylor Scott & White Research Institute, Dallas, United States

BACKGROUND: People with HIV (PWH) have increased risk of serious non-AIDS events (SNAEs). Perturbations in bile acids have been implicated in cardiovascular disease, fatty liver disease, and other pathologies. We hypothesized that PWH who had SNAEs would have altered bile acid profiles.

METHODS: We identified 19 PWH with a SNAE, e.g. death, cardiovascular event, malignancy, end-stage renal or hepatic disease, and 19 age- and sex-matched controls. Biomarkers were measured by ELISA on plasma from entry (T1) and proximal to the event (T2), and bile acids by liquid chromatography - tandem mass spectrometry at T1. Bile acids in PWH and 10 healthy persons were compared with the Mann-Whitney U test and cases and controls with the Wilcoxon signed-rank test. Spearman correlation coefficient was calculated for biomarkers and bile acids.

RESULTS: Median age was 48 years for cases and 47 for controls; 79% were male. Median time between T1 and T2 was 34 and 35 months in cases and controls; median time between T2 and event was 18 months. Cholic acid (CA; P=0.04), glycocholic acid (GCA; P=0.008), taurocholic acid (TCA; P=0.01), and taurochenodeoxycholic acid (TCDCA; P=0.007) levels at T1 were higher, and lithocholic acid (LCA; P=0.0005) levels were lower in PWH. CA (P=0.066) and tauromuricholic acid (TMCA; P=0.08) levels were higher whereas ursodeoxycholic acid (UDCA; P=0.098) and glycoursodeoxycholic acid (GUDCA; P=0.055) levels were lower in cases versus controls.

Higher sCD163 levels at T2 were associated with higher T1 CA (r=0.39, P=0.02) and TMCA (r=0.39, P=0.02) levels, and lower UDCA (r=-0.49, P=0.002) and GUDCA (r=-0.41, P=0.01) levels. IL-6 levels at T2 correlated with baseline TCA (r=0.35, P=0.04), and inversely with UDCA (r=-0.44, P=0.007), GUDCA (r=-0.40, P=0.02), and tauroursodeoxycholic acid (TUDCA) (r=-0.43, P=0.008).

CONCLUSIONS: Higher primary bile acids levels and lower UDCA levels and its conjugate GUDCA tended to predict SNAEs that occurred 4 years later. Levels of primary bile acids and conjugated bile acids were higher whereas the secondary bile acid LCA was lower in PWH. As intestinal microbiota convert primary to secondary bile acids, the shift from secondary to primary bile acid predominance in PWH, especially with SNAEs, may reflect underlying dysbiosis.

CIRCULATING WHITE BLOOD CELL POPULATIONS IN PLHIV ON CART COMPARED TO HEALTHY CONTROLS

L. Van de Wijer[1], W. Van der Heijden[2], R. ter Horst[2], M. Jaeger[2], W. Tripsteen[3], S. Rutsaert[3], M. Netea[1], I. Joosten[2], H. Koenen[2], L. Vandekerckhove[3], A. van der Ven[2], Q. de Mast[2]
[1]Radboud University Medical Center, Internal Medicine, Nijmegen, Netherlands, [2]Radboud University Medical Center, Nijmegen, Netherlands, [3]Ghent University, Ghent, Belgium

BACKGROUND: HIV infection alters the immune cell architecture, which may be partially restored by cART. In these individuals, HIV persists in a small pool of latently infected cells, the so-called viral reservoir. Our aim was to comprehensively assess the peripheral blood white blood cell (WBC) composition of people living with HIV (PLHIV) on long-term suppressive cART. We compared their WBC subpopulations with those of healthy individuals and explored clinical and lifestyle factors, as well as the association with the viral reservoir.

METHODS: We included Caucasian PLHIV, aged ≥18 years, on cART >6 months and with HIV-RNA <200 copies/ml. Healthy controls were simultaneously sampled every three months for four times. A total of 133 WBC subpopulations were characterized using flow cytometry on whole blood and peripheral blood mononuclear cells (PBMCs). The HIV reservoir was quantified by ddPCR on HIV-DNA and cell-associated HIV-RNA (caHIV-RNA)in CD4+ cells. Data were analyzed using linear regression and corrected for age, sex, and seasonal effects. FDR-corrected p-values <0.05 were considered statistically significant.

RESULTS: PLHIV (n=211) were older than controls (n=56), with median (IQR) age of 52.5 (13.2) years vs. 30.0 (27.1) years (p<0.001), and more often male (91.0% vs 60.7%, p<0.001). Besides decreases in proportions of CD4+ cells and increases proportions of regulatory T cells (Tregs) and CD8+ cells, PLHIV showed significant changes in B cell maturation stages. In addition, PLHIV had fewer naive cells and an expansion of effector cells. These changes were accompanied by increased proportions of cells expressing the proliferation marker Ki67 or activation marker HLA-DR+. While age, sex, smoking, and nadir CD4+ significantly influenced the WBC composition, no effects were found for cART regimen. HIV-DNA and caHIV-RNA were significantly associated with lower proportions of (naïve) CD4+ cells, higher proportions of CD8+ cells and Tregs, as well as decreases in memory B cells.

CONCLUSIONS: Despite long-term suppressive cART, the immune cell architecture of PLHIV remains significantly altered. Next to age, sex, smoking, and nadir CD4+, the viral reservoir influences the WBC composition and these changes are not restricted to the (infected) CD4+ cells.

PLASMA CYTOKINE PREDICTORS OF HIV DISEASE PROGRESSION

S. Ngcobo[1,2], R.P. Molatlhegi[1,2], R. Talakgale[1], N. Sumsunder[1], N. Garrett[1], S.S. Abdool Karim[1,3], Q. Abdool Karim[1,3], L.R. McKinnon[1,4,5], A. Sivro[1,2,4]
[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Department of Mucosal Immunology, Durban, South Africa, [2]University of KwaZulu-Natal, Department of Medical Microbiology, Durban, South Africa, [3]Columbia University, Department of Epidemiology, New York, United States, [4]University of Manitoba, Department of Medical Microbiology, Winnipeg, Canada, [5]University of Nairobi, Department of Medical Microbiology, Nairobi, Kenya

BACKGROUND: Previous studies have highlighted the role of pre-infection systemic inflammation on HIV acquisition risk however they did not examine the impact on disease progression outcomes. Here we characterised the association between pre-infection plasma cytokine/chemokine expression and the rate of disease progression in the CAPRISA 004 cohort, a phase IIb, randomised, double-blinded, placebo-controlled study which compared 1% tenofovir gel with a placebo gel in South African women from KwaZulu-Natal.
METHODS: We used Bio-PlexTM 200 system to measure the expression of 47 cytokine/chemokines in a cohort analysis of 783 samples from the CAPRISA 004. The study included 69 cases and 714 controls with cases sampled 330 (IQR 211 to 493) days prior to HIV infection. Cox proportional hazards regression analyses were used to measure associations between pre-infection cytokine expression and the rate of CD4 decline prior to ART initiation (cases only). Pearson correlation was used to measure the correlation between log10 pre-infection plasma cytokines with viral load (peak and set-point) and CD4:CD8 ratio (< and >180 days post infection).
RESULTS: We identified several cytokines that were associated with HIV disease progression outcomes (including IL16, SCGFβ, MCP-3, IL-12p40 and TNFβ). The strongest associations were found for SCGFβ, which correlated with peak viral load (r=0.42, p=0.001) and faster CD4 decline below 500µl (HR=3.71;95% CI 1.28-10.80; p=0.016) in univariate analysis and this remained true in multivariable analysis correcting for contraception, age, study site, baseline HSV-2 and study arm.
CONCLUSIONS: Our results show that pre-infection systemic inflammation is associated with the rate of HIV disease progression.

PEA0044

MONOCYTES FROM PEOPLE LIVING WITH HIV ARE LESS SENSITIVE TO INHIBITION OF TNF-ALPHA PRODUCTION BY PROSTAGLANDIN E2

F. Di Diego Garcia[1], G. Cabrerizo[1], N. Bello[2], P. Perez[1], A. Paletta[1], V. Friedman[2], D. Stecher[2], A. Ceballos[1], F. Remes Lenicov[1]
[1]University of Buenos Aires, INBIRS (Institute for Biomedical Research on Retroviruses and AIDS), Buenos Aires, Argentina, [2]University of Buenos Aires, Hospital de Clinicas - División Infectología, Buenos Aires, Argentina

BACKGROUND: Monocyte activation plays a central role in the persistent inflammation associated to HIV chronic infection. Prostaglandin E2 (PGE2) is an immune modulator known to mediate inflammatory and anti-inflammatory effects, notably the inhibition of tumor necrosis factor alpha (TNF) production by monocytes. Our aim was to investigate the role of PGE2 in the pathogenesis of chronic inflammation associated to HIV infection.
METHODS: We recruited a group of people living with HIV (PLHIV, median age 37y, n=37) with viral load undetectable for at least 2 years and no comorbidities or coinfections. Healthy non-infected (NI) persons matched by sex and age were recruited as control group (median age 40y, n=29). All comparisons reported between groups are statistically significant (p<0.05) after Mann Whitney U test.
RESULTS: First, we confirmed that PLHIV showed signs of systemic inflammation including monocyte activation. Plasma levels of TNF and IFN-gamma were increased compared to NI individuals. PLHIV presented increased proportions of non-classical monocytes (CD16+). Furthermore, monocytes isolated from PLHIV produced more spontaneous and LPS-induced TNF than monocytes from NI controls. Importantly, levels of plasma PGE2 were higher in PLHIV than controls. Then we investigated gene expression of PGE2-related genes in purified monocytes by quantitative PCR. Increased expression of PTGS2 and mPGE-S1 (both involved in PGE2 synthesis) was observed in PLHIV, but lower levels of PTGER2 (PGE2 receptor EP2). Using specific receptor antagonists we demonstrated that EP2 receptor mediates PGE2 inhibition of TNF production in monocytes.
Therefore we investigated whether monocytes from PLHIV were less sensitive to inhibition of PGE2. For this, we determined inhibitory concentration 50% (IC50) of PGE2 using dose-response curves in which monocytes were exposed to serial dilutions of PGE2 and then LPS-induced TNF production was measured by ELISA (n=6).
Curves obtained with monocytes from PLHIV showed higher IC50 than curves produced with control monocytes, indicating that PGE2 was less potent to inhibit TNF production in monocytes from PLHIV.
CONCLUSIONS: Our results suggest that monocytes from PLHIV are less sensitive to the inhibitory effect of PGE2 on TNF production. Loss of this negative feedback could be a factor contributing to exacerbated TNF secretion by monocytes and ultimately to persistent inflammation.

PEA0045

PLATELET SEROTONIN REGULATION AND CONSEQUENCES IN HIV INFECTED INDIVIDUALS

N. Vadaq[1,2], L. van der Wijer[1], K. M. Mothapo[1], W. van der Heijden[1], M. G. Netea[1], Q. de Mast[1], A. J.A.M van der Ven[1]
[1]Radboud University Medical Center, Department of Experimental Internal Medicine, Nijmegen, Netherlands, [2]Universitas Diponegoro/Dr. Kariadi Hospital, Center for Tropical and Infectious Diseases (CENTRID), Semarang, Indonesia

BACKGROUND: Serotonin (5-HT) is mainly synthesized in the gut and thereafter stored inside platelet dense granules and released upon activation. While higher platelet 5-HT levels are linked with thrombosis, selective serotonin reuptake inhibitors usage is associated with bleeding risk. Platelets can also interact with immune cells and change their phenotype. Various factors known to regulate 5-HT biosynthesis are altered in HIV infection, including tryptophan metabolism, intestinal microbiome, intestinal CD4 cells. In this study, we first aimed to compare platelets 5HT levels and tryptophan metabolism shifting in people living with HIV (PLWHIV) vs healthy controls. Next, we linked platelet serotonin levels with platelet reactivity and immune cell differentiation.
METHODS: This study included 208 viral suppressed PLWHIV and 56 Dutch healthy controls. Validation was done in Art-NeCo-HIV cohort. Intra-platelet 5-HT concentrations were determined by fluorescence spectrophotometer. Quadrupole time-of-flight mass spectrometer was used to measure tryptophan metabolism pathway. Immunophenotyping and platelet reactivity were measured using flowcytometry.

RESULTS: Platelet 5-HT concentrations were significantly higher in PLWHIV compared to healthy controls (mean±SD 659±280 vs 535±214 nmol/1011 platelets; p=0.004). This was also observed in the Art-NeCo cohort (mean±SD 1125±253 vs 596±96 nmol/1011 platelets; p=6 x 10-7). Ratio of breakdown product of 5-HT (acetyl-n-formyl-5-methoxykynuneramine; 5-hydroxyindoleaceticacid) and kynurenine (2-oxoadipate) to tryptophan were higher in PLWHIV compared to healthy controls (p<0.0001). This suggests higher turnover rates of tryptophan to both serotonin and kynurenine in PLWHIV. As a consequence, increase in platelet 5-HT levels was associated with higher αIIbβ3 integrin binding, both in low dose and cross-linked collagen-related-peptide (CRP-XL) stimulation and in basal condition (p<0.05). Increased platelet 5-HT concentration correlated positively with the percentage of Th17 cells among CCR6(+) memory T helper cells, while it correlated negatively with the percentage of CCR6+ cells among mTreg cells (p<0.05). PLWIH showed a significant reduction of CCR5(+) expression in CD45 cells, granulocytes and mTreg cells in association with higher platelet 5-HT content.
CONCLUSIONS: Platelet 5-HT concentration and turnover of tryptophan towards serotonin were higher in viral suppressed PLWHIV. Increased in platelet 5-HT was associated with higher platelet reactivity and altered percentage of CCR5(+) immune cells, memory T-helper and T-regulatory cells.

PEA0046

CHANGES IN THE Vα7.2+ CD161++ MAIT CELL COMPARTMENT IN EARLY PREGNANCY ARE ASSOCIATED WITH PRETERM BIRTH IN HIV-POSITIVE WOMEN

K. Ravi[1], C. Chan[1], C. Akoto[1], W. Zhang[1], M. Vatish[1], S. Norris[2], P. Klenerman[3], J. Hemelaar[1]
[1]University of Oxford, Nuffield Department of Women's & Reproductive Health, Oxford, United Kingdom, [2]University of the Witwatersrand, South African Medical Research Council Developmental Pathways for Health Research Unit, Department of Paediatrics, School of Clinical Medicine, Johannesburg, South Africa, [3]University of Oxford, Peter Medawar Building for Pathogen Research, Oxford, United Kingdom

BACKGROUND: HIV infection is associated with an increased risk of adverse pregnancy outcomes, including preterm birth (PTB), despite viral suppression with antiretroviral therapy. Mucosal-associated invariant T (MAIT) cells are an immune cell subset involved in antimicrobial immunity at mucosal surfaces. MAIT cells have been found at the maternal-fetal interface and MAIT cells are typically depleted early in HIV infection. We aimed to investigate changes in MAIT cells in relation to maternal HIV/ART status and PTB.
METHODS: We conducted flow-cytometric analysis of peripheral blood samples from 47 HIV-positive (HIV+) and 45 HIV-negative (HIV-) pregnant women enrolled in a prospective pregnancy cohort study in Soweto, South Africa. Frequencies of Vα7.2+ CD161++ MAIT cells and proportions of CD4+, CD8+ and CD4-/CD8- MAIT cells were compared between women with and without HIV infection, and between women with and without PTB or spontaneous preterm labour (Sp-PTL).
RESULTS: Although overall MAIT cell frequencies were the same between HIV+ and HIV- patients, HIV+ patients had a higher proportion of CD8+ MAIT cells in the first two trimesters. Women with PTB and spontaneous preterm labour (Sp-PTL) also had a higher level of CD8+ MAIT cells in the first trimester compared to women without these outcomes. An additive effect on MAIT cell subsets was seen in women with both HIV infection and PTB/Sp-PTL.
CONCLUSIONS: Imbalances in MAIT cell subsets in early pregnancy may contribute to the increased risk of PTB in HIV+ patients by altering the overall functionality of the peripheral MAIT cell compartment.

T CELL DEPLETION AND RECONSTITUTION, AND IMMUNE AGEING

PEA0047

MULTIMORBIDITY AND IRREVERSIBLE DEPLETION OF CD4+ T-CELLS IN HIV INFECTED GUT MUCOSA SAMPLED WITHIN HIGH HIV ENDEMIC AREAS IN SOUTH AFRICA

O.E. Asowata[1], A. Singh[1], A. Ngoepe[1], R. Fardoos[1,2], F. Nene[1], A. Ntuli[1], T. Naidoo[1], F. Karim[1], K. Govender[1], J. Adamson[1], F. Anderson[3], A. Leslie[1,4], H. Kløverpris[1,2,4]
[1]Africa Health Research Institute, Durban, South Africa, [2]University of Copenhagen, Department of Immunology and Microbiology, Copenhagen, Denmark, [3]Inkosi Albert Luthuli Central Hospital, University of KwaZulu-Natal, General Surgery, Durban, South Africa, [4]University College London, Department of Infection and Immunity, London, United Kingdom

BACKGROUND: HIV pathology involves gut barrier breakdown, microbial translocation and immune activation that drives disease progression, which is not reversed by current antiretroviral therapy (ART). However, the underlying mechanisms for the lack of immune reconstitution remain unknown.
METHODS: Here, we present a large cohort of 463 patients from a gastrointestinal (GI) clinic in KwaZulu-Natal, South Africa recruited within extremely high HIV endemic areas. Human gut biopsies were collected during Endoscopy, colonoscopy and Endoscopic retrograde cholangiopancreatography (ERCP) procedures to obtain duodenum and colon (ascending, transverse and sigmoid) pinch biopsies with matching blood. Phenotypic characterization of immune markers in these samples such as CD4+ T cells, activation and inflammation markers was done using multiparameter flow cytometry and fluorescent immunohistochemistry. Luminex and Enzyme-linked immunosorbent assay (ELISA) was used to elucidate markers of microbial translocation. Antiretroviral (ARV) drug levels in plasma were quantified by mass spectrometry.
RESULTS: Clinical symptoms were dominated by non-infectious comorbidities such as dysphagia, colon-cancer, polyps and obstructive jaundice. Strikingly, HIV infected women and men presented to the GI clinic 13 and 8 years earlier than uninfected patients (P<0.0001), respectively, suggesting that HIV infection drives early GI pathology. The overall HIV prevalence in the cohort was 30% (137/463) with every second woman under 50 years testing HIV positive. We observed persistent immune activation and inflammation in HIV infected patients despite suppressive ART. We quantified ARV levels in plasma and found 19% (17/90) treatment failures with viremia in the presence of ART in plasma. Despite 81% plasma viral suppression and long-term ART in this cohort, severe depletion of gut CD4 T-cells was observed in the duodenum (3.7% vs 9.5%, P<0.0001) and colon (6.9% vs 13.7%, P=0.008). Sustained CD4 T-cell loss remained in fully viral suppressed (VL<20cps/ml) patients (P<0.0001) that was confirmed by fluorescent immunohistocytometry.
CONCLUSIONS: This large GI cohort is a unique opportunity to further reveal the unknown mechanisms of gut barrier breakdown central to both HIV pathology and continued comorbidities in the growing population of individuals receiving ART in Sub-Saharan Africa that may be different to that of Caucasian populations.

PEA0048

AKT BLOCKADE LIMITS T CELL CHEMOTAXIS AND FAVORS T CELL CLEARANCE IN HIV-1 INFECTION

G. Herbein[1], A. Kumar[1], S. Pasquereau[1]
[1]University of Franche-Comté, Besancon, France

BACKGROUND: Akt signaling plays a central role in many biological processes, which are key players in human immunodeficiency virus 1 (HIV-1) pathogenesis. Akt activation favors cell mobility and survival and interacts with the HIV-1 Nef protein. HIV-1 Nef inhibits T cell chemotaxis in response to the physiological ligands CXCL12 and CCL5, and modulates T cell apoptosis. We assessed the role of Akt inhibition on both T cell chemotaxis and apoptosis in HIV-1 infection.
METHODS: Peripheral blood lymphocytes (PBLs) isolated from healthy donors were assessed for apoptosis and for CXCL12- and CCL5-mediated chemotaxis in response to exogenous Nef, in the absence and presence of Akt inhibitors. In addition, in PBLs infected with wild type HIV-1 (HIV-WT) and an isogenic mutant infectious HIV-1 clone deleted for the nef gene (HIVΔNef) we compared the rate of apoptosis and CXCL12- and CCL5-mediated chemotaxis in the presence and absence of Akt inhibitors. Chemotaxis assay was performed in a 24-well plate that carries transwell inserts of a 5 micron pore size. Apoptosis measurement was assessed using an annexin V assay.
RESULTS: We found that exogenous Nef inhibits T cell chemotaxis in response to CXCL12 and CCL5. Following infection with the wild type HIV-1 virus, HIV-WT, but not with HIVΔNef, T cell chemotaxis in response to CXCL12 and CCL5 was inhibited. In agreement with a positive role for Akt activation on chemotaxis, Akt inhibitors further blocked the inhibition of T cell chemotaxis induced by exogenous and virus-associated Nef. T cell apoptosis observed with both exogenous and virus-associated Nef was increased using Akt inhibitors.
CONCLUSIONS: We observed that Nef-mediated inhibition of T cell chemotaxis in response to CXCL12 and CCL5 could be further enhanced by Akt inhibitors. In addition, Akt inhibitors enhanced the rate of apoptotic T cells exposed to Nef. By limiting the spread of infected T cells and enhancing their elimination, Akt inhibitors could be a new therapeutic approach to fight HIV-1 infection.

MICROBIOMES AND MICROBIAL TRANSLOCATION

PEA0049

HIV ASSOCIATED MICROBIAL TRANSLOCATION IDENTIFIED BY 16S SEQUENCING

J. Arredondo[1], M. Rolston[1], C. Rocha[1], S. Dandekar[1], S. Sankaran-Walters[1]
[1]University of CA, Medical Microbiology and Immunology, Davis, United States

BACKGROUND: Recent studies have shown that blood from healthy humans contains DNA from translocating microbes. Human blood has been thought to be a sterile environment, the finding of components of microbes in blood was interpreted as an indication microbial translocation. The evidence for the existence of a healthy human blood-microbiome is gradually accumulating. Although the origin, identities and functions of blood microbiota remains to be elucidated, studies on blood-borne microbial phylogeny is increasing. The Human Microbiome Project revealed that the blood microbiome are most likely to have originated from the mucosal and skin microbiome. We hypothesized that the microbiome in HIV+ plasma will differ from that in HIV- plasma from participants. In this study, we isolated DNA from plasma samples from both HIV infected and Healthy donors, and the samples were analyzed by 16S rRNA gene sequencing.
METHODS: DNA for each plasma sample was purified by using the QIA symphony DSP Circulating DNA kit. Dual barcoding amplification was used to provide maximum flexibility for V3-V4 regions of the 16S rRNA bacterial gene. The 127 libraries were sequenced on the Illumina MiSeq to a depth sufficient to capture the total taxonomic composition of our samples. The data was demultiplexed and split into FASTQ files, and the pair-ends reads were processed in DADA2 pipeline. Data analysis was performed in RStudio.
RESULTS: The taxonomic diversity and profile of the bacterial DNA present in the serum of HIV-infected and Healthy donors is distinctly different. The distribution of reads assigned at the phylum level reveals that the HIV-infected plasma contain bacterial DNA mostly from the Firmicutes phylum, and HIV-negative with Proteobacteria. At a deeper taxonomic level the Bacilli class is mostly found in HIV-positive, and Class Gammaproteobacteria and Alphaproteobacteria in HIV-negative serum.The Statistical analysis showed that the HIV+ and HIV-neg populations were significant (p=0.001).
CONCLUSIONS: We demonstrate in this study the presence of a highly diversified plasma microbiome in HIV infected and healthy donors, which is quantitatively significant and differs between plasma fractions and donors. HIV positive patients have higher levels of systemic inflammation and the increased microbial translocation could be a contributing factor.

TEMPORAL SHIFTS IN VAGINAL MICROBIOTA AND CYTOKINES IN WOMEN TREATED FOR BACTERIAL VAGINOSIS

A. Mtshali[1], S. Ngcapu[2], E.J. San[3], F. Osman[4], N. Garrett[4], C. Balle[5], J. Giandhari[6], H. Onywera[5], K. Mngomezulu[1], G. Mzobe[2], T. de Oliveira[6], A. Rompalo[7], A. Mindel[4], S.S. Abdool Karim[4,8], J.S. Passmore[5], Q. Abdool Karim[4,8], H.B. Jaspan[5,9], L.J. Liebenberg[2,3]
[1]University of KwaZulu-Natal, Medical Microbiology, Durban, South Africa, [2]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Medical Microbiology, Durban, South Africa, [3]University of KwaZulu-Natal, KwaZulu-Natal Research Innovation and Sequencing Platform, Durban, South Africa, [4]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [5]University of Cape Town, Institute of Infectious Disease and Molecular Medicine (IDM), Cape Town, South Africa, [6]KwaZulu-Natal Research Innovation and Sequencing Platform, Durban, South Africa, [7]Johns Hopkins University, Baltimore, United States, [8]Columbia University, Department of Epidemiology, New York City, United States, [9]Seattle Children's Research Institute, University of Washington, Department of Paediatrics and Global Health, Seattle, United States

BACKGROUND: BV increases genital inflammation and risk for HIV infection, although current standard treatment for bacterial vaginosis (BV), with oral metronidazole, is often ineffective, and recurrence rates are high. To evaluate whether BV has a long-term influence on mucosal immune function, we investigated the effects of the BV treatment on the genital microbiota, including the relative effects of BV eradication or recurrence on vaginal microbiota and genital inflammation.
METHODS: Fifty-six HIV-negative women were screened for BV and STIs and followed up six weeks and three months after treatment. The composition of vaginal microbial communities were characterized using 16S rRNA gene sequencing of lateral vaginal swabs of BV+ women pre- and post-metronidazole treatment for BV. Concentrations of 48 cytokines were measured via Luminex, including several

pro-inflammatory, hematopoietic, regulatory and adaptive cytokines and growth factors were measured in Softcup secretions. Genital inflammation was defined by 6 of 9 chemokines and/or inflammatory cytokines being in the top 75th percentile.

RESULTS: Of the 56 women treated for BV, 17/56 resolved BV and remained Nugent score <3 at 6 weeks post-treatment, while 39/56 were considered to have persistent BV (Nugent score >3). At 3 months post-treatment, 5/39 in the persistent BV group resolved their BV, while 9/17 of the cleared group had a recurrent BV episode. BV treatment temporarily reduced the relative abundance of BV-associated anaerobes (particularly Gardnerella vaginalis and Atopobium vaginae) and increased lactobacilli species abundance, resulting in significantly altered mucosal immune milieu over time. Women who cleared BV had decreased concentrations of TNF-α, IL-1β, IL-8, and LIF, while those with persistent BV following treatment had elevated concentrations of IL-1α, IL-18, MIF, IL-7, and LIF; even after adjusting for potential confounders like age, recent sexual activity, and genital examination.

CONCLUSIONS: Our findings demonstrate that BV treatment induces a but short-term shift in the vaginal microbiota and mucosal cytokines. Novel therapeutic strategies against BV-related vaginal biofilms are needed to provide sustained cure and efficacy against BV-associated sequelae in women.

CORRELATES OF HIV SUSCEPTIBILITY AND DISEASE PROGRESSION (BIOMARKERS AND GENETICS)

PEA0051

HOST GENETIC VARIATION IN TOLL-LIKE RECEPTOR 3, RETINOIC ACID SIGNALING, NK CELL ACTIVATION, AND HEMATOPOIESIS ARE ASSOCIATED WITH THE HIV RESERVOIR SIZE IN PERIPHERAL CD4+ T CELLS

D.A. Siegel[1], C. Thanh[1], E. Wan[2], R. Hoh[1], D.L. Kroetz[3], T.J. Heinrich[1], S.G. Deeks[1], S.A. Lee[1]
[1]University of California, Department of Medicine, San Francisco, United States, [2]University of California, Institute for Human Genetics, San Francisco, United States, [3]University of California, Department of Bioengineering and Therapeutic Sciences, San Francisco, United States

BACKGROUND: Several factors are known to influence the size of the HIV reservoir, including timing of ART initiation, T cell activation, and host genetics. Although polymorphisms in HLA and CCR5 genes have been associated with HIV replication in the absence of therapy, they only explain a small proportion of the person-to-person variability and have not been linked to HIV persistence in a genome-wide study of treated HIV disease.

METHODS: Whole exome and custom sequencing was performed from 202 HIV+ ART-suppressed individuals in the UCSF SCOPE cohort. HIV-1 cell-associated total DNA and unspliced RNA were quantified from CD4-enriched cryopreserved peripheral blood cells. To test for associations with common variants (minor allele frequency (MAF)>5%), linear mixed models were adjusted for sex, timing of ART initiation, cell count, and genetic ancestry. Associations with rare variants (MAF<5%) were analyzed using variant Set Mixed Model Association Test (SMMAT). Gene set enrichment analyses were performed using the MSigDB database.

RESULTS: 1,281,473 variants and 21,649 genes from 197 participants passed quality control. Participants were mostly male (95%) with median age 46, nadir CD4+ count 341 cells.mm3, pre-ART HIV RNA 4.3 log10copies/mL, median 5.1 years ART suppression and 1.9 years from infection to ART initiation. Race/ethnicity was most commonly self-reported as Caucasian (63%), African-American (12%), and Latino (11%). Gene-based analyses identified 1,786 genes associated with HIV RNA; top gene sets included STAT signaling, retinoic acid receptor signaling, NK cell activation, and hematopoiesis. Genes involved in toll-like receptor 3 (TLR3) signaling were associated with HIV DNA.

[Figure.]

CONCLUSIONS: Our analysis suggests that host genetic variation in pathways such as TLR3, retinoic acid receptor, and type I interferon signaling, as well as novel pathways involved in NK cell activation and hematopoiesis may shape the size of the HIV reservoir and warrant further study for their potential functional impact on HIV persistence.

PEA0052

PLACENTA AND PLASMA EXPRESSION PROFILES OF MIR3181 AND MIR199A IN HIV+ CAMEROONIAN PREGNANT WOMEN

L. Esemu[1,2], H. Awanakam[1], M. Besong[1], D. Nanfa[1], I. Tsayem[1], C. Nkenfou[3], J. Bigoga[1], R. Leke[1,2], L. Ndhlovu[4], G. Ekali Loni[1]
[1]University of Yaounde I, The Biotechnology Center, Yaounde, Cameroon, [2]Insititute Medical Research and Medicinal Plant Studies, Yaounde, Cameroon, [3]Chantal Biya International Reference Centre, System Biology, Yaounde, Cameroon, [4]University of Hawaii, Tropical Medicine, Honolulu, United States

BACKGROUND: HIV infection during pregnancy has devastating effects on both the mother and her unborn child, one of which is a reduced transfer of protective maternal antibodies needed during early postnatal life. Although the underlining mechanisms of the transplacental transfer of antibodies are not well understood, it is believed that microRNAs (miR) could play an important role. MicroRNAs 3181 and 199a have been associated with the transfer of antibodies into tissues; however, their implication in the reduced placental transfer of protective antibodies in HIV+ women has not been extensively investigated. We proposed to determine the effect of HIV on the expression levels of miR3181 and miR199a in the placenta and plasma of HIV+ women on ART at delivery.

METHODS: In this pilot case-control study, plasma and placenta biopsies were obtained from 36 (18 HIV+ and 18 HIV-) pregnant Cameroonian women at delivery. MicroRNA was extracted from samples, cDNA synthesized and microRNAs 3181 and 199a levels were measured by RT-qPCR. Wilcoxson matched-paired rank test and Mann-Whitney test were used to compare microRNA levels between placenta and plasma and, HIV+ and HIV- women respectively. SPSS v22.0 and R v3.60 were used to analyze data and p-values less than 0.05 were considered significant.

RESULTS: Maternal and fetal sociodemographic and clinical characteristics were not significantly different between HIV+ and HIV- women. HIV+ women were on known regimen Tenofovir-Lamivudine-Efavirenz and had suppressed viral loads. Similar levels of miR3181(p>0.05) were seen in the placenta and plasma of HIV+ and HIV- women. miR199a levels were higher in overall plasma vs placenta(p=0.00005). Similarly, levels of miR199a were higher in plasma of HIV+ than HIV-women(p=0.027). miR199a was also higher in

plasma of HIV+ vs HIV- women (p=0.028). Linear regression models adjusted for systolic pressure showed no association (p>0.05) between levels of the two microRNAs in the plasma and placenta with HIV.

CONCLUSIONS: Our findings suggest that even though ART uptake by HIV+ women might play a role in maintaining FcRn synthesis at comparative levels to those of their HIV- counterparts, the significantly lower levels of miR199a in the plasma of HIV+ women requires further investigation.

PEA0053

LONG-TERM CART MARKEDLY MITIGATES THE POTENCY OF CXCR4 TROPIC HIV-1 ON MORTALITY AND MORBIDITY: UP TO 18 YEARS FOLLOW-UP IN A WOMEN'S COHORT

B. Weiser[1], B. Shi[2], K. Kemal[3], H. Burger[1], H. Minkoff[4], Q. Shi[5], W. Gao[6], E. Robison[6], S. Holman[7], T. Schroeder[3], A. Gormley[3], K. Anastos[6], C. Ramirez[8]

[1]University of California, Davis School of Medicine, Department of Medicine, Sacramento, United States, [2]Albany College of Pharmacy, Department of Basic and Clinical Sciences, Albany, United States, [3]Wadsworth Center, New York State Department of Health, Infectious Disease, Albany, United States, [4]State University of New York Health Science Center at Brooklyn, Department of Obstetrics/Gynecology, Brooklyn, United States, [5]New York Medical College, Department of Statistics, Valhalla, United States, [6]Albert Einstein College of Medicine and Montefiore Health Systems, Department of Medicine, Bronx, United States, [7]State University of New York Health Science Center at Brooklyn, Department of Medicine, Brooklyn, United States, [8]University of California, Fielding School of Public Health, Department of Biostatistics, Los Angeles, United States

BACKGROUND: CXCR4(X4)-tropic HIV-1 strains are well documented to herald CD4 cell depletion and accelerated disease progression, even in those receiving cART. Most individuals previously studied, however, were antiretroviral naïve or received cART for only a few years. To update this finding, we investigated whether the deleterious effect of X4 strains is mitigated by long-term cART.

METHODS: We examined the relationship of HIV-1 tropism to morbidity and mortality in 529 participants followed for up to 18 years in the Women's Interagency HIV Study, a prospective, observational study of HIV-1 infection in women. 61% of participants were African American and 30%, Hispanic. Tropism of plasma-derived HIV-1 was determined genotypically.

RESULTS: We categorized participants into groups according to reported number of visits on cART after initiation: Group 1) ≤3 visits, 74% of whom reported no cART, called little or no cART; Group 2) ≥4 and <70% of visits on cART, called intermittent cART; Group 3) ≥70% of visits on cART, consistent cART. AIDS mortality rates for participants in each group with detectable X4 compared to exclusively R5 strains, respectively, were: 1) little or no cART: 62% vs 40% (P=0.0088); 2) intermittent cART: 23% vs 22% [Nonsignificant (NS)]; 3) consistent cART: 7% vs 14% (NS).

Logistic Regression found that HIV-1 suppression for ≥10 semiannual visits (≥5 years total) mitigated X4 tropism's deleterious effect on mortality, controlling for maximal viral load and nadir CD4. Logistic Regression analysis of all participants found that women who achieved <10 visits with complete viral suppression on cART were three times [OR 3.342 (1.952-5.72)] more likely to experience mortality due to AIDS compared to those who achieved 10 or more visits with viral suppression. Kaplan-Meier curves depicting time to AIDS death or new AIDS defining illness showed more rapid progression in participants with ≤3 cART visits and X4 viruses (P=0.0028), but no difference in progression rates stratified by tropism in the other groups.

CONCLUSIONS: Long-term cART markedly mitigated the potency of X4 strains on AIDS morbidity and mortality. Mitigation of disease progression was correlated with the duration of viral suppression on cART, supporting HIV-1 suppression as a crucial treatment goal.

VIRAL MECHANISMS OF HIV/SIV PERSISTENCE AND LATENCY

THE EMERGING VIRAL STRAINS OF HIV-1 SUBTYPE C MAINTAIN LATENCY THROUGH TFBS VARIATION: AN EXTENSION OF A CLINICAL STUDY FROM INDIA

D. Bhange[1], N. Prasad[1], H. Prajapati[1], S. Singh[1], K. Mehta[1], B. Anangi[1], S.P. Maurya[2], P.G. Bindu[3], S. Nadig[3], B. Das[2], A. Shet[3], M. Dias[3], M. Thakar[4], R. Gangakhedkar[4], S. Saravanan[5], P. Balakrishnan[6], U. Ranga[1]

[1]Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR), Molecular Biology and Genetics Unit, Bengaluru, India, [2]All India Institute of Medical Sciences, Department of Microbiology, Virology Section, New Delhi, India, [3]St. John's Hospital, Division of Infectious Diseases, Bengaluru, India, [4]National AIDS Research Institute, Department of Immunology and Serology, Pune, India, [5]YRG Centre for AIDS Research and Education (YRG CARE), Infectious Diseases, Chennai, India, [6]YRG Centre for AIDS Research and Education (YRG CARE), Voluntary Health Services, Chennai, India

BACKGROUND: In a collaborative clinical study, after screening primary viral strains from nearly 800 ART-naïve patients from four geographically distant clinical sites in India (Bangalore, Chennai, Delhi, and Pune), we report the emergence of a large number of transcription factor binding site (TFBS) variant HIV-1 strains over the past ten years in India. The common theme of the variation appears to be duplication of NF-κB and RBEIII motifs, with implications for latency. We examined the impact of RBEIII (R) and NF-κB (N) site duplication on the latency kinetics and activation of the virus.

METHODS: We constructed the panels of reporter sub-genomic and full-length viral vectors expressing d2EGFP under the control of canonical (RN3, One RBEIII, and three NF-κB sites) or three variant LTRs (RN4, R2N3, and R2N4) identified from the patient samples. We used T-cell lines or primary CD4 cell model (Bcl-2 expression) to evaluate the latency kinetics and activation profiles under diverse activation conditions, with the help of flow cytometry. To further understand this phenomenon in the patient samples, we performed Illumina sequencing of LTR variants from five patients for at least 3 time-points. We amplified the LTR region from genomic DNA and plasma RNA to identify the reservoir and actively replicating virus, respectively, in the patients infected with RN3 and R2N3 or R2N4 virus.

RESULTS: We observed that the LTRs containing RBEIII site duplication (R2N3- and R2N4-LTRs) entered latency at a significantly faster rate as compared to the RN3-LTR. Importantly, latency reversal was profoundly influenced by a delicate balance between the number and position of RBEIII and NF-κB sites in the LTR. The R2N4- but not R2N3-LTR could be reversed from latency under comparable activation conditions as that of the canonical RN3-LTR. The R2N3-LTR established avid latency and needed several folds higher concentration of activators or cocktails of activators for reversal.

CONCLUSIONS: Our work demonstrates that a fine balance between the number and position of NF-κB and RBEIII sites present in the emerging variants influences the viral latency. Some of the emerging strains could be achieving greater levels of replication fitness and may establish expanding epidemics in the future, which requires monitoring.

DUSQ (DNA ULTRA-SENSITIVE QUANTIFICATION): A NEW TECHNOLOGY FOR QUANTIFYING THE HIV UNINTEGRATED LINEAR DNA RESPONSIBLE FOR PRE-INTEGRATIVE LATENCY

H. Roux[1,2], S. Figueiredo[1], J. Migraine[3], M. Salmona[4,5,2], J. Hamroune[1], N. Arhel[6], A. Hance[7], F. Clavel[5], R. Cheynier[1], J. Dutrieux[1]
[1]Institut Cochin, INSERM U 1016/CNRS UMR 8104, Paris, France, [2]Université de Paris, Paris, France, [3]INSERM U 1259, Tours, France, [4]INSERM U 976, Paris, France, [5]Assistance Publique Hôpitaux Paris, Paris, France, [6]Institut de Recherche en Infectiologie de Montpellier, CNRS UMR 9004, Montpellier, France, [7]INSERM U 941, Paris, France

BACKGROUND: HIV latency is the major barrier to viral eradication. Our study focuses on pre-integrative latency, more specifically on processed Unintegrated Linear DNA (ULD). Due to the lack of a sufficiently sensitive and specific quantification method, ULD stability has not yet been evaluated in vivo. We have successfully developed such a method (DUSQ: DNA Ultra-Sensitive Quantification) based on NGS, in order to study the dynamics of ULDs and their importance in latency.

METHODS: DUSQ combines Linker Mediated PCR (LM-PCR) to a new method of ultra-deep sequencing. An adapter carrying a Unique Molecular Identifier (UMI) that acts as a molecular barcode is ligated to ULDs. LM-PCR is then used to specifically pre-amplify ligated ULDs, followed by a second PCR round using oligonucleotides harboring Illumina sequences. Sequencing is then performed and reads carrying the same UMI are sorted – as they are considered to be products of amplification of the same ULD – and counted, allowing an ultrasensitive quantification.

RESULTS: We first evaluated the sensitivity of DUSQ on a dilution gradient of artificial ULD and compared it to that of the canonic qPCR. We found a detection threshold for DUSQ of 5 copies of ULD/105 cells, which indicates that our technology is 100 fold more sensitive than the canonic qPCR.

We then quantified the ULD proportion over time in MT4-R5 infected cells using either qPCR or DUSQ, and showed comparable results for most samples. However, due to the difference in their detection threshold, the qPCR method is not as efficient as DUSQ for the quantification of samples with low amounts of ULD. In fact, this qPCR method was unable to detect ULDs from viremic infected patients' PBMCs, but ULDs were indeed present in these samples, as we were able to quantify an average of 1 copy/103 cells using DUSQ.

CONCLUSIONS: Our data shows the efficiency of DUSQ, a new high throughput technology, to efficiently detect ULDs in vitro and in vivo with a very high sensitivity. Such a technology could be further used to explore the roles and dynamics of ULDs in order to develop a new modeling of pre-integrative latency.

PEA0056

LYMPH NODE-BASED CD3+CD20+ CELLS RESULT FROM MEMBRANE EXCHANGE BETWEEN FOLLICULAR HELPER T-CELLS AND B-CELLS AND EXPAND FOLLOWING SIV INFECTION IN RHESUS MACAQUES

S. Samer[1], A. Chowdhury[1], P.d. Rio[2], S. Bosinger[1], J.D. Estes[3], G.R. Teran[2], M. Betts[4], G. Silvestri[1], M. Paiardini[1]
[1]Emory University, Atlanta, United States, [2]Centro de Investigacion en Enfermedades Infecciosas, Mexico City, Mexico, [3]Oregon Health & Science University, Portland, United States, [4]University of Pennsylvania, Philadelphia, United States

BACKGROUND: CD4+ T follicular helper cells (TFH), residing within B-cell follicles, support the development of class-switched antibodies by promoting germinal center B-cell responses. During their complex interaction TFH and B-cells signal each other through a series of receptor-ligand pairs, involving cell-to-cell contact events. TFH cells have also been identified as a key cellular target for HIV replication and persistence. Here, we describe and characterize a subset of lymphocytes that are found in secondary lymphoid organs that express both T- and B-cell lineage markers.

METHODS: The presence of CD3 and CD20 on the same cell (double positive, DP) was demonstrated by using a combination of flow cytometry, image stream, and immune-histochemistry analyses. DP functional and transcriptional profile were evaluated by intracellular cytokine staining and gene expression signature, respectively. Cell-associated SIV-DNA was measured by qPCR and compared between sorted CD3+CD20+ and CD3+CD4+ lymph node (LN) cells.

RESULTS: DP cells were identified in LN and spleen, but not blood, of RMs. A large fraction of DP cells shows similar phenotypic (expression of PD-1, CXCR5, ICOS, Bcl-6), functional (IL-21 production), and transcriptional profile of TFH cells. They also express other B-cell markers like CD21, HLA-DR, CD79, and surface immunoglobulins. This phenotype was confirmed in the LN of HIV-uninfected and HIV-infected humans. Of note, upregulation of CD40L following brief in vitro stimulation transcriptionally identified DP cells that are TFH in origin vs. those of B-cell lineage. Analysis of 56 RMs revealed a significant expansion in the frequency of DP cells following SIV infection as compared to uninfected animals (p=0.007). DP cells were significantly reduced by ART, and expanded again to a significantly higher level then pre-infection following ART-treatment interruption (p=0.003).

CONCLUSIONS: The DP phenotype may identify a subset of lymphoid TFH and B-cells that have recently undergone high affinity interactions. These cells expand following SIV infection and during active replication. Due to the critical role of TFH and B-cell interaction to the maintenance of TFH cells, a critical component of the persistent HIV reservoir, our data highlight the need for further research to determine how the expansion of DP cells impact HIV/SIV pathogenesis and persistence.

IDENTIFICATION AND CHARACTERIZATION OF HIV RESERVOIRS

PEA0057

DIVERSITY OF THE REPLICATION-COMPETENT HIV RESERVOIR IN PATIENTS WITH DIFFERENT TREATMENT HISTORY

A. Nicolas[1,2], J. Migraine[2], J. Dutrieux[2], M. Salmona[3,2], A. Tauzin[1,2], A. Hachiya[4], J.-M. Molina[3,2], F. Clavel[3,2], A. Hance[2], F. Mammano[1,2]
[1]Université de Paris, Inserm U 1124, Paris, France, [2]Université de Paris, Inserm U 941, Paris, France, [3]APHP Hôpital Saint-Louis, Paris, France, [4]National Hospital Organization Nagoya Medical Center, Nagoya, Japan

BACKGROUND: Viral rebound after treatment discontinuation is considered to originate mostly from viral genomes integrated in resting CD4+ T-lymphocytes. Replication-competent proviral genomes represent a minority of the total HIV DNA, and their characterization is relevant for strategies aiming the reduction of the reservoir. Here, we evaluated the consequences of the timing of treatment initiation and its duration on the diversity of replication-competent viruses, as measured by near full-length genome sequencing and phenotypic characterization.

METHODS: Resting CD4+ T-lymphocytes were isolated from 40 ml of peripheral blood from 8 successfully treated patients. Cells were stimulated and cultured under limiting dilution conditions with activated donor CD4+ T-lymphocytes, to allow individual virus outgrowth. Viral replication was monitored by p24 quantification, and between 4 and 14 (mean 8) individual viral isolates per patient were collected after short-term culture. The near full-length genomes of individual viral isolates were obtained by next generation sequencing, and their single-cycle infectivity was compared.

RESULTS: In 5 of the 8 patients, genotypically identical viral isolates were observed in independent wells, suggesting clonal expansion of infected cells. In these patients, identical viruses represented between 25 and 60% of the isolates (mean 48%). Although some viruses shared large identical portions of their genomes (e.g env), they displayed differences elsewhere, raising caution on the extrapolation of clonality from partial genome sequencing. The mean pairwise distances (MPD) observed in different patients correlated with the time before treatment initiation (r=0.96, p=0.003), suggesting that the complexity of the replication-competent reservoir mirrors that present at treatment initiation. No correlation was observed between MPD and the duration of successful treatment (mean 8 years, range 2-15). Moreover, a correlation was observed between the proportion of identical viral isolates and the duration of treatment (r=0.82, p=0.019), suggesting progressive clonal expansion of infected cells during ART. Consistent with genotypic data, a broader range of infectivity (up to 100-fold) was observed among isolates from patients with delayed treatment initiation than in those treated early.

CONCLUSIONS: This work unveiled differences in the genotypic and phenotypic properties of the replication-competent reservoir from treated patients, and suggests that delaying treatment results in increased diversity of the reservoir.

PEA0058

QUANTIFICATION AND CHARACTERIZATION OF HIV RESERVOIRS IN INDIVIDUALS TREATED DURING HYPER-ACUTE INFECTION

K. Reddy[1], G. Lee[2], N. Reddy[1], K. Dong[3,4,5], B. Walker[4,3,5,6], M. Lichterfeld[6,5,4], T. Ndung'u[1,3,4]
[1]Africa Health Research Institute (AHRI), Durban, South Africa, [2]Weill Cornell Medicine, New York, United States, [3]HIV Pathogenesis Programme, Durban, South Africa, [4]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [5]Harvard Medical School, Boston, United States, [6]Brigham and Women's Hospital, Boston, United States

BACKGROUND: ART is not curative and is unable to completely eradicate HIV, which persists as a latent reservoir in long-lived memory CD4+ T cells and other tissue sanctuaries. We hypothesized that initiation of ART in the hyperacute phase of infection may significantly reduce the size of the viral reservoir presenting a greater chance of achieving HIV remission after ART interruption.

METHODS: Study participants were females from the FRESH study cohort, established in Durban, South Africa, where acute infections were identified through twice weekly screening of high-risk individuals. We used an ultrasensitive real time PCR assay to longitudinally quantify subtype C HIV-1 DNA levels in PBMCs from 20 participants who initiated treatment during acute infection and in 11 participants who initiated treatment during chronic infection. We also used near-full-length, single genome next-generation sequencing to longitudinally genotype HIV-1 DNA in a subset of these participants.

RESULTS: There was a slow but steady decrease of total HIV DNA from ART initiation (median = 2.43 log copies/106 cells) to 12 months post treatment initiation (1.64 log copies/106 cells) (p=0.0007) in patients identified with Fiebig I acute HIV infection. Treatment initiated during Fiebig stage I of infection significantly blunted peak viral load (p=0.001) but not peak total HIV DNA (p=0.20). Participants who initiated treatment in early versus chronic infection did not differ significantly in one-year post treatment levels of total HIV-1 DNA (p=0.15). Viral sequencing revealed that at the earliest stages of infection majority of HIV genomes are intact, with a few having large deletions, and no observable APOBEC hypermutations. ART initiation altered the viral DNA landscape such that it was predominated by defective, truncated genomes.

CONCLUSIONS: Total HIV DNA is detectable very early and even in early treated participants the size during acute infection is similar to chronic treated participants. Early initiation of cART leads to slow but steady decay of the total HIV DNA reservoir. At 12 months post-treatment initiation total HIV DNA could still be detected, however intact HIV genomes are no longer detectable. These data have implications for cure strategies in patients initiated on ART during the acute HIV infection stage.

PEA0059

INTRAGENIC PU-BOXES CONTROL HIV-1 TRANSCRIPTION AND REPLICATION IN MYELOID LINEAGES

C. Van Lint[1], R. Verdikt[1], O. Hernalsteens[1], C. Vanhulle[1], N. Delacourt[1], S. Fauquenoy[1], V. Monceaux[2], A. David[2], H. Galons[3], V. Gautier[4], A. Saez-Cirion[2], O. Rohr[5]
[1]University of Brussels (ULB), Service of Molecular Virology, Gosselies, Belgium, [2]Laboratoire HIV, Infection et Persistance, Institut Pasteur, Paris, France, [3]Unité de Technologies Chimiques et Biologiques pour la Santé (UTCBS), CNRS UMR8258-U1267 Inserm, Faculté des Sciences Pharmaceutiques et Biologiques, Paris, France, [4]Centre for Research in Infectious Diseases, University College Dublin, Dublin, Ireland, [5]IUT Louis Pasteur, Université de Strasbourg, Schiltigheim, France

BACKGROUND: Accumulating data evidence the persistence of HIV-1 in cells of myeloid lineages, although the specific molecular mechanisms controlling HIV-1 transcription in these reservoirs remain poorly understood. Here, we revealed the presence of three binding sites for the myeloid-restricted transcription factor PU.1 in the intragenic cis-regulatory region (IRR) of HIV-1 and further demonstrated their importance in controlling viral gene expression in infected myeloid lineages.

METHODS: PU.1 binding sites were studied in vitro by EMSA and in vivo by ChIP experiments. Reporter assays were used to assess the role of PU.1 binding sites in the enhancer activity of the IRR. Following site-directed mutagenesis in full-length infectious HIV-1 proviral clones, we evaluated the functional effects of mutations in the PU.1 sites by infection studies.

RESULTS: We report that HIV-1 intragenic PU.1 binding sites positively regulate the enhancer activity of the HIV-1 IRR. We then further showed that the three HIV-1 intragenic binding sites for PU.1 are crucial for HIV-1 replication, since their mutation impaired viral fitness. Together, our biochemical and functional studies highlight the importance of the IRR transcriptional control in the HIV-1 life cycle.

CONCLUSIONS: The HIV-1 intragenic region brings an additional element in an already complex network of regulators affecting the level of HIV-1 transcription. In particular, the IRR appears to be important for a cellular-specific control of HIV-1 gene expression. To tackle HIV- 1 persistence, targeted approaches for each specific reservoir are needed. As a proof-of-concept, we reveal the potential therapeutic application of specific inhibitors that interfere with PU.1 binding as a new anti-HIV-1 strategy for myeloid reservoirs.

PEA0060

SAFETY AND EFFICACY OF COPPER-64 LABELLED 3BNC117 COMBINED WITH PET/MRI TO IMAGE HIV

J. McMahon[1,2], J. Zerbato[3], J. Lau[1], J. Lange[4], K. Alt[4], A. Carey[5], R. McIntyre[5], P. Beech[5], G. O'Keefe[6,7], M. Roche[3], T. Rasmussen[3], M. Caskey[8], M. Nussenzweig[8,9], G. Egan[5], C. Hagemeyer[4], A. Scott[6,7], S. Lewin[3,1,10]
[1]Alfred Hospital and Monash University, Infectious Diseases, Melbourne, Australia, [2]Monash Medical Centre, Infectious Diseases, Melbourne, Australia, [3]The Peter Doherty Institute for Infection and Immunity, University of Melbourne and Royal Melbourne Hospital, Melbourne, Australia, [4]Monash University, Australian Centre for Blood Diseases, Melbourne, Australia, [5]Monash University, Monash Biomedical Imaging, Melbourne, Australia, [6]Austin Health, Department of Molecular Imaging and Therapy, Melbourne, Australia, [7]Olivia Newton-John Cancer Research Institute, Tumour Targeting Laboratory, Melbourne, Australia, [8]The Rockefeller University, Laboratory of Molecular Immunology, New York, United States, [9]Howard Hughes Medical Institute, The Rockefeller University, New York, United States, [10]Royal Melbourne Hospital, Victorian Infectious Diseases Service, Melbourne, Australia

BACKGROUND: Non-invasive methods to detect and quantify HIV persistence in tissue in people living with HIV (PLWH) on antiretroviral therapy (ART) are needed. Infusing copper-64 (^{64}Cu) radiolabelled broadly neutralising antibodies (bNAbs) targeting HIV envelope (Env) with CT scan and positron emission tomography (PET) identified HIV Env in tissues in SIV infected non-human primates . We aimed to determine if a similar approach was effective in PLWH

METHODS: Unmodified 3BNC117 was compared with 3BNC117 bound to the chelator MeCOSar and ^{64}Cu (^{64}Cu-3BNC117) in vitroto assess binding (to plate-bound gp140 and detection by ELISA or Env expressed in HEK cells and detection by flow cytometry) and neutralization (using viruses pseudotyped with different Env strains). ^{64}Cu-3BNC117 was infused into HIV uninfected (Group 1), HIV infected and viremic (viral load, VL >1000 c/mL; Group 2) and HIV infected aviremic (VL <20 c/mL; Group 3) participants using two dosing strategies: high protein (3mg/kg unlabeled 3BNC117 combined with <5mg ^{64}Cu-3BNC117) and trace (<5mg ^{64}Cu-3BNC117 only). All participants were screened for 3BNC117 sensitivity from virus obtained from viral outgrowth. Magnetic resonance imaging (MRI)/PET and pharmacokinetic (PK) assessments (ELISA for serum 3BNC117 concentrations and gamma counting for ^{64}Cu) were performed 1, 24- and 48-hours post dosing.

RESULTS: Comparison of unmodified and modified 3BNC117 in vitro demonstrated no difference in HIV binding or neutralisation. 17 individuals were enrolled of which 12 were dosed including Group 1 (n=4, 2 high protein, 2 trace dose), Group 2 (n=6, 2 high protein, 4 trace) and Group 3 (n=2, trace only). HIV+ participants had a mean CD4 of 574 cells/microL and mean age 43 years. There were no drug related adverse effects and no differences in tissue uptake in regions of interest (ROI, e.g lymph node gut, pharynx) between the 3 groups. In the high protein dosing group, serum concentrations of 3BNC117 and gamma counts were highly correlated demonstrating that ^{64}Cu-3BNC117 remained intact in vivo.

CONCLUSIONS: In PLWH on or off ART, infusion of ^{64}Cu-3BNC117 and MRI/PET imaging over 48 hours, there was no detection of HIV-1 Env expression in vivo. Future studies should investigate alternative radiolabels such as zirconium which have a longer half-life in vivo.

ELIMINATING/SILENCING LATENCY

PEA0061

IDENTIFICATION OF NOVEL COMPOUNDS THAT REACTIVATE HIV REPLICATION FROM LATENTLY INFECTED CD4 T CELLS

L. Liu[1,2], J. Liang[1], J. Peng[1], J. Fang[1], G. Liu[3], H. Wang[2], Z. Chen[2]
[1]University of Hong Kong, Hong Kong, Hong Kong, SAR of China, [2]Shenzhen Third People's Hospital, Shenzhen, China, [3]Tsinghua University, Beijing, China

BACKGROUND: Human immunodeficiency virus (HIV) persists in a latent form in infected individuals under antiretroviral therapy (ART) through integrating proviral DNA into the genome of host immune cells. The lack of therapeutic cure and the propensity of HIV-1 to develop resistance to commonly used drugs require continued development of novel drugs for HIV/AIDS treatment and cure. One therapeutic strategy for HIV eradication aims to reactivate HIV production in the latently infected cells, so that these cells could be detected and eliminated by the immune system. In this study, we aimed to identify novel small molecules with new targets for HIV treatment.
METHODS: Using cells that contain an integrated HIV LTR linked to the luciferase reporter gene, and HIV latently infected cell lines A72, J lat and U1, we screened small molecules isolated from traditional Chinese medicines and a library of heterocyclic compounds. The library is constructed using "scaffold-directed" methods to efficiently generate novel benzofused compound scaffolds with a high degree of structural diversity and ability to bind to multiple receptors with high affinity and favourable pharmacokinetic properties.
RESULTS: We identified four hit novel small-molecules. Two compounds inhibited HIV-1 entry, one inhibited HIV reverse transcription, and one compound isolated from Spatholobus suberectus Dunn., Daidzein and its analogues, reactivated HIV replication from latently infected CD4 T cell lines J lat and A72 dose dependently, but not monocytes U1. Moreover, by using TZM-b1 and 293T cells that contain an integrated HIV LTR linked to the luciferase reporter gene, we found that Daidzein activates HIV replication at the level of transcription. This effect is through Akt signaling pathway, and do not induce global T cell activation. Structure-activity relationships (SARs) analysis of Daidzein and its five analogues revealed that three analogues, Daidzin, Glycitein and Glycitin, reactivate HIV replication without obvious cell toxicity observed, and 4'-hydroxyisoflavone is their bio functional core structure.
CONCLUSIONS: Therefore, Daidzein and its analogues reactivate HIV replication from latently infected CD4 T cells. Moreover, identification of the bio functional core structure enables their potential to be modified to improve their potency and developed into significant components for HIV therapy.

GENE THERAPY

PEA0062

EPIGENETIC SILENCING SIRNA DELIVERED TO THE NUCLEUS OF HIV-1 INFECTED CELLS VIA NANOPARTICLE SYSTEM

V. Klemm[1], E.I. Czuba-Wojnilowicz[2,3], C. Cortez-Jugo[3,2], S.G. Turville[1], F. Cavalieri[3,2], F.C. Caruso[3,2], A.D. Kelleher[1], C.L. Ahlenstiel[1]
[1]Kirby Institute, The University of New South Wales, Sydney, Australia, [2]ARC Centre of Excellence in Convergent Bio-Nano Science and Technology, The University of Melbourne, Melbourne, Australia, [3]Department of Chemical and Biomolecular Engineering, The University of Melbourne, Melbourne, Australia

BACKGROUND: Inhibition of virus transcription via RNA-directed epigenetic silencing of HIV-1 is used as a potential targeted functional cure approach. However, the delivery of such a gene therapeutic into primary human cells is a big challenge. Avoiding the issues involved in viral delivery, we hypothesize the use of novel nanoparticle technology as an efficient method for siRNA delivery to cell lines and primary human cells.
METHODS: The epigenetic silencing siRNA siPromA, targeting the HIV-1 5'LTR or siScrambled control is loaded onto a Layer-by-Layer nanostructured film to treat HIV-1NL4.3 fluorescent virus infected cells. For this study we used primary human Monocyte-derived Macrophages. Visualization of the localization of fluorescence-labelled siRNA inside infected cells we use a fluorescent microscope DeltaVision Elite and identify successful delivery into cells and localization in the nucleus by Arbitrary line intensity profile and 3D Volume Viewer. Functional delivery is being analysed using Reverse Transcriptase Assay and RT-qPCR.
RESULTS: Imaging confirmed the entry, detachment and successful delivery into the nucleus of MDMs 48h after the siRNA caring Nanoparticles were added to the cultures. RT-Assays were unable to show clear functional data, however RT-qPCR was used and results for all three donors for MDMs showed a slower increase in viral RNA than all four controls.
CONCLUSIONS: This study in primary human cells shows successful nanoparticle delivery of epigenetic silencing siRNA and release inside the cell for transport to the nuclei. Here we have shown a pathway for RNAi therapeutic delivery in primary human cells. Successful targeted delivery of gene-therapy agents via the use of a nanoparticle system provide an important step for the future use of gene-therapy agents.

ARVS, SMALL MOLECULES AND IMMUNOMUDULATING AGENTS

PEA0063

DUAL BROMODOMAIN-HISTONE DEACETYLASE INHIBITORS DESIGNED AS LATENCY-REVERSING AGENTS

J.L. Dos Santos[1], J.R. Lopes[2], I.M. Prokopczyk[3], M.C. Chung[3]
[1]State University of São Paulo, School of Pharmaceutical Science, Drugs and Medicines, Araraquara, Brazil, [2]State University of São Paulo, Chemistry Institute, Araraquara, Brazil, [3]State University of São Paulo, School of Pharmaceutical Science, Drugs and Medicine, Araraquara, Brazil

BACKGROUND: HIV reservoir remains one of the main barriers to eliminate the virus. Latency-reversing agents, such as histone deacetylase (HDAC) and bromodomain (BRD) inhibitors have been described to decrease HIV reservoirs, however, these classes alone exhibited several limitations. Here, we described the design, preparation and evaluation of optimized hybrid compounds designed to target both bromodomain (BRD4) and HDAC 1-3, simultaneously.

METHODS: Docking simulation was performed using CovDock (Covalent Docking approach) by Schrödinger® using BRD4 (pdb code: 4WIV; resolution 1,56 Å) and HDAC-2 (pdb code: 4LY1; resolution 1,56 Å). All compounds were prepared through divergent synthesis in four steps. First, it was performed a Suzuki coupling reaction between the methyl 4-iodobenzoate and boronic acid derivatives. The ester function was hydrolyzed, and the compound was coupled with o-phenylenediamine using EDC as coupling reaction. The ability of all compounds (at 10mM) to inhibit both enzymes HDAC 1-10 and BRD-4 were evaluated. BRD assay was performed using TR-FRET technology using recombinant bromodomain and BET Ligand. Vorinostat and JQ-1 was used as drug references for HDAC and BRD assays, respectively.

RESULTS: Docking simulation suggests that all compounds are able to interact with BRD-4 and HDAC-2 with best docking scores values than references drugs vorinostat and JQ-1. After computational study, five compounds were synthesized at global yields ranging from 11-20%. All structures were characterized by analytical methods. Enzymatic assays using HDAC reveals that all compounds are selective for class I, specifically HDAC 1-3. Compounds inhibited HDAC-1 at values ranging from 8-95%, for HDAC-2 those values were 10-91% and for HDAC-3 were 3-77%. Against BRD-4, the inhibitory effect ranged from 14-25%. The most promising compound was able to inhibit HDAC 1, 2 and 3 and BRD4 at values of 75 %, 72 %, 57 % and 21 %, respectively.

CONCLUSIONS: Hybrid compounds were designed, synthesized and evaluated against the enzymes HDAC and BRD. These dual compounds were able to inhibit BRD4 and HDAC 1-3 (class I) suggesting its potential use as latency-reversing agents. In the next steps, these compounds will be evaluated in vitro against infected HIV cells in order to characterize its latency-reversing effects.

PEA0064

CHRONIC HIV-1 PATIENTS ON TREATMENT WITH TYROSINE KINASE INHIBITORS HAVE A LOW RESERVOIR SIZE AND ACTIVE CYTOTOXIC CELL POPULATIONS

L. Vigón[1], S. Rodríguez-Mora[1], V. García-Gutiérrez[2], J. Ambrosioni[3], A. Navarro[4], A. Spivak[5], M. Cervero[6], J.L. Steegmann[7], J.M. Miró[3], P. Prieto[4], C. Wyen[8], C. Hoffmann[9], J. Alcamí[1], V. Briz[1], V. Planelles[5], M.R. López-Huertas[1], M. Coiras[1]
[1]Instituto de Salud Carlos III, Madrid, Spain, [2]Hospital Universitario Ramón y Cajal, Madrid, Spain, [3]IDIBAPS, Hospital Clínic, Barcelona, Spain, [4]Hospital Universitari de Bellvitge, Barcelona, Spain, [5]University of Utah School of Medicine, Salt Lake City, United States, [6]Hospital Universitario Severo Ochoa, Madrid, Spain, [7]Hospital Universitario La Princesa, Madrid, Spain, [8]University Hospital of Cologne, Cologne, Germany, [9]ICH Study Center, Hamburg, Germany

BACKGROUND: We previously demonstrated that tyrosine kinase inhibitors (TKIs) significantly interfere with HIV-1 proviral infection and transcription in CD4+ T cells of humanized mice. In this transversal study, we analyzed how treatment with TKIs of HIV-1 infected patients with chronic myeloid leukemia (CML) may affect the reservoir size and immune response.

METHODS: PBMCs from 6 HIV-infected patients with CML that were on treatment with TKIs (imatinib, dasatinib or nilotinib) for 4.6 yrs (range 0.4-11 yrs) were analyzed (estimated incidence of both diseases 1:65,000). CD4>500 in 4/6 patients (CD4/CD8 ratio 0.93±0.7). PBMCs from 18 HIV+ patients with CD4>500 (CD4/CD8 0.95±0.3) were used as controls. Cell populations and synthesis of cytokines were analyzed by flow cytometry. Plasma cytokines were analyzed by Luminex. Proviral integration was quantified by Alu-qPCR. All HIV+ patients were on standard cART with undetectable viral RNA.

RESULTS: 1) HIV-patients on TKIs showed a reduction of 2.9-fold on average in proviral integration ($p<0.05$).

2) TEM and TEMRA CD4 subpopulations were reduced 2.4- and 10.2-fold, respectively.

3) IL-7 levels in plasma were reduced 2.1-fold. However, IL-15 and IL-21 were reduced only in HIV-patients treated with dasatinib. The levels of IL-2 were similar in all patients.

4) HIV-patients treated with TKIs and cART showed a 1.6-fold increased expression of NK activation marker CD56. NK cells also showed 1.4-fold and 1.7-fold increased expression of markers CD57 and PD1, respectively.

5) Plasma levels of cytotoxic mediator granzyme B were increased 2.6-fold and proinflammatory cytokines IFNγ and TNFα were increased 2.4-fold and 1.8-fold, respectively.

6) Stimulation of CD8 from patients on TKI and cART with NL4-3 virus did not induce IFNγ release, indicating that IFNγ was mostly released by NK cells.

Stimulated CD8+TCRγδ+ cells released 1.7-fold more TNFα than HIV-patients only on cART.

CONCLUSIONS: Long-term treatment of HIV-patients with TKIs such as imatinib and dasatinib was safe. Treatment with TKIs reduced effector CD4 subpopulations and plasma levels of homeostatic cytokines involved in reservoir replenishment. TKIs increased cytotoxic populations of functional NK and CD8 with antiviral activity. Therefore, TKIs may constitute novel and promising adjuvant therapy of cART to control reservoir size and replenishment in chronic HIV patients.

NOVEL ANTIVIRALS AND FORMULATIONS

PEA0065

ALTERNATIVE "MORNING AFTER" RECTAL OR VAGINAL ADMINISTRATION APPROACH FOR POST-EXPOSURE PROPHYLAXIS OF HIV

C. Sanders[1], V. Taresco[2], S. Rosen[3], A. Kam-Tuck Yip[4], M. Stocks[1], P. Fischer[1], C. Alexander[1], P. Gershkovich[1]
[1]University of Nottingham, School of Pharmacy, Nottingham, United Kingdom, [2]University of Nottingham, School of Chemistry, Nottingham, United Kingdom, [3]University of Nottingham, School of English, Nottingham, United Kingdom, [4]University of Nottingham, School of Sociology and Social Policy, Nottingham, United Kingdom

BACKGROUND: Since 2013 the annual incidence of newly diagnosed cases of HIV has practically remained unchanged. Current post-exposure prophylaxis (PEP) involves prolonged oral systemic treatment, often with considerable side effects. Under WHO guidelines, PEP in a sexual exposure (PEPSE) is limited to only high-risk scenarios. The size of the population exposed to low to moderate risk scenarios is unclear.

The overarching aim of this project is to develop a nanoparticle-based PEP for local rectal or vaginal administration after a low to moderate risk sexual exposure. We also aim to assess the size of the population in need for this alternative PEP approach.

METHODS: A 14-question survey in Bristol Online Surveys was designed, focusing on sexual behavior and condom usage. 3,217 participants were recruited. The target population for a novel PEPSE was defined based on sexual activity, self-reported condom usage, HIV negative test, and the disclosure of scenarios with a low to moderate risk of HIV infection in the last 3 years.

To increase drug loading, dolutegravir was chemically modified, producing a dolutegravir myristate (MDTG). A two-step nanoprecipitation system was designed. In the first step, an unstable MDTG nanoparticle system was obtained. These unstable MDTG nanoparticles were coated with different masses of polymeric carriers. Dynamic light scattering (DLS), and transmission electron microscopy (TEM) were used to assess both steps. MDTG content in the nanoformulations was measured by means of HPLC-UV.

RESULTS: As many as 28% of the surveyed sexually active population reported at least one incident of low to moderate risk in the last 3 years, and therefore is a target for a novel PEPSE. The uncoated nanoparticles were on average about 190 nm in size, while coated nanoparticles were 215 nm. Importantly, all developed nanoformulations had drug content above 50%.

CONCLUSIONS: The survey provided evidence on the surprisingly large size (28%), currently unprotected by prophylactic approaches. This identified unmet need could be addressed by alternative PEP approaches. Nanoformulations with a very high drug content of MDTG were developed. A high drug content is of paramount importance, as absorption of nanoparticles from rectum or vagina is likely to be quantitatively low.

NUCLEIC ACID-BASED HIV THERAPIES

PEA0066

A PILOT STUDY: CRISPR/CAS9 THERAPY FOR AN EFFECTIVE CONTROL OF GENETICALLY DIVERSE HIV-1

R. Nithya[1], T.D. Kumitaa[1]
[1]Universiti Sains Malaysia, Advanced Medical and Dental Institute, Kepala Batas, Malaysia

BACKGROUND: Although HAART effectively suppresses HIV replication, the compromised effectiveness of HAART against non-B subtypes, challenge in eliminating latent proviruses, life-long treatment, and viral resistance complicates the cure for HIV-1. CRISPR/Cas9, the latest genome editing tool, is able to overcome some of the problems seen with HAART. By targeting LTR, the promoter of HIV, CRISPR/Cas9 is able to disrupt the latent reservoirs of HIV. In this study, we designed an improved CRISPR/Cas9 system to concurrently knockdown the structural genes (Pol and Gag), regulatory genes (Rev and Tat) and accessory genes (Vif) of HIV. We investigated the efficacy of this tool as a therapy against different viral subtypes in a subset population, which reflects other low and middle-income countries with similar HIV pathogenicity and comorbidities.

METHODS: Our in-vitro study showed a huge decrease in viral load and we verified the safety of CRISPR in human cells. Next, we subtyped the virus from HIV-1 positive HAART naïve patients in Malaysia. Subtyping of the HIV-1 was done with nested PCR. Infected peripheral blood mononuclear cells (PBMCs) were treated with combinatorial CRISPR/Cas9 to determine its efficacy in reducing the viral load with p24 measurements, and its effect on cell proliferation with CD4+ quantification. We also determined the correlation of the efficacy of tool with gender and age.

RESULTS: There was a 19-fold decrease in p24 expression compared to untreated samples, and a 30-fold increase in CD4+ cell proliferation. CRISPR gave the greatest reduction in viral production and better immune recovery in patients with B viral subtype, male and younger patients.

CONCLUSIONS: This preliminary pilot study in HIV patient samples suggests CRISPR/Cas9 could serve as a therapy to control the morbidity of HIV-1 in Malaysia. The potentially of this tool can be extrapolated to other low and middle-income countries where treatment is not easily accessible, hence giving an overall effect on the pathogenicity, comorbidity and immune system exhaustion, which in turn, affects the efficacy of treatment. In the future, we will be investigating the efficacy of CRISPR in combination with other currently existing therapies, and in patients on HAART.

HIV AND CO-MORBIDITIES

PEA0067

HIV INFECTION INDUCES HUMAN ENDOGENOUS RETROVIRUSES AND LINE-1 EXPRESSION IN BREAST CANCER TISSUES

G. Curty[1], G. Beckerle[2], L. Iñiguez Rábago[2], P. Santos[1], J. Marston[3], S. Champiat[4], J. Heymann[5], M. Soares[1], D. Nixon[3], M. Bendall[1], F. Leal[1], M. de Mulder Rougvie[2]
[1]Brazilian National Institute of Cancer, Oncovirology Program, Rio de Janeiro, Brazil, [2]Weill Cornell Medicine, Division of Infectious Diseases, New York, United States, [3]Weill Cornell Medicine, Division of Infectious Diseases, Rio de Janeiro, Brazil, [4]Université Paris-Saclay, Gustave Roussy, Villejuif, France, [5]Weill Cornell Medicine, Department of Pathology and Laboratory Medicine, New York, United States

BACKGROUND: Despite the sharp decline in AIDS defining cancers in people living with HIV (PLWHIV) in the HAART era, non-AIDS defining cancers are still one the leading causes of death among PLWHIV. Intriguingly, breast cancer (BC) has a lower incidence rate among women living with HIV when compared to matched HIV-negative women, suggesting unidentified biological mechanisms confer protection to development of BC in PLWHIV. PBMCs infected with HIV and BC cell lines express locus specific retrotransposons. We hypothesized that HIV might upregulate some retrotransposons in BC tissue.

METHODS: We sequenced the transcriptome and retrotranscriptome from formalin-fixed paraffin-embedded BC samples of 10 women (4 HIV+: 6 HIV-). We performed RNA extraction, cDNA library preparation and total RNA sequencing. Paired-end reads were filtered and illumina adapters were removed using Trimmomatic. Filtered reads were aligned to hg38 using Bowtie2 and HISAT2. Bowtie2 output was used in Telescope and HISAT2 output was used in HTSEq. Differentially expressed genes (DEG) were analyzed by DESeq2 and graphs created using R. Gene Set Enrichment Analysis (GSEA) using reactome pathway functional database was performed in WebGestalt.

RESULTS: We found a total of 192 DEG (q-value < 0.05): 174 host genes (171 upregulated and 3 downregulated); 4 HERVs and 14 L1 upregulated in BC samples from PLWHIV. Principal component analysis distinguished two groups of samples, BC HIV+ and BC HIV-. Using GSEA, we found immune system, extracellular matrix organization and metabolic signaling genes as upregulated pathways in BC HIV+.

CONCLUSIONS: Our findings show that HERVs and L1 are upregulated in BC tissue from PLWHIV, but not in women without HIV infection.

SALT-SENSITIVITY IS ASSOCIATED WITH HYPERTENSION, INFLAMMATION AND NON-DIPPING BLOOD PRESSURE IN HIV

S.K. Masenga[1,2,3,4], A. Kirabo[3,4], B.M. Hamooya[1,2,3], S. Nzala[2,4], G. Kwenda[2], D.C. Heimburger[3], W. Mutale[2], J.R. Koethe[3], L. Pilic[5,4], S.M. Munsaka[2]
[1]Mulungushi University School of Medicine and Health Sciences, Livingstone, Zambia, [2]University of Zambia, Lusaka, Zambia, [3]Vanderbilt Institute for Global Health, Vanderbilt University Medical Center, Nashville, United States, [4]Hypertension HIV/AIDS Nutrition Diabetes (HHAND) Research Group, Livingstone, Zambia, [5]St. Mary's University, Faculty of Sport, Health and Applied Science, Twickenham, United Kingdom

BACKGROUND: Apart from HIV, increased intake of dietary salt is associated with inflammation and development of hypertension in animals and in some human studies but the mechanisms are elusive. A significant change in blood pressure following salt loading or deprivation is termed salt-sensitivity. Though the relationship between salt-sensitivity and hypertension in HIV is unknown we hypothesized that salt altered inflammation, blood pressure and dipping status. We conducted a study to determine associations between salt-sensitivity and hypertension, dipping and inflammatory markers in people living with HIV (PLWH).

METHODS: This was a cohort study conducted at Livingstone Central Hospital where we recruited 85 adult participants consisting of 43 PLWH (22/43 hypertensive) and 42 HIV negative controls matched for hypertension status (1:1), age and sex. Salt-resistance and salt-sensitivity were defined by a mean arterial pressure (MAP) difference of ≤5mmHg and ≥8mmHg respectively, between the last day of low (4g) and high (9g) dietary salt intake week. Dipping was defined as 10-15% decrease in nocturnal blood pressure. Cytokine production was determined by flow cytometry using BioLegend's LEGENDplex™ bead-based immunoassay. Electrolytes were measured using Ion Selective Electrode (ISE) technology. We used logistic regression, chi-square and Mann-Whitney tests for inferences.

RESULTS: Mean age was 40± 3.5 (SD). 51% (43/85) and 55% (47/85) were hypertensive and female respectively. In PLWH, salt-sensitivity among hypertensive and normotensives was 96% (21/22) and 10% (2/22) respectively compared with the 71% (15/21) and 29% (6/21) HIV-negative. Salt-sensitivity was associated with hypertension (OR 28 95%CI 7,116, p<0.001) regardless of HIV status, body mass index, sex and age. Compared with the HIV negative, salt-sensitivity in PLWH was associated with increased levels of IL-6, monocyte count and expression of CD80+ (immune activation), siglec-8 (eosinophils) on total leucocytes (CD45+), and expression of D11 (IsoLevuglandin) on monocytes (CD14+) (p<0.01). In both PLWH and HIV negative salt-sensitivity was associated with non-dipping blood pressure (p<0.05).

CONCLUSIONS: Sensitivity to dietary salt is significantly associated with inflammation and immune activation in HIV and with hypertension and non-dipping blood pressure irrespective of HIV status. Modulation of dietary salt intake has potential to improve blood pressure and dipping.

PEA0069

RE-IMAGINING RESILIENCE: HIV, THE TRAUMA TRAJECTORY AND THE OPIOID CRISIS

S. Pullen[1], A. Olson[2]
[1]Emory University School of Medicine, Rehabilitation Medicine, Atlanta, United States, [2]Emory University Oxford College, Women's, Gender and Sexuality Studies, Atlanta, United States

BACKGROUND: Resilience – positive adaption and "bouncing forward" from trauma – has been deployed as a crucial strategy for increasing survivability among people living with HIV/AIDS (PLH) and for surviving the HIV/AIDS crisis more broadly. In this interdisciplinary project, we consider the limitations of a resilience model for patient-based HIV care. We highlight chronic pain-and often subsequent opioid dependence- as one indication of these limits. We describe how an integrative trauma-informed care approach that recognizes chronic pain as a corporeal manifestation of stored trauma may address gaps in resilience-based care paradigms for people living with HIV and opioid dependence.

DESCRIPTION: In Atlanta's Ponce de Leon Center, we are piloting an innovative NIH-funded pain management and opioid mitigation study. To date, 100% of participants report decreased or full elimination of pain and opioid use after program participation. Our program emphasizes:

1) the deep structural vulnerability of marginalized populations, particularly in regard to access to HIV care;

2) the pervasive role of stored trauma in the face of HIV and chronic pain;

3) that investing in resilience need not be synonymous with suffering but must directly address the physiological, psychological and historical roots of that suffering.

LESSONS LEARNED: While we do not advocate for abandoning resilience as a broader framework through which to understand survival in the face of unimaginable odds, we offer caution about the unintended effects of care models that place the onus of resilience on marginalized individuals. We have learned from our work that order to be most effective as activists and as caregivers for people living with HIV, we must revise how we apply resilience to our practices.

CONCLUSIONS/NEXT STEPS: Resilience is as crucial as ever for the HIV community. Paradoxically, however, demanding resilience of individuals and communities can produce a persistent vulnerability. Instead, we aim to disrupt a linear trajectory of a "resilience" paradigm that unintentionally results in the storing of trauma, diffuse chronic pain and subsequent opioid dependence. Fully addressing trauma - ranging from the collective experience of surviving the early HIV/AIDS crisis to individual burdens carried by marginalized PLH - is central to a fuller commitment to maximizing wellbeing and reimagining resilience.

PEA0070

REGIONALIZATION AND INTEGRATION OF SCREENING SERVICES FOR COLLABORATIVE PREVENTION AND CONTROL OF HIV, HBV, HCV, SYPHILIS AND HSV

J. Mwangi[1,2], R. Lel[1]
[1]Kenya Medical Research Institute, Centre for Virus Research, Nairobi, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology, Institute of Tropical Medicine and Infectious Diseases, Nairobi, Kenya

BACKGROUND: Because of specialization and structure of health service provision in many resource constrained setting, health services are provided in standalone-specially designated clinics. New services, especially those for program priority disease come with dedicated funding. Due to requirements for accountability, monitoring and evaluation, integration of such disease management together with routine health services remain a desirable goal. To identify need for collaborative integration of screening services for HBV, HCV, Syphilis and HSV, we tested HIV clients attending comprehensive care clinics for the 5 infections.

METHODS: Samples were collected voluntarily from clients attending specialized HIV clinics upon informed consent. Serological screening and confirmatory testing followed approved in-country testing algorithms with modifications where necessary. Sampling criteria took into consideration the country diversity in terms of health service distribution, demographics, and geographical localities including regions and administrative counties. In this study, 7 out the 8 regions and 11 of the 47 administrative counties were included in the study.

RESULTS: Three thousand two hundred and fifity samples were collected from clients across the health facilities in Kenya. Overall prevalence of HBV, HCV, HSV and Syphilis was 29%, 14%, 50% and 14% respectively. Co-infections were at 71%, while geographical distribution ranged between 19-31% for HBV, HCV (8-19%), syphilis (4-26%), and HSV (29-67%).There was no integration of services for these five infections. Routine screening services were only available for HIV.Testing for HBV, HCV, Syphilis and HSV were only available upon request with clinical indication.

CONCLUSIONS: Considering the high prevalence and potential for co-infections, availability of testing services for HBV, HCV, Syphilis and HSV in health facilities across the country is necessary. While testing for HIV is readily accessible, screening for HBV, HCV, Syphilis and HSV is a desired goal. This can be provided under integration of services, leveraging on the successful infrastructure and capacity build over the years for HIV. Model integrated screening facilities to serve regions are recommendable to cater for large populations within counties and regions as reference labs.

PEA0071

EVALUATION OF SECOND LINE ANTIRETROVIRAL PROGRAMMATIC AND TREATMENT OUTCOMES IN MOZAMBIQUE BETWEEN 2015-2017

A. Muteerwa Pene[1], A. Juga[2], P. Kerndt[1], A. Nguimafack[3]
[1]Centers for Disease Control, ADS, Maputo, Mozambique, [2]Centers for Disease Control, Data Analysis, Maputo, Mozambique, [3]Centers for Disease Control, Care and Treatment, Maputo, Mozambique

BACKGROUND: Access to antiretroviral therapy (ART) has improved considerably in Mozambique, with a significant impact on reducing morbidity and mortality among people living with HIV (PLHIV). In June 2018, there were 1,216,427 patients on ART of which an estimated 16,325 patients (1.3%) were on second-line treatment. Monitoring and optimizing clinical outcomes of these patients is important for programs treating PLHIV. This study evaluates the characteristics, virological suppression (< 1000 copies), and treatment outcomes of patients on second-line treatment in Mozambique.

METHODS: This is a retrospective cohort study using routinely collected program data. We extracted data registered in the Mozambique Electronic Patient Tracking System for all PLHIV with at least one viral load (VL) who initiated second-line treatment between January 2015 to December 2017 in six provinces where data was available. Variables of interest included patients' characteristics (age, gender), treatment outcomes (death, loss to follow up (LTFU), transferred to another site, and active in treatment) and virological suppression (yes/no) 12 months after treatment. Frequency tables and descriptive statistics were produced.

RESULTS: Of 416,030 patients on ART by December 2017, 8,140 (~2.0%) were on second-line ART during the study period. Out of these 6,911 (84.9%) were adults ≥ 25 years (4,180 female and 2,731 male), and 1,229 (15.1%) were adolescents aged 15 to 24 years (927 female and 302 male). At the end of a total follow-up duration of 12 months on second line treatment, 9 (0.1%) patients died, 540 (6.6%) were LTFU, 5 (0.1%) were transferred and 7,586 (93.2%) were retained in treatment. Among retained patients, 2,588 (34.1%) had VL suppression.

CONCLUSIONS: In Mozambique few (~2%) HIV patients were enrolled on second line treatment up to December 2017. More than 93% of these patients were retained on treatment 12 months after second line regimen initiation though only 34% of them had a suppressed viral load. This is challenging as alternatives to the second line treatment may not be accessible to most patients. Tailored strategies for these patients should also consider strengthening and refining counseling on adherence and improving clinical care.

PEA0072

ABORTIVE VIRAL REPLICATION IN HIV-INFECTED HEPATOCYTES: IS IT BENEFICIAL OR DETRIMENTAL?

M. New-Aaron[1], M. Ganesan[2], R.S. Dagur[2], E. Makarov[3], L. Poluektova[3], N. Osna[2]
[1]University of Nebraska Medical Center, Environmental Health, Occupation Health and Toxicology, Omaha, United States, [2]University of Nebraska Medical Center, Internal Medicine, Omaha, United States, [3]University of Nebraska Medical Center, Pharmacology and Experimental Neuroscience, Omaha, United States

BACKGROUND: Despite the emergence of potent antiretroviral therapy, liver disease remains one of the leading causes of mortality among HIV infected individuals. Liver disease accounts for 18% of all-cause mortality, and approximately 50% of mortality from HIV-related liver disease in the United States is attributed to alcohol. Here, we hypothesize that ethanol metabolism potentiates accumulation of HIV in hepatocytes, causing oxidative stress and massive apoptotic cell death. Engulfment of HIV-containing apoptotic hepatocytes by hepatic stellate cells (HSC) triggers their activation and liver injury progression.

METHODS: This study was performed on Huh 7.5 cells safely transfected with CYP2E1 (designated as RLW cells) and LX2 cells (HSC model) Since RLW cells do not effectively metabolize alcohol, they were treated with acetaldehyde generating system (AGS) to mimic alcohol metabolism in hepatocytes. Cells were exposed to HIV-1_{ADA} at 0.1 MOI for 18 hours, washed and cultured for additional 3 - 5 days. Viral replication was measured by HIV RNA (RT-PCR), viral protein (P24) expression (western blot), reverse transcriptase (RT) activity and integrated HIV DNA by ddPCR. LX2 cells were exposed to apoptotic bodies from HIV-infected RLW cells for 2 hours and measured profibrotic markers (Collagen 1A1 and TGFβ) by RT-PCR.

RESULTS: HIV RNA was detected in RLW HIV-infected cells, also p24, reverse transcriptase activity and HIV DNA were detected. When the RLW HIV-infected cells were exposed to AGS, there was an upregulation of intracellular HIV RNA expression, p24 concentration, RT and massive apoptosis when compared to AGS-untreated RLW cells. RLW HIV-infected apoptotic cells upregulated collagen 1A1 by 2.5 folds higher, and TGFβ by 2 folds higher in LX2 cells when compared to the control.

CONCLUSIONS:

[Figure. Alcohol metabolism potentiates HIV accumulation in hepatocytes, causing oxidative stress and massive apoptotic cell death. Engulfment of HIV-containing hepatocytes by hepatic stellate cells (HSC) triggers their activation and liver injury progression]

We conclude that while HIV and ethanol metabolism-triggered apoptosis clears up HIV-infected hepatocytes, continued generation of HIV-expressing apoptotic bodies may be detrimental for progression of liver fibrosis due to constant activation of LX2.

CERVICAL HUMAN PAPILLOMAVIRUS DNA DETECTION IN WOMEN LIVING WITH HIV AND HIV-UNINFECTED WOMEN LIVING IN LIMBE, CAMEROON

A. Adedimeji[1], R. Ajeh[2], A. Dzudie[2], E. Kendowo[2], N. Funhgwa[2], D. Nsame[3], A.-G. Simo-Wambo[3], E. Orock[4], T. Hebert[1], A. Pierz[1], D. Murokora[5], K. Anastos[1], P.E. Castle[1]
[1]Albert Einstein College of Medicine, Epidemiology and Population Health, Bronx, United States, [2]Clinical Research, Education, Networking and Consultancy, Yaounde, Cameroon, [3]Limbe Regional Hospital, Limbe, Cameroon, [4]University of Buea, Biomedical Sciences, Buea, Cameroon, [5]Brick By Brick, Kampala, Uganda

BACKGROUND: There are limited data on cervical HPV prevalence in Cameroon and none from its Anglophone region. We investigated cervical HPV prevalence in HIV-uninfected (HIV[-]) and HIV-infected (WLWH) women living in the region.
METHODS: A convenience sample of consecutively recruited HIV[-] women (n=295) and women living with HIV (WLWH) (n=560) attending the Limbé Regional Hospital were enrolled into a cervical screening study. Women underwent screening that included HPV testing of self-collected and provider-collected specimens. We calculated the HPV prevalence by HIV status, overall and stratified by age, and among WLWH, stratified by CD4 counts. We compared the concordance for the detection of HPV between self- and provider-collected specimens.
RESULTS: Crude HPV prevalence was 21.69% (95% confidence interval [95%CI]=17.21-26.48%) for HIV[-] women and 46.43% (95%CI=42.24-50.66%) for WLWH (p<0.001). Among WLWH, older age (ptrend=0.01) and higher CD4 counts (ptrend=0.007) were associated with lower HPV prevalence. There was a good-to-excellent agreement for HPV detection between specimens, and self-collected were more likely than provider-collected specimens to test HPV positive, for all women and stratified by HIV status.
CONCLUSIONS: HIV-related immunosuppression was a risk factor for HPV prevalence in this population. HPV testing of self-collected specimens appeared to be less specific than HPV testing of provider-collected specimens.

PEA0074

A SYSTEMATIC REVIEW AND META-ANALYSIS ON HIV INFECTED INDIVIDUALS WITH MULTI-DRUG RESISTANT TUBERCULOSIS

M.M. Hasan[1]
[1]Kurmitola General Hospital, Medicine, Dhaka, Bangladesh

BACKGROUND: The progressive HIV epidemic and the increasing number of MDR-TB are serious threats to the global tuberculosis control programs. The study was aimed to summarize available evidences on the association of HIV infection and development of MDR-TB, and to provide a pooled estimate of risks.
METHODS: Search was based on PubMed, MEDLINE, Google Scholar and ScienceDirect databases to select eligible observational studies for meta-analysis, published between January, 2010 and July, 2019 in English. Considering low statistical power, studies fewer than fifty participants were excluded. Random-effects model was used to obtain the pooled odds ratio of the crude association between HIV infection and MDR-TB with 95% confidence interval. Publication bias was affirmed by funnel plot symmetry and confirmed by Egger's test. Heterogeneity was determined by Cochran's Q statistic and quantified by I2.
RESULTS: Identifying 1496 records 47 articles (60754 enrolled TB patients) in the study were included. Overall, the pooled odds ratio was 1.47(95%CI 1.19- 1.81, I2=80.49%) with substantial heterogeneity and evidence of publication bias (p=0.13). Subgroup analysis revealed, the estimated pooled odds ratio for European countries (OR=2.31, 95% CI 1.80-2.96, I2=32.26%) was higher than the South American, Asia, African. Effect estimate was higher for primary MDR-TB (OR=3.13, 95% CI 1.59-6.13, I2=13.13%) with no heterogeneity among the studies. Additionally, the pooled odds ratio for MDR-TB and HIV increased with age (mean or median age of MDR-TB cases >=40, OR=1.96, 95% CI 1.41-2.73, I2=69.11%), higher in female (>60%) predominant studies (OR=1.97, 95% CI 1.03-3.78, I2=80.35%), significant in countries with high burden for TB/HIV and/or MDR-TB (OR=1.51, 95% CI 1.18-1.92, I2=78.1%) and with high income (OR=2.64, 95% CI 2.01-3.48, I2=15.01%).
CONCLUSIONS: The meta-analysis demonstrates that the risk of MDR-TB increases significantly with HIV coinfected individuals based on evidences from last decade. It has become imperative to improve the detection and overall management of MDR-TB in HIV endemic settings to achieve the aims of Eradication of HIV by 2030 along with WHO End TB strategy 2035.

PEA0075

FACTORS ASSOCIATED WITH SPUTUM ORDERING FOR TUBERCULOSIS DIAGNOSIS IN PEOPLE LIVING WITH HIV IN THE GREATER ACCRA REGION

D.E. Kasozi[1], B. Sarfo[1], P. Govure[1], S.P. Katongore[2]
[1]University of Ghana, Epidemiology and Disease Control, Accra, Ghana, [2]University of Ghana, Health Policy, Accra, Ghana

BACKGROUND: People living with HIV (PLHIV) have an increased risk of developing TB. The World Health Organization recommends systematic and routine screening of PLHIV for TB and further testing using sputum for those with a positive TB screen test. Not all PLHIV with a positive TB screen test in Ghana are further tested for TB and the factors for this are not well understood. This study assessed factors associated with sputum ordering for TB diagnosis in PLHIV who screened positive for TB in the Greater Accra region of Ghana.
METHODS: Mixed method study performed at three purposively selected hospitals providing HIV care and treatment services in the Greater Accra region. The study involved a cross-sectional review of patients' charts and in-depth interviews with health workers involved in the care and treatment of PLHIV. Quantitative data were analyzed using STATA version 15. The backward elimination method with a threshold of 0.2 was used to construct the multiple logistic regression model. Inductive thematic analysis was used to determine emerging themes from the interviews.
RESULTS: 400 patient charts were reviewed of which 67.7% were female with a median age of 39 (IQR 31-49). TB screening was recorded in 78% of the patients of whom 92 patients had a positive TB screen test. Only 53 (57.6%) who had a positive screen test had sputum ordered. Patient general appearance described as abnormal (OR=3.05, p=0.036), having more than one TB symptom (OR=3.42, p=0.028) and presence of an alternative presumptive diagnosis (OR=0.34, p=0.023) were associated with having a sputum test ordered. Lack of training, high patient numbers, inability to produce sputum and unwillingness of the not so sick patients to provide sputum.

CONCLUSIONS: Almost half of PLHIV with a positive TB screen test did not have a sputum test documented. Sputum testing was likely to be done in patients with an abnormal general appearance and more than one TB symptom and unlikely in those with an alternative presumptive diagnosis. High workload, costs of TB tests, lack of training for health workers and inability to produce sputum by patients were the barriers to sputum testing highlighted by the health workers.

PEA0076

SEROPREVALENCE OF HIV-SYPHILIS COINFECTION AND ASSOCIATED RISK FACTORS AMONG PREGNANT IN CAMEROON, 2016

C. Kengne Nde[1], J.d.D. Anoubissi[1], J. Fokam[2,3,4], A. Zeh Meka[1], D.G. Toghoua Tseuko[5], A. Messeh[1], Y. Moussa[1], M. Ngo Nemb[1], D. Kob Same[6], G. Loni-Ekali[1], C. Nguefeu Nkenfou[3,7], S.-C. Billong[1,2,4], J.-B. Elat Nfetam[1,2]
[1]National AIDS Control Committee, Central Technical Group, Yaounde, Cameroon, [2]National HIV Drug Resistance Surveillance and Prevention Working Group, National AIDS Control Committee, Yaounde, Cameroon, [3]Chantal BIYA International Reference Centre (CBIRC) for Research on HIV/AIDS Prevention and Management, Yaounde, Cameroon, [4]University of Yaounde 1, Faculty of Medicine and Biomedical Sciences (FMBS), Yaounde, Cameroon, [5]National Laboratory of Public Health, Yaounde, Cameroon, [6]USAID, Yaounde, Cameroon, [7]University of Yaounde I, Higher Teachers' Training College, Yaounde, Cameroon

BACKGROUND: Syphilis and HIV remain a public health problem in Africa and can be transmitted by pregnant women to their children. These infections are diagnosed during Demographic Health Surveys planned every five years and sentinel surveillances every two years among first antenatal care (ANC-1) attendees. Our objective was to estimate seroprevalence of HIV, Syphilis and HIV-Syphilis coinfection and explored associated risk factors.

METHODS: We conducted a cross-sectional study in Cameroon, targeting 7000 ANC-1 attendees (4000 from urban and 3000 rural area) over 60 sites selected according to antennal care services and technical platform. All pregnant women coming for their ANC-1 from September to December 2016 were enrolled and sociodemographic as well as clinic information were collected. HIV test was performed blindly by the on 'site' laboratory and the National Reference Laboratory (NRL) following the national guidelines. Syphilis testing was performed using the Treponema Palladium Hemagglutination assay (TPHA) / Veneral Diseases Research Laboratory (VDRL). Prevalences were estimated and associated risk factors explored using multinomial logistic regression.

RESULTS: Of 6859 women enrolled, 6566 were invited to take the HIV test and 6513 accepted (99.19% of acceptability). The median age was 26 years [IQR: 21-30] and 46.47% of them were housewife. The estimated HIV prevalence was 5.7% (95% CI: 4.9-6.4), the Syphilis prevalence was 5.63% (95% CI:4.9-6.4) and HIV-Syphilis coinfection prevalence was 0.59% (95% CI:0.4-0.9). Pregnant women residing in rural areas were more likely to be infected with syphilis than those living in the urban area (aOR=1.8 [95% CI: 1.3–2.4]) Single pregnant women were three time more likely to be infected by HIV/Syphilis Co-infection than married, cohabiting, widow and divorced pregnant women (aOR=2.8 [95% CI: 1.3–2.4]). Pregnant women aged 25 – 49 years old were strongly more likely to be co-infected (aOR=15.1 [95% CI: 3.0–75.7]) by HIV and Syphilis than those aged 15-24 years.

CONCLUSIONS: Our results have shown the burden of HIV and syphilis among pregnant women and probably in general population. Our findings support the fact that while emphasizing strategies to fight HIV among adult women, to also find out strategies to prevent and fight Syphilis infection especially in rural and northern regions.

IN SILICO PREDICTION OF HUMAN LEUKOCYTES ANTIGEN (HLA) CLASS II BINDING HEPATITIS B VIRUS (HBV) PEPTIDES IN BOTSWANA

W.T. Choga[1,2], M. Anderson[2], E. Zumbika[3], K.K. Seatla[2,4], B.B. Phinius[2], T. Mbangiwa[2], L.N. Bhebhe[2], K. Baruti[4], R.M. Musonda[2], T.G. Bell[5], S. Moyo[2], J.T. Blackard[6], S. Gaseitsiwe[2]
[1]University of Cape Town, Pathology, Cape Town, South Africa, [2]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]National University of Science and Technology, Bulawayo, Zimbabwe, [4]University of Botswana, Gaborone, Botswana, [5]Wits, Johannesburg, South Africa, [6]University of Cincinnati, College of Medicine, Cincinatti, United States

BACKGROUND: Hepatitis B virus (HBV) is the primary cause of liver-related malignancies worldwide, and currently there is no cure for chronic HBV infection (CHB). Strong immunological responses induced by T cells are associated with HBV clearance during acute infection; however, the repertoire of epitopes (epi) presented by major histocompatibility complexes (MHCs) to elicit these responses in various populations is not well understood.

METHODS: In silico approaches were used to map and investigate 15-mers restricted to 9 HLA class II alleles that have high population coverage in Botswana. Sequences from 44 genotype A and 48 genotype D non-recombinant, complete HBV surface-gene (PreS/S) from Botswana were included. A cascade of bioinformatics pipelines inlcluding were used to sort the determined epitopes and reconstruct 3D tertiary structure of the candidate vaccine.

RESULTS: Of the 1,853 epi predicted, 12.6% were strong binders (SB) and none were promiscuous to all 9 haplotypes suggesting that multi-epitope, genotype-based population-based candidate vaccines (MEPBGBV) will be effective against CHB as opposed to previously proposed broad potency vaccines. Epitope-densities (Depi) between genotype A –PreS1 (8%), PreS2 (34%), and S (34%) – and genotype D – PreS1 (13%), PreS2 (21%), and S (37%) – were similar. Polymorphisms that hindered HLA-epitope binding were 86T, 90T, and 94P in PreS1A; 54P, 79E, 84S, and 85Q in PreS1D; 12I, 31I, and 54P in PreS1A; 5F, 22H, 22L, 22P, 32H, 36L, and 42S in PreS1D. We also identified antigenic and genotype-specific peptides with characteristics that are well suited for the development of sensitive diagnostic kits. The results obtained were validated using available 18,161 HBV sequences of genotypes (A-I), and 3 HepB vaccines currently in use.

CONCLUSIONS: This study identified candidate peptides that can be used for developing multi-epitope vaccines and highly sensitive diagnostic kits against HBV infection and suggests that HBV variability may hinder peptide-HBV epitope-MHC binding required to initiate a cascade of immunological responses against infection.

NOVEL ASSAYS OF IMMUNE RESPONSES

PEA0078

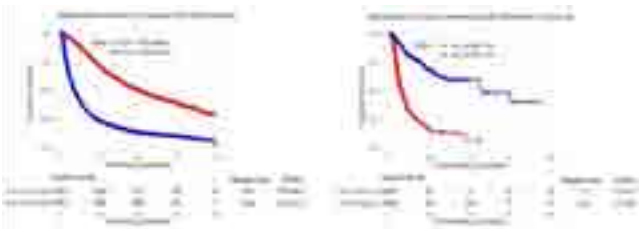
A CHALLENGE FOR HIV TREATMENT: THE LONG TIME TO IMMUNE RECOVERY OF PEOPLE LIVING WITH HIV UNDER ANTIRETROVIRAL THERAPY. A LONGITUDINAL STUDY IN A BIG STATE OF BRAZIL

C. C. P. Mendicino[1], M.D. Crosland Guimarães[2,1], E. E.M. Moody[3], G.J. da Silva[4], L. Penna Braga[5], C. Menezes de Pádua[1]
[1]Federal University of Minas Gerais / Pharmacy Faculty, Social Pharmacy Department, Belo Horizonte, Brazil, [2]Federal University of Minas Gerais / Medicine Faculty, Public Health Post-Graduate Program, Belo Horizonte, Brazil, [3]McGill University, Department of Epidemiology, Biostatistics, & Occupational Health, Montreal, Canada, [4]Federal University of Minas Gerais / Medicine Faculty, Tropical Medicine and Infectology Pos-Graduate Program, Belo Horizonte, Brazil, [5]National School of Public Health-Fiocruz, Epidemiology on Public Health Pos-Graduate Program, Rio de Janeiro, Brazil

BACKGROUND: The impact of antiretroviral therapy (ART) on morbidity and mortality of people living with HIV (PLHIV) depends on the CD4-count distribution in treated individuals. Increased CD4 indicating immune-recovery (IR) is a reflection of the health of treated PLHIV. In order to get attention to long time and to propose improvements to IR, our study estimates the median-time until IR and associates it to factors that may impair the IR.

METHODS: Retrospective analysis was performed among PLWH (>18 years) living in Minas Gerais state, Brazil, using data obtained from national health care databases. Eligible patients initiated ART between 2009-2018 and had CD4 measurements recorded before and after ART-initiation. Descriptive analyses, cumulative and person-time incidence of IR (≥500 cells/µl) were calculated. The general median-time to IR and stratified by CD4-baseline and time-varying variables (ART-adherence: ≤45 days between consecutive ART dispensing dates) were estimated via Kaplan-Meier and the associated by Cox-regression, adjusted for age, gender and ART-initiation year.

RESULTS: Most participants (n=8,014) were male (67%), with mean age(SD)=38.7(11.5) years and baseline CD4(SD)=228(137) cells/µl. Follow-up time was 15,872 person-years. Cumulative-incidence of IR was 58% (n=4,678), corresponding to an incidence-rate of 29.47/100 person-years. General median-time to IR was 22.8 months (CI95%:21.9-24.0). Baseline CD4≥200 cells/µl was associated with presence of IR that the median-time to IR was 5.6 times lower and hazard-risk (HR)=4.2(CI95%:3.9-4.5), compared to patients with lower CD4. Presence of ART-adherence decreases 7.5 times the median-time to IR and HR=3.1(CI95%:2.87–3.4)(Figure 1-Table 1).



[Figure 1. Kaplan Meier for median-time to immune recovery stratified by CD4-baseline and time-varying ART adherence, in people living with HIV under antiretroviral therapy (n:8014), in Minas Gerais, Brazil.
Immune recovery: CD4≥ 500 cells/µl; baseline CD4 count: CD4 measurement within 90 days before ART initiation; ART adherence presence: until 45 days between two consecutive ART date registers; CI: confidence interval.]

Covariables	n (%)	event (%)	Multivariate analysis	
CD4 count baseline			HR (CI95%)	p-value
<200cells/µl	3443	1200 (35)		
≥200cells/µl	4571	3478 (76)	4.2 (3.9-4.5)	<0.05
ART-adherence				
No	1058	181 (17)		
Yes	6956	1670 (24)	3.1 (2.87–3.4)	< 0.05

[Table 1 - Adjusted HR, fitted via Cox-Regression, Summarizing the Relationship between time to IR and each of baseline CD4 and Time-varying ART-adherence, adjusted for gender, age and year ART initiation.]

CONCLUSIONS: The IR time remains long and depends on early treatment and ART adherence. Overcoming these factors represents the principal challenges to success on IR.

NOVEL APPROACHES TO ASSESS VIRAL LOAD AND ARV RESISTANCE/TROPISM

PEA0079

DIAGNOSTIC ACCURACY OF PAN DEGENERATIVE AMPLIFICATION AND ADAPTION ASSAY FOR DRUG RESISTANCE MUTATIONS AMONG HIV-1 INFECTED ADOLESCENTS FAILING ART THERAPY IN ZIMBABWE: ROLE OF A POINT MUTATION ASSAY

V.M. Kouamou[1], J. Manasa[2], D. Katzenstein[3], A. McGregor[1], C.E. Ndhlovu[1]
[1]University of Zimbabwe, Department of Medicine, Harare, Zimbabwe, [2]University of Zimbabwe, Medical Microbiology, Harare, Zimbabwe, [3]Biomedical Research and Training Institute, Molecular Virology, Harare, Zimbabwe

BACKGROUND: HIV drug resistance (HIVDR) is a barrier to sustainable virological suppression among HIV infected people in resource limited settings (RLS). Point mutation assays targeting priority mutations are being developed, validated and implemented to improve accessibility to HIV drug resistance (HIVDR) testing in RLS. Here, we evaluated the diagnostic accuracy of a simple, rapid, and affordable assay to monitor HIVDR mutations among HIV-infected young people failing ART.

METHODS: In a cross-sectional study between June 2018 and September 2019, we evaluated the diagnostic accuracy of the PANDAA assay (cutoff >5%) compared to the reference standard Sanger sequencing (cutoff > 15%-20%). Plasma samples from young people (10-24 years) at the HIV treatment clinic failing ART (VL>1000 cps/mL X 2) were collected at baseline in a randomized clinical trial. Sensitivity and specificity of each DRM (K65R, K103N, Y181C, M184V and G190A) were determined by a diagnostic algorithm (diagt) using Stata version 14. Agreement between genotyping methods was evaluated by the Cohen's kappa coefficient as follow: values ≤ 0 indicating no agreement; 0.01-0.20 slight; 0.21-0.40 fair; 0.41-0.60 moderate; 0.61-0.80 substantial; 0.81-1.00 almost perfect agreement.

RESULTS: 150 participants were included. For each mutation detected (K65R, K103N, Y181C, M184V and G190A), PANDAA showed a sensitivity and a specificity of >=95% and >=83% respectively. For acquired NRTI drug resistance, sensitivity (95%CI) and specificity (95%) were reported in 98% (92%-100%) and 100%(94% - 100%) respectively with an accuracy of 99%. For NNRTI-DRMs, sensitivity and specificity were reported in 100%(97%-100%) and 76%(61%-87%) respectively

both with an accuracy of 93%. PANDAA showed a strong agreement with Sanger sequencing for K65R, K103N, M184V and G190A (r>0.85) and a substantial agreement for Y181C mutation (r=0.720).

CONCLUSIONS: With high sensitivity in detecting DRMs, PANDAA assay could be used in RLS to monitor HIV-1 infected patients failing ART. The low specificity of PANDAA to Sanger may be explained by the presence of minority variants detected by the PANDAA assay (cutoff >5%). With the implementation of TLD (tenofovir, lamivudine and dolutegravir) in many low and middle-income countries, PANDAA may be suitable to inform strategies for the use of alternative NRTIs to optimize responses to Dolutegravir.

PEA0080

A98S MUTATION/POLYMORPHISM ON RT REGION OF HIV-1 SUBTYPE C ISOLATES: POSSIBLE IMPACT OF GEOGRAPHICAL VARIATION ON DRUG RESISTANCE

A. Mulu[1], M. Maier[2], U.G. Liebert[2]
[1]Armauer Hansen Research Institute, Viral Diseases Research, Addis Ababa, Ethiopia, [2]Leipzig University, Institute of Virology, Leipzig, Germany

BACKGROUND: The mutation A98S at reverse transcriptase (RT) region of the polymerase (Pol) genome of HIV-1 has been known as a common polymorphism that does not reduce non nucleoside reverse transcriptase inhibitors (NNRTIs) susceptibility. However, recently it is introduced as a resistance mutation to nevirapine (NVP) by the French drug resistance interpretation's algorithm (ANRS) for only subtype C isolates.

METHODS: HIV-1 chronically infected antiretroviral treatment naïve (n=220) and treatment experienced (n=100) patients visiting Gondar University Hospital, Northwest Ethiopia were recruited consecutively. Antiretroviral treatment (ART) was initiated based on the WHO clinico-immunological parameters. HIV RNA level and sequence of the entire protease and partial RT (76%) region was determined at baseline and after a median time of 30 months on ART.

RESULTS: At baseline, A98S mutation was detected in 24.4% (39/160) of the treatment naïve Ethiopian patients infected with subtype C. Nineteen out of 22 patients with A98S polymorphisms at enrolment initiated NVP containing regimen. After a median time of 30 months on ART, all of the 22 patient were found to be virological suppressed (HIV RNA less than 400 copies/ml). The mean CD4+ T cell count was increased from 189 to 367 cells/mm3 after 30 months of ART. All isolates with and without this mutation had various genetic signatures and polymorphisms in their protease (PR) region which are considered as compensatory drug resistance mutation in HIV-1 subtype B isolates (I13V, K20I, M36I, H69K, T74S, V82I, L89M, and I93L).

CONCLUSIONS: A98S mutation is a frequently observed natural polymorphism among Ethiopian HIV-1 subtype C isolates and hence shall not be considered as mutation conferring resistance to NVP among subtype C sub-Saharan isolates.

PEA0081

IMPROVING GENO2PHENO[CORECEPTOR] TO PREDICT THE TROPISM OF CLINICAL HIV-1 CRF01_AE SAMPLES

N. Marty[1], S. Saeng-aroon[2], E. Heger[3], M. Obermeier[4], N. Peifer[5], R. Kaiser[3], T. Klimkait[1]
[1]University of Basel, Department of Biomedicine, Basel, Switzerland, [2]National Institute of Health, Nonthaburi, Thailand, [3]University of Cologne, Institute of Virology, Cologne, Germany, [4]Medizinisches Infektiologiezentrum, Berlin, Germany, [5]University of Tuebingen, Department of Computer Science, Tuebingen, Germany

BACKGROUND: HIV-1 uses either CCR5 (R5) or CXCR4 (X4) as coreceptor for entry. A tropism switch to X4 is associated with accelerated disease progression and, especially in perinatally HIV-1 infected children, frequent tropism switches have been observed over time (Foster_et_al.2015). Also, in antiretroviral therapy the tropism plays a key role, i.e in the usage of the CCR5 antagonist Maraviroc (MVC).
This indicates that accurate monitoring of viral tropism is critically needed for suitable treatment, and reliable tools are key for tropism determination.The widely used genotyping tool geno2pheno was developed based on subtype B sequences, and recently we and others demonstrated an X4-overcalling in HIV-1 CRF01_AE isolates by the current version of the geno2pheno [coreceptor] algorithm (Matsuda_et_al.2018).
The aim of this study was therefore the suitable adaptation of the prediction tool geno2pheno [coreceptor] to subtype CRF01_AE isolates.

METHODS: V3-sequences of 44 clinical HIV-1 subtype CRF01_AE samples from female Thai sex workers were analyzedby geno2pheno [coreceptor] and, in parallel on the same samples, by replicative phenotyping in human cells in the presence of specific X4- or R5-inhibitors.

RESULTS: The combination of genotypic data and corresponding phenotypic profiles confirmed a dramatic systematic overcalling of X4-tropism for CRF01_AE viruses in the current version of geno2pheno [coreceptor] using the false-positive-rate (FPR) cut-off of 10%.
A cut-off of 10% FPR showed a sensitivity of detecting 100% of the phenotypically classified X4-tropic viruses in our cohort, indicating that no X4-tropism is misclassified. However, too many R5 variants were misclassified as X4-variants indicating a low specificity (35%) for R5 viruses. Lowering the FPR in our sample collection to 4.5% or 1% improved the specificity to 67.5% or 97.5% respectively, while maintaining a sensitivity of 100%.

CONCLUSIONS: This study demonstrates the necessity of adjusting the FPR for subtype CRF01_AE. Although in our cohort, a theoretical FPR cutoff of 1% could be used, a more conservative cutoff of 4.5% would prevent incorrect prescription of MVC. Our study will be of utility for clinical therapy guidance and an appropriate use of MVC for patients carrying HIV-1-CRF01_AE. With this knowledge, prediction tools might be improved also for other non-B subtypes and benefit future strategies towards eliminating and eradicating HIV.

PEA0082

INTEGRATED POINT-OF-CARE (POC) DIAGNOSTICS FOR TB AND HIV (EID/VL) IN CAMEROON – EARLY IMPLEMENTATION RESULTS ACROSS FIVE GENEXPERT (GX) TESTING SITES

C. Atem[1], M. Elungndelle[1], D. Nguafack[2], V. Mbassa[2], D. Nzuobontane[3]
[1]Clinton Health Access Initiative, Laboratory Systems, Younde, Cameroon, [2]National TB Program, Monitoring and Evaluation, Younde, Cameroon, [3]Clinton Health Access Initiative, Country Team, Younde, Cameroon

BACKGROUND: Cepheid GeneXpert® platforms can be used for multiplex testing. In Cameroon, these platforms are mainly used for Tuberculosis (TB) diagnosis. However, the average device spare capacity with just TB testing in 2016 was 80% indicating the platforms could be used to perform additional testing for HIV, HPV, and HCV. In 2017, CHAI/UNICEF through Unitaid funding supported the National TB Program to leverage five GeneXpert devices used for TB testing to integrate HIV (EID/VL).

DESCRIPTION: Firstly, a mapping and site selection exercise was conducted using criteria such as device spare capacity, accessibility, and existing sample transport system, staff capacity, turn-around time and test volumes. Of the 08 GeneXpert sites assessed, 05 were selected and trained to process EID and VL samples. Following site selection, EID and VL commodities were procured and distributed to the selected sites. The study was conducted from June 2017 to June 2019. Data collected included the number of TB tests conducted before integration, number of TB, EID and VL tests conducted after integration. Hub and spoke mini-sample transport models were used for testing and return of results. Data was entered and analyzed using MS Excel 2016.

LESSONS LEARNED: Overall, 7280 tests were conducted. Of these, 3978 (55 %) VL, 2296 (36 %) TB and 1006 (14 %) EID tests. In 11 months at 80% device capacity, an increase in device utilization rate from 13% (with TB testing only) to 42% (with TB-HIV integration) was observed, corresponding to a drop in spare capacity from 80% to 58%. Of the 7280 tests run, 6875 successful tests were recorded (6% error rate), of which 931 HIV-exposed infants had access to EID testing and 3705 PLHIV had access to at least one VL test across all 05 sites.

CONCLUSIONS/NEXT STEPS: TB/HIV Integrated POC testing is beneficial, feasible and improves access to EID and VL testing services. Adding HIV (EID/VL) testing increases the device utilization rate without compromising TB testing run on GensXpert. Replicating the mini STS hub and spoke model and running the laboratory 24/7 can create opportunities to integrate testing for other diseases such as HPV and HCV.

ARV PHARMACODYNAMICS AND PHARMACOKINETICS

PEA0083

DOSE ADJUSTMENT OF DORAVIRINE MITIGATES THE PHARMACOKINETIC INTERACTION WITH THE MODERATE CYP3A INDUCER, RIFABUTIN

S. Khalilieh[1], R.I. Sanchez[2], K.L. Yee[3], Y. Liu[4], I. Triantafyllou[1], S. McClain[1], P. Auger[5], A. Stoch[1], M. Iwamoto[1]
[1]Merck & Co., Translational Pharmacology, Kenilworth, United States, [2]Merck & Co., PPDM, Kenilworth, United States, [3]Merck & Co., Quantitative Pharmacokinetics Pharmacodynamics, Kenilworth, United States, [4]Merck & Co., BARDS, Kenilworth, United States, [5]Celerion, Lincoln, United States

BACKGROUND: Doravirine (PIFELTRO™), is a novel non-nucleoside reverse transcriptase inhibitor for the treatment of HIV type 1 (HIV-1). Doravirine is primarily metabolized by oxidation via CYP3A4. A previous clinical trial demonstrated that coadministration of the clinical dose of doravirine (100 mg once-daily (QD)) with multiple dose (MD) rifabutin, a moderate CYP3A4 inducer, resulted in decreased doravirine exposure. Non-parametric superposition supported adjusting the doravirine dose to 100 mg doravirine twice-daily (BID) during rifabutin coadministration to achieve exposures similar to the clinical dose without rifabutin co-administration; thus, this study was conducted to confirm the adequacy of this dose adjustment.

METHODS: This was an open-label, 2-period, fixed-sequence study in healthy adult participants. In Period 1 (P1), 100 mg doravirine QD was administered for 5 days. In Period 2 (P2), following at least a 72-hour washout, 300 mg rifabutin was administered QD for 16 days and coadministered with 100 mg doravirine BID on Days 10- 14. Blood samples to measure doravirine concentrations were collected through 72 hours post dose on Day 5 in P1 and Day 14 in P2.

RESULTS: Sixteen participants (10 female and 6 male) were enrolled. Following coadministration with rifabutin, pharmacokinetics of 100 mg doravirine BID was similar to 100 mg doravirine QD alone; The geometric mean ratios (90% confidence intervals) [doravirine BID + rifabutin/doravirine QD] for Cmax, AUC0-24, and Ctrough were 0.97 (0.87, 1.08), 1.03 (0.94, 1.14), and 0.98 (0.88, 1.10), respectively. There were no serious adverse experiences (AEs) and most AEs were mild in intensity. No AEs were reported following doravirine administration in P1. The most common AEs (number of participants) were rash (5), pruritus (5) headache (4), nausea (3), chills (3), feeling hot (3). Two participants discontinued the study due to multiple AEs in P2 including: headache, feeling hot, chills, pyrexia, nausea, vomiting, asthenia, pallor, tachycardia, hypotension and myalgia. These participants also experienced decreased lymphocyte and neutrophil counts. All AEs resolved by the end of study.

CONCLUSIONS: Coadministration of 100 mg doravirine BID and rifabutin was generally well tolerated. Adjusting the dose of doravirine to 100 mg BID when doravirine is coadministered with rifabutin mitigates the induction of doravirine metabolism by rifabutin.

PEA0084

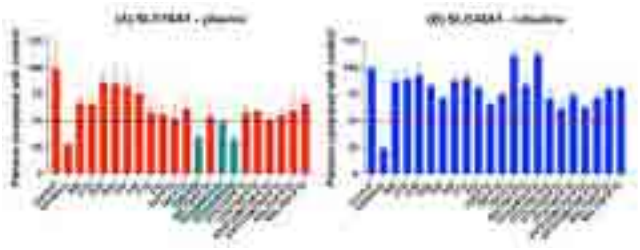
EFFECTS OF INSTI AND OTHER ARV COMBINATIONS ON FOLATE DISTRIBUTION VIA FOLATE TRANSPORTERS: IMPLICATIONS FOR NEURAL TUBE DEFECTS

H. Okochi[1], J. Pintye[2], L. Benet[1], M. Gandhi[1]
[1]University of California, San Francisco, United States, [2]University of Washington, Seattle, United States

BACKGROUND: Updated results from the Tsepamo cohort found the incidence of neural tube defects (NTD) among newborns born to mothers using dolutegravir (DTG) dropped from 0.94% to 0.30%, still higher than the general population rate (0.10%). DTG has been postulated to inhibit folate (FOL) transport via the FOL receptor or transporters. Some in vitro studies revealed that DTG at clinical concentrations slightly inhibited both FOL-receptor and FOL-transporters without statistical significance. Studies to date have only looked at DTG and other integrase inhibitors (INSTIs) alone in cell models. We investigated the inhibitory effect of combination ART that includes INSTIs on FOL transporters.

METHODS: FOL transporter (SLC19A1 and SLC46A1)-overexpressing cells were established by transfecting cDNA plasmids into HEK293 cells. Cells were seeded and grown until confluent. The effects of individual antiretrovirals (ARVs) and ART combinations on FOL transporters were evaluated at pH 7.4 at maximum drug plasma concentrations using 10nM methotrexate (MTX, with [3H]-MTX) and at pH 5.5 (intestinal condition) using 20nM FOL (with [3H]-FOL) at maximum doses of ARVs and ART combinations. Uptake studies were performed, and radiochemical activity measured.

RESULTS:



[Figure 1. Effects of INSTI and ART combinations on FOL transporter (A) SLC19A1 (plasma, pH 7.4) and (B) SLC46A (pH 5.5)]

SLC19A1 was the major FOL transporter in plasma, with activity >3-fold that of SLC46A1. No single INSTI significantly inhibited MTX uptake via SLC19A1; however, combinations of TDF/FTC, DTG/ABC/3TC, and DTG/TDF/3TC inhibited >50% of SLC19A1 activity (Fig. 1A). SLC46A1 was a major FOL transporter at pH 5.5 with activity >24-fold higher than SLC19A1. No single INSTI and none of the ART combinations significantly inhibited (>50%) FOL uptake via SLC46A (Fig. 1B).

CONCLUSIONS: No single INSTI significantly inhibited FOL transporters in cell models. However, commonly used INSTI-containing ART combinations caused significant decreases in SLC19A1 activity in plasma, which serves as a mechanism by which FOL transfers to the developing fetus. These findings emphasize the need for preconception FOL fortification for women on INSTI-based ART combinations.

PEA0085

TARGETING TIPRANAVIR TO MESENTERIC LYMPH NODES (MLNS) FOR IMPROVED TREATMENT OF HIV/AIDS

Y. Chu[1], C. Qin[1], W. Feng[1], J. Ali[1], C. Sheriston[1], B. Ling[2], M. Stocks[1], P. Fischer[1], P. Gershkovich[1]
[1]University of Nottingham, School of Pharmacy, Nottingham, United Kingdom, [2]Tulane National Primate Research Center, Division of Comparative Pathology, Covington, United States

BACKGROUND: Tipranavir (TPV) is an HIV protease inhibitor efficiently suppressing drug resistant strains of the virus. However, TPV has limited bioavailability following oral administration if not boosted with co-administered ritonavir. It has been reported that the bioavailability of TPV is increased when the drug is taken with a high-fat meal. Intestinal lymphatic transport is one of the absorption pathways of lipophilic molecules when they are co-administered with lipids. Gut-associated lymphoid tissues (GALTs), including mesenteric lymph nodes, is one of the most important HIV reservoirs. Delivering antiretroviral agents to GALTs via intestinal lymphatic transport can lead to high levels of antiretroviral drugs in this reservoir.

METHODS: The intestinal lymphatic transport potential of TPV was assessed by our previously reported in silico and in vitro methodologies. The chylomicron association assay was initiated by incubating TPV with chylomicron-like emulsion at 37 °C for 1 hour. Chylomicrons were then isolated by density gradient ultracentrifugation and TPV concentration was determined by means of HPLC. Male Sprague Dawley rats were used in pharmacokinetic and biodistribution studies. Blood samples were collected at predetermined time points following intravenous and oral administration. Mesenteric lymph nodes (MLNs), lymph fluid and additional viral reservoir tissues were collected at plasma t_{max} and t_{max-1} hour following oral administration and analyzed for TPV.

RESULTS: In silico model predicted CMs association of 57.2% for TPV and in vitro association model demonstrated 31.7 ± 4.7% (mean ± SD, n=22) of CMs association. The absolute oral bioavailability of TPV following oral administration in lipid-based formulation (57.3%) was higher compared to lipid-free formulation (38.9%). Finally, following oral administration of TPV in lipid-based formulation, at plasma t_{max} the concentration of TPV in MLNs, lymph fluid and plasma were 3119 ng/g, 8129 ng/mL, and 1866 ng/mL, respectively, suggesting very efficient targeting of TPV to GALTs viral reservoir.

CONCLUSIONS: Oral administration of TPV in lipid-based formulation to rats resulted in substantial intestinal lymphatic transport with high concentration of the drug in GALTs, an important viral reservoir. This could be a promising direction in optimization of treatment of HIV/AIDS with TPV and other antiretroviral drugs.

USE OF TRADITIONAL MEDICINES AND EFFECT OF CLAY-BASED REMEDIES IN PREGNANT HIV-POSITIVE WOMEN

J. Kaboggoza[1], E.M. Hodel[2], N. Neary[2], J. Sharp[2], S. Penchala[2], E. Challenger[2], F. Hern[2], K. Seden[2], L. Else[2], A. Owen[2], S. Rannard[2], C. Orrell[3], D. Kiiza[1], T. Malaba[3], C. Papamichael[4], D. Wang[5], T. Chen[5], A. Colbers[6], C. Waitt[2], L. Myer[3], M. Lamorde[1], S. Khoo[2], DoLPHIN-2 trial team
[1]Infectious Diseases Institute, Kampala, Uganda, [2]University of Liverpool, Liverpool, United Kingdom, [3]University of Cape Town, Cape Town, South Africa, [4]Synthesis Center for Research and Education, Nicosia, Cyprus, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]Radboud University, Nijmegen, Netherlands

BACKGROUND: In Africa, traditional medicines (TM) are commonly used during pregnancy. DolPHIN-2 (NCT03249181) evaluated dolutegravir (DTG) vs efavirenz regimens in 268 HIV+ pregnant women in Uganda and South-Africa during third trimester. Use of TM was recorded and managed to avoid drug interactions. In addition, use of a clay-based TM ('Mumbwa') was evaluated for potential to reduce DTG absorption through cationic binding. Mumbwa is a carrier system frequently containing other herbal remedies.

METHODS: We used the WHO definition of TM. Where a potential drug interaction was identified, participants were counselled appropriately. Samples of Mumbwa were procured from street vendors across Kampala, and their elemental content evaluated using energy dispersive X-ray fluorescence.

To assess the potential for Mumbwa to reduce the absorption of DTG, male Balb C mice (average weight 22.5g) were administered 150mg/kg DTG in water (n=42) or in a Mumbwa slurry (n=42) via oral gavage. Groups of 6 mice from each dosing regimen were serially sacrificed at 0, 0.5, 1, 2, 4, 8- and 24-hours post-dose and plasma collected for measurement of DTG concentrations by LC-MS.

RESULTS: At screening, TM was used during pregnancy in 34.32% (92/268) of mothers (65.5% (91/139) in Kampala and 0.8% (1/129) in Cape Town). Following the introduction of ART, this figure fell to 8.44% (15.6% (19/122) in Kampala and 0.9% (1/115) in Cape Town) of evaluable mothers. TM was mostly used to enhance general well-being of the pregnant women (32/92), treat pregnancy-related symptoms such as nausea, vomiting, and pica (24/92), make the unborn baby healthier (22/92), or prevent obstructed labor (14/92).

The most common TM was Mumbwa (used in 75% of 92), which was found to contain 8.4-13.9% aluminum, 4-6% iron and traces of Mg++, Ca++, and Zn++. In mice, coadministration of Mumbwa resulted in a reduction in the AUC0-24 (↓21%, p=0.0271) and C24 (↓53%, p=0.0028) of DTG.

CONCLUSIONS: TM use during pregnancy was common in Kampala. Concomitant administration of Mumbwa was associated with reduced DTG exposure in mice and should be avoided in pregnant women receiving DTG.

PHARMACOKINETICS AND SAFETY OF LONG-ACTING TENOFOVIR ALAFENAMIDE IMPLANTS IN MACAQUES FOR HIV PREVENTION

I. Massud[1], A. Krovi[2], S. Ruone[1], A. Holder[1], J. Gary[1], P. Mills[1], F. Deyounks[1], R. Johnson[1], L. Johnson[2], G. Gatto[2], E. Luecke[3,4], W. Heneine[1], G. García-Lerma1[1], C. Dobard[1], A. van der Straten[3,4]
[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]RTI International, Research Triangle Park, United States, [3]RTI International, Women's Global Health Imperative, San Francisco, United States, [4]University of California, Center for AIDS Prevention Studies, San Francisco, United States

BACKGROUND: To fulfill the promise of ending the global HIV epidemic in the absence of an effective vaccine, sustained release of antiretrovirals for months to years is needed. We assessed the pharmacokinetic release profile and biocompatibility of polycaprolactone (PCL) biodegradable implants containing tenofovir alafenamide (TAF) in rhesus macaques.

METHODS: TAF or placebo implants were administered subcutaneously in the arm using a trocar. Three macaques were enrolled in one of 3 dosage groups (Table). Drug release and local skin reactions were monitored once-weekly for 8-20 weeks. We measured tenofovir (TFV) in plasma (LOD=10ng/ml) and TFV diphosphate (TFV-DP) in PBMCs and rectal/vaginal tissues. Local toxicity (erythema/swelling) was documented using Draize scale (0-4) and H&E staining following implant removal.

RESULTS: TFV was undetectable in plasma. Median TFV-DP in PBMCs in the LD, MD and HD groups were high and sustained during the entire study (378.5, 868.5, and 1,527 fmols/10^6 cells, respectively). TFV-DP was detected in rectal tissues (4 [BLOQ-10], 8.5 [BLOQ-19], and 32 [10-104] fmols/mg of tissue for LD, MD and HD groups, respectively). TFV-DP in vaginal tissues was mostly undetectable.

Local skin reactions were none (grade 0) in 33.3% (LD), 21.2% (MD) and 46.9% (HD) of observations. Mild reactions (grade 1-2) were seen in 61.9% (LD), 69.7% (MD), and 37.5% (HD) of observations. Moderate to severe reactions (grade 3-4) occurred once in the LD group after documented implant breakage and in 9.1% and 3.1% of observations in the MD and HD groups, respectively. H&E staining in the LD and MD group revealed moderate to marked deep dermal inflammation. No local reactions were noted with placebo implants.

Implant dosage group	Total expected TAF release rate	# of TAF implants/ animal	# of Rhesus Macaques	Duration in situ (weeks)	Median TFV-DP in PBMCs (fmol/10^6 cells) [range]	Local reactivity/ observations (grades 0-4)
Low dose (LD)	**0.16** mg/day	1	3	8	378.5 [87.3-1,678]	Grade 0: 7/21 Grade 1-2: 13/21 Grade 3-4: 1/21
Mid dose (MD)	**0.35** mg/day	1	3	11	868.5 [205.6-1,669]	Grade 0: 7/33 Grade 1-2: 23/33 Grade 3-4: 3/33
High dose (HD)	**0.7** mg/day (0.35 mg/day x 2)	2	3	16 (on-going	1,527 [394.9-3,710]	Grade 0: 45/96 Grade 1-2: 36/96 Grade 3-4: 3/96

[Table]

CONCLUSIONS: Our TAF implants delivered high and sustained TFV-DP levels in PBMCs for more than 3 months, exceeding those from oral TAF (>10-50x above known correlates of PrEP protection by TDF/FTC). Local toxicity was noted in some animals after prolonged use. Our results support further pre-clinical evaluation of these implants in SHIV challenge models for long-lasting protection and minimal toxicity.

NEUROPATHOGENESIS

PEA0088

PREDICTORS OF SENSORY NEUROPATHY AND NEUROPATHIC SYMPTOM WORSENING AFTER 12 YEARS IN AGING PEOPLE WITH HIV

R. Ellis[1], M. Diaz[2], N. Sacktor[3], C. Marra[4], A.C. Collier[5], D.B. Clifford[6], N. Calcutt[7], J.A. Fields[8], R.K. Heaton[8], S.L. Letendre[9], CHARTER
[1]University of California, Neurosciences and Psychiatry, San Diego, United States, [2]University of California, Neurosciences, San Diego, United States, [3]Johns Hopkins University, Neurology, Baltimore, United States, [4]University of Washington, Neurology, Seattle, United States, [5]University of Washington, Medicine, Seattle, United States, [6]Washington University, Neurology, St. Louis, United States, [7]University of California, Pathology, San Diego, United States, [8]University of California, Psychiatry, San Diego, United States, [9]University of California, Medicine, Psychiatry, San Diego, United States

BACKGROUND: Little is known about the long-term evolution of distal sensory polyneuropathy (DSP) and distal neuropathic pain (DNP) in older people with HIV (PWH). Whether those without DNP will go on to develop it is unknown. We evaluated these issues in the CHARTER Aging cohort, which enrolled individuals soon after the roll-out of combination antiretroviral therapies and brought them back 12 years later.

METHODS: Participants at 6 U.S. centers underwent standardized clinical and laboratory evaluations at baseline and 12 years. Evaluations included examination for signs (bilateral distal vibration, sharp and touch loss) and symptoms (pain, numbness, paresthesias). DNP severity was rated on a standardized scale. Additional assessments measured instrumental activities of daily living (IADLs), quality of life and employment. Factors potentially associated with DSP and DNP progression included HIV disease severity and treatment indicators, demographics and co-morbidities. Odds ratios were calculated for DSP and DNP at follow-up.

RESULTS: Of 262 participants, 22.5% were women and 58.0% were non-white. Mean baseline age was 43.6 (± 8.03) years and median (interquartile range) nadir and current CD4 were 175 (IQR 30, 280) and 454 (284, 620). DSP prevalence increased from 25.9% at baseline to 43.5% at 12 years; 21.1% had incident DSP. Of 183/262 individuals without pain at baseline, 45 (24.9%) had incident DNP. Of 81 with DNP at baseline, 23 (28.4%) worsened, and 14 improved. Individuals who were employed at baseline were much less likely to have incident DNP at 12 years than those who were unemployed (OR 0.166 [95% CI 0.0561, 0.489]). Higher baseline BMI was associated with incident DNP (OR 1.06 [1.00, 1.12] per unit increase). Participants with DNP at follow-up had significantly worse physical and mental health at follow-up than those without, and were more likely to have become dependent in IADLs.

CONCLUSIONS: HIV DSP and DNP increased in prevalence and severity over 12 years. The burden of these complications remains high, with many long-term survivors experiencing pain and disability. Protective factors for incident DNP included being employed and having lower BMI at baseline. Understanding the risk factors for incident and worsening DSP and DNP will inform the development of preventative strategies.

PED0771

TRANSLATION AND VALIDATION OF THE HIV STIGMA SCALE TO MOSHI, TANZANIA

S. Sao[1], L. Minja[2], M. Watt[3], B. Mmbaga[2], J. Vissoci[4]
[1]Duke University, Duke Global Health Institute, Durham, United States, [2]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [3]University of Utah, Population Health Sciences, Salt Lake City, United States, [4]Duke Global Health Institute, Durham, United States

BACKGROUND: Enacted, anticipated and internalized HIV stigma are informed by individual and community-level stigmatizing attitudes that impede all steps of the HIV care continuum. While much research has been conducted to understand HIV stigmatizing attitudes from the perspective of people living with HIV, little psychometric evidence exists on scales that evaluate stigmatizing attitudes in the general population. Furthermore, HIV stigma has been shown to vary by cultural context, pointing to the need for measures validation in various regions and across languages.

METHODS: A scale to measure HIV stigmatizing attitudes in Tanzania was developed from a modification of the HIV stigma scale (HSS) by Visser et al. Items were added to the original scale based on the team's formative qualitative research and other stigma instruments. The resulting 18-item scale was translated into Swahili and back translated into English by the team's native Swahili speakers. The scale was pilot tested and further modified for cultural context and ease of understanding. From April to November 2019, 1008 women and 489 male partners were enrolled in an HIV stigma reduction study at two antenatal care clinics in Moshi, Tanzania. The validity and reliability of the HSS scale were analyzed using rigorous statistical methods for scale validation.

RESULTS: The translated version of the HSS scale was found to have acceptable domain coherence. Reliability was strong (Cronbach's alpha = 0.92). Exploratory and confirmatory factor analysis of one, two, and three factor models were conducted, and the two-factor model showed ample results, pointing to subscales of blame/moral judgement and isolation/social distancing. HSS scores were externally validated with the anticipated HIV stigma scale scores and were moderately positively correlated ($r = 0.43$, $n = 1497$, $p < 0.001$).

CONCLUSIONS: Given the role that HIV stigma plays as a barrier to HIV care engagement, the development of tools to adequately evaluate HIV stigmatizing attitudes is critical for public health research. This study presents one of the only Swahili adaptations and validations of the HSS instrument. The tool had acceptable psychometric properties, suggesting it can be used to measure stigma in a Tanzanian setting and is adaptable to other locales.

THE FEASIBILITY AND CHALLENGES OF DIAGNOSING AND TREATING ACUTE HIV INFECTION IN A RESOURCE LIMITED HIGH HIV INCIDENCE SETTING IN ESWATINI

B. Kerschberger[1], A. Aung[1], Q. Mpala[1], N. Ntshalintshali[1], C. Mamba[1], S. Mthethwa-Hleza[2], D. Sibandze[3], G. Maphalala[3], L. Dube[2], R. Kashangura[4], T. Obulutsa[1], M.L. Tombo[1], R. de la Tour[5], A. Calmy[6], A. Telnov[5], B. Rusch[5], A. Gonzalez[5], I. Ciglenecki[5]
[1]Médecins Sans Frontières, Mbabane, Eswatini, [2]Ministry of Health (ENAP), Mbabane, Eswatini, [3]Ministry of Health (NRL), Mbabane, Eswatini, [4]Ministry of Health (Nhlangano Health Centre), Nhlangano, Eswatini, [5]Médecins Sans Frontières, Geneva, Switzerland, [6]University Hospital (HIV/AIDS Unit), Geneva, Switzerland

BACKGROUND: Diagnosing and treating acute HIV infection (AHI) is challenging in resource-poor settings, limiting HIV epidemic control. We evaluated the feasibility of diagnosing and treating AHI in a high HIV incidence setting in Eswatini.

METHODS: Patients were prospectively screened for and diagnosed with AHI using Xpert HIV-1 viral load (VL) quantification in one secondary care outpatient department in Shiselweni (Eswatini), between March and October 2019. Patients were eligible for VL testing if they

1) were HIV-negative as per routinely used rapid-diagnostic-tests (RDT) (Alere Determine™, Unigold™) and had conditions suggestive of AHI (fever/ sore throat/ symptoms of sexual transmitted infection (STI)), or;

2) had an inconclusive RDT test result, or;

3) were referred from the pre- and post-exposure prophylaxis programme as a presumptive AHI case.

AHI was confirmed if at least two VL measurements were between 40 to 9,999 copies/mL, or one VL measurement ≥10,000 copies/mL.

We used descriptive statistics and Kaplan-Meier estimates to describe the AHI care continuum. Generalized linear models determined predictors of highly infectious cases of AHI, defined as patients with VLs >10,000 copies/mL.

RESULTS: Of 530 patients screened for AHI, 22 (4.2%) had AHI with a median VL of 53,100 (IQR: 4,980-903,000) copies/mL. Seven (1.3%) had two VL results between 40-9,999 copies/mL and 15 (2.8%) had one VL ≥10,000 copies/mL. Predictors of highly infectious AHI were an inconclusive RDT test result (aRR 12.74; 95% CI: 3.81-42.65), diagnosed STI (aRR 2.87; 1.22-6.72), oral ulcer (aRR 9.15; 4.21-19.87) and patient self-reported fatigue (aRR 4.14; 1.53-11.26). Of all AHI cases (n=22), 14 (63.6%) initiated ART at a median of 1.5 (IQR 0-4) days since diagnosis of AHI, with 5 (35.7%) on the same day as diagnosis.

Overall ART retention was 78.6% (95% CI: 47.3%-92.5%) and 71.4% (40.6%-88.2%) at 14 and 180 days after treatment start. Of patients due for VL testing and available VL measurements, 7/10 (70.0%), 8/9 (88.9%) and 6/6 (100%) had a suppressed VL at 2 weeks, 2 and 3 months after ART initiation.

CONCLUSIONS: AHI screening can contribute to timely HIV diagnosis with potential public health benefits. Despite rapid VL suppression, ART initiation and retention remained suboptimal.

PEB0089

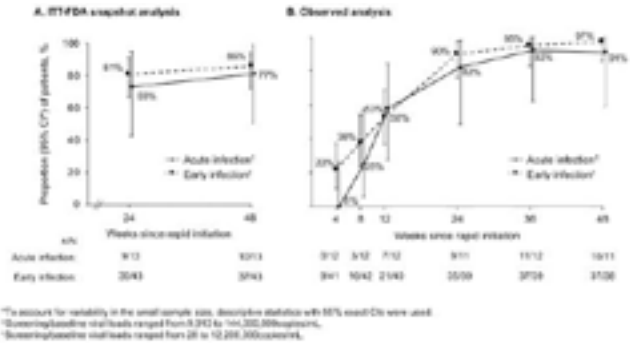
RAPID INITIATION OF DARUNAVIR/COBICISTAT/ EMTRICITABINE/TENOFOVIR ALAFENAMIDE (D/C/F/TAF) IN ACUTE AND EARLY HUMAN IMMUNODEFICIENCY VIRUS (HIV)–1 INFECTION: A DIAMOND SUBGROUP ANALYSIS

K. Dunn[1], R. Rogers[1], R.B. Simonson[1], D. Luo[2], S. Sheng[2], P. Kassam[1], S. Seyedkazemi[1], H. Hardy[1]
[1]Janssen Scientific Affairs, LLC, Titusville, United States, [2]Janssen Research & Development, LLC, Titusville, United States

BACKGROUND: Patients with acute or early HIV-1 infection tend to have high viral loads. Treatment is associated with virologic benefits and reduced transmission risk, but adherence may be challenging.

METHODS: DIAMOND (ClinicalTrials.gov: NCT03227861), a phase 3, prospective study, assessed the efficacy/safety of D/C/F/TAF 800/150/200/10mg in rapid initiation. Adults were enrolled ≤14 days after diagnosis and started D/C/F/TAF prior to screening/baseline laboratory result availability. In this analysis, virologic response (HIV-1 RNA <50copies/mL) was evaluated at Week 48 by intent-to-treat FDA snapshot and observed analysis (excluding patients with missing data) in subgroups of patients with acute (HIV-1 antibody negative and HIV-1 RNA positive/p24 positive) or early (HIV-1 antibody positive and suspected infection ≤6 months before screening/baseline) infection.

RESULTS: Among 109 patients, 13 had acute and 43 had early HIV-1 infection. At screening/baseline, 6 (46%) acute and 9 (21%) early infection patients had HIV-1 RNA ≥100,000copies/mL; 12 (92%) acute and 40 (93%) early infection patients had CD4+ cell count ≥200cells/μL. At Week 48, high rates of virologic response were demonstrated with both FDA snapshot and the observed analysis (Figure). No patients discontinued due to baseline resistance or lack of efficacy, and none developed protocol-defined virologic failure. Across both subgroups, mean (SD) cumulative adherence (pill count) through Week 48 was 95% (12%). Over 48 weeks, 7 (54%) acute and 22 (51%) early infection patients had any D/C/F/TAF-related adverse event (AE). D/C/F/TAF-related AEs for acute and early infection patients, respectively, were: grade 3-4 AE, 0 and 2 (5%); AE leading to discontinuation, 0 and 1 (2%); serious AE, none.



[Figure. Virologic response (HIV-1 RNA <50 copies/mL) with D/C/F/TAF rapid initiation over time in patients with acute or early HIV-1 infection.]

CONCLUSIONS: These data support that high rates of suppression during acute/early infection can be achieved with rapid initiation of D/C/F/TAF, including in patients with high baseline viral loads. No treatment-emergent resistance mutations were observed, adherence was high, and D/C/F/TAF was safe and well tolerated.

IMPACT OF CO-FACTORS (E.G., VIRAL CLADE, TROPISM, GENETIC FACTORS) ON DISEASE PROGRESSION

PEB0090

EVALUATION OF VIRAL SUPPRESSION ONE YEAR AFTER GENOTYPING TEST TO GUIDE SALVAGE THERAPY AMONG ADULT PATIENTS INFECTED WITH HIV-1 B OR HIV-1 F SUBTYPE AT POLYMERASE REGION

C.M. Ahagon[1], G. de Faria Romero Soldi[1], G. Ibete Silva López Lopes[1], I. Coutinho Ribeiro[1], G. Bastos Cabral[1], L. Portes Ozório Coelho[1], N.C. Campos[1], J.L. de Paulo Ferreira[1], L.F. de Macedo Brigido[1], Salvage Therapy Working Group

[1]Instituto Adolfo Lutz, Virologia, São Paulo, Brazil

BACKGROUND: The impact of subtypes on antiretroviral response is controversial. Subtype F is rare in most of the world but is an important minor variant in most South America and in areas of Europe, with some studies suggesting a worse antiretroviral response.

METHODS: We evaluated the virological response at one year (52 weeks) after genotyping (Sanger sequencing, BigDye, Applied) from retrotranscribed plasma RNA to guide ARV therapy modification in adult patients with virological failure. Stanford db, used for mutations (NRTI, NNRTI, PI) and GSS, were sent to clinical service. NCBI and Rega for subtyping. All subtype F cases (2014-2017) and randomly selected subtype B control cases (1:3) from the same period were anonymized for analysis. Cases failing a first- line regimen were tested in logistic regression. Adjusted analysis was performed for variables with p< 0.2 at unadjusted analysis (Stata10). Pearson-Chi, Kruskal-Wallis or Mann-Whitney were used as appropriate.

RESULTS: Table 1 shows some demographic and laboratory variables at enrollment of the 507 patients according to HIV -1 subtype.

	All N = 507	Subtype B N = 341 (67%)	Subtype F N= 166 (33%)	p
Male Sex	289 (57%)	208 (72%)	81 (28%)	0.009
Age (years)	44 (37 - 51)	44 (37 - 52)	44 (38 - 51)	0.7864
CD4+ T count (cells/mm^3)	284 (155 - 479)	294 (145 - 480)	253 (160 - 466)	0.5878
HIV RNA (log_{10})	3.88 (3.07 - 4.66)	3.79 (3.04 - 4.63)	4.01 (3.12 - 4.76)	0.1934

[Table 1.]

The proportion of cases with TCD4>500 was similar at enrollment (F=21.1% vs B=23.3%, p=0.6), but lower at W52 outcome (F=19.4% vs B=30.1%, p=0.017). Viral suppression (<200cp/mL) was also lower for F=55% vs B=66%, p=0.022. (For supression at <40, F=42% vs B=54%, p=0.012). From 507 patients, 132 (26%) were at first-line failure. Higher number of regimens was associated to lower suppression at W52 (p=0.007). Logistic analysis for cases failing first-line in table 2.

References	Unadjusted Odds Ratio	P	95%CI	Adjusted Odds Ratio	P	95%CI
CD4+T count >500 cells/mm^3	2.95	0.042	1.04 - 8.36	3.05	0.044	1.03 - 9.00
Male sex	2.29	0.045	1.02 - 5.16	2.32	0.055	0.98 - 5.47
Subtype B	3.04	0.008	1.33 - 6.92	2.79	0.018	1.19 - 6.56
Only variables with p<0.2 at unadjusted analyses are shown. Older age, viremia at enrollment, number of mutations to NRTI, NNRTI and NNRTI classes and GSS to drug used in the genotype guided therapy did not reach the p=0.2 cutoff.						

[Table 2: Logistic regression of demographic and laboratory variables and W52 suppression (<200 c/mL) in patients failing a first-line regimen.]

CONCLUSIONS: Although limited by potential confounders, the study adds to literature suggestions that ART response of individuals living with HIV-1 subtype F may be worse than those with HIV-1 B. As shown in previous studies, subtype F is more common among women in Brazil.

MORBIDITY, MORTALITY AND LIFE EXPECTANCY IN CLINICAL RESEARCH

PEB0091

TRENDS IN CLINICAL FOLLOW-UP BETWEEN 2008-2018 AMONG PEOPLE LIVING WITH HIV IN THE TREAT ASIA AND AUSTRALIAN HIV OBSERVATIONAL DATABASES (TAHOD AND AHOD)

A. Jiamsakul[1], M. Boyd[2], J.Y. Choi[3], N. Edmiston[4], N. Kumarasamy[5], J. Hutchinson[1], M. Law[1], R. Ditangco[6]

[1]The Kirby Institute, UNSW Sydney, Sydney, Australia, [2]University of Adelaide, School of Medicine, Faculty of Health and Medical Sciences, Adelaide, Australia, [3]Yonsei University College of Medicine, Division of Infectious Diseases, Department of Internal Medici, Seoul, Korea, Republic of, [4]University of Sydney, Faculty of Medicine and Health, Sydney, Australia, [5]The Voluntary Health Services (VHS), Chennai Antiviral Research and Treatment Clinical Research Site (CART CRS), Chennai, India, [6]Research Institute for Tropical Medicine, Manila, Philippines

BACKGROUND: To reduce the financial burden on people living with HIV (PLHIV) and health care services, the World Health Organization recommends less frequent clinical visits for PLHIV on stable antiretroviral therapy (ART). This study aimed to assess frequency of follow-up visits and survival outcomes among PLHIV in Asia and Australasia.

METHODS: PLHIV who have been on ART for at least one year enrolled in TAHOD or AHOD between 2008-2018 were included. Follow-up visits were defined as a combination of recorded clinic visit, and laboratory testing dates. Visit rates during this period were analysed using repeated measure Poisson regression. Survival was analysed using competing risk regression.

RESULTS: There were 7705 PLHIV (70% male) included from TAHOD, and 3269 (91% male) from AHOD. The overall visit rate during 2008-2018 was 4.41 per 1 person-years (/PYS) in TAHOD, and 3.72/PYS in AHOD. Adjusting for statistically significant risk factors, there was no trend observed in TAHOD visit rates across calendar years. However, AHOD showed a decreasing trend in visit rates in later years (2010-2012: IRR=0.81, 95% CI 0.79-0.83; 2013-2015: IRR=0.71, 95% CI 0.70-0.73; and 2016-2018: IRR=0.71, 95% CI 0.69-0.72) compared to 2008-2009, p-trend <0.001. In TAHOD, females had higher visit rates compared to males (IRR=1.07, 95% CI 1.05-1.10). The mortality rate was 0.53/100PYS in TAHOD and 0.72/100PYS in AHOD. Calendar year was not associated with survival in either cohort. Compared to those with 2 visits in the previous 12 months, those with ≥4 visits had poorer survival, while those with ≤1 visit had no significant differences in mortality: TAHOD: ≤1 visit: SHR=1.30, 95% 0.70-2.39; ≥4 visits: SHR=2.06, 95% CI 1.30-3.27; AHOD: ≤1 visit: SHR=0.96, 95% CI 0.54-1.73; ≥4 visits: SHR = 1.80, 95% CI 1.13-2.86. Sex was not associated with mortality.

CONCLUSIONS: Visit rates in TAHOD have remained steady over the past 10 years, while rates have declined in AHOD. Survival was not affected by having fewer visits. However, those with more frequent follow-up visits were at increased risk of mortality, which was possibly due to poorer health as a cause of the visits.

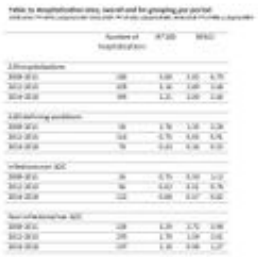
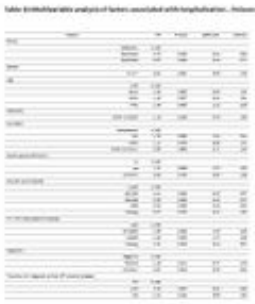
Spallanzani, Clinical Epidemiology Unit, Rome, Italy, [3]University of Bari Aldo Moro, Department of Infectious Diseases, Bari, Italy, [4]S. Maria Nuova IRCCS Hospital, Department of Infectious Diseases, Reggio Emilia, Italy, [5]ICONA Foundation, Milano, Italy, [6]ASST Grande Ospedale Metropolitano Niguarda, Division of Infectious Diseases, Milano, Italy, [7]University of Foggia, Clinical Experimental Medicine, Foggia, Italy, [8]National Institute for Infectious Diseases L. Spallanzani, HIV/AIDS Clinical Unit, Rome, Italy, [9]ASST Santi Paolo e Carlo, University of Milano, Clinic of Infectious and Tropical Diseases, Department of Health Sciences, Milano, Italy, [10]AOU Modena, University of Modena and Reggio Emilia, Modena, Italy

BACKGROUND: Data on the rates of hospitalizations in the more recent HAART era are useful for both healthcare planning and the development of strategies to improve health status of persons living with HIV (PLWHIV). We aimed to describe the change in the incidence of hospitalization between 2008 and 2018, and the reasons for hospitalization among patients who started antiretroviral therapy (cART) from 2008 onwards.

METHODS: We included participants in the ICONA cohort in cART from 2008. The study differentiated hospitalizations in: AIDS defining conditions (ADC), infections non-ADC and non-infections/non-ADC. Hospitalization rates reported per 100 person-years (PY). Comparisons of rates across time assessed using Poisson regression. Poisson multivariable model evaluated risk factors for hospitalizations, including both demographic and clinical characteristics.

RESULTS:





9705 PLWHIV were included. During 36167 PY there were 1058 hospitalizations in 748 (7.7%) subjects (2.9/100 PY): 12.4% IDU, 36.5% MSM, 43.6% heterosexuals, 74.6% males, 42.3% smokers, 16.6% coinfected with HCV and 6.8% with HBV. At hospitalization 34.9% had HIVRNA>50 copies mL, 25.8% CD4<200/mmc. Causes of hospitalization were: 23.3% ADC, 22.7% infections non-ADC, 54.1% non-infections/non-ADC (11.1% cancers; 8.8% gastrointestinal-liver; 6.2% cardiovascular; 4.6% renal-genitourinary; 4.5% psychiatric; 3.9% pulmonary; 14.9% other). Over the study period, IR decreased significantly (from 5.8, in 2008-2011 to 2.2 in 2016-2018). Whereas hospitalization rates for ADC and for non-infections/non-ADC also showed a decreasing trend, the infections non-ADC remained stable throughout the period (Table 1a). Female, age>50 years, IDU, familiarity for cardiovascular disease, HIV-RNA>50, CD4 <200, longer time from HIV diagnosis to first cART were independently associated with a higher hospitalization risk; age, nationality, HCV coinfection were not. Results of multivariate analysis in Table 1b.

CONCLUSIONS: Chronic degenerative diseases are the main cause of morbidity leading to hospitalization in PLWHIV after cART start since 2008.

PEB0093

A COMPARISON OF MORTALITY IN PATIENTS WITH AGGRESSIVE AIDS-RELATED LYMPHOMA TREATED WITH AND WITHOUT RITUXIMAB

P.C.M. Manyau[1], E.T. Mberi[2], T. Mudzviti[1], S. Rusakaniko[3], C.C. Maponga[1], G.D. Morse[4]
[1]University of Zimbabwe, Pharmacy, Harare, Zimbabwe, [2]University of Zimbabwe, Haematology, Harare, Zimbabwe, [3]University of Zimbabwe, Community Medicine, Harare, Zimbabwe, [4]University at Buffalo, Pharmacy and Pharmaceutical Sciences, Buffalo, United States

BACKGROUND: In 2018, non-Hodgkin lymphomas (NHL) contributed 2.8% to the total global cancer incidence. In Zimbabwe, NHL contributed 6.8% to cancer incidence, and the majority these cases were attributable to a large, ageing HIV+ population. Rituximab revolutionised the treatment of B-cell NHL. Treatment options for AIDS-related lymphomas (ARLs) in Zimbabwe include chemotherapy +/- rituximab. Currently, the effectiveness of rituximab in the treatment of ARLs in resource limited settings is unknown. This study sought to determine mortality of patients with ARL treated with chemotherapy +/- rituximab.

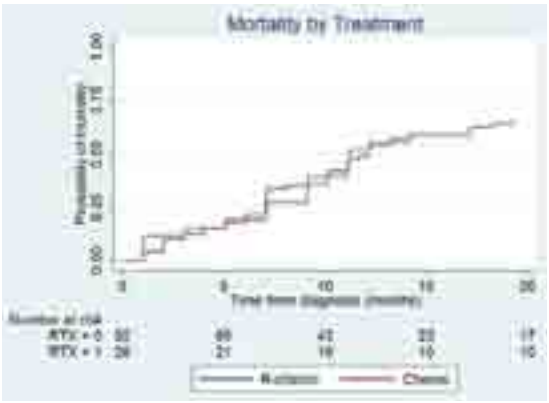
METHODS: A retrospective review of records of adult HIV+ patients treated for high-grade NHL with chemotherapy +/- rituximab between 2015-2017 was conducted. Mortality and disease progression/relapse at 18 months were determined. Mortality functions were estimated using Kaplan-Meier methodology. Risk factors and treatment effects were assessed with Log-rank tests and Cox regression.

RESULTS: One hundred and twenty-four eligible medical records were identified. This was a cohort of black Africans with a median age of 42 (IQR: 20-56) and a 57% male gender distribution. Baseline clinical characteristics are shown in table 1:

Variable	All (N=124)	R-Chemo (n=27)	Chemo (n=97)	P
Ann Arbor clinical Stage, n (%) I/II III/IV	 14 (11.8) 105 (88.2)	 2 (7.7) 24 (92.3)	 12 (12.9) 81 (87.1)	 0.466
Time on cART, n (%) <6 months ≥ 6 months	 46 (37.1) 78 (62.9)	 7 (25.9) 20 (74.1)	 39 (40.2) 58 (59.8)	 0.174
CD4+ cells/mm3, n (%) <100 ≥100	 32 (25.8) 92 (74.2)	 8 (29.6) 19 (70.4)	 24 (24.7) 73 (75.3)	 0.608

[Table 1: Baseline characteristics]

Progressive/refractory disease was diagnosed in 51.6% of the cohort. Rituximab was not associated 18-month mortality, hazard ratio (HR) 1.35 (95% CI: 0.68-2.70). On multivariate analysis, risk factors for 18-month mortality were male gender (HR 1.90, p=0.02), age≥ 40 years (HR 2.38, p=0.005), <3 treatment cycles (HR 2.04, p=0.02), low socioeconomic status (HR 2.06, p=0.03).



[Figure 1: Kaplan-Meier mortality functions by treatment]

CONCLUSIONS: Rituximab did not reduce mortality in Zimbabwean patients diagnosed with ARL. Immune dyregulation may have ameliorated rituximab activity in this cohort. Socio-demographic characteristics and number of treatment cycles predicted mortality. Results suggest that health disparities exist in the population.

EVALUATION OF LOW LEVEL VIREMIA IN A MULTINATIONAL STUDY AND ASSOCIATIONS WITH CLINICAL OUTCOMES, IMMUNOLOGIC OUTCOMES AND MICRONUTRIENTS

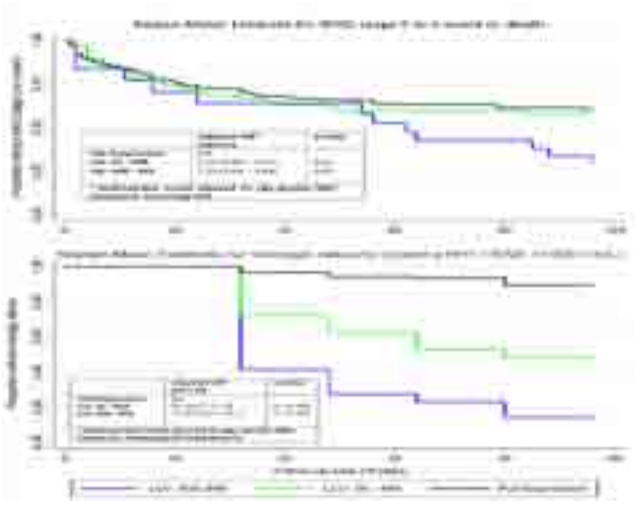
H. Dunlevy[1], M. Dsouza[2], N. Gupte[3], K. Harrington[2], S. Badal-Faesen[4], S. Pillay[5], M. Hosseinipour[6], S. Berendes[7], K. Supparatpinyo[8], C. Riviere[9], J. Lama[10], J. Hakim[11], R. Rapaport[12], D. Asthmus[13], A. Balagopal[3], A. Gupta[3], T. Campbell[1], ACTG PEARLS and NWCS 319 study teams

[1]University of Colorado, Internal Medicine, Division of Infectious Diseases, Aurora, United States, [2]Hologic, Inc., San Diego, United States, [3]Johns Hopkins University, Baltimore, United States, [4]University of Witwatersrand, Johannesburg, South Africa, [5]University of KwaZulu-Natal, Durban, South Africa, [6]University of North Carolina, Chapel Hill, United States, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]Chiang Mai University, Chiang Mai, Thailand, [9]Haitian Group for the Study of Kaposi's Sarcoma and Opportunistic Infections, Port-au-Prince, Haiti, [10]Asociacion Civil Impacta Salud y Educacion, Lima, Peru, [11]University of Zimbabwe College of Health Sciences, Harare, Zimbabwe, [12]University of Colorado, Aurora, United States, [13]UC Davis, Sacramento, United States

BACKGROUND: Few studies have investigated the outcomes of low-level viremia (LLV) in resource-limited settings. PEARLS (ACTG A5175) was a randomized clinical trial of the efficacy of three antiretroviral regimens in low-, middle- and high-income countries in Africa, Asia, North and South America. Using a highly sensitive assay to measure plasma HIV-1 RNA (VL) in stored specimens from a subset of PEARLS participants, we investigated the significance of LLV after initiation of ART.

METHODS: Plasma and data from 251 individuals previously selected for a case-cohort study of immunologic and micronutrient outcomes in PEARLS were analyzed. VL was measured by Aptima Quant HIV-1 every 3 months after ART initiation. Participants were categorized by VL ≥16 weeks after ART: LLV (consecutive 30-499 or 500-999 c/mL; N=56 and 21, respectively); Never suppressed (NS, ≥1000 c/mL after 16 weeks; N=8); Full suppression (FS, <30 c/mL; N=166). Cox regression models estimated hazards for primary endpoint of WHO stage 3/4 event or death (WHO endpoint) and secondary endpoint of subsequent virologic rebound (VR).

RESULTS:



[Figure]

LLV was associated with the following baseline characteristics: country (P<0.001), HIV subtype (P=0.003), race/ethnicity (P=0.04), randomized study treatment (P=0.01), higher entry viral load (P<0.001), lower serum albumin (P=0.03), lower hemoglobin (P=0.04), lower platelets (P=0.03), higher CXCL-10 (P<0.001), higher TNFα (P=0.003) and higher levels of lutein (p=0.03). In multivariate analyses, participants with LLV 500-999 c/mL had increased hazards of subsequent WHO endpoint (aHR 1.94; 95% CI 1.04-3.46). LLV at both 30-499 and 500-999 c/mL had increased hazards of subsequent VR (aHR 8.4; 95% CI 4.0-17.4; and aHR 31.6, 95% CI 14.5-69.1, respectively).

CONCLUSIONS: Across diverse multinational settings, LLV at 16 weeks or later after ART initiation was associated with having a subsequent WHO stage 3/4 or death and virologic rebound. These findings reinforce the importance of frequent VL monitoring in these settings early post-ART initiation.

PEB0095

TIME TO ART INITIATION FROM HIV DIAGNOSIS AND SURVIVAL TO FATAL AND NON-FATAL SEVERE EVENTS: AN ANALYSIS OF THE HIV ATLANTA VETERANS AFFAIRS COHORT STUDY, 2005-2019

E.M. Rabold[1,2], J.L. Guest[2,1], V.C. Marconi[3,4,5]

[1]Emory University School of Medicine, Department of Family and Preventive Medicine, Atlanta, United States, [2]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States, [3]Emory University School of Medicine, Department of Infectious Diseases, Atlanta, United States, [4]Emory University Rollins School of Public Health, Department of Global Health, Atlanta, United States, [5]Atlanta VA Medical Center, Atlanta, United States

BACKGROUND: Studies have shown benefits in viral load suppression and mortality for people living with HIV who initiate antiretroviral treatment (ART) immediately after diagnosis, but the impact of early treatment on multiple causes of morbidity and mortality have not been explored.

This analysis aimed to compare time to death and other severe non-fatal events between veterans who initiated ART within 60 days of HIV diagnosis (early) and intermediate (61-365 days) or late (>365 days) initiation.

METHODS: Using data from the HIV Atlanta Veterans Affairs Cohort Study (HAVACS) and Clinical Case Registry, we identified all treatment-naive veterans who initiated ART at the Atlanta Veterans Affairs Medical Center between January 2005 and May 2018; veterans missing key dates such as HIV diagnosis or ART initiation date were excluded from the analysis. Using Cox proportional hazards models, we calculated the unadjusted and Veterans Aging Cohort Study (VACS) index-adjusted hazard ratios (aHR) for the primary composite outcome [death, AIDS-defining diagnosis, malignancy, severe renal or liver disease, atherosclerotic cardiovascular disease (ASCVD), or invasive infection] and all-cause mortality during the study period (January 2005 to May 2019).

RESULTS: In total, 520 veterans (2991.8 person-years) were included in this analysis with 159 total events and 65 deaths. Unadjusted models for the composite outcome and all-cause mortality were not statistically significant. Compared to veterans with early initiation, late initiation was associated with an increased adjusted hazard of the composite outcome [aHR 1.27; 95% confidence interval (CI), 0.76-2.12 and aHR 1.81; 95% CI, 1.15-2.87 for intermediate and late initiation, respectively). Both intermediate and late initiation increased the adjusted hazards of all-cause mortality (aHR 2.49; 95% CI, 1.05-5.94 and aHR 2.81; 95% CI, 1.24-6.33, respectively).

CONCLUSIONS: Independent of baseline characteristics, early ART initiation is associated both with improved overall survival and a reduction in morbidity across a range of severe conditions. These findings highlight the importance of rapid diagnosis and linkage to care. Adopting strategies to streamline treatment initiation soon after diagnosis may lead to improved morbidity and mortality, closing the survival gap between people with and without HIV.

PEB0096

RISK OF HOSPITALISATION ACCORDING TO DEMOGRAPHIC, SOCIOECONOMIC, MENTAL HEALTH AND LIFESTYLE FACTORS AND CAUSES FOR ADMISSION IN PEOPLE LIVING WITH HIV IN THE UK

S. Rein[1], C. Smith[1], C. Chaloner[1], A. Stafford[2], A. Rodger[1], M. Johnson[2], J. McDonnell[1], F. Burns[1,2], S. Madge[2], A. Miners[3], L. Sherr[1], S. Collins[4], A. Speakman[1], A. Phillips[1], F. Lampe[1]
[1]University College London (UCL), Institute for Global Health, London, United Kingdom, [2]Royal Free Hampstead NHS Trust, London, United Kingdom, [3]London School of Hygiene and Tropical Medicine (LSHTM), London, United Kingdom, [4]HIV i-Base, London, United Kingdom

BACKGROUND: Hospitalisation is a major marker for AIDS and non-AIDS morbidity in people with HIV (PLHIV). However, little is known about the rate, causes and factors associated with hospitalisations in PLHIV in the UK in the recent ART era.

METHODS: In a sub-study of the ASTRA questionnaire study, 798 individuals recruited at a London, UK, site who consented to routine clinical data linkage were included. A medical record review identified occurrence and ICD-10 classified causes of all hospital admissions from questionnaire completion (2011-2012; baseline) until 1 June 2018.

We used Prentice-Williams-Peterson gap time models to calculate hazard ratios (HR) of repeated all-cause hospitalisation according to baseline clinical, demographic, socioeconomic, mental health and lifestyle factors.

RESULTS: 274 hospitalisations occurred (153 had ≥1 hospitalisation): an overall rate of 6.2/100 person-years. 80% of hospitalisations were emergencies. The re-admission rate was 64/100 person-years. Factors predicting hospitalisation included: older age, being a woman or heterosexual man with ethnicity other than Black African, financial hardship, no stable partner, having children, low CD4, ART non-adherence, injection drug use and depressive symptoms (table). The most common causes of hospitalisation were circulatory, digestive and respiratory diseases, infectious diseases and injury, poisoning and other consequences of external causes (figure).

Demographic group (vs. MSM)	Unadjusted HR (95% CI)	p-value	Adjusted HR (95% CI) (adjusted for age; demographic group; years since diagnosis)	p-value
Black African heterosexual men	1.2 (0.7, 1.9)	0.0081	1.2 (0.7, 2.0)	0.0071
Other heterosexual men	1.8 (1.3, 2.7)		1.9 (1.3, 2.8)	
Black African women	0.8 (0.6, 1.3)		0.9 (0.6, 1.4)	
Other women	1.4 (1.0, 2.1)		1.5 (1.0, 2.3)	
Age (vs. <=35)

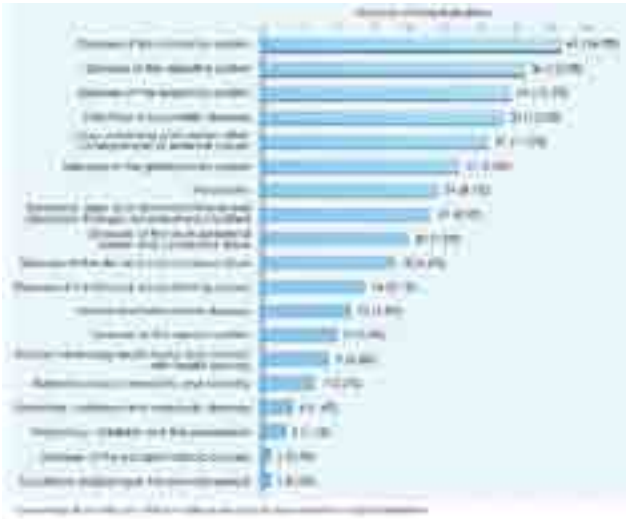
PHQ-9 depression based on score (vs. none/minimal)				
Mild	1.3 (0.9, 1.9)	0.0070	1.3 (0.9, 1.9)	0.0048
Moderate	1.6 (1.1, 2.3)		1.7 (1.2, 2.4)	
Severe	1.8 (1.3, 2.6)		1.9 (1.3, 2.8)	

[Table]



[Figure. ICD-10 classified causes of hospitalisation]*

CONCLUSIONS: Socioeconomic hardship, poor mental health and adverse lifestyle factors are important predictors of hospitalisation in people with HIV. The causes of hospitalisation are wide-ranging with no single cause dominating. Better understanding of causal mechanisms is needed to inform possible interventions. Given the high costs of hospitalisation such interventions could be cost-effective.

PEB0097

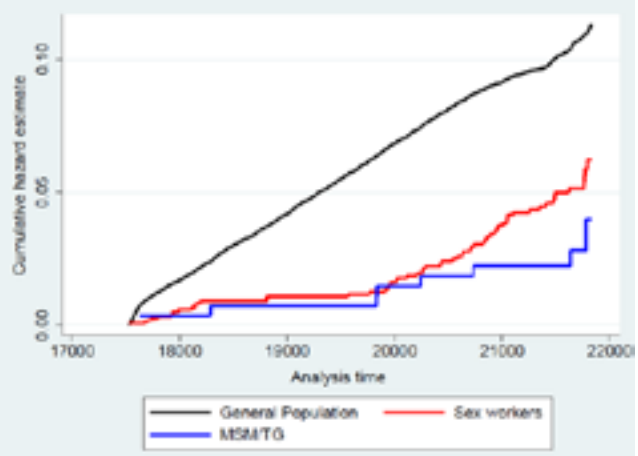
COHORT STUDY ON HIV/AIDS-RELATED MORTALITY FOR KEY POPULATIONS MANAGED UNDER PROGRAMMATIC CONDITIONS IN PAPUA NEW GUINEA: 2008 - 2019

S.M. Machekera[1,2], N. Lote[3,2], Z. Mosende[4], W. Sikukula[1], G. Nano[2], P. Boas[2], A. Gurung[3]
[1]World Vision International, TB/HIV, Port Moresby, Papua New Guinea, [2]HIV/AIDS & STIs Program - National Department of Health, Port Moresby, Papua New Guinea, [3]World Health Organisation, Port Moresby, Papua New Guinea, [4]UNAIDS, Port Moresby, Papua New Guinea

BACKGROUND: Since roll-out of the ART program in Papua New Guinea (PNG) deaths among people living with HIV (PLHIV) have declined. However, there lacks empirical evidence on differences in mortality across subpopulations. Our aim was to compare HIV-mortality between key populations (KPs) and the general population (GPs).

METHODS: We conducted a retrospective cohort study using routine cased-based program data. Anonymised electronic data from the national server with all patients enrolled on ART in 26 health facilities across the country between January 2008 and September 2019 was included. We excluded incomplete or erroneous records. Survival analysis using Cox regression was conducted to determine hazard ratios and mortality rates.

RESULTS: A total of 46,851 patients were followed-up for 973,141,441 person years. Of these, 1.57% were sex workers (SWs), 0.31% men-who-have-sex with men and/or transgender (MSM/TGs) and 98.1% general population (GPs). Throughout the follow-up period 3,919 deaths were reported with the majority of them occurring among the GPs. Surprisingly, mortality rates for SWs and MSM/TGs at 0.22 (95% CI 0.17 – 0.29) and 0.13 (95% CI 0.07 – 0.29) where significantly lower than that of GPs. Similarly, the KPs groups had statistically significant lower hazard ratios than the GPs (see figure 1). Although both point estimates of mortality rates and hazard ratios for MSM/TGs were lower than that of SWs, it was not statistically significant.



[Figure 1: Nelson-Aalen cumulative hazard estimates for key populations]

CONCLUSIONS: In this cohort, KPs had significantly lower HIV/AIDS-related mortality compared to the general population. KPs may be at high risk for HIV transmission however, GPs are the biggest sub-population of PLHIV who also have a much higher mortality. Resource allocation to bring the epidemic under control should thus leave no-one behind. We recommend that another study be carried out to understand factors associated with mortality so that appropriate solutions can be crafted.

PEB0098

FACTORS ASSOCIATED WITH HIGH MORTALITY AND LOSS TO FOLLOW-UP AMONG "CHALLENGING" PATIENTS IN ARGENTINA RE-ENGAGING IN HIV CARE

O. Sued[1], M.I. Figueroa[1], E. Dell´Isola[1], D. Cecchini[2], J.M. Abbamonte[3], L. Mandell[3], I. Cassetti[2], P. Cahn[1], S.M. Weiss[3], D.L. Jones[3], COPA Study Group
[1]Fundación Huésped, Research, Buenos Aires, Argentina, [2]Helios Salud, Buenos Aires, Argentina, [3]University of Miami, Miller School of Medicine, Dept. of Psychiatry & Behavioral Sciences, Miami, United States

BACKGROUND: Re-engaging "challenging" HIV-infected patients – those not retained in care – is a critical component of national HIV programs to achieve the 90-90-90 goals. Argentina guarantees comprehensive HIV care services, including free ART. Yet, dropout occurs at every stage of the care continuum.

METHODS: The COPA2 study (NCT02846350) is a cluster-randomized clinical trial to test the effectiveness of physician-delivered Motivational Interviewing (MI) to improve retention and viral suppression among "challenging" patients in Argentina. From November 2016 to March 2018, 360 individuals were enrolled in 7 clinics (3 intervention, 4 standard of care). Demographic, psychosocial, and clinical information was collected at baseline. Participants were asked to return for follow-up visits at 6, 12, 18 and 24 months. This analysis looked at baseline factors associated with death, loss to follow-up, or new AIDS events during the first 18 months.

RESULTS: 353 individuals were included in analyses. The average age was 39 years old, 78.5% were white, 51.3% were cisgender women (48.7% cisgender men), and 55.2% were currently employed. The average monthly household income was $278 USD, and 46% completed high-school education. 51% were randomized to MI and 69.7% were seen at public clinics. Over the first 18 months, 16 (4.5%) died, 97 (27.5%) were lost to follow-up and 33 (9.3%) developed a new AIDS event. Death rate was constant along the period and multivariate analysis could not find baseline factors significantly associated to death. Regarding retention, those with drug abuse at baseline were 3 times more likely to be lost at 18-months, while those who changed ART regimens at enrollment were 44% less likely. Only baseline viral load (VL) was associated with new AIDS events: for every one log10 increase, participants were 2.3 times more likely to experience a new AIDS event.

CONCLUSIONS: This study highlights the high mortality and loss to follow-up among challenging patients. Drug abuse and higher VL predicted loss to follow-up and new AIDS events, respectively, while changing ART regimen was associated with better retention. Rapid ART change and comprehensive interventions, including harm reduction, might have an impact in reducing adverse outcomes in individuals previously disengaged from care.

HIV TESTING AND RETESTING (E.G., POINT-OF-CARE DIAGNOSTICS)

PEB0099

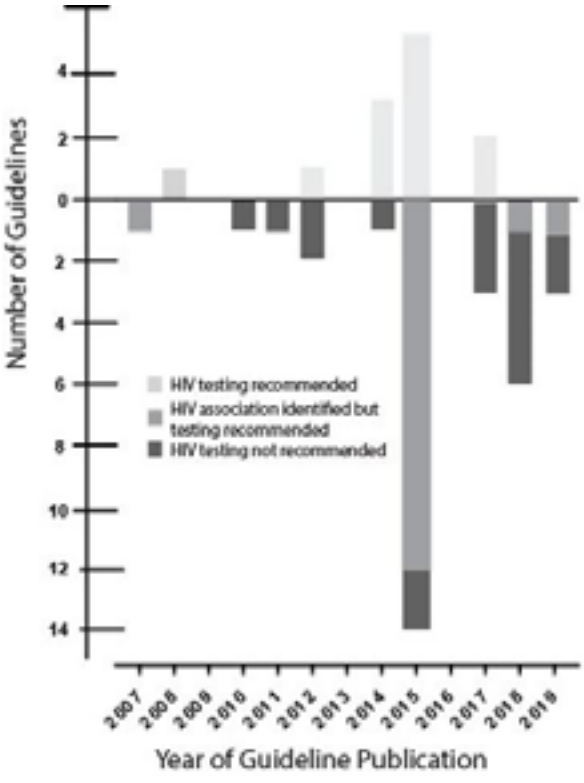
ASSESSMENT OF HIV TESTING RECOMMENDATIONS IN GREEK SPECIALTY GUIDELINES: A MISSED OPPORTUNITY FOR RECOMMENDING TESTING

K. Akinosoglou[1], G.E. Kostaki[2], D. Paraskevis[2], C. Gogos[1]
[1]University Hospital of Patras, Internal Medicine and Infectious Diseases, Patras, Greece, [2]National and Kapodistrian University of Athens, Athens, Greece

BACKGROUND: European guidelines recommend HIV testing for patients presenting with indicator conditions (ICs) including AIDS-defining conditions (ADCs). The extent to which non-HIV specialty guidelines recommend HIV testing in these conditions remains unknown. Our aim was to review specialty guidelines in Greece and ascertain if HIV was discussed and testing recommended

METHODS: European HIV testing guidelines were reviewed to produce a list of 25 ADCs and 48 ICs. Greek guidelines for these conditions were identified from searches of the websites of specialist societies, the National Public Health Organization / Ministry of Health website, and from Google searches

RESULTS: We identified guidelines for 11/25 (44%) ADCs and 30/48 (63%) ICs. Fourteen out of 25 key ADCs and 18 of ICs had no Greek guidelines available. In total, 47 guidelines were reviewed (range 1–6 per condition); 11 (23%) for ADCs and 36 (77%) for ICs. Association with HIV was discussed in 7/11 (64%) ADC and 8/36 IC guidelines (22%), whereas HIV testing was appropriately recommended in 2/11 ADC (18%) and 10/36 IC guidelines (28%). Significant differences were found for the distribution of recommendation to test in both types of condition (ADCs or ICs), with ICs having higher percentage of non-recommendation (50%, p<0.05).No association was observed between source of guideline or year of publication and recommendation to test (p=0.54 and p=0.07, respectively).



[Figure]

	Number of guidelines identified n (% of total)	GR guidelines where HIV testing is recommended n (%)	GR guidelines where association with HIV reported but not advise testing n (%)	GR guidelines where HIV is not mentioned n (%)
All guidelines	47 (100)	12 (26)	15 (32)	20 (42)
AIDS-defining conditions (ADC)	11 (23)	2 (18)	7 (64)	2 (18)
Indicator conditions (IC)	36 (77)	10 (28)	8 (22)	18 (50)
Source of guidelines				
Specialty society guidelines	41 (87)	11 (27)	14 (34)	16 (39)
National Public Health Organization / Ministry of Health	6 (13)	1 (17)	1 (17)	4 (66)

[Table 1. Recommendation for HIV testing and reporting of association with HIV, stratified by type of guideline]

CONCLUSIONS: The majority of guidelines for ICs and ADs do not recommend testing. Clinicians managing ICs may be unaware of recommendations produced by HIV societies or the prevalence of undiagnosed HIV infection among these patients

PEB0100

EVALUATION OF THE USE OF HIV ORAQUICK AMONG MALNOURISHED CHILDREN BELOW 5 YEARS IN UGANDA

T. Fred[1]
[1]Mbarara University of Science and Technology, Infectious Diseases Institute, Global Health Security, Kampala, Uganda

BACKGROUND: Blood is the most commonly used specimen to test for HIV in the past 30 years, use of saliva as an alternative specimen for HIV testing has been explored.

Most tests on the use of saliva have been carried out on adults and have yielded positive results however such studies have not been explored in children.

Studies in adults have also seen advantages of OraQuick method such as ease of specimen collection and high degree of acceptability. This would make oral fluid testing a good alternative for HIV screening in infants where its challenging to perform a venepuncture especially in the malnourished population.

METHODS: We conducted a clinical trial to evaluate the effect of Modified F75 among malnourished children with severe diarrhoea attending Mulago National Hospital for a period of 18 months. A total of 400 children were enrolled, ART naïve children between 18-56 months were tested for HIV using OraQuick test and blood based tests according to the Uganda testing algorithm. Statistical analyses were done using STATA Version 14.

RESULTS: The prevalence of HIV among the study population was 23%, the HIV oral fluid was accurate with sensitivity of 100%, specificity of 100% (95% CI), Positive and Negative predictive values at 100%. Phlebotomists and ward nurses preferred HIV OraQuick because it was easy to collect the sample and non-painful to the participants (93%, n=45).

CONCLUSIONS: The HIV OraQuick test has high specificity and sensitivity and acceptable method by phlebotomists and nurses on paediatric wards. This method is required to be added to National HIV testing Algorithm with ability to increase access to HIV testing especially in malnourished and anaemic populations.

PEB0101

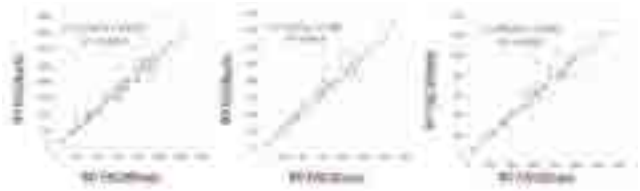
EVALUATION OF CD4 T-CELLS ON THE BD FACSLYRIC, BD FACSPRESTO AND BD FACSCOUNT SYSTEMS

Y. Zeng[1], A. Chen[1], H. Rohamare[1], F. Oreizy[1]
[1]*BD Life Sciences, San Jose, United States*

BACKGROUND: CD3+CD4+ count remains one of the most important indicators in HIV/AIDS staging and patient management. BD developed a new clinical flow cytometer, the BD FACSLyric™ *, featuring streamlined workflow and standardization to help maximize cross-lab compatibility and data quality. The BD FACSPresto™ is a portable CD4 counter.The BD FACSCount™ has been used for CD4 counting worldwide for over a decade. In this study, we compare CD4 absolute count and CD4% on the BD FACSLyric, BD FACSPresto, and BD FACSCount.

METHODS: De-identified remnant HIV+ blood specimens(n = 77) were enrolled in the study. Each specimen was stained using the BD Tritest™* CD3FITC/CD4PE/CD45PerCP in BD Trucount™ tubes, the BD FACSPresto Cartridge (CD4PE-Cy5/CD3APC/CD45RAAPC/CD14PE), and the BD FACSCount reagent (CD4PE/CD3PE-Cy5 and CD8PE/CD3PE-Cy5).The stained samples were simultaneously acquired on the three instruments. Results of CD4 count and CD4% were analyzed using linear regression. A two-by-two contingency table was used to assess agreement about CD4 cutoff at 200 cells/μL.

RESULTS: Linear regression results are shown in Figures 1 and 2.On each of the three instruments, seven samples presented CD4 count below 200 cells/μL, while 70 samples were above.



[Figure 1. Comparison of CD4 absolute count (cells/ μL]

[Figure 2. Comparison of CD4%]

CONCLUSIONS: The BD FACSLyric, BD FACSPresto and BD FACSCount are designed to meet the needs of CD4 testing in central laboratories with high sample throughput, small testing laboratories or testing applications that need portable CD4 counters. Using 77 remnant HIV+ samples, we demonstrated consistent results in CD4 T-cell absolute count and CD4% on three instruments.

*The BD Tritest CD3/CD4/CD45 on the BD FACSLyric is not available for sale in the USA.

PEB0102

EXPLORING THE CONTRIBUTION OF INDEX TESTING IN HIV CASE-FINDING IN EGPAF-MACRO SUPPORTED DISTRICTS IN MALAWI: THE CASE OF THYOLO, BLANTYRE, ZOMBA, MWANZA AND CHIRADZULU

P. Mbulaje[1]
[1]*Malawi AIDS Counseling and Resource Organisation, Programs, Lilongwe, Malawi*

BACKGROUND: Elizabeth Glazer Paediatric AIDS Foundation (EGPAF) with support from Centres for Disease Control and Prevention (CDC) has sub granted Malawi AIDS Counseling and Resource Organisation (MACRO) to assist in HIV case finding in the districts of Thyolo, Chiradzulu, Blantyre, Zomba, and Mwanza.

HIV active and passive Index testing has been rarely used to improve HIV case-finding in sub-Saharan Africa because of concerns regarding privacy protection and possibly high costs. In Malawi, Active Index testing has been intensified since 2018 and this is now being widely introduced to the remaining districts where the prevalence of HIV is high based on the lessons learnt from the other districts.

METHODS: We estimate the contribution of identifying an undiagnosed HIV infection through index testing compared to client-initiated voluntary Counseling and testing (VCT) and provider-initiated testing and counselling (PITC). We used data from 1st Quarter of 2019 Country Operation Plan (COP 19) to inform these calculations so that we ascertain the contributions that index testing has done in HIV case finding.

RESULTS: In the 5 implementing districts, the probability of clients offered HIV index testing and accepting ranged from 78% to 100% giving the average index testing acceptance rate of 85% across the districts. HIV prevalence ranged from 8% to 47% among the partners who were tested with the average HIV prevalence for all the districts standing at 13%.

The average HIV positive contribution of PITC and VCT was 70% against 30% in Index testing across the districts. Mwanza registered a higher contribution from Index testing with 36% and the lowest was Chiradzulu with 28% contribution.

CONCLUSIONS: Intensified active and passive index testing contributes greatly to HIV case finding and complements client-initiated VCT and PITC in a large number of populations affected by generalized epidemics of varying magnitudes.

PEB0103

TEST PERFORMANCE OF THE NEW VERSION OF SERODIA AGGLUTINATION TEST IN HIV-1 INFECTED THAI PATIENTS

S. Pattanachaiwit[1], T. Pankam[1], C. Arsaman[1], S. Areeyolwattana[1], S. Sirivichayaku[2], P. Phanuphak[1]
[1]*Thai Red Cross AIDS Research Centre, Bangkok, Thailand,* [2]*Chulalongkorn University, Faculty of Medicine, Bangkok, Thailand*

BACKGROUND: Sensitive rapid test (RT) for HIV is still desperately needed, especially in community-based testing. Serodia HIV-1/2 agglutination test (Fujirebio Inc., Japan) is a reliable RT test available in the market for quite some time until recently the company has replaced it with a newer version, Serodia-HIV1/2 MIX which uses recombinant HIV antigens instead of viral lysate like in the older version. In this study, we compared the newer version with the older version of which the Thai Red Cross Anonymous Clinic had used for over a decade.

METHODS: A total of 140 plasma samples (50 HIV-negative, 50 established HIV infections and 40 acute HIV infection (AHI)) were included in the study. Established HIV infection was defined by positive screening with Architect HIV Ag/Ab Combo test, confirmed by Alere Determine HIV-1/2 and Serodia HIV-1/2 tests (the old version). HIV-negative was defined by negative screening test. AHI was defined by positive screening test, HIV-RNA positive, but both confirmatory tests were negative. All specimens were simultaneously tested by Serodia-HIV1/2 MIX (the new version) and Serodia HIV-1/2 (the old version). Results were read by 3 technicians. Any discrepancies were re-tested to confirm the results. Statistical differences between 2 test kits were calculated by Kappa statistic.

RESULTS: Of the 50 HIV-negative samples, Serodia HIV-1/2 gave negative results in all samples but Serodia-HIV1/2 MIX showed indeterminate results in 2. Of the 50 samples with established infections, Serodia HIV-1/2 correctly diagnosed all but Serodia-HIV1/2 MIX showed indeterminate results in 6. Of the 40 AHI samples, Serodia HIV-1/2 couldn't detect any but Serodia-HIV1/2 MIX could diagnose 3 samples but again showed 1 indeterminate result. Substantial agreement was found between 2 Serodia test kits (k=0.73(0.61-0.80),p-values<0.001).

Sample Type	Serodia-HIV1/2 MIX (new version)			Serodia HIV-1/2 (old version)		
	Non-Reactive	Reactive	Indeterminate	Non-Reactive	Reactive	Indeterminate
HIV-Negative	48	0	2	50	0	0
Established HIV Infection	0	44	6	0	50	0
AHI	36	3	1	40	0	0
Total	84	47	9	90	50	0

[Table 1 Comparison of Serodia-HIV1/2 MIX (new version) with Serodia HIV-1/2 (old version)]

CONCLUSIONS: Although both Serodia test kits had concordant results, the new version, Serodia-HIV1/2 MIX was slightly more sensitive since it could detect 3/40(7.5%) of antibody-negative AHI. However, the newer version had many indeterminate test results which required additional work as semi-quantitative assay.

PEB0104

RANDOMIZED COMPARISON OF THE PREFERENCE AND USABILITY OF TWO HIV SELF-TESTING KITS AMONG AUSTRALIAN GAY AND BISEXUAL MEN

J.J. Ong[1,2,3], K. Smith[4], M. Jamil[5], D.Y. Lee[2], R. McIver[6], R. Wigan[1], M. Kaiser[1], K. Maddaford[1], A. McNulty[6], J. Kaldor[4], C.K. Fairley[1,2], R. Guy[4], PUSH Study Group
[1]Melbourne Sexual Health Centre, Melbourne, Australia, [2]Monash University, Central Clinical School, Melbourne, Australia, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]University of New South Wales, Kirby Institute, Sydney, Australia, [5]World Health Organization, Department of HIV, Hepatitis and STIs, Geneva, Switzerland, [6]Sydney Sexual Health Centre, Sydney, Australia

BACKGROUND: HIV self-testing is acceptable and increases uptake of testing, however in many high-income settings, only one test has received regulatory approval. To our best knowledge, there is no randomized real-world preference and usability study of HIVST among gay, bisexual and other men who have sex with men (GBM) living in a high-income country.

METHODS: We invited GBM age >18 years from two sexual health clinics (Melbourne, Sydney) and advertisements via a gay dating app (Grindr). Participants used two self-test kits in random order(one oral, one finger-prick test) and completed a questionnaire regarding their testing experience. A study nurse observed the participant during self-testing to note any deviations from kit instructions.

RESULTS: A total of 170 GBM with mean age 36.9±11.5 participated, 46% born in Australia and New Zealand, and 36% from South America or South-East Asia. Most (77%) had completed tertiary education and 9% had never tested or tested for HIV more than one year ago. In the last 6 months, 31% reported >10 sexual partners and 57% group sex.

In total, 58% preferred the oral HIVST, with ease of use being the top reason for preference (32%). The top reason for the participants who preferred the finger-prick HIVST was perceived greater accuracy of a blood-specimen (28%).

Regarding the oral HIVST kit, 159 (94%) read the written instructions only, 1 (1%) viewed the video only, and 9 (5%) used both. Overall, 24% had difficulty in placing the buffer solution in the stand, 14% had difficulty in swabbing the mouth properly, and 10% did not read the result in the correct timeframe.

Regarding the finger-prick HIVST kit, 160 (94%) read the written instructions only, 1 (1%) viewed the video only and 7 (4%) used both. Overall, 9% had difficulties lancing the finger, 41% had difficulties filling the device test channel, and 9% did not read the result in the correct timeframe.

CONCLUSIONS: Both oral and finger-prick HIVST kits should be made available to optimize uptake of HIVST. Errors that might affect test accuracy were relatively common in an educated group of men using HIVST. Further refinements of the instructions and kit design might improve usability.

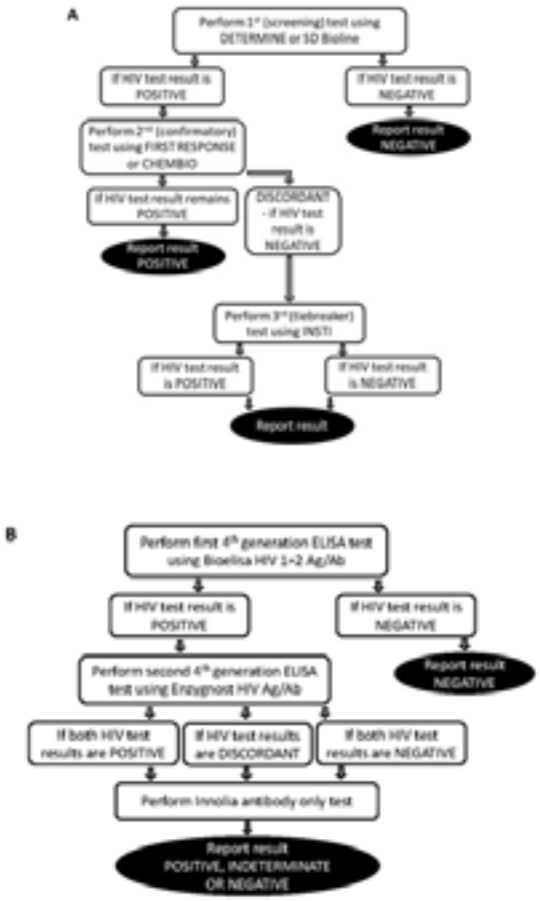
PEB0105

DOES ART CONTRIBUTE TO FALSE-NEGATIVE RESULTS IN ROUTINE PMTCT TESTING? EVIDENCE FROM NATIONAL HIV SURVEILLANCE IN ZIMBABWE

S. Gregson[1,2], B. Pinsky[3], J. Mayini[2], L. Moorhouse[1], T. Dadirai[2], R. Maswera[2], B. Moyo[4], J. Dzangare[4], O. Mugurungi[4], C. Nyamukapa[1,2]
[1]Imperial College London, DIDE, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe, [3]Stanford University, Stanford, United States, [4]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe

BACKGROUND: People with a previous HIV-positive test result already on ART may be retested in antenatal care because they don't disclose their status or it cannot be confirmed in clinic records. ART may reduce the sensitivity of antibody-based HIV rapid diagnostic tests (RDTs) leading to false-negative results, discontinuation of treatment, and bias in HIV estimates using PMTCT programme data. We investigate levels of false-negative antibody test results in PLHIV on ART in Zimbabwe.

METHODS: The study was conducted in the 2017 national HIV surveillance using data from pregnant women and male partners extracted from PMTCT programme records and quality assurance testing at central laboratories. Figure 1 shows the HIV testing algorithms used in PMTCT (RDTs) (A) and for quality assurance (4th-generation antibody/antigen ELISA and INNO-LIA antibody tests) (B). Following national guidelines, individuals reporting ART, confirmed in clinic records, were classified as 'known-positives'. A GeneXpert pro-viral DNA test (with high sensitivity [PPA=98.2%] and low limit-of-detection [531 cp/mL]) was used as a gold standard to measure the fractions of false-negative results produced by RDT, ELISA and INNO-LIA tests in genuine HIV-positive 'known-positive' individuals on ART.



[Figure 1.]

RESULTS: HIV-negative results were obtained from the laboratory-test algorithm for 5.3% (95%CI=4.3%-6.4%; 92/1744) of PMTCT 'known-positive' pregnant women – 47 cases were negative in initial ELISA tests; 45 cases were HIV-positive in ELISA tests and HIV-negative in confirmatory INNO-LIA tests. No cases were found for 'known-positive' men tested at a different laboratory (N=173). HIV-negative Determine and Chembio RDT results occurred in 0.9% (95%CI=0.5%-1.5%; 16/1744) and 0.3% (95%CI=0.1%-0.7%; 5/1744) of PMTCT 'known positive' cases confirmed using the pro-viral DNA test. Based on the pro-viral DNA test results, 3.5% (95%CI=2.7%-4.4%; 68/1921) of people on ART are HIV-negative in this population.

CONCLUSIONS: RDTs using antibody detection can produce false-negative results in PLHIV on ART but these errors may have been exaggerated. Further research is needed.

PEB0106

LAUNCHING OF A CAPILLARY BLOOD-BASED HIV SELF-TESTING IN A MULTICULTURAL ENVIRONMENT IN CAMEROON

F.X. Mbopi-Keou[1,2], G.C.M. Kalla[3,4], P. Anankeu[5], J.-E. Pondi[6]
[1]University of Yaounde I, Faculty of Medicine & Biomedical Sciences, Department of Laboratory Medicine, Microbiology, Hematology, Immunology and Infectious Diseases, Yaounde, Cameroon, [2]The Institute for the Development of Africa (The-IDA), Yaounde, Cameroon, [3]University of Yaounde I, Faculty of Medicine & Biomedical Sciences, Department of Peadiatrics, Yaounde, Cameroon, [4]Yaounde Teaching Hospital, Department of Peadiatrics, Yaounde, Cameroon, [5]University of Yaounde I, Faculty of Medicine & Biomedical Sciences, Yaounde, Cameroon, [6]University of Yaounde II, International Relations Institute of Cameroon (IRIC), Yaounde, Cameroon

BACKGROUND: At a time when knowledge of HIV status among people living with HIV lags far behind in Western and Central Africa, HIV self-testing (HIVST) is a new approach that should be incorporated into implementation strategies, particularly for use among populations not reached by existing testing options. On 15 May 2019, HIVST was launched in Cameroon, in a remote rural health district of the Center region named Ngog Mapubi. Our aim was to evaluate socio-demographic factors and behavioural factors associated with acceptability of supervised HIV self-testing among the local population including students.

METHODS: Inclusion criteria were age (≥15 years), and to have willingness to provide verbal consent. Participants were trained on the instructions for use of the CE-IVD marked capillary blood-based Exacto® HIV Self-test (Biosynex, Strasbourg, France) using typical pictures showing the principal steps of self-testing. The testing procedure was also translated into the native Bassa language. The questionnaire was writing on the basis of the different approaches and access to HIVST proposed by WHO. Administrative and ethical approval were obtained.

RESULTS: A total of 322 participants fulfilled the inclusion criteria including 39.4% males (n = 127) and 60.6 % females (n= 195). More than three quarter (78.3%) of participants were single. The mean age was 22 ± 4 years; the majority (71.4%; n = 230) were young students (age ≤ 24 years). It is noteworthy that more than three quarter (77.3%; n = 249) never received HIV counselling and testing in the past. Furthermore, 25% of the study population could only understand the HIVST procedure in the native Bassa language. The acceptability of the test was 99% and 98.13 % of the study population could perform the test.

CONCLUSIONS: HIV self-testing circumvents many of the logistical and stigma-related barriers associated with traditional testing modalities conducted at fixed locations during specific times, and it allows learning one's status to be simpler, more private and convenient. The anonymity offered by self-testing and its high acceptability offers great promise for increasing knowledge of HIV status and improving the efficiency of testing services by reducing burdens on health facilities and health care workers.

PEB0107

EVALUATION OF AN EMERGENCY DEPARTMENT-BASED OPT-OUT HIV SCREENING PROGRAM IN SOUTH FLORIDA

P.A. Eckardt[1], J. Niu[2], J.C. Lemos Ramirez[1], E. Sherman[1], T. Griffin[1], R. Katz[1]
[1]Memorial Healthcare System, Memorial Division of Infectious Disease, Hollywood, United States, [2]Memorial Healthcare System, Office of Human Research, Hollywood, United States

BACKGROUND: Undiagnosed HIV infection remains a significant public health challenge. Miami and Fort Lauderdale are the geographic area with the highest incidence of HIV infections. As part of the strategy by our community hospital to tackle the epidemic, an opt-out testing site at the busiest emergency department (ED) in this area was implemented. This study aimed to determine testing acceptance, yield and its potential impact on follow-up care.
METHODS: All ED patients aged 16 years or older were approached for a 4th generation HIV testing using an opt-out approach in Memorial Regional Hospital, Hollywood, Florida. Data were extracted from HIV testing program records and administrative hospital databases from July 2018 through June 2019 to obtain the number of ED visits and HIV tests. Acceptance of testing and linkage to care were analyzed.
RESULTS: Over the 12-month study period, there were 96,016 ED patient visits, of whom 54,932 (57.2%) were screened and 22,067 (40.2%) accepted testing for HIV. 121 (0.5%) of these patients had a positive test result. Of these, 38 (31.4%) were newly diagnosed with HIV and 83 (68.6%) had a known diagnosis that was not previously disclosed (P < 0.001). The mean age for patients with HIV was 43 years with 64% male and 86% racial and ethnic minorities. 51.3% of patients with previous HIV diagnoses who were not engaged in HIV care were successfully relinked to care after testing, and engagement in care increased from 53% pre-testing to 77.1% post-testing (P = 0.001). Of the newly diagnosed patients, 84.2% were linked to HIV care.
CONCLUSIONS: Opt-out HIV testing can be successfully implemented in a community hospital ED setting, and was able to identify many new infected patients and link them to care, and also improves re-engagement in care in patients previously diagnosed HIV.

PEB0108

INTEGRATION OF SCREENING RISK BEHAVIOR AND SYMPTOMS SUGGESTIVE OF HIV INFECTION INTO NATIONAL HIV TESTING SERVICES IN MOZAMBIQUE, 2019

G. Amane[1], A. Couto[1], N. Chicuecue[1], I. Sathane[1], J. Seleme[2]
[1]MOH, National Program to Control STIs HIV/AIDS, MOH, Mozambique, MAPUTO, Mozambique, [2]MOH, National Program to Control STIs HIV/AIDS, MOH, Maputo, Mozambique

BACKGROUND: With the introduction of Test and Start strategy and the commitment to achieve the 90-90-90 goals set by the WHO, In April 2018, Mozambique has begun to implement the DSD Guidelines. The first module of the national DSD mention about Differentiated HIV Prevention, Screening, and Linkage Approaches, included the implementation in national health system three screening risk behavior and symptoms suggestive of HIV algorithms, to ensure HIV testing for adults, adolescents and children which are really suggestive of being infected with HIV. This approach avoids massive HIV testing by ensuring that testing providers implement focused HTS.
METHODS: In March 2019, Mozambique started to implement the screening risk behavior and symptoms suggestive of HIV algorithms in specific services such as Emergency consultations, Outpatient and External consultations, to ensure HIV testing eligibility for adults, adolescents and children at all public HTS facilities in Mozambique (N = 1,634). HTS providers were trained using a DSD prevention package to ensure focused identification of people living of HIV.
RESULTS: We analyzed HTS routine program data from April to December 2019. Of 2,709,331 persons receiving HIV counseling and testing during this time, 126,001 were tested in Emergency consultations, 1,146989 were tested in Outpatient consultations and 146,229 were testes in External consultations. The proportion testing positive was highest in Emergency consultations (8%), Outpatient consultations with 6% and External consultations with 5% people tested positive.
CONCLUSIONS: Mozambique is one of the high HIV prevalence countries which implements screening risk behavior and symptoms suggestive of HIV algorithms, to ensure the eligibility for HTS of people who are truly at risk of being infected with HIV at national health facilities. Data confirms that the implementation of this approach in the HTS services allows the identification of people living with HIV. The use of screening algorithms also allows the HTS providers to not test for HIV all clients, ensuring quality of testing, psychosocial support, linkages and retention.

PEB0109

DECENTRALIZED EID AND VL TESTING IN SENEGAL: RESULTS FROM THE POINT-OF-CARE PILOT

K.D. Coulibaly[1], P. Ndiaye[1], F. Dieye[1], A. Sow[2], P. Sene[2], S. Diallo[2], N. Ngom[3], B. Kiernan[4], R. Mbaye[4], A.N. Diallo[5], N. Diop[5], K. Diop[1], H.D. Ndiaye[2], C.T. Kane[6], C.T. Ndour[1]
[1]Division of AIDS Control/STI, GAS Office, Dakar, Senegal, [2]LBV A Ledantec, Molecular Biology, Dakar, Senegal, [3]UNICEF, EID, Dakar, Senegal, [4]CHAI, EID/VL, Dakar, Senegal, [5]CNLS, Monitoring and Evaluation, Dakar, Senegal, [6]Hospital Dalal Diam/IRESSEF, Laboratory, Dakar, Senegal

BACKGROUND: In 2018, only 49% of HIV exposed infants (HEI) in Senegal received an Early Infant Diagnosis (EID) and 23% of people living with HIV (PLHIV) on treatment received a Viral Load (VL) test. Point-of-Care (POC) devices, GeneXpert (Cepheid) and m-PIMA (Abbott), were piloted in decentralized health settings in Senegal to improve access to testing, result return to patients, clinical decision making, and to reduce testing turnaround time.
METHODS: A retrospective pre-post study was carried out at 8 GeneXpert and m-PIMA sites. The study population consisted of HEI aged 6 weeks or older, and PLHIV on treatment for 6 months or longer. Data was obtained from health facility registers and were collected using SurveyCTO. A comparison was carried out during the same three-month period in 2018 (pre-POC intervention) and in 2019 (post-POC intervention).
RESULTS: Only 34% of EID tests and 68% of VL tests requested were actually processed in 2018 pre-POC intervention. This rate was over 90% post-POC intervention. At the GeneXpert sites in 2018, no EID or VL data was available due to poor access. Post-GeneXpert introduction in 2019, 32 EID and 422 VL tests were carried out during the intervention period with 0% of the EID results being positive for HIV and 71.1% of the VL results suppressed (VL< 1000cpm). The median (IQR) turnaround time for EID and VL tests were 0 (0-0) and 0 (0-1) days respectively. At the m-PIMA sites in 2018, 12 EID and 107 VL tests were performed with an 8.3% positivity rate for EID and 67.3% of VL results suppressed. Post-m-PIMA introduction in 2019, 54 EID and 392 VL tests were performed; 3.7% of the EID tests were positive and

84.4% of the VL tests were suppressed. The median (IQR) turnaround time for EID tests decreased from 106 (89-200) in 2018 to 0 (0-0) days in 2019, and for VL tests from 97 (76 -98) in 2018 to 1 (0-9) days in 2019.
CONCLUSIONS: The use of POC at the decentralized level improves access and turnaround time for EID and VL testing with the potential for better clinical management of patients

PEB0110

USING POINT-OF-CARE TESTING OPERATED BY NON-TECHNICAL STAFF TO IMPROVE HEALTHCARE PROVISION TO INFANTS EXPOSED TO HIV IN MOZAMBIQUE

C. Mudenyanga[1], H. Guambe[2], B. Meggi[3], D. Mutsaka[1], O. Loquiha[4], N. Mabunda[3], L. Samuel[4]
[1]Clinton Health Access Initiative, New Innovations, Maputo, Mozambique, [2]Ministerio de Saúde, Prevenção Transmissão Vertical (PTV), Maputo, Mozambique, [3]Instituto Nacional de Saúde, Research, Maputo, Mozambique, [4]Clinton Health Access Initiative, Monitoring and Evaluation, Maputo, Mozambique

BACKGROUND: The early infant diagnosis (EID) testing volumes remain high despite having five reference laboratories that test EID samples in Mozambique. Timely availability of results is a major hindrance to early ART initiation of infected children and a leading cause of loss to follow up. Alternative diagnostic approaches to the use of the conventional systems could be game changers in reducing Turn Around Time between sample collection and results availability thus improving treatment initiation rates in areas with limited resources for conventional EID testing.
METHODS: A prospective cluster-randomized trial was conducted at 16 primary health care clinics (PHC) in Mozambique's two provinces of Maputo and Sofala between September 2015 and December 2016. Eight intervention PHCs implemented the Abbott HIV-1/2 Detect point-of-care (POC) EID test conducted by nurses using whole blood collected from infants aged 1 – 18 months. Eight control sites collected Dried Blood Spots for testing at reference laboratories. We conducted nurses' focus group sessions with 40 nurses from the intervention health facilities to get their views on how point of care testing impacted their work and healthcare provision for infants. Feedback was reviewed to determine impact of POC EID testing.
RESULTS: Operators found POC testing simple to use while giving valuable diagnostic results that are essential for patient treatment and care. POC EID was easily adopted into the nurses' routine work with proper scheduling of consultations even at high volume health facilities. The use of POC at the Consultation for Children at Risk (CCR) enabled the adoption of the One Stop model as children would be tested, diagnosed and initiated on therapy in one visit. Nurses appreciated that mothers did not require multiple visits to follow up infants' results and this in turn reduced redundant consultations where mothers would be following up on results that would not be available.
CONCLUSIONS: Point-of-care testing is essential to improving timely healthcare provision for HIV exposed infants and improves healthcare providers' services in Mozambique. Incorporating non-laboratory based diagnostic approaches enables timely diagnosis of HIV exposed infants in Mozambique. POC EID boosted nurses' morale as they had diagnostic capacity and not relied on the laboratory.

VIRAL LOAD AND CD4 MONITORING

PEB0111

FACTORS ASSOCIATED WITH HIGH-LEVEL VIREMIA IN SOUTH AFRICAN ADULTS ON ANTIRETROVIRAL THERAPY: A RECURRENT EVENTS ANALYSIS FROM AN 8-YEAR PROSPECTIVE COHORT STUDY

N. Yende-Zuma[1], R. Hassan-Moosa[1], K. Naidoo[1]
[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa

BACKGROUND: Cross-sectional surveys are commonly used in monitoring the UNAIDS 90-90-90 targets. However, robust data from low- and middle-income settings on patients' ability to sustain virological suppression is crucial to monitor the last 90 in the UNAIDS targets. The aim of this study was to assess the long-term rates of high-level viremia (>1000 copies/ml) and identify predictors of these events.
METHODS: We analyzed data for previously ART naïve adults with TB and HIV, who were initially enrolled in the Starting Antiretrovirals at Three Points in TB treatment (SAPIT) trial from June 2005 to July 2008 in South Africa. Upon SAPIT completion, participants were subsequently enrolled in TB Recurrence upon Treatment with HAART (TRuTH) cohort from October 2009 to April 2014. Viral load monitoring was done at enrolment, six monthly and when clinically indicated. In time to event analyses, follow-up started at the date of the first viral suppression. Noteworthy, participants were retained after switching to second-line ART. We used Prentice-Williams-Peterson total time model, allowing for recurring events, to identify predictors of high-level viremia.
RESULTS: We analyzed data for 369 participants (54.7% women) with an average of 6 years on ART (range: 2-8). Of these, 19.0% (n=70; 206 events) presented with at least one measurement of high-level viremia, which occurred in a median (IQR) of 2.0 (1.0-3.4) years post initial viral suppression. The incidence rate of high-level viremia post viral suppression was 5.3/100 person-years (p-y) (95% CI: 3.4-8.3) and 3.1/100 p-y (1.2-8.3) in the first and sixth year, respectively. Older participants (aHR: 0.74; 95% CI: 0.62-0.88) and those with high CD4 count overt time (aHR: 0.60; 95% CI: 0.48-0.76) had lower hazards of high-level viremia. However, viral load measurements taken when participants were on second-line ART (aHR: 5.75; 95% CI: 3.31-10.00) were associated with an increased hazard of high-level viremia.
CONCLUSIONS: Almost three-quarters of participants maintained viral suppression throughout the eight year follow-up, suggesting overall high levels of sustained viral suppression. However, younger participants and those who have been switched to second-line ART were more likely to present with high-level viremia indicating the need for intensified adherence, resistance testing and the correction of the regimen.

PEB0112

VIROLOGIC OUTCOMES AMONG PATIENTS ON FIRST-LINE ANTIRETROVIRAL THERAPY (ART) FOLLOWING TRANSITION TO DOLUTEGRAVIR IN A TERTIARY HIV CLINIC IN UGANDA

A. Wailagala[1], E. Laker[1], M.S. Nabaggala[1], L. Najjemba[1], A. Onyege[1], R. Mirembe Nabisere[1], M. Atwiine[1], A. Mugume[1], A. Ddungu[1], A. Arinaitwe[1], N. Kalema[1], A. Kiragga[2], N.C. Owarwo[1], M. Larmorde[3], B. Castelnuovo[4]
[1]Infectious Diseases Institute, Prevention Care and Treatment, Kampala, Uganda, [2]Infectious Diseases Institute, Statistics, Kampala, Uganda, [3]Infectious Diseases Institute, Global Health Security Project, Kampala, Uganda, [4]Infectious Diseases Institute, Research, Kampala, Uganda

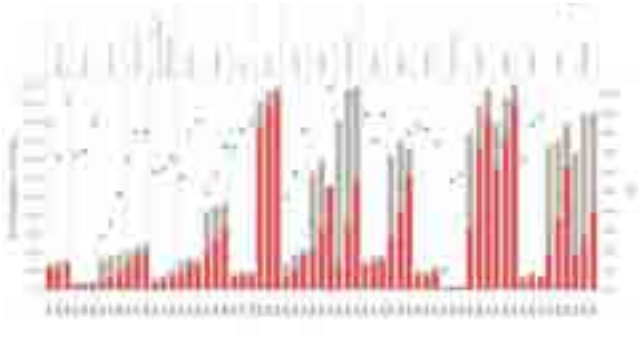
BACKGROUND: Uganda adopted dolutegravir (DTG) as a first-line ART for HIV patients in 2018 replacing non-nucleoside reverse transcriptase inhibitors (NNRTIs). Only virologically suppressed (viral load <1000 copies/ml) individuals were eligible for switch to DTG-based ART. We sought to compare the virologic outcomes of patients on first-line ART during the transitioning to DTG in Uganda.
METHODS: This study was conducted at the Infectious Diseases Institute (Kampala, Uganda) a PEPFAR funded center of excellence for HIV care and treatment. We included electronically collected data for all patients who attended the clinic between January, 2018 and October, 2019. Descriptive statistics were used to compare virologic outcomes among patients on first-line ART regimens and multivariate logistic regression to assess factors associated with a detectable Viral Load (VL) using R version 3:6:1. A detectable VL was defined as ≥75 copies/ml the clinic standard, different from ≥1000copies/ml for Ministry of Health.
RESULTS: We included 6,971 patients in the study, majority female 4,358 (62.5%) with median age of 44 years (IQR: 36 – 51). The ART status during the study period was; 3,216/6,971 (46.1%) still on NNRTIs, 3447/6971 (49.5%) transitioned from NNRTIs to DTG, and 308/6,971 (4.4%) ART naive initiated on DTG based regimen. VL results were available for 6,623/6971(95.0%) patients. 309/6623 (4.7%) had a detectable VL; 150/3081 (4.9%) still on NNRTIs, 17/182 (9.3%) newly initiated on DTG and 142/3360 (4.2%) transitioned from NNRTIs to DTG. At the multivariable level adjusting for age, sex, ART status and duration on ART; males had increased odds of a detectable VL (aOR 1.72, 95% CI; 1.32 – 2.3) compared to females and the odds for patients that were transitioned to DTG were not different from those who stayed on NNRTIs (aOR 1.34, 95% CI; 0.75 – 2.38). Those started on DTG had reduced odds of a detectable VL (aOR 0.73, 95% CI; 0.56-0.97) compared to patients who stayed on NNRTIs.
CONCLUSIONS: A large proportion of patients achieved virologic suppression in our clinic population. Virologic outcomes among individuals transitioned to DTG were similar to those that remained on NNRTIs. Being female and initiating ART with DTG-based regimen was associated with reduced risk of a detectable VL.

PEB0113

NEED FOR IMPROVED DEMAND CREATION AND ACCELERATED VIRAL LOAD TESTING COVERAGE TO MEET UNAIDS HIV TREATMENT TARGETS

G. Alemnji[1], Y. Obeng-Aduasare[2], C. Godfrey[3], H. Watts[4]
[1]Office of the Global AIDS Coordinator and Health Diplomacy (OGAC), Laboratory, Washington, United States, [2]Office of the U.S. Global AIDS Coordinator and Health Diplomacy (OGAC), ICPI, Washington, United States, [3]Office of the U.S. Global AIDS Coordinator and Health Diplomacy (OGAC), Care and Treatment, Washington, United States, [4]Office of the U.S. Global AIDS Coordinator and Health Diplomacy (OGAC), HIV Prevention, Washington, United States

BACKGROUND: A suppressed HIV viral load (VL) indicates effective antiretroviral therapy (ART) and represents the UNAIDS 3rd HIV treatment target. Measuring the VL of all patients on ART and acting upon these results remains a challenge in many countries. Low testing demand, issues with sample transport, laboratory testing, and utilization of test results are all factors impacting the viral load testing coverage in PEPFAR countries.
METHODS: PEPFAR collaborates with countries to improve demand for VL testing. A first viral load for PLHIV is assessed at six months after initiating ART. Site level VL testing coverage and gaps data from 21 countries between FY2017 and 2019 were compared using a nested Welch Two-Sample T-test to determine differences between eligible PLHIV receiving VL testing (testing coverage) and those who did not (testing gaps).
RESULTS:



[Figure 1. Significant decrease in viral load testing gaps between FY17 - 19]

There was significant improvement (P<0.05) between FY17 and FY19 in number of PLHIV with VL test documented in medical records in 17 countries (Figure 1). Four of the 21 countries (Burundi, Democratic Republic of Congo, Namibia, Vietnam) show no significant change over the years in number of PLHIV who received a VL test.
CONCLUSIONS: Meeting VL testing targets among PLHIV on ART continues to be a challenge in some countries and is critical to determine viral suppression. There is need for more demand creation activities such as treatment literacy training and promoting awareness and education of VL testing and utilization of results for patient management to increase testing.

PEB0114

IMPROVING DOCUMENTED VIRAL LOAD SUPPRESSION RESULTS AMONG PEOPLE LIVING WITH HIV IN URBAN LUSAKA

C. Katamba[1], F. Mwape[1], N. Sinyangwe[1], P. Kabula[1], J. Simpungwe[2], P. Minchella[2], B. Kaliki[2], S. Fwoloshi[3], B. Tambatamba[1], O. Onaluwa[1], A. Sukwa[1], J. Mwansa Musonda[1], N. Malambo[1], S. Taonga Msiska[1], M. Adetinuke Boyd[2], C. Mwale[1]

[1]Lusaka Provincial Health Office, Lusaka, Zambia, [2]Centers for Disease Control and Prevention – Zambia, Lusaka, Zambia, [3]Zambia Ministry of Health, Lusaka, Zambia

BACKGROUND: Timely, accurate viral load (VL) results is critical for patient outcomes and HIV epidemic control. However, results are often lost, delayed, or never documented due to poor recording and reporting systems. We used a quality improvement (QI) model to:
(a) increase documentation of VL results in 16 high-volume facilities in Lusaka Province, Zambia, and
(b) increase the documented VL suppression (<1,000 copies/mL) rate in people living with HIV (PLHIV) receiving antiretroviral therapy (January 2019–September 2019).

DESCRIPTION: We selected the highest volume facilities that would have the highest impact on overall provincial performance. Plan-Do-Study-Act (PDSA) cycle methodology was used to review and monitor changes throughout the project while implementing change ideas. We trained 160 healthcare staff and site leaders in QI. QI teams presented their performance and shared best practices at joint quarterly learning sessions. We built capacity of VL champions through on-the-job mentorship and regular granular review and management of site performance with key stakeholders.

LESSONS LEARNED: Lusaka province improved the documented VL suppression results from 84,050 (29.4% of 285,632 PLHIV) at baseline to 171,494 (60%_ of 285,632 PLHIV) at the end of the project. Lessons learned included: educating patient literacy about the importance of routine VL monitoring; identifying at least one VL champion (triage nurses) per facility to ensure that the VL cascade is effectively monitored and managed; introducing viremia clinics on specific days to better manage unsuppressed clients; and documenting VL results in the electronic health record system (smart care) upon receipt from the central laboratory.

	PVLHIV VL Target: A	Total Documented VL Result: B	Achievement (%): B/A	Suppression rate (%): C/B	Documented Suppressed VL result: C	Documented VLS rate: (C/A)
Oct-Dec 2018	285,632	96,610	34%	87%	84,050	29.4%
Jul-Sep 2019	285,632	187,595	66%	91%	171,494	60%

[Table 1: Documented Viral Load Results in Lusaka from Baseline to Endline - DATA source: DATIM, CDC ZAMBIA]

CONCLUSIONS/NEXT STEPS: The improved VL suppression results achieved is an important step towards HIV epidemic control. Our recommendation is to scale up this VL QI project to other provinces for the greatest impact in Zambia.

PEB0115

EFFECTIVENESS OF ENHANCED ADHERENCE COUNSELING AT ACHIEVING VIRAL SUPPRESSION AMONG VIRALLY UNSUPPRESSED HIV POSITIVE CLIENTS IN NASARAWA STATE, NIGERIA

C.E. Awunor[1], E.O. Chukwu[1], J.P. Ojedokun[2]

[1]Aids Healthcare Foundation, Nursing (Prevention, Care and Treatment), Abuja, Nigeria, [2]Aids Healthcare Foundation, Monitoring and Evaluation, Lafia, Nigeria

BACKGROUND: World Health Organisation (WHO) currently recommends periodic assessment of viral loads (at least once a year) in all PLHIV on ART and to achieve viral load suppression in those with high plasma viral loads (≥1000 copies/ml) by addressing the common reasons for it. Thus, WHO recommends that, if the viral load is high, enhanced adherence counseling (EAC) should be carried out, followed by a second/repeated viral load test after 3 months. This study was to access the effectiveness of the EAC at achieving viral suppression among the initial virally unsuppressed clients.

METHODS: Retrospective cohort study using routinely collected Programme data of PLHIV who were on ART. 89 participants aged 18-50 years were disproportionately selected for the study using systematic random sampling. The study was conducted in one general hospital and 5 Primary Healthcare Centres (PHC) across Nasarawa State, Nigeria from January to November 2019. The facilities uses a fixed-dose combination once daily pill of Tenofovir + Lamuvidine + Efavirenze (TDF +3TC+EFV) or Tenofovir + Lamuvidine + Dolutegravir (TDF+3TC+DTG) as the preferred first line ART regimen among adult PLHIV of which all those used for the study were on first line regimen.

RESULTS: 60 (67.4%) of the participants were female with mean average age of 32.3 and unsuppressed viral load result of 52346.33copies/ml. 29 (32.6%) of the participants were male with mean average age of 36 and unsuppressed viral load result of 86329.59copies/ml. Following the 3-months EAC, the mean average viral load result for the female participants was 161.33copies/ml while that of male was 183.68copies/ml showing effectiveness of the EAC as a tool for achieving viral suppression among the participants. During EAC, most clients reported lack of adequate information on ART during time of enrollment as leading cause for poor adherence on ART.

CONCLUSIONS: EAC was seen to be a very effective strategy to ensure viral suppression among virally unsuppressed clients. Adequate counseling was seen to be very crucial especially at time of ART initiation and enrollment to enhance adherence. Healthcare workers especially in PHC should have periodic training to be more effective in conducting EAC.

RESISTANCE TO ART

PEB0116

INCREASED HIV-1 PRETREATMENT DRUG RESISTANCE WITH CONSISTENT CLADE HOMOGENEITY AMONG ART-NAIVE HIV-1 INFECTED INDIVIDUALS IN ETHIOPIA

M. Kiros[1,2], D. Hailu[2], H. Andualem[3], E. Gebrekidan[3], B. Yeshitela[2], A. Mihret[2], M. Maier[4], W. Erku[5], A. Mulu[2]
[1]Debre Tabor University, Department of Medical Laboratory Science, College of Medicine and Health Science, Debre Tabor, Ethiopia, [2]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [3]The Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [4]Leipzig University, Institute of Virology, Leipzig, Germany, [5]Addis Ababa University, Department of Medical Microbiology, Immunology and Parasitology, School of Medicine, Addis Ababa, Ethiopia

BACKGROUND: The development of pretreatment drug resistance (PDR) is becoming an obstacle to the success of antiretroviral therapy (ART). Besides, data from developing settings including Ethiopia is still limited. Therefore, this study was aimed to assess HIV-1 genetic diversity and PDR mutations among ART-naive recently diagnosed HIV-1 infected individuals in Addis Ababa, Ethiopia.

METHODS: An institutional based cross-sectional study was conducted from June to December 2018 in Addis Ababa among ART-naive recently diagnosed individuals. Partial HIV-1 pol region covering the complete protease (PR) and partial reverse transcriptase (RT) regions of 51 samples were amplified and sequenced using an in-house assay. Drug resistance mutations were examined using calibrated population resistance (CPR) tool version 6.0 from the Stanford HIV drug resistance database and the International Antiviral Society-USA (IAS-USA) 2019 mutation list.

RESULTS: According to both algorithms used, 9.8% (5/51) of analyzed samples had at least one PDR Mutation. PDR mutations to Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs) were the most frequently detected mutation (7.8% and 9.8%, according to the CPR tool and IAS-USA algorithm, respectively). The most frequently observed NNRTIs-associated mutations by both algorithms were K103N (2%), Y188L (2%), K101E (2%), and V106A (2%) while E138A (2%) was observed according to IAS-USA only. Y115F and M184V (mutations that confer resistance to NRTIs) dual mutations were detected according to both criteria in a single study participant (2%). Similarly, PDR mutation to protease inhibitors was found to be low (G73S; 2%) but according to the CPR tool only. With regard to HIV-1 genetic diversity, phylogenetic analysis showed that 98% (50/51) of the study participants were infected with HIV-1 subtype C virus while one individual (2%) was infected with HIV-1 subtype A1 virus.

CONCLUSIONS: This study showed an increased level of PDR and persistence HIV-1C clade homogeneity after 15 years of the rollout of ART and 3 decades of HIV-1C circulation in Ethiopia, respectively. Therefore, we recommend routine baseline genotypic drug resistance testing for all newly diagnosed HIV infected patients before initiating treatment. This will aid the selection of appropriate therapy in achieving 90% of patients having an undetectable viral load in consonance with the UN target.

PEB0117

HIGH DRUG RESISTANCE LEVELS COMPROMISE THE CONTROL OF HIV IN PAEDIATRIC AND ADOLESCENT POPULATION IN KINSHASA, DEMOCRATIC REPUBLIC OF CONGO

M. Rubio-Garrido[1], G. Reina[2], A. Rodriguez-Galet[1], A. Valadés-Alcaraz[1], J.M. López-Pintor[1], A. Ndarabu[3], S. Mbikayi[3], B. Makonda[3], S. Carlos[4], A. Holguin[1]
[1]Ramón y Cajal Research Institute, Microbiology Service, Madrid, Spain, [2]Clínica Universidad de Navarra. Navarra Institute for Health Research., Microbiology Department, Pamplona, Spain, [3]Hospital Monkole, Kinshasa, Congo, Democratic Republic of the, [4]Universidad de Navarra. Navarra Institute for Health Research., Department of Preventive Medicine and Public Health, Pamplona, Spain

BACKGROUND: The lack of HIV viral load and resistance monitoring in sub-Saharan Africa leads to uncontrolled circulation of HIV strains with drug resistance mutations (DRM) and compromises antiretroviral therapy (ART) efficacy. This study describes DRM prevalence and the predicted antiretroviral susceptibility in HIV-infected children and adolescents from Kinshasa (Democratic Republic of Congo, DRC).

METHODS: Between 2016 and 2019, dried blood spots (DBS) from 71 HIV-infected children/adolescents under clinical follow-up in two pediatric units from Kinshasa, were collected to amplification and sequencing of protease, retrotranscriptase and integrase at HIV-1 pol. DRM and predicted susceptibility to antiretrovirals were provided by Stanford-HIVdb-Program-v8.8.

RESULTS: The median [IQR] age at DBS collection was 14 [11-16.3] years. HIV-1 sequences were recovered from 55 (77.5%) patients. Of those, 54 (98.2%) were on ART, all had experience to nucleoside retrotranscriptase inhibitors (NRTI) and to non-NRTI (NNRTI), and 7.4% were protease inhibitors (PI) experienced. None was integrase inhibitor (INI) experienced. Despite ART, 89.1% presented >1,000cp/ml, reflecting potential virological failure according to WHO. Most patients (60.4%) carried viruses with DRM to NRTI, mainly M184V (45.8%) and K70R/N (14.6%). DRM to NNRTI were present in 72.9% participants, with high prevalence of K103N/H/S (31.3%), Y181C (25%) and G190A (25%). The most frequent DRM to PI were M46I (8.3%) and I54V (5.6%). Accessory-DRM to INI were present in 15% subjects. We observed reduced predicted susceptibility in 75% patients for nevirapine or efavirenz, 52.1% for emtricitabine or lamivudine, 50% for rilpivirine, and 12.5% with potential INIs resistance, despite the absence of INI exposure. HIV-infected children and adolescents carried viruses with DRM to one (12.7%), two (43.6%), three (10.9%) or four (1.8%) antiretroviral families.

CONCLUSIONS: The high DRM prevalence observed in HIV-infected children and adolescents could compromise 90-90-90 UNAIDS objectives in DRC. Moreover, we have found resistance to IP and INI in treated-patients without previous experience to these drugs, limiting the ARV efficacy to future treatments. The routine access to resistance monitoring is necessary for the best election of rescue ART in this vulnerable population, and to control resistant HIV spreading in the country.

PEB0118

SIGNIFICANCE OF ARCHIVED HIV RESISTANT ASSOCIATED MUTATIONS IN THE ERA OF TWO DRUG ART THERAPY

S. Gudipati[1], I. Brar[1], Z. Hanna[1], A. Golembieski[1], N. Markowitz[1]
[1]Henry Ford Hospital, Infectious Disease, Detroit, United States

BACKGROUND: A large population exists of older, highly ART-experienced long term survivors with complex virologic and ART histories for whom a simplified regimen is desired. Due to virologic suppression, intracellular (IC) DNA sequencing was performed as an aid to ART modification. We examined the occurrence of the NRTI mutation M184V/I and Integrase Strand Inhibitor (INSTI) resistance associated mutations (RAMS), since starting or switching INSTIs was a consideration.

METHODS: IC DNA genotype records of HIV+ patients (pts) seen from 11/2015-3/2019 were reviewed. Demographics, laboratory data, and ART history were obtained via EMR. NGS genotyping on DNA extracted from PBMCs for reverse transcriptase, protease, and integrase inhibitors was done with ion semiconductor technology. Thresholds for RAMS were ≥10% for majority and 1-10% for minority HIV variants. HIV Stanford Database was utilized for interpretation. Chi squared and ANOVA non-parametric hypothesis testing were performed to assess statistical significance at the $p<0.05$ level.

RESULTS: IC DNA genotypes were performed for 55 patients. Plasma viral load was < 20 and < 200 copies mL in 87% and 96% of pts. 58% were on INSTIs at the time of sampling. Pts were sorted by the presence or absences of M184V/I. Pts with M184V/I mutations were older (55 vs 47) (p=0.03), had lower CD4 counts (p=0.01), and had a longer duration of ART (p=0.03). M184V/I was detected at a frequency of >10% in 53% of pts; 25% also had major and 28% had accessory INSTI RAMS. In 54%, there was evidence of hyper-mutated HIV. In those without M184V/I, 0.07% had major and 27% had accessory INSTI RAMS, which were detected at a frequency <10% in both groups. M184V/I was significantly associated with the presence of major INSTI RAMS (p= 0.008).

CONCLUSIONS: IC DNA sequencing revealed INSTI RAMS in a significant proportion of pts. Those with M184V/I defined a population of older and very highly ART-experienced pts, who were more likely to have major and multiple INSTI RAMS. Although the clinical significance of archived mutations has not been defined, this data suggest that INSTI-based simplification strategies should be approached with caution in ART-experienced pts.

PEB0119

LOW LEVEL VIREMIA IN NAÏVE AND EXPERIENCED HIV+ PATIENTS BEGINNING DIFFERENT INTEGRASE STRAND-TRANSFER INHIBITOR-BASED REGIMEN

M. Ceccarelli[1], A. Pampaloni[1,2], D. Scuderi[1,2], A. Marino[1,2], F. Cosentino[1,2], V. Moscatt[1,2], G. Bruno[1], B. Busà[3], G. Nunnari[2], V. Boscia[4], R. Bruno[1], B. Cacopardo[1,4], B.M. Celesia[1,4]
[1]University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy, [2]University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy, [3]"Garibaldi-Nesima" Hospital, Pharmacy Unit, Catania, Italy, [4]"Garibaldi-Nesima" Hospital, Infectious Diseases, Catania, Italy

BACKGROUND: Low level viremia (LLV) and residual viremia are common features in clinical setting during ART; however, it is unclear what is its clinical and prognostic value. A possible association of LLV with ARV regimen and/or adherence remains unclear.
Our primary aim was to study the effects of different INSTI-based ART regimens (RAL vs EVG/c vs DTG) on the risk of LLV.

METHODS: This is a longitudinal retrospective study. We collected and analyzed data (pVL, CD4, CD8, CD4/CD8) at five different timepoints (before treatment, at 4, 16, 48 and 96 weeks) from patients who started cART with an INSTI (RAL, EVG/c, DTG) either as part of a 3DR or a 2DR during the period 01/01/2009-10/31/2018.
Chi-square test and, t-student test and analysis of variance were used to determine any statistically significant difference between treatments. A p value < 0.05 was considered significant. Confidence interval (CI) was 95%.

RESULTS: We collected data from 365 patients, 128 naïve patients (35.1%) and 237 experienced ones (64.9%).
Overall, no difference was found with the different treatments (RAL vs EVG/c vs DTG) in terms of time to target-not-detected (TND) (p=0.4999). There was no statistically significant difference between the different INSTIs (RAL vs EVG/c vs DTG) in terms of prevalence of 20-50 cps/mL blips (p=0.3466) or median time to the 1st 20-50 cps/mL blip (p=0.3735) or median time to 1st >50 cps/mL blip (p=0.0661). However, individuals treated with EVG/c showed blips more frequently than individuals treated with RAL (p=0.0141).
Baseline pVL either below or above 100,000 cps/mL influences time to TND in naïve patients (p=0.0314), but not in experienced ones (p=0.5794).
Forty-four experienced patients (12.0%) showed an LLV at the baseline, 4 (9.1%) had to stop the RAL-based treatment because of viral failure, and 3 patients (6.8%), on a DTG-based treatment, never reached TND during the period of follow-up.

CONCLUSIONS: Overall, 15.9% of the experienced individuals showing an LLV in our population did not reach TND under treatment with an INSTI. Although LLV long-term interpretation is still controversial, the data presented should raise the attention of clinicians using INSTIs more frequently, for it can point out an underlying resistance.

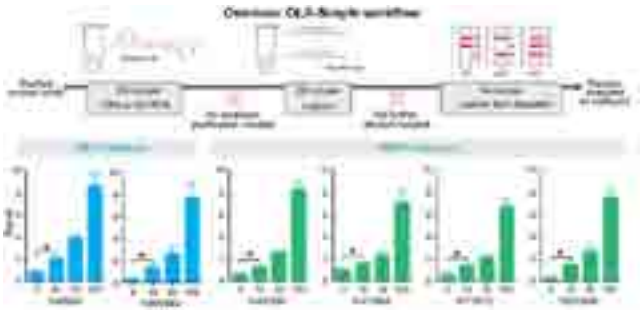
BACKGROUND: To develop a rapid HIV drug resistance (**DR**) test, we investigated recombinase polymerase amplification (**RPA**) as a faster alternative to PCR. We coupled the RPA assay with the simplified oligonucleotide ligation assay (**OLA-Simple**) that detects point-mutations using lyophilized reagents for easy assay setup and lateral flow tests for visual readout.

METHODS: We developed ***(i)*** novel RPA and reverse-transcription RPA (**RT-RPA**) assays that amplify 531bp DNA/RNA spanning HIV-1 mutations associated with resistance to nucleoside reverse transcriptase inhibitors (TDF/3TC) and non-nucleoside reverse transcriptase inhibitors (EFV/NVP), and ***(ii)*** a streamlined workflow that integrates RPA and OLA-Simple, eliminating post-amplification purification. RPA primers were designed to match majority sequences from >3,500 HIV-1 Group M sequences. The RPA assay was evaluated on 76 sequences derived from plasma and dried blood spots which included HIV subtypes A, B, C, D, and AE. RPA-amplified products were subjected to ligation reactions with codon-specific probes and visualized as bands on lateral flow strips. The band signals were analyzed using in-house software. Test results were classified as wild-type, mutant, or indeterminate, and compared to sensitive assays (MiSeq or plate-based oligonucleotide ligation assay).

RESULTS: The RPA and RT-RPA amplified 20 copies of HIV-1 DNA/RNA to levels detectable by gel electrophoresis in 20 minutes at 39°C. RPA amplified 100% (76/76) of sequences. This RPA assay coupled with the 40-minute OLA-Simple differentiated 10% mutant from wild-type HIV DNA standards. This HIV DR test showed 99.0±0.6% concordance across subtypes with 98.6±0.8% sensitivity and 100% specificity as compared to sensitive assays.

CONCLUSIONS: Excluding nucleic acid extraction, this HIVDR assay requires 1-hour wait-time and 10-minute hands-on time for rehydration of reagents and lateral flow detection. This rapid and inexpensive (~$10 reagents/specimen) assay has the potential to improve the treatment paradigm in low-resource settings by enabling guided treatment selection within the timeframe of a patient visit.



*[Figure 1: Workflow and analytical sensitivity of one-hour OLA-Simple assay. Standards containing 0%, 10%, 20% or 100% mutant in wild-type HIV underwent recombinase polymerase amplification, ligation and lateral flow tests. Signal of the mutant bands (meant ±SE) on lateral flow tests (n=4) were plotted. *indicates significant difference of p<0.01 (t-test).]*

BACKGROUND: Children and adolescents living with HIV face tremendous adherence challenges. ART resistance in these years can impact future treatment options for that vulnerable group. We assessed drug resistance in children and adolescents ≤23 years of age at GHESKIO in Port-au-Prince, Haiti.

METHODS: From October 2018 to July 2019, we conducted HIV genotyping for 159 children and adolescents (see Table): 68 patients were ≤15 years (median age 9 [IQR: 6.75, 13]) and 91 (median age 19; (IQR: 18, 21) were 16-23 years of age. Resistance was defined by the Stanford HIV Drug Resistance Database score: >=15 at least low-level resistance.

RESULTS:

At Least Low-Level Resistance (Score of ³15 by Stanford HIV Drug Resistance Database)												
Children ≤ 15 years (n = 68)	**EFV**	**DOR**	**RPV**	**ETR**	**Any NRTI**	**TDF**	**AZT**	**ABC**	**3TC/ FTC**	**TDF & 3TC**	**Any PI**	**DTG**
PDR (n=9)	44.4%	22.2%	11.1%	0%	33.3%	0%	0%	33.3%	33.3%	0%	0%	0%
First-Line NNRT Failure (n=35)	91.4%	62.9%	65.7%	54.3%	74.3%	11.4%	11.4%	74.3%	74.3%	11.4%	0%	0%
Second-Line Failure (n=24)	75.0%	41.7%	58.3%	45.8%	54.2%	16.7%	29.2%	54.2%	50.0%	12.5%	4.2%	0%
Adolescents 16-23 years (n=91)	**EFV**	**DOR**	**RPV**	**ETR**	**Any NRTI**	**TDF**	**AZT**	**ABC**	**3TC/ FTC**	**TDF & 3TC**	**Any PI**	0%
PDR (n=38)	26.3%	13.2%	13.2%	7.9%	7.9%	2.6%	2.6%	7.9%	7.9%	2.6%	0%	0%
First-Line NNRTI Failure (n=18)	66.7%	27.8%	33.3%	22.2%	11.1%	5.6%	0%	11.1%	11.1%	5.6%	11.1%	0%
Second-Line Failure (n=35)	71.4%	51.4%	42.9%	28.6%	37.1%	14.3%	17.1%	34.3%	31.4%	11.4%	8.6%	0%

[Table 1. Proportion of Patients with Genotypic Resistance, by Age Group, by Treatment Regimen, and Drug]

Among ART-naive patients, 44.4% of <=15 years, and 26.3% of 16-23 years had at least low-level resistance to EFV. Among patients failing first-line NNRTI, 91.4% of <=15 years and 66.7% of 16-23 years had at least low-level resistance to EFV. The rates of resistance to rilpivirine (RPV) and Doravirine (DOR) in this cohort were 65.7% and 62.9% in <=15 year olds, and 33.3% and 27.8% in 16-23 years. Abacavir (ABC) resistance was detected in 33.3%, 74.3% and 54.2% of ART-naive, failing 1st and 2nd line ART respectively in the younger group while Tenofovir (TDF) resistance was 14.3% in older adolescents.

CONCLUSIONS: High rates of EFV resistance in children and adolescents are concerning for all countries with long history of NNRTIs use. While HIV guidelines now recommend PI-based regimens for children <20 kg and DTG-based ART for those >20kg, many children worldwide remain on suboptimal NNRTI-based regimens due to international production delays of PIs and unavailability of pediatric DTG.

Furthermore, cross resistance with RPV jeopardizes future treatment options with long acting injectables during adolescence, when it may be most needed. High ABC resistance, the recommended first line NRTI backbone in children, may contribute to weak regimens and suboptimal viral suppression in children globally.

PEB0122

IBALIZUMAB SHOWS IN VITRO ACTIVITY AGAINST GROUP A AND GROUP B HIV-2 CLINICAL ISOLATES

Q. Le Hingrat[1], G. Collin[1], C. Charpentier[1], J. Ghosn[2], A. Bachelard[3], S. Chalal[3], J. Pacanowski[4], G. Peytavin[5], S. Weinheimer[6], C. Marsolais[7], F. Damond[1], S. Matheron[2], D. Descamps[1], and the ANRS CO5 HIV-2 Cohort
[1]Hôpital Bichat-Claude Bernard, Laboratoire de Virologie, Université de Paris, INSERM IAME UMR1137, Paris, France, [2]Hôpital Bichat-Claude Bernard, Service de Maladies Infectieuses et Tropicales, Université de Paris, INSERM IAME UMR1137, Paris, France, [3]Hôpital Bichat-Claude Bernard, Service de Maladies Infectieuses et Tropicales, Paris, France, [4]Hôpital Saint-Antoine, Service de Maladies Infectieuses et Tropicales, Paris, France, [5]Hôpital Bichat-Claude Bernard, Laboratoire de Pharmaco-toxicologie, Université de Paris, INSERM IAME UMR 1137, Paris, France, [6]TaiMed Biologics Inc, Irvine, United States, [7]Theratechnologies Inc, Montreal, Canada

BACKGROUND: In addition to being naturally resistant to NNRTI and enfuvirtide, HIV-2 easily selects drug-resistance associated mutations to protease, NRTI and integrase inhibitors at time of virological failure, leading to multi-drug resistant (MDR) viruses. Ibalizumab (IBA) is a long-acting humanized monoclonal antibody that blocks entry of virus into the host cell. It is approved by the FDA and the EMA for treatment-experienced persons infected with MDR HIV-1. No data were available on the activity of IBA against HIV-2 isolates.

METHODS: Isolates from 6 HIV-2-infected persons (4 group B, 2 group A), the ROD HIV-2 group A reference strain and the BRU HIV-1 reference strain were assessed for IBA phenotypic susceptibility. We adapted a PBMC phenotypic assay. Briefly, PHA-activated PBMC were incubated with increasing concentrations of IBA for 1h, prior to infection. Two hours post-infection, cells were washed and then resuspended in complete RPMI media containing IBA. At day 4 post-infection, HIV-2 replication was assessed on cell supernatant using a qRT-PCR (Biocentric-HIV-2). Phenotypic susceptibility was assessed through 50% inhibitory concentrations (IC_{50}) and Maximum-Percent-Inhibition (MPI). All HIV-2 isolates were previously obtained by co-cultivation of PHA-activated PBMC pool obtained from healthy blood donors.

RESULTS: IBA inhibited viral replication for all seven HIV-2 isolates, with IC_{50} ranging from 0.002 to 0.18µg/mL, and for the HIV-1 reference strain (IC_{50}=0.06µg/mL). MPI was below 80%, between 80 and 90%, and >90% for 2, 1 and 4 strains, respectively. The 2 isolates with the lowest MPI (74 and 77%) also had the highest IC_{50} (0.18 and 0.09µg/mL, respectively).

HIV Isolate	IC_{50} (µg/mL)	Maximum Percent Inhibition (%)
BRU (HIV-1)	0.06	97
ROD (HIV-2)	0.01	97
Isolate#1	0.18	74
Isolate#2	0.02	91
Isolate#3	0.008	99
Isolate#4	0.014	99
Isolate#5	0.09	77
Isolate#6	0.002	83

CONCLUSIONS: These data demonstrate for the first time that IBA is active *in vitro* against both HIV-2 epidemic groups, with similar IC_{50} and MPI to those observed for HIV-1. IBA could be included in therapies for HIV-2-infected-persons displaying MDR viruses, a more frequently observed situation in HIV-2 than in HIV-1. Clinical studies of IBA-based regimens in HIV-2-infected-patients are warranted.

DIAGNOSTICS OF CO-INFECTIONS AND CO-MORBIDITIES

PEB0123

COMPARISON OF 3 IMMUNODIAGNOSTIC TESTS FOR LATENT TUBERCULOSIS INFECTION AMONG THAI PRISONERS

S. Ubolyam[1], T. Iampornsin[1], T. Jaimulwong[1], K. Supakawee[1], J. Sophonphan[1], W. Harnpariphan[2], R. Supanun[2], A. Mahanontharit[1], S. Gatechumpol[1,3], K. Kawkitinarong[3], K. Ruxrungtham[1], P. Phanuphak[1], A. Kelleher[4], A. Avihingsanon[1,3]
[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Medical Correctional Institution, Medical, Bangkok, Thailand, [3]Chulalongkorn University, Faculty of Medicine, Tuberculosis Research Unit, Bangkok, Thailand, [4]University of New South Wales, The Kirby Institute for Infection and Immunity in Society, Sydney, Australia

BACKGROUND: Currently, there is no gold standard immunodiagnostic test to detect latent tuberculosis infection (LTBI). Prisoners are at risk of acquiring and spreading tuberculosis infection. We compared the performance of 3 LTBI immunodiagnostic tests: Tuberculin skin test (TST), QuantiFERON-TB Gold Plus (QFT Plus) and CD25/CD134 (OX40) assay among prisoners from a high TB prevalence country.

METHODS: A cross-sectional study to determine LTBI by TST among 1032 male prisoners in Thailand was performed from August 2018 to November 2019. All prisoners were screened for active TB by symptoms and chest x-ray. For this sub-study: the 3 LTBI assays were performed on the first 97 sequential prisoners. A trained nurse administered the TST. The QFT Plus was performed on whole blood. OX40 assay was performed on cryopreserved cells and co-expression of activation markers, CD25 and CD134, was measured after stimulation with ESAT-6 and CFP-10 antigens. TST positive was defined as an induration > 10 mm. Sensitivity and specificity of each test was determined using a composite diagnosis (defined as any positive test result) as comparator or using latent class analysis assuming an imperfect gold standard.

RESULTS: A total of 97 prisoners were analyzed. 32% (31/97), 62.9%(61/97) and 84.5% (82/97) of the prisoners were positive for LTBI by TST, QFT Plus and OX40, respectively. The performance of TST, QFT Plus and OX40 is shown in the tables 1 and 2 respectively. Agreement between QFT Plus and OX40 assay is 76.3%.

	TST	IGRA	OX40
Sensitivity	36.9 (26.6-48.1)	72.6 (61.8-81.8)	97.6 (91.7-99.7)
Specificity	100 (75.3-100)	100 (75.3-100)	100 (75.3-100)
PPV	100 (88.8-100)	100 (94.1-100)	100 (95.6-100)
NPV	19.7 (10.9-31.3)	36.1 (20.8-53.8)	86.7 (59.5-98.3)

[Table 1. Composite diagnoses (defined as any positive test) as comparator]

	TST	IGRA	OX40
Sensitivity	45.5 (33.1-58.2)	90.9 (81.3-96.6)	100 (94.6-100)
Specificity	93.3 (68.1-99.8)	93.3 (68.1-99.8)	100 (78.2-100)
PPV	96.8 (83.3-99.9)	98.4 (91.2-100)	100 (94.6-100)
NPV	28 (16.2-42.5)	70 (45.7-88.1)	100 (78.2-100)

[Table 2. A latent class analysis assuming an imperfect gold standard]

CONCLUSIONS: The prevalence of LTBI among prisoners in Thailand was 32%, 62.9% and 84.5% by TST, QFT Plus and OX40, respectively. The estimated sensitivities of the in vitro assays were higher than TST. OX40 assay should be further developed for LTBI diagnosis.

PEB0124

DIAGNOSTIC PERFORMANCE OF MULTIPLEXED PLATFORM AND POINT-OF-CARE RAPID TESTS FOR HIV AND SEXUALLY-TRANSMITTED BLOOD-BORNE INFECTIONS: A SYSTEMATIC REVIEW

A. Karellis[1,2], F. Naeem[1,2], S. Rourke[3], J. Kim[4], N. Pant Pai[1,2]
[1]McGill University, Medicine, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, Canada, [3]University of Toronto, St Michael's Hospital, CIHR Centre for REACH in HIV/AIDS, Toronto, Canada, [4]National Laboratory for HIV Reference Services, Winnipeg, Canada

BACKGROUND: Multiplexed testing of HIV and associated sexually transmitted infections (STIs) by rapid point-of-care (POC) tests and platform devices offers a convenient, alternative screening and diagnostics option to screen/test/treat for multiple STIs in fewer patient visits. Data on their real-world diagnostic performance has not yet been synthesized. We conducted a systematic review to fill this gap.

METHODS: For the period 2009-2019, two independent reviewers searched two databases (Pubmed and Embase), retrieved 3911 citations and abstracted data. A lack of complete stratified data by pathogens/devices obviated pooling/meta-analyses, a narrative review was thus performed. Sensitivities and specificities were compared and evaluated against lab reference standards.

RESULTS: Across 23 countries, 31 observational studies were conducted in N=26,537 at-risk populations (men who have sex with men, transgender, injection drug users, female sex workers, Aboriginal communities, pregnant women). Overall, 22 studies evaluated platform devices and 9 evaluated POC tests. Pathogens screened by POC tests were HIV, hepatitis B and C, and *Treponema pallidum*. Platforms assessed *Chlamydia trachomatis*, *Neisseria gonorrhoeae*, *Mycoplasma genitalium*, *Mycoplasma hominis*, *Trichomonas vaginalis*, *Ureaplasma urealyticum*, *Treponema pallidum*, herpes simplex virus and human papillomavirus. Overall, platform tests yielded both a higher specificity and sensitivity, while POC tests yielded a higher sensitivity. Both technologies were comparable on turnaround time to result. On th following page Table 1 presents data on Platform Devices and POC Devices.

CONCLUSIONS: Diagnostic performance varied by pathogens, subpopulations, disease prevalence, incidence, type of technology (POC/platform) and reference standards deployed for each setting. We conclude that due to their high specificity, platform tests are suited for confirmatory testing while POC tests remain suited for initial screening because of their portability and ease of use.

INDIRECT OPHTHALMOSCOPY AS A SCREENING TOOL FOR THE DIAGNOSIS OF OPPORTUNISTIC INFECTIONS IN HOSPITALIZED PATIENTS WITH ADVANCED HIV DISEASE IN MAPUTO, MOZAMBIQUE

C.M. Siufi[1], A.G. Gutierrez[1], N. Tamayo Antabak[1], H.V. Andela[1], A. Guadarrama[1], A. Loarec[1], J.F. Weng San[2], I. Magaia[2], L. Monteiro[2], E. Chamba[2], I. Ciglenecki[3], P. Saranchuk[4], D. Heiden[4]
[1]Médecins sans Frontiéres, Maputo, Mozambique, [2]Minister of Health, Maputo, Mozambique, [3]Médecins sans Frontiéres, Geneva, Switzerland, [4]SEVA Foundation, Berkeley, United States

BACKGROUND: Patients with advanced HIV Disease (AHD) in resource limited settings have a high risk of mortality attributable to opportunistic infections (OIs)
Retinal examination using indirect ophthalmoscope can diagnose a number of OIs, including cytomegalovirus and tuberculosis.
Médecins sans Frontières (MSF) in collaboration with the Ministry of Health, supports care for AHD in the emergency room of the General Hospital of Jose Macamo (HGJM) in Maputo. In March, 2019, MSF included indirect ophthalmoscopy in a screening package for patients with AHD . Here we present findings of indirect ophthalmoscopy performed between March and December, 2019.
METHODS: Patients admitted to emergency room of HGJM were eligible for screening if they had CD4 count below 100 cells/µl. Ophthalmoscopy was performed by trained non-ophthalmologist medical doctors using indirect ophthalmoscopy on fully dilated pupils. We analysed routinely collected clinical data,using a standarized form and entered it into an Access database.
The results were interpreted according to the abnormal findings.
RESULTS: Between March and December, 2019, 241 (32%) patients of 746 eligible patients were screened with indirect ophthalmoscopy. The median age was 38 years (IQR=30-42), 135 (56%) were women, 188 (78%) reported ART experience, 148 (79%) were on ART at time of admission. Among them, 89 (37%) presented an abnormal ophthalmoscopy: 48 (54%) had cotton wool spots, 14 (16%) presented signs of cytomegalovirus retinitis and 14(16%) papilledema. In smaller proportion, 6 (7%) patients presented signs of choroidal tuberculosis, 4(4%) non-specific lesions and finally 3(3%) patients with signs of syphilitic retinitis.
Patients with a pathological exam were referred for specific care following to the screening results.
CONCLUSIONS: A high proportion of abnormal exams were found among patients with CD4<100 presenting to the emergency room of HGJM. Indirect ophthalmoscopy is a non-invasive point of care test, that was successfully performed by general practitioners. Integration into routine care and better access to this screening tool could facilitate critically important early diagnosis of OIs.

BIOMARKERS FOR THE PREDICTION OF MORBIDITY AND MORTALITY

PEB0126

MITOCHONDRIAL DNA "COMMON DELETION" IS INVERSELY ASSOCIATED WITH NEUROINFLAMMATION AND NEURODEGENERATION IN PEOPLE WITH HIV

D. Solanky[1], R. Ellis[2], J. Iudicello[3], S. Mehta[4]
[1]University of California, San Diego, Internal Medicine, San Diego, United States, [2]University of California, San Diego, Neurosciences, San Diego, United States, [3]University of California, San Diego, Psychiatry, San Diego, United States, [4]University of California, San Diego, Infectious Diseases, San Diego, United States

BACKGROUND: Accumulation of damage and loss of integrity in mitochondrial genomes contribute to physiologic aging in humans. HIV infection is also associated with premature aging and inflammation. However, limited reliable markers for aging currently exist. The mitochondrial DNA (mtDNA) common deletion (mtCD) is a 4977-bp deletion associated with aging, degenerative neurological conditions and malignancy, but is not well characterized in people with HIV (PWH). We examined how the relative proportion of mtCD to mtDNA correlates with markers of aging, inflammation, comorbidity, and neurodegeneration among PWH.
METHODS: We examined the relationships between demographic and the clinical measures and mtCD, measured from buccal swabs, in PWH on antiretroviral therapy (ART) in the Translational Methamphetamine AIDS Research Center cohort.
RESULTS: Eighty-two subjects (median age, 48.5 years; 15% female; 45% white) were included. Quantile regression analysis demonstrated that the relative proportion of mtCD to mtDNA per subject was inversely proportional to 8-Oxo-2'-deoxyguanosine (8-oxodG), neurofilament light chain (NFL) and tau protein (TAU) in the cerebrospinal fluid (CSF) of subjects (Table 1). Given the role of reactive oxygen species and aging in the pathogenesis of neurodegenerative conditions, multivariate regression was performed adjusting for age. In this model, 8-oxodG was directly proportional to NFL and TAU levels, and independent of mtCD.

Variable	P-Value (Significance considered at values < 0.05)
Age	0.35
Immune Recovery (current CD4 count minus all-time CD4 nadir)	0.37
C-reactive Protein	0.65
CSF 8oxodG	**0.015**
CSF NFL	**0.013**
CSF TAU	**0.013**
CSF Aβ42	0.44
Framingham Cardiovascular Disease Risk Score	0.30
HDL Cholesterol	0.97

[Table 1.]

CONCLUSIONS: Lower relative proportions of mtCD significantly correlated with higher CSF 8-oxodG levels in PWH. Higher 8-oxodG levels in turn significantly correlated with greater levels of TAU and NFL in the CSF – influenced by increasing age. We hypothesize that the inverse relationship between mtCD and 8-oxodG relates to altered fission and fusion from inflammation and direct toxicity from

HIV and ART, resulting in greater clearance of damaged mitochondria when oxidative stress is present. Future research to improve mitochondrial function and quality may serve as a gateway to interventions that minimize the inflammatory and neurodegenerative consequences of chronic HIV infection.

PEB0127

URINARY EXOSOME-DERIVED MICRO-RNAS AS BIOMARKERS FOR TENOFOVIR DISOPROXIL FUMARATE-ASSOCIATED (TDF) RENAL TOXICITY IN HIV-1-INFECTED PATIENTS

F. Hernandez-Walias[1], P. Vizcarra[1], J.M. Del Rey[2], C. Santiuste[2], A. Abad[1], A. Vallejo[1], J.L. Casado[1]
[1]Ramon y Cajal Hospital, Infectious Diseases, Madrid, Spain, [2]Ramon y Cajal Hospital, Biochemistry, Madrid, Spain

BACKGROUND: Tenofovir disoproxil fumarate (TDF) could led to tubular renal toxicity, but its severity and outcome is controversial and specific biomarkers are still required. The aim of this study was to identify differences in urinary exosome-derived micro-RNA (miR) expression profiles according to TDF toxicity.

METHODS: Urine samples were cross-sectionally collected from 70 virologically suppressed HIV-1-infected patients (61 of them on TDF). In all cases, different tubular parameters and urinary low-weight molecular proteins (LWMP, beta-2-microglobulin, retinol-binding protein, urinary cystatin C) were analyzed. Tubular dysfunction was defined as the presence of at least 2 tubular abnormalities. Urine exosomes were precipitated and a pre-selected panel of miRs were isolated and quantified using miR-specific real-time qPCR.

RESULTS: Overall, median time on TDF was 65 months (38-82.6), and mean eGFR was 90.9 ml/min/1.73m2 (50.1-122; 6% of patients with CKD). A number of miRs, including miR-let-7d, miR-203a, miR-127, miR-23a, and miR-29a correlated with time on TDF therapy, with statistical significance. At evaluation, miR-let-7d, miR-423 were found to have increased expression in patients with tubular dysfunction (proteinuria, phosphaturia, uricosuria, glycosuria). Of note, miR-15b were upregulated in urinary exosomes of patients with decreased eGFR with statistical significance (p=0.028). In an evaluation performed after 9 months (IQ 4-13), and similar to proteinuria and phosphaturia, miR-let-7d predict tubular dysfunction (AUC 0.733), and miR-15b identified those with subsequent eGFR decrease (AUC 0.633).

CONCLUSIONS: The expression profile of miRs was altered in urinary exosomes from patients with TDF-associated toxicity. We identified exosome-derived miRs in urine that could be used as non-invasive biomarkers for the detection of renal toxicity associated with TDF.

TUBERCULOSIS: PREVENTION, DIAGNOSIS, TREATMENT

PEB0128

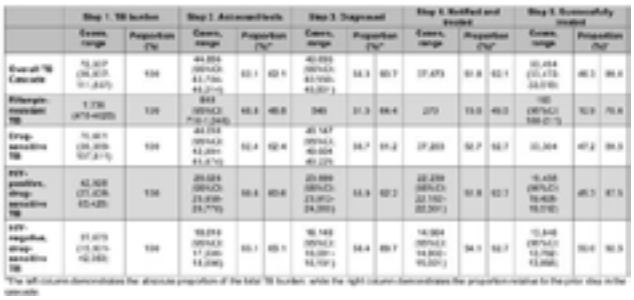
THE TUBERCULOSIS CARE CASCADE IN ZAMBIA: IDENTIFYING THE GAPS IN ORDER TO IMPROVE OUTCOMES

A. Kerkhoff[1], C. Kasapo[2], J. Mzyece[2], S. Nyimbili[2], M. Kagujje[3], M. Muyoyeta[3], K. Malama[4], P. Lungu[2]
[1]University of California San Francisco, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [2]National Tuberculosis and Leprosy Control Programme, Lusaka, Zambia, [3]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [4]Ministry of Health, Lusaka, Zambia

BACKGROUND: Tuberculosis (TB) remains a leading cause of morbidity and mortality among individuals in Zambia, especially people living with HIV (PWH). To accelerate progress towards improved TB outcomes, we undertook a care cascade analysis to enumerate the largest gaps and align TB programme improvement measures with areas of greatest need.

METHODS: We derived national-level estimates for each step of the TB care cascade in Zambia in 2017: 1) total TB burden, 2) number who accessed TB testing, 3) number diagnosed with TB, 4) number notified and started on TB treatment, 5) number completing TB treatment. We characterized the overall cascade as well as disaggregated by drug-susceptibility results and HIV-status. Estimates were informed by WHO incidence estimates, nationally aggregated laboratory and notification registers, and individual-level programme data from four provinces.

RESULTS: In 2017, the total burden of TB in Zambia was estimated to be 72,337 (range, 39,837-111,837). Of these, 44,886 (62.1%) accessed TB testing, 40,693 (overall proportion - 56.3%, relative proportion – 90.7%) were diagnosed with TB, 37,473 (51.8%, 92.1%) were started on TB treatment and 33,494 (46.3%, 89.4%) completed TB treatment. PWH tended to have worse outcomes throughout the cascade and were less likely than HIV-negative individuals to successfully complete TB treatment (45.3 vs. 50.0%; Table 1). Among those with rifampicin-resistant TB, there was substantial attrition at each step of the cascade and only 10.9% of all patients were estimated to have successfully completed treatment (Table 1).



[Table 1. Overview of the tuberculosis care cascade in Zambia in 2017 according to tuberculosis type]

CONCLUSIONS: Losses throughout the cascade, especially not accessing TB testing, results in a large proportion of individuals with TB in Zambia who are not successfully completing treatment. Ongoing systems-strengthening is required throughout the TB care continuum, however, implementation of active case finding strategies coupled with a continued focus on PWH and those with rifampicin-resistance are urgently needed to improve TB-related outcomes in Zambia.

PEB0129

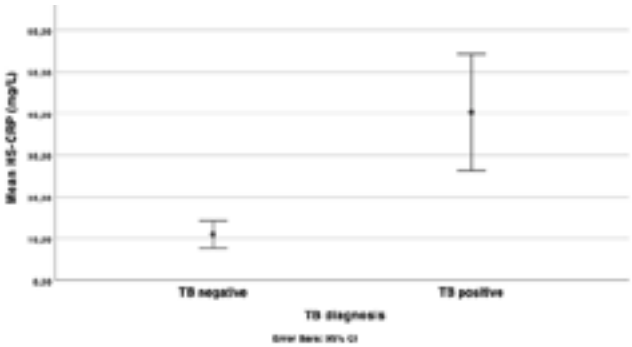
ENHANCING TB DIAGNOSIS IN HIV+ PATIENTS IN KENYA: PRELIMINARY RESULTS OF IDEA-TB STUDY IN A COHORT FROM DREAM PROGRAM

F. Ciccacci[1], K. Wouters[2], B. Welu[3], H. Ndoi[3], I. Karea[3], S. Orlando[4], D. Brambilla[5], K. Munene[3], P. Giglio[5], B. Opanga[6], A. Ronoh[7], S. Mukwanjagi[8], R. Mwiraria[8], G. Guidotti[9], M.C. Marazzi[10]
[1]UniCamillus, International University of Health and Medical Science, Rome, Italy, [2]Institute of Tropical Medicine, Department of Clinical Sciences, Antwerp, Belgium, [3]Community of Sant'Egidio, DREAM program, Meru, Kenya, [4]University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [5]Community of Sant'Egidio, DREAM program, Rome, Italy, [6]National AIDS and STIs Control Programme, Nairobi, Kenya, [7]National Tuberculosis, Leprosy and Lung Disease Program, Nairobi, Kenya, [8]Consolata Hospital, Nkubu, Kenya, [9]ASL RM 1, Rome, Italy, [10]LUMSA, Rome, Italy

BACKGROUND: TB has still a high prevalence and mortality worldwide, also representing the leading cause of death in HIV+ people. In Kenya, in 2018, 32.000 people died due to TB, and 40.000 HIV+ patients were diagnosed with TB in the same year. In 2016 only 63,4% of people with TB worldwide were diagnosed; the individuation of TB among HIV+ patients is particularly challenging. The objective of the present study is to improve TB diagnosis among HIV+ patients. HS-CRR, LF-LAM test, 4SS and Gene Xpert will be evaluated in order to define diagnostic algorithms for TB in HIV+ patients.

METHODS: IDEA (Innovative Diagnostic Enhancement Against) TB is a prospective study aimed to evaluate innovative diagnostic tools for TB in HIV+ patients. HIV+ consecutive adult patients attending the sites of the study (DREAM Centers in Meru/Nchiru, Chaaria, Nkubu) who were clinically suspected of having TB and referred for Gene Xpert were enrolled. Each participant was entered in the datasheet (demographic, anthropometric and clinical data) and tests were performed: urinary LF-LAM-test, serum HS-CRP and Gene Xpert on sputum.

RESULTS: In nine months (May-December 2019), 389 TB-suspected patients were enrolled. 62.5%(243/389) were female, the median age was 46(±12) years, 26.7%(104/389) patients were malnourished, and the median CD4 count was 417 [IQR 237-643]. TB was diagnosed on a total of 63(16.19%) patients (either LAM or Xpert positive test). Concordance between Xpert and LAM test was 85.3%. HS-CRP was significantly higher in TB patients (40.2 mg/L vs 11.0 mg/L, p<0,000) (Figure 1). The only predictor of TB diagnosis was plasmatic HS-CRP level higher than 10 mg/L (OR 4.01 [2.28-7.06]). No association between TB, CD4 count or BMI was observed.



[Figure. Difference in HS-CRP in TB positive and negative patients]

CONCLUSIONS: Diagnosing TB infection in HIV+ patient remains challenging, as concordance among different tests is suboptimal. HS-CRP could serve as an additional tool in TB diagnosis in HIV+ patients.

PEB0130

RADIOGRAPHERS' ROLE EXTENSION IN RWANDA: ULTRASONOGRAPHIC DETECTION OF ABDOMINAL TUBERCLOSIUS IN HIV/AIDS PATIENTS IN RURAL DISTRICT HOSPITALS

O. Mizero[1,2], J.F. Habimana[2], S. Mushimiyimana[2]
[1]Rwanda Military Hospital, Kigali, Rwanda, [2]Society of Medical Imaging and Radiation in Rwanda, Kigali, Rwanda

BACKGROUND: The diagnosis of abdominal tuberculosis in HIV/AIDS patients is challenging especially in rural hospitals in developing countries where resources are limited and often there are no radiologists. The procedure requires radiographers to have good knowledge of ultrasonographic imaging. The objective of the program was to improve the detection of abdominal tuberculosis in HIV/AIDS patients in rural district hospitals of Rwanda through radiographers' role extension.

DESCRIPTION: In December of 2017 and 2018, a training on abdominal sonography has been offered to 1 radiographer in every district hospital in Rwanda by SMIR(Society of Medical Imaging and Radiation in Rwanda) on the support of University of Rwanda ,department of Medical Imaging Sciences. Every year 25 to 30 radiographers were trained in a 5days session. The methodology included the detection of main sonographic features of abdominal tuberculosis in HIV diseases by focusing on abdominal lymphadenopathy, abdominal solid organs nodules and ascites. In addition, the training included other common abdominal pathologies encountered in HIv patients but that are not always tuberculous. The trainings were jointly delivered by medical imaging lectures from University of Rwanda and Senior ultrasound practitioners from different referral hospitals in Rwanda.

LESSONS LEARNED: During 2019,a cross sectional study was carried out to evaluate the outcome of this training by SMIR through senior sonographers working in referral hospitals by comparing the referred sonographic diagnosis from a district hospital with the sonographic diagnosis in the referral hospital. In 207 cases received(83 done by non trained personnel and 144 done by trained radiographers),the capacity of detecting abdominal tuberculosis were significantly better in the trained radiographers than in non trained personnel.

CONCLUSIONS/NEXT STEPS: Extending the role of radiographers through specific training can improve the detection of HIV diseases especially abdominal tuberculosis in rural district hospitals where resources are limited.

PEB0131

ENHANCED TUBERCULOSIS SCREENING AND DIAGNOSIS FOR HOSPITALIZED INDIVIDUALS IN A HIGH HIV PREVALENCE SETTING IN KWAZULU-NATAL, SOUTH AFRICA: A BEFORE AND AFTER STUDY

A.B. Bulti[1], A.Y. Dumicho[1], L. Ohler[1], S.J. Steele[2], G. Van Cutsem[2], G. Ferlazzo[2], P. Isaakidis[2], O.A. Olowe[3], S. Buthelezi[4], M. Mbatha[5], A. Shigayeva[1], L.T. Duran[1], J. Furin[6], C. Laxmeshwar[1]
[1]Médecins Sans Frontières (MSF), Eshowe, South Africa, [2]Médecins Sans Frontières (MSF), Southern Africa Medical Unit (SAMU), Cape Town, South Africa, [3]Mbongolwane Hospital, Mbongolwane, South Africa, [4]Eshowe Hospital, Eshowe, South Africa, [5]KwaZulu-Natal Department of Health, Empangeni, South Africa, [6]Harvard Medical School, Department of Global Health & Social Medicine, Boston, United States

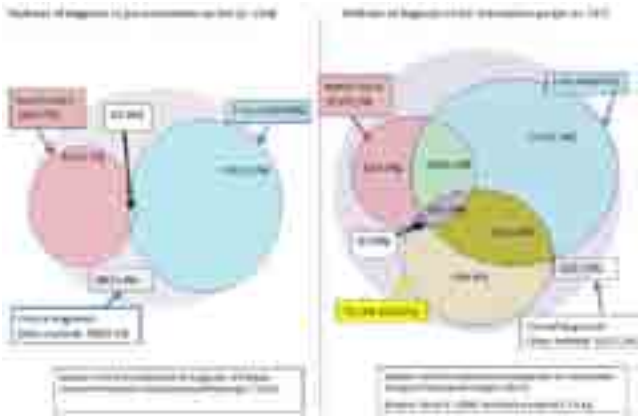
BACKGROUND: WHO estimated 10 million cases of tuberculosis (TB) globally in 2018 but only 7 million were reported, signifying a gap between incidence and detection. Diagnostic difficulties in HIV co-infected patients, who have more smear-negative and extra-pulmonary TB, contribute to this challenge and high mortality. King Cetshwayo District, KwaZulu-Natal, South Africa, in 2018 reported an HIV prevalence of 26.4% among those ≥15 years. This study describes the changes in TB diagnosis by implementing a systematic screening and enhanced diagnostic package for patients admitted to two hospitals in King Cetshwayo District.

METHODS: Patients aged ≥ 18 years admitted to Eshowe and Mbongolwane hospitals were provided systematic screening and enhanced diagnostic packages for HIV, diabetes, and TB during the intervention period as shown in the table. A comparison of TB diagnosis and in-hospital mortality was made with the pre-intervention period.

	Pre-intervention period (March 2018 to November 2019)	Intervention period (March 2019 to November 2019)
Diabetes screening and diagnosis	Random blood sugar (RBS) by glucometer clinically prompted	Systematic screening by RBS by glucometer and confirmation by fasting blood sugar or with HbA1c
HIV screening and diagnosis	HIV testing clinically prompted	HIV testing provided for all admitted patients
TB screening and diagnosis	Symptom-based screening not systematically done	Systematic symptom screening after TB education by community health workers
	Xpert MTB/RIF Ultra if a clinical presumption of TB	Xpert MTB/RIF Ultra provided for HIV positive, diabetic patients regardless of symptoms and for HIV negative with symptoms Culture for presumptive TB but negative GeneXpert
	No use of urine Determine TB- lipoarabinomannan (TB-LAM)	Systematic urine TB-LAM for HIV positive patients regardless of symptoms or CD4 count
	Chest X-ray (CXR) done for presumptive TB patients and interpreted by medical officers	CXR was systematically done for all HIV positive, diabetics regardless of symptoms and in HIV negative patients with TB symptoms. CXR interpreted by expert radiologists via telemedicine when medical officers needed further advice

[Table]

RESULTS: Of 3269 patients enrolled in the pre-intervention period, the median age was 50 years (interquartile range (IQR): 32-67) and 1852(56.7%) were females. Of 2315 patients enrolled during the intervention period, the median age was 53 years (IQR: 34-68) and 1476(63.7%) were females. TB diagnosis was higher in the intervention period (347(15.0%) vs. 259(7.9%)) showing an increase of 89.9% (p<0.001). Among those diagnosed with TB, 72.3%(170/235) in pre-intervention and 73.3%(251/342) in the intervention, had HIV co-infection. TB related in-hospital mortality was lower in the intervention period (13.3% vs 15.4%; p =0.316).



[Figure. Comparison of methods of diagnosis and time from admission to diagnosis between the pre-intervention and the intervention groups]

CONCLUSIONS: Systematic screening for HIV, TB and enhanced TB diagnostic package for hospitalized patients significantly improved TB case detection and shortened time to TB diagnosis. This should be part of routine hospital care in a high TB and HIV burden settings.

PEB0132

SYSTEMATIC LATERAL FLOW URINE LIPOARABINOMANNAN ASSAY (LF-LAM) FOR DIAGNOSIS OF TUBERCULOSIS AMONG HIV POSITIVE HOSPITALIZED PATIENTS IN KWAZULU-NATAL, SOUTH AFRICA

A.Y. Dumicho[1], A.B. Bulti[1], L. Ohler[1], A. Shigayeva[1], L.T. Duran[2], M. Mbatha[3], J. Furin[4], C. Laxmeshwar[1]
[1]Médecins Sans Frontières (MSF), Eshowe, South Africa, [2]Médecins Sans Frontières (MSF), Cape Town, Cape Town, South Africa, [3]Department of Health, Empangeni, South Africa, [4]Harvard Medical School, Department of Global Health & Social Medicine, Boston, United States

BACKGROUND: Diagnosis of tuberculosis in people with HIV is challenging. The lateral flow urine lipoarabinomannan assay (LF-LAM) (Alere, Abbott Laboratories, Illinois, USA) is useful for diagnosis of TB but there is limited evidence on its use for systematic screening of hospitalized patients with HIV.

This study describes the systematic TB screening with LF-LAM among HIV positive patients admitted to two hospitals in KwaZulu-Natal, South Africa.

METHODS: From March 2019 to December 2019 patients aged >18 years admitted with medical and psychiatric conditions to Eshowe and Mbongolwane hospitals were systematically assessed for HIV and TB. HIV-positive patients were systematically tested with GeneXpert, Chest X-ray (CXR) and urine LF-LAM. Patients with a positive LF-LAM but geneXpert/culture negative/test not done and CXR not

suggestive of TB were classified as "potentially missed". Patients with a positive LF-LAM and a CXR suggestive of TB were classified as "LF-LAM-assisted".

RESULTS: Of 913 HIV-positive patients, 549(60.1%) were female, median age with interquartile range (IQR) of 40(34-51) years. Median CD4 count was 382(IQR: 140-625) cells/μL and 618 (67.7%) had at least one TB symptom. Among these, 266(29.13%) were diagnosed with TB and 265(99.6%) were started on TB treatment.

Methods	Test done	Test positive or suggestive of TB(CXR) n(%)	Test not done	Total
GeneXpert	371	63(17.0)	542	913
GeneXpert/culture	373	66(17.7)	540	913
LF-LAM	828	139(16.8)	85	913
CXR	577	171(30.0)	336	913
From the total diagnosed with TB, 39 were diagnosed based on clinical or other methods. Among LF-LAM positive patients, 7/139(5.0%) were not considered to have TB by the treating physicians.				

[Table 1: The proportion of TB diagnosis by methods of diagnosis.]

Among geneXpert/culture negative patients, 20/306 (6.5%) were potentially missed and 35/307 (11.4%) were LF-LAM assisted. From patients unable to produce a specimen for geneXpert/culture testing, 18/540 (3.3%) were potentially missed and 23/540 (4.3%) were LF-LAM assisted.Among geneXpert/culture positive patients, LF-LAM was positive in 27/36 (75%) patients with CD4<200 cells/μL & 9/19 (47.4%) of patients with CD4≥200 cells/μL. The sensitivity and specificity of LF-LAM compared to geneXpert/culture positive patient with CD4 count >200 cells/μL was 50% (95%CI:27.2%-72.8%) and 81.4 % (95%CI:74.8%-86.9%) respectively. In patients with CD4 count < 200 cells/μL LF-LAM sensitivity was 74.3% (95%CI: 56.7%-87.5%) and specificity was 72.8% (95%CI: 61.8%-82.1%).

CONCLUSIONS: Urine LF-LAM improved TB diagnosis in HIV-positive hospitalized patients. It also contributes towards diagnosis among patients with CD4>200, however, the sensitivity was low.

PEB0133

WHAT IS THE PERFORMANCE OF TUBERCULOSIS MANAGEMENT AMONG PEOPLE LIVING WITH HIV IN HIV CARE AND TREATMENT SETTINGS IN TANZANIA?

W. Maokola[1], P. Faustine[1], B. Mpondo[1], K. Renatus[1], S. Msuya[2], J. Todd[3], B. Mutayoba[1]
[1]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program, Dodoma, Tanzania, United Republic of, [2]Kilimanjaro Christian Medical University College, Institute of Public Health, Moshi, Tanzania, United Republic of, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: Comprehensive HIV care and treatment services entail routine screening for Tuberculosis (TB) symptoms and signs during every visit to HIV care and treatment clinic (CTC). Individuals with positive screening are further evaluated for TB disease whereas those who screen negative are evaluated for TB preventive therapy. TB management cascade among People Living with HIV (PLHIV) needs to be evaluated.

METHODS: We carried out a retrospective cohort analysis to evaluate the performance of the TB diagnosis cascade among PLHIV attending CTC between January 2012 and December 2016 in three regions of Tanzania: Dar es Salaam, Iringa and Njombe using descriptive epidemiology.

RESULTS: The cohort had 169,741 PLHIV who made 2,638,876 visits to CTC during the study period. We excluded 2,074 (0.80%) visits as these involved PLHIV enrolled in CTC with a prior TB disease diagnosis. Of the 2,636,802 visits, 2,524,494 (95.67%) had TB screening according to the national HIV guidelines, of which 88,028 (3.49%) had TB screening positive results. Of the 88,028 visits with a positive TB screening, 27,810 (31.59%) had no records for further TB diagnosis following positive TB screening. Of all visits with positive TB screening, 32,986 (37.50%) had TB disease diagnosis.

CONCLUSIONS: There was a high TB screening among CTC attendees, however, with one third of the visits with positive screening missing evidence for further TB diagnosis evaluation.

PEB0134

ISONIAZID ANTI-TUBERCULOSIS CHEMOPROPHYLAXIS IN HIV-INFECTED PATIENTS

F. Ihbibane[1], N. Tassi[1]
[1]Faculty of Medicine and Pharmacy- Cadi Ayyad University- University Hospital Center Mohamed VI, Infectious Diseases, Marrakech, Morocco

BACKGROUND: People living with HIV are at increased risk of developing active TB. WHO recommends a series of measures to reduce the burden of tuberculosis in these patients. In this work, we will cover the topic of preventive treatment of isoniazid tuberculosis (INH) through a prospective study. The aim of this study is to assess the efficacy and safety of isoniazid in prophylaxis against tuberculosis in patients with HIV infection.

METHODS: We present through this summary, the preliminary results of our prospective study started in January 2013 concerning anti-tuberculosis chemo prophylaxis by INH in HIV infected patients followed in the service of infectious diseases at the university hospital center Mohamed VI in Marrakech. Patients whose active tuberculosis was eliminated before the start of INH were retained.

RESULTS: Three hundred and sixteen patients currently receiving INH chemoprophylaxis. One hundred and sixty four patients (52%) were male with an average age of 38.2 years [14 - 69 years]. A history of tuberculosis was found in 42 patients (14.55%). When chemoprophylaxis started, the CD4 average was 496.2 cells / mm3. Compliance was good in 303 patients (96%). Adverse reactions to INH were noted in 72 cases (23%), mainly epigastralgia in 44 cases (14%). INH was discontinued in one patient due to hepatic cytolysis. After 6 years of follow-up, none of our patients had shown signs of active tuberculosis.

CONCLUSIONS: HIV infection is an important risk factor for tuberculosis, hence the importance of preventing it in this population through effective chemoprophylaxis.

PEB0135

DELAYS AND BARRIERS TO HEALTH-SEEKING AMONG NEWLY DIAGNOSED TUBERCULOSIS PATIENTS IN ZAMBIA

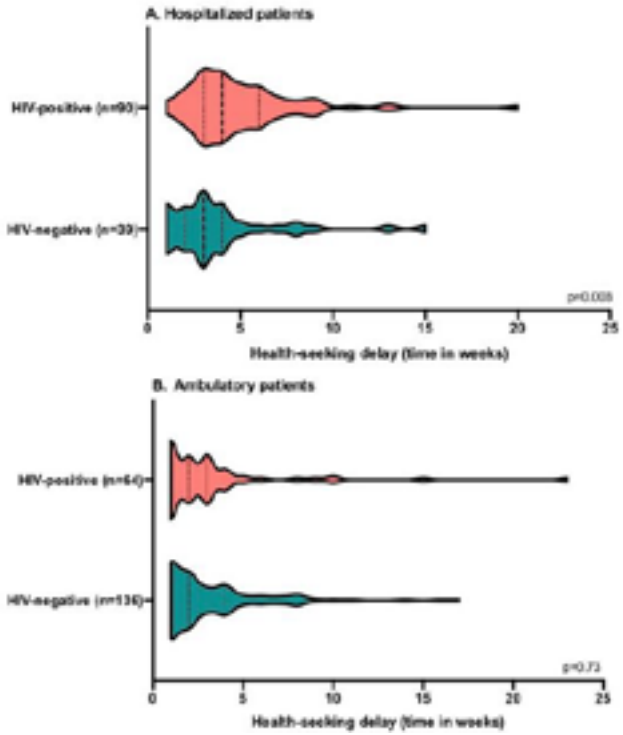
A. Kerkhoff[1], M. Kagujje[2], S. Nyangu[2], K. Mateyo[3], N. Sanjase[2], P. Somwe[2], L. Chilukutu[2], D. Havlir[1], M. Muyoyeta[2]

[1]University of California San Francisco, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, Lusaka, Zambia, [3]University Teaching Hospital, Department of Internal Medicine, Lusaka, Zambia

BACKGROUND: Delayed tuberculosis (TB) diagnoses are a key driver of ongoing TB-related mortality, especially among people living with HIV (PWH). We sought to characterize health-seeking behavior among TB patients and understand potential barriers to timely diagnosis.

METHODS: In an ongoing prospective, cross-sectional study, we enrolled consecutive adults with newly microbiologically-confirmed TB at two public health facilities in Lusaka, Zambia. All patients were administered a survey that assessed their experiences accessing TB services, including self-reported health-seeking delay (symptom onset to first provider visit), barriers to health-seeking and healthcare preferences. Health-seeking delays and barriers/preferences were compared by HIV-status using Wilcoxon and Chi-squared tests, respectively.

RESULTS: Of 340 patients enrolled (median age 33, 69.9% male), 69/211 (32.7%) outpatients versus 90/129 (69.8%) inpatients were PWH (p<0.001). Overall, the median health-seeking delay was 3 weeks (IQR, 2-5) and was longer among HIV-positive inpatients (Figure 1);



[Figure 1. Violin plots of self-reported health-seeking delay, according to HIV-status among a) hospitalized patients (n=129) and b) ambulatory patients (n=200) in Lusaka Zambia. Health-seeking delay is defined as the time in weeks from self-reported symptom onset to self-reported first provider visit. P-values represent Wilcoxon rank-sums comparing median values. The bolded central dash represents the median value, while the fine dashes represent the interquartile range.]

73/154 (47.4%) HIV-positive patients vs. 60/175 (34.3%) HIV-negative patients waited ≥4 weeks before seeking evaluation (p=0.016). Most patients (n=304;88.9%) initially presented to a public health facility – proximity to home was most important to HIV-negative patients, while PWH tended to choose a facility based on perceived measures of quality (Table 1). Most patients (n=182;53.5%) contemplated presenting earlier than they did – key reasons reported for delayed health-seeking were: symptoms were not initially felt to be serious (91.2%), TB symptoms were unknown (80.2%), and lack of time (47.8%) – these did not differ by HIV-status.

	Overall (n=340)	HIV-positive (n=159)	HIV-negative (n=181)	P-value
Close to home	209 (61.5)	85 (53.5)	124 (68.5)	0.004
Close to work	96 (28.2)	39 (24.5)	57 (31.5)	0.16
Short wait times	96 (28.2)	55 (34.6)	41 (22.7)	0.015
Services are inexpensive	133 (39.1)	73 (45.9)	60 (33.2)	0.016
Good quality service	169 (49.7)	95 (59.8)	74 (40.9)	0.001
Private/confidential	142 (41.8)	82 (51.6)	60 (33.2)	0.001
Providers are receptive	127 (37.4)	73 (45.9)	54 (29.8)	0.002
Familiar with the provider	102 (30.0)	53 (33.3)	49 (27.1)	0.21
My friends/colleagues go there	126 (37.1)	62 (39.0)	64 (35.4)	0.49

Chi-squared tests were used to calculate p-values comparing proportions.
*Of note, proportions in each column do not sum to 100% as a patient could name more than one factor that influenced where they initially sought care.

[Table 1. Factors reported for selection of first provider for evaluation of symptoms among newly diagnosed tuberculosis patients in Zambia, according to HIV-status (n=340)

CONCLUSIONS: Delays ≥4 weeks to TB presentation were common, especially among PWH, and factors influencing engagement in TB services differed substantially by HIV-status.

PEB0136

EFFECT OF TUBERCULOSIS INFECTION ON MORTALITY AMONG HIV-INFECTED PATIENTS IN NORTHERN TANZANIA

E. Mollel[1], J. Todd[2], M. Mahande[1], S. Msuya[1]

[1]Kilimanjaro Christian Medical University College, Department of Epidemiology and Biostatistics, Moshi, Tanzania, United Republic of, [2]London School of Hygiene and tropical Medicine, Department of Population Health, London, United Kingdom

BACKGROUND: Despite the decreasing burden of these two diseases they still make a significant contribution to mortality. TB is still a burden among HIV patients.

METHODS: Routine data over 6 years from Care and Treatment Centres in three regions of Northern Tanzania were analyzed, using Poisson regression with frailty model was used to analyze the data to determine mortality rates.

RESULTS: The overall mortality rates for PLHIV is 28.4 (95% CI 27.6-29.2), while for those who had not TB is 26.2 (95% CI 25.4-27.0), and for those with HIV/TB co-infection is 57.8 (95% CI 55.6-62.3). The mortality rates for HIV/TB patients has always been higher than for PLHIV with no TB over the six-year period. The following subgroups were significantly associated with mortality among PLHIV; age 35-44 years and age above 55 years, adjusted rate ratios (ARRs) of 1.30 (95%CI 1.05-1.61) and 1.88 (95% CI 1.50-2.37) respectively. Female sex ARR of 0.62 (95% CI 0.56-0.69), body weight 40-60kg and above 60kg with ARRs of 0.50 (95% CI 0.43-0.58) and 0.26 (95%CI 0.22-0.31) respectively. Those with HIV/TB co-infection had ARR of 1.4 (95% CI 1.24-1.67) and those with moderately and severely poor nutritional status had ARRs of 1.61 (95% CI 1.39-1.85) and 1.90 (95% CI 1.24-2.90) respectively. Among HIV/TB patients, interactions for mortality was observed between TB and the following independent variables; female sex ARR 0.63 (95%CI 0.53-0.75) , HIV stage 4 ARR 1.74 (95% CI 1.16-2.62) and having moderate nutritional status ARR 1.28 (95% CI 1.03-1.61).

CONCLUSIONS: The mortality rates for HIV/TB patients has always been higher than for PLHIV who have no TB over the six-year period. More efforts should be directed into improving nutritional status among HIV patients, as it has destructive interaction with TB for mortality. This will improve patients' body weight and CD4 counts which are protective against mortality. Also attention should be given to those who are in WHO HIV stage 3 or 4 and having TB co-infection.

PEB0137

TUBERCULOSIS AND CRYPTOCOCCAL CO-MORBIDITY AMONG PATIENTS WITH ADVANCED HIV DISEASE IN LESOTHO

V. Tukei[1], M. Mungati[1], F. Asiimwe[2], M. Mokone[1], I. Oboho[3], E. Agyemang[4], R. Machekano[5], L. Maama-Maime[6], A. Masheane[6], A. Tiam[5], H. Paulin[3]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Maseru, Lesotho, [2]US Centers for Disease Control and Prevention, Maseru, Lesotho, [3]US Centers for Disease control and Prevention, Atlanta, United States, [4]US Centers for Disease control and Prevention, Maseru, Lesotho, [5]Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington DC, United States, [6]Lesotho Ministry of Health, Maseru, Lesotho

BACKGROUND: Tuberculosis (TB) and cryptococcal disease are frequent co-morbidities in patients with advanced HIV disease (AHD). We aimed to determine the prevalence of these co-morbidities among AHD patients in two district hospitals in Lesotho to inform programmatic interventions.

METHODS: We enrolled a cohort of newly diagnosed HIV-positive patients with AHD (aged ≥15 years) to receive World Health Organization–recommended AHD interventions (November 2018–May 2019) in Berea and Motebang hospitals. Patients were screened for TB with the 4-symptom screen at every visit with further evaluation of patients who screened positive. Patients with laboratory-confirmed TB (Xpert MTB/RIF) initiated anti-TB treatment. Isoniazid preventive therapy (IPT) was offered to patients without TB symptoms. Patients with CD4 ≤100 cells/μL (or per clinical judgment) were screened for serum Cryptococcal antigen (CrAg), followed by cerebrospinal fluid (CSF) CrAg, if serum CrAg positive. Patients were treated for cryptococcal meningitis or cryptococcemia. Data were abstracted from routine records and summarized as proportions.

RESULTS: Of 110 enrolled AHD patients, 56.9% were men, and the median age was 38 years. At baseline, 36 (32.7%) patients screened positive for TB symptoms; 66 (60.0%) screened negative, and 8 (7.3%) were receiving TB treatment. Of the 36 patients with TB symptoms, 17 were confirmed TB cases, resulting in a baseline TB prevalence of 22.7% (25/110). Fifty-six (84.8%) of 66 patients with negative symptom screen were started on IPT. Four patients developed TB symptoms during follow-up of whom three (75.0%) were confirmed TB cases and treated.

Of 70 (63.6%, n=110) patients with baseline CD4 results, 36 had CD4 ≤100 cells/μL, and 32 (88.9%) underwent serum CrAg screening. Of these, five patients had positive serum CrAg result and underwent CSF CrAg screening, and four had positive results; all five were treated for meningitis.

CONCLUSIONS: TB infection was common in our AHD patient cohort, and 1 in 8 patients with CD4≤100cells/mm3 had cryptococcal meningitis. AHD interventions for TB and cryptococcal disease should be prioritized.

PEB0138

SCREENING AND TREATMENT STRATEGIES FOR LATENT TUBERCULOSIS INFECTION IN NEWLY HIV DIAGNOSED PEOPLE LIVING IN LOW-ENDEMIC COUNTRY: A SIMULATION FOR ITALY

L. Timelli[1], S. D'Amato[2], E. Girardi[1]
[1]"L. Spallanzani" National Institute for Infection Diseases, IRCCS, Rome, Italy, [2]Ministry of Health, Rome, Italy

BACKGROUND: People living with HIV are at increased risk for tuberculosis (TB), even in a low-incidence TB country. WHO recommends screening newly HIV diagnosed people (NHIVP) for Latent Tuberculosis Infection (LTBI) and providing preventive treatment (PT). Screening for LTBI in all NHIVP is currently recommended by Italian guidelines; however, its potential impact has not been evaluated. We aimed to estimate the effect of this intervention in a low-incidence TB country considering different strategies of LTBI screening and PT, based on CD4 cells count level and area of origin.

METHODS: Primary outcome was the absolute number of TB cases averted through PT. We simulated the incidence of TB in five year after HIV diagnosis, according to 4 LTBI screening strategies: screening all NHIVP (S1); screening all NHIVP with CD4 count<200 copies/ml (S2); screening foreign-born NHIVP with CD4 count<200 cells/ml (S3); screening all foreign-born (S4). The model was based on compartments linked to each other by probabilities of transition. The definitions and values of the model parameters were derived from literature review. We run the simulation on a cohort of NHIVP distributed by level of CD4 count and country of birth as newly diagnosed cases reported in Italy over the past 5 years (from the Italian Surveillance System). We assumed 90% of NHIVP started antiretroviral therapy immediately upon HIV diagnosis.

RESULTS: The cohort consisted of 17,218 NHIVP, 71% Italians and 29% foreign-born persons of whom 23% from a high-burden country. Thirty-six percent both of Italian and low-TB-burden country born, had CD4 count<200 copies/ml versus 40% of high-TB-burden country born. Without LTBI screening/PT, 118 TB cases are expected over a 5-years period with an Event Rate (ER) of 1.42 per 1,000 person-years. Under S1 strategy 73 cases are expected (ER=0.88, a Relative Risk Reduction (RRR)=38.1%), 104 cases with S2 (ER=1.25, RRR=11.9%), 107 cases with S3, (ER=1.30, RRR=9.3%), and 84 cases with S4 (ER=1.01, RRR=28.8 %).

CONCLUSIONS: Screening and treatment of LTBI would have a moderate impact if implemented for all NHIVP (S1) or limited to foreign-born persons (S4), while its impact would be minimal for other strategies. This simulation provide the basis for a cost-effectiveness analysis.

PEB0139

A COMPARATIVE ANALYSIS OF ADHERENCE AND COMPLETION RATES IN TB PREVENTIVE THERAPY (TPT) AMONG PEOPLE LIVING WITH HIV ON 3-MONTHS & 6-MONTHS MULTI-MONTHS ART DISPENSING

K. Kakanfo[1], U. Akpan[2], I. Iyamu[3], H. Khamofu[1], M. Bateganya[4], T. Badru[2], A. Olarinoye[2], C. Obanubi[5], E. James[5], S. Raj Pandey[1]
[1]Family Health International (FHI360, Nigeria), Akwa Ibom, Nigeria, [2]Achieving Health Nigeria Initiative, Nigeria, Akwa Ibom, Nigeria, [3]University of British Columbia , Vancouver, Canada, School of Population and Public Health, Vancouver, Canada, [4]Family Health International (FHI360, Nigeria), Technical Support, Durham, United States, [5]United States Agency for International Development (USAID), Nigeria, Care & Treatment , Office of HIV/AIDS & TB, Abuja, Nigeria

BACKGROUND: Multi-month dispensing (MMD) of antiretroviral therapy (ART) can reduce the pressure on already overburdened health systems. As more programs transition patients to longer refill intervals, the impact of spaced client visits with medications as TB preventive Therapy (TPT) remains unknown. We sought to compare adherence to completion rates of TPT among patients on MMD at comprehensive HIV centers in Akwa Ibom State.

METHODS: A retrospective review of routinely collected program data for stable HIV infected patients on ART and TPT between March 2017 and October 2018 was done with data collected from initiation of TPT to 6 months after TPT initiation .Adherence was assessed as good (≥95%) or poor (<95%) while TPT completion was assessed as either completed or not at the end of 6 months. De-identified data extracted from client records were analyzed using SPSS ver. 20. Data was summarized using descriptive statistics and multivariable logistic regression was used to determine differences in adherence and completion rates between the MMD groups.

RESULTS: With total of 917 patients on MMD initiated on IPT, with a mean age of 39.3 years (SD: 11.6). Of these, 648 (70.7%) were females and the median duration on ART was 4 years (IQR: 2 years - 6 years). Majority of patients were on MMD6 (n = 642; 70.0%), while 275 (30.0%) were on MMD3. Adherence to TPT was 95.6% (n=263) among patients on MMD3 compared with 98.3% (n=631) among those on MMD6 (p=0.19). In addition, 95.6% (n=263) of patients on MMD3 completed TPT compared with 98.4% (n=631) among those on MMD-6 (p=0.011). In multivariable analysis, patients on MMD-3 similar odds of being adherent to TPT (aOR = 0.46 95% CI: 0.12-1.13, p=0.09) and completing TPT (aOR = 0.49, 95% CI: 0.20-1.19, p=0.12) compared with patients on MMD-6, adjusted for age, sex and duration on ART.

CONCLUSIONS: Overall, adherence to TPT and TPT completion rates were good in both MMD models. We also found that TPT adherence and completion rates were comparable both MMD-3 and MMD-6. MMD-6. However, client centered care approaches should be considered in implementing differentiated models of care for clients also receiving TB Preventive therapy.

PEB0140

HIGH PREVALENCE OF VENOUS THROMBOEMBOLIC DISEASE AMONG HIV PATIENTS CO-INFECTED WITH DRUG-RESISTANT TB IN LESOTHO

D. Holtzman[1], M. Asfaw[1], L. Maama[2], P. Nkundanyirazo[1], L. Oyewusi[1]
[1]Partners In Health - Lesotho, Maseru, Lesotho, [2]Lesotho Ministry of Health, Maseru, Lesotho

BACKGROUND: Venous thromboembolism (VTE) is an important medical condition that can be triggered by conditions causing systemic inflammation, including HIV and tuberculosis. Case series have reported on the occurrence of VTE among TB patients but none have examined VTE among drug-resistant (DR) TB exclusively. We describe the prevalence of VTE among DR TB patients in Lesotho with high rates of HIV co-infection.

METHODS: A retrospective cohort study of VTE among DR TB patients enrolled into an observational cohort was conducted. Participants enrolled between October 2015-June 2018 were included. The study database and pharmacy records were searched for adverse events and anticoagulant prescriptions to identify VTE cases. Manual file review was performed to confirm VTE diagnosis. Univariate analyses were conducted for relevant covariates.

RESULTS:

Variable	VTE (N=17, 8%)	No VTE (N=194, 92%)
Median age (years)	41	43
Female	10 (59%)	67 (35%)
HIV positive	16 (94%)	154 (79%)
Baseline CD4 (cells/mm^3)	187	202
Baseline VL (copies/ml)	419,718	328,424
Ever hospitalized*	16 (94%)	123 (63%)
Hospitalized before VTE	12 (71%)	--
Median time from TB treatment initiation to VTE diagnosis (days)	69	--
* p-value < 0.05		

[Table]

211 individuals were enrolled into the cohort and 17 (8%) developed VTE (Table 1). Most patients were HIV-positive (94% of VTE cases, 79% of those without VTE) with low baseline CD4 counts and high viral loads. Most patients were hospitalized prior to their VTE diagnosis (71%); the median time from TB treatment initiation to VTE diagnosis was 69 days. There were no significant differences in TB treatment outcomes between patients with and without VTE and the majority (69%) of patients had a favorable TB treatment outcome although mortality was high (23%).

CONCLUSIONS: VTE was a common co-morbidity among this DR TB cohort with high HIV co-infection. The true prevalence of VTE was likely higher due to underdiagnosis of asymptomatic VTE cases and pulmonary emboli. The early onset of VTE in most cases suggests an initial hypercoagulable state after start of TB and HIV treatment. Further study is needed to better understand the factors associated with VTE among HIV/DR TB co-infected patients in order to reduce occurrence of VTE in this population and mitigate the associated morbidity and mortality when VTE occurs.

PEB0141

DO PEOPLE LIVING WITH HIV/AIDS KNOW AND ADHERE TO ISONIAZID PREVENTIVE THERAPY?: FINDINGS FROM SELECTED FACILITIES IN SOUTH-EAST NIGERIA

I. Okedo-Alex[1], I. Akamike[2], L. Ogbonnaya[2]
[1]Alex Ekwueme Federal University Teaching Hospital Abakaliki, Community Medicine, Abakaliki, Nigeria, [2]Alex Ekwueme Federal University Teaching Hospital, Abakaliki, Ebonyi State, Nigeria, Community Medicine, Abakaliki, Nigeria

BACKGROUND: Isoniazid preventive therapy (IPT) is an important component of collaborative tuberculosis (TB) and human immunodeficiency virus (HIV) care aimed at reducing the burden of TB in People Living with HIV (PLHIV). The objective of this study was to assess the knowledge and adherence to isoniazid preventive therapy among PLHIV in selected facilities in South-East Nigeria

METHODS: A cross-sectional survey was carried out in 2019 in six of the eight public and private high patient load (>100 HIV patients) health facilities providing comprehensive HIV care in Ebonyi State, South-East Nigeria. Systematic random sampling using proportionate allocation was used to select 200 PLHIV on HIV care for at least 6 months in the selected facilities. Information was collected using interviewer-administered questionnaires and patient treatment cards. Adherence was assessed by self-reports as adherence grading was not done for any of the treatment cards assessed. Descriptive, bivariate and multivariate logistic regression analyses were conducted using SPSS version 20. Statistical tests were conducted at 5% level of significance.

RESULTS: Respondents were mostly females (females:147, 73.5%) with an overall mean age of 39.4±10.3 (females: 42.5±9.2, males: 38.4±10.5). Over half of them had ever received IPT (110, 55%) and been counseled on IPT (124, 62,0%). Few of the respondents (35, 17.5%) were on IPT during the study. Most respondents (120, 60%) had poor knowledge of IPT and this was higher in females (73.3% vs 26.7%, P=0.949). Only 22 (11%) and 82 (41.0%) knew the name of the drug used for IPT and the duration of IPT respectively. Marital status was the only predictor of IPT knowledge (AOR=1.96; 95% CI:1.03–3.74; P=0.041). Among those who were on IPT, the majority (32, 91.4%) reported good adherence in the 30 days preceding the survey. Only one patient (0.5%) had missed taking IPT in the 3 days preceding the survey.

CONCLUSIONS: There was poor knowledge of IPT among the respondents however self-reported adherence was high. We recommend intensification of general and personalized education of PLHIV on IPT by health workers. Routine adherence assessment and documentation should also be strengthened among health workers.

PEB0142

SENSITIVITY AND SPECIFICITY OF XPERT ULTRA AND PREDICTIVE VALUE OF SYMPTOMS OF TUBERCULOSIS IN PATIENTS NEWLY DIAGNOSED WITH HIV

N. Dorvil[1], O. Ocheretina[1], C. Riviere[1], P. Severe[1], H. Bang[2], J. Devieux[3], L. Kerlyne[1], S. Bousleiman[4], D. Emelyne[1], A. Apollon[1], B. Charles[1], G. Saintyl[1], M. Faustin[1], V. Rivera[5], R. Berman[4], E. Orvis[4], S. Koenig[6], J.W. Pape[1]
[1]GHESKIO, Port-au-Prince, Haiti, [2]UC Davis, Davis, United States, [3]Florida International University, Miami, United States, [4]Analysis Group, Boston, United States, [5]Cornell University, Ithaca, United States, [6]Brigham Women's Hospital, Boston, United States

BACKGROUND: The WHO recommends excluding active tuberculosis (TB) before starting ART in patients with HIV. However, with the new recommendation for rapid ART, TB diagnostic testing must be completed quickly.

METHODS: In a sub-study of a larger randomized trial, we tested all patients with cough, fever, night sweats, or weight loss at HIV diagnosis with both spot and early morning Xpert Ultra and mycobacterial culture. We compared the sensitivity, specificity, and predictive power of each of the four symptoms, as well as weight loss in combination with low BMI. We also calculated the sensitivity and specificity of spot and early morning Xpert Ultra in patients with culture-positive TB.

RESULTS: 487 patients with cough, fever, night sweats, or weight loss were enrolled in this study, and 56 (11.5%) were diagnosed with culture-positive TB. Of these, 40 (71.4%) were Xpert Ultra positive on a spot specimen, 45 (80.4%) were positive on early morning specimen, and 49 (87.5%) were detected with either spot or early morning specimen. All patients with Xpert positive TB were also culture positive. See Table 1 for predictive values and sensitivity and specificity of each symptom.

CONCLUSIONS: Early morning Xpert Ultra is more sensitive than a spot specimen for detection of TB at HIV diagnosis. Sensitivity is highest if if Xpert Ultra is conducted on both spot and early morning specimens. Isolated weight loss had a low positive predictive value for TB, however, weight loss in combination with BMI < 18.5 had a positive predictive value greater than cough.

	Negative predictive value	Positive predictive value	Sensitivity	Specificity
Cough	93.4	26.5	73.1	65.1
Fever	93.4	26.5	73.1	65.1
Night sweats	88.9	34.8	35.8	88.5
Isolated weight loss	63.6	14.1	94.0	1.8
Weight loss with BMI < 18.5	89.9	30.7	46.2	82.1

[Table 1]

PEB0143

SURVIVAL OF TUBERCULOSIS/HIV CO-INFECTED PATIENTS BETWEEN 2009 AND 2013

E.M. Brand[1], L.B. Teixeira[1], M. Rossetto[2], K.d.S. Calvo[1], G.B. Winkler[1], F.V. Machado[1], L.C. da Silva[1], S.C. Vasques[1]
[1]UFRGS, Porto Alegre, Brazil, [2]UFFS, Chapecó, Brazil

BACKGROUND: Tuberculosis is the infectious disease with the highest mortality rate in the world. The risk of death in individuals with tuberculosis increases in cases of HIV coinfection. The aim of this study was to analyze the survival time of cases of tuberculosis (TB)/HIV coinfection in Porto Alegre, Brazil.

METHODS: Retrospective cohort study conducted with patients with TB/HIV co-infection enrolled between 2009 and 2013. The survival analysis compared patients according to entry classification (new cases, relapses, re-entry after abandonment and transfer) and whether or not the treatment was directly observed (DOT). The statistical techniques used were Kaplan Meier survival curves and Cox regression models. The significance level adopted was 5%.

RESULTS: Of the 2,417 cases of coinfection, 25.8% died. Entry and hospitalization situation were risk factors, and the performance of DOT a protective factor. New cases had a 4.58 times greater risk of death (p = 0.032; 95% CI 1.14-18.4), relapse 4.51 (p = 0.035; 95% CI 1.11-18.4), and re-entry after abandonment a 4.54 times greater risk (p = 0.034; 95% CI 1.12-18.4) in relation to the transfer. The performance of DOT gave a protection rate of 41% for the death event (p<0.001; 95% CI 0.45-0.77). Cases that were hospitalized during follow-up were 4.06 times more likely to die than those who were not (p<0.001; 95% CI 3.28-5.04).

The overall cumulative probability of survival dropped to 79.6% in 12 months. Considering the comparison by entry status, the probability of survival at 12 months was 75.7% for new cases, 80.9% for recurring cases, 86.5% for re-entry after abandonment, and 94.7% for transferred cases (p<0.05). Patients receiving DOT were more likely to survive throughout the period (p <0.01).

CONCLUSIONS: The predictors of death were the type of entry and occurrence of hospitalization. There is a large drop in the probability of survival of co-infected patients over 84 months. This difference is greater in the first 12 months. New and relapsed cases are the groups that are least likely to survive and thus constitute priority groups. The study shows that performing DOT contributes to the likelihood of survival, especially in the first year

OPPORTUNISTIC INFECTIONS (EXCLUDING TB): BACTERIAL, NON-TB MYCOBACTERIAL, VIRAL AND PARASITIC INFECTIONS

PEB0144

THE FREQUENCY AND YIELD OF CRYPTOCOCCAL ANTIGEN SCREENING AMONG NEWLY DIAGNOSED AND ANTI-RETROVIRAL THERAPY EXPERIENCED HIV PATIENTS IN RURAL UGANDA

J.B. Baluku[1,2], P. Mugabe[1], S. Mwebaza[1], J. Nakaweesi[1], C. Senyimba[1], B. Mukasa[1]
[1]Mildmay Uganda, Programs, Wakiso, Uganda, [2]Mulago National Referral Hospital, Internal Medicine, Kampala, Uganda

BACKGROUND: The World Health Organisation recommends screening for the cryptococcal antigen (CrAg), a predictor of cryptococcal meningitis, among newly diagnosed HIV positive patients with a CD4 count of <100 cells/mm3. The frequency and yield of cryptococcal antigen screening among antiretroviral therapy (ART)-experienced HIV patients is not well established in programmatic settings. We compared the frequency and yield of CrAg screening among newly diagnosed HIV patients with CD4<100 cells/mm3 and ART-experienced patients with suspected virological failure (viral load >1000 copies/ml) attending rural public health facilities in Uganda.

METHODS: We analysed data from publicly available programmatic reports on CrAg screening from 107 health facilities in 8 rural districts in Uganda from January 2018 to July 2019. A serum CrAg is used as the screening test for cryptococcal disease in Uganda. We compared the frequency of screening and yield of CrAg positivity among newly diagnosed HIV patients with CD4<100 cells/mm3 and ART-experienced patients with suspected virological failure (viral load >1000 copies/ml) using Pearson's chi-square test.

RESULTS: Among the 15,417 newly diagnosed HIV patients during the period under study, 37.1% were offered a CD4 count measurement of which 16.4% (937/5,719) had a CD4 <100 cells/mm3. Also, of 71,860 ART experienced HIV patients, 10% were reported to have suspected virological failure. CrAg testing was performed among 891 (95.1%) and 830 (11.5%) (p<0.001) newly diagnosed HIV positive with CD4<100cells/mm3 and ART-experienced patients with suspected virological failure respectively. Similarly, CrAg positivity was reported to be 13.8% (123/891) and 10.5% (87/830) (p=0.035) among newly diagnosed HIV positive with CD4<100cells/mm3 and ART experienced with suspected virological failure respectively. CrAg positivity among newly diagnosed and ART experienced patients differed by district (p<0.001) and level of health facility (p<0.001).

CONCLUSIONS: There was a low frequency of screening and a high yield of CrAg positivity among ART-experienced HIV patients with suspected virological failure. The lack of guidelines for the screening of cryptococcal disease in this population contributes to the low screening rate and thus a large proportion of these patients with cryptococcal disease is missed. We recommend an evaluation of the cost effectiveness of screening ART-experienced HIV patients with suspected virological failure in programmatic settings.

PEB0145

CMV CO-INFECTION IN HIV ELITE CONTROLLERS: IMPORTANCE FOR DISEASE PROGRESSION AND INFLAMMATION

S. Isnard[1,2], R. Ramendra[1,2], J. Lin[1,2], B. Fombuena[1,2], J. Ouyang[1,2,3], X. Peng[1,2,4], D. Sohail Ahmed[1,2], C. Tremblay[5], N. Bernard[5], J.-P. Routy[1,2]
[1]McGill university Health Centre, Montréal, Canada, [2]McGill University, Infectious Diseases and Immunity in Global Health Program, Montréal, Canada, [3]Chongqing Public Health Medical Center, Chongqing, China, [4]National Clinical Research Center for Infectious Diseases, The First Affiliated Hospital, College of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China, [5]Centre de Recherche du Centre Hospitalier de l'université de Montréal, Montréal, Canada

BACKGROUND: We recently demonstrated that CMV co-infection was associated with a lower CD4/CD8 ratio, and high levels of gut damage, microbial translocation and inflammatory markers in people living with HIV (PLWH) under antiretroviral therapy (ART). Elite controllers (EC), a subgroup of PLWH, can maintain plasma HIV viremia below 50 copies/mL without antiretroviral therapy. However, EC present with increased risk of developing non-AIDS comorbidities due to persisting inflammation. Herein, we evaluated the link between CMV seropositivity, disease progression and microbial translocation among EC.

METHODS: Blood samples and clinical parameters were collected from 25 EC of the Canadian Slow progressor cohort. EC had viremia <50 copies/ml and were ART-naïve. We categorized EC regarding their expression of protective HLA alleles (B*27, B*57, B*58). CD4 and CD8 T-cell counts, CMV seropositivity were assessed clinically. Plasma levels of anti-CMV IgG, gut damage marker Intestinal fatty acid binding protein (I-FABP), microbial translocation markers lipopolysaccharide (LPS) and β-D-Glucan (BDG) were measured by ELISA.

RESULTS: Seventy-six percent of EC participants, followed for a median of 7 years, were CMV seropositive. CMV seropositive and seronegative EC presented with similar age, male/female ratio, CD4 and CD8 T-cell counts and CD4/CD8 ratio.

The median annual CD4 count variation tended to be different between CMV seropositive (-6.1 CD4 per year [IQR -35.1;13.3]) compared to seronegative EC (+14.1 [-3.7;54)], p=0.1). Anti-CMV IgG titer correlated inversely with annual CD4 count variation (r=-0.48, p=0.02) in EC participants. Moreover, compared to their seronegative counterpart, CMV seropositive EC had elevated plasma levels of I-FABP (p=0.03), LPS (p=0.003) and BDG (p=0.05).

Protective HLA allele were expressed by 50% of the EC. As expected, EC with protective HLA alleles had higher CD4 T-cell count compared to those without protective alleles (p=0.03). However, the expression of protective HLA alleles was not associated with differences in annual CD4 count variation nor inflammatory markers.

CONCLUSIONS: CMV co-infection, irrespectively of the expression of protective HLA alleles, was associated with CD4 decay, possibly linked with increased gut damage and inflammation. Therefore, co-infection with CMV emerges as an important contributor to disease progression and chronic inflammation in HIV elite controllers.

PEB0146

PATHOGENIC SPECTRUM AND CLINICAL CHARACTERISTICS OF PULMONARY FILAMENTOUS FUNGAL INFECTION IN AIDS PATIENTS IN GUANGDONG AREA

L. Li[1], Y. Cao[1], F. Liu[2], W. Chen[1], D. Gong[1], F. Hu[1], W. Cai[1], X. Tang[1]
[1]Guangzhou Eighth People's Hospital, Infectious Diseases, Guangzhou, China, [2]Guangzhou Red Cross Hospital, Guangzhou, China

BACKGROUND: Filamentous fungal infection is increasing in AIDS patient, however, its spectrum is unclear. This study aims to explore the pathogenic spectrum and clinical features of pulmonary filamentous fungal infection in AIDS patients in Guangdong, providing evidence for diagnosis improvement.

METHODS: We used the molecular biological method to identify 143 filamentous strains and then analyzed the clinical characteristics. All strains were obtained from the culture of bronchoalveolar lavage fluid (BALF) of 143 AIDS cases complicated with pneumonia in Guangzhou Eighth People's Hospital.

RESULTS: 110 males and 33 females were enrolled with an average age of 43.3±12.2 years. Of the 143 isolates, 56 were identified as Aspergillus spp. (39.2%), 37 were Talaromyces marneffei (TM) (25.9%), 22 were Penicilium spp. (15.4%), and 28 were other genera of filamentous fungi (19.6%). The top three species of Aspergillus spp. included Aspergillus fumigatus (24 strains), Aspergillus niger (9 strains), and Aspergillus flavus (7 strains).

The top three species of Penicilium spp. included Penicillium nucleatum (4 strains), Penicillium meleagrinum (3 strains), and Penicillium oxalicum (3 strains). The top three of other genera included Cladosporium (5 strains), Paecilomyces variabilis (5 strains), Schizophyllan, and Spodoptera (3 strains each). Of the 143 patients, 110 (76.9%) had fever. The main respiratory symptoms consisted of cough (73.4%), expectoration (58.0%), and anhelation (41.3%). The major abnormalities of chest CT manifested as diffuse infection (83.2%), pleural effusion (30.8%), thoracic lymphadenopathy (31.5%), and miliary lesions (8.4%).

The median CD4+ T lymphocyte count was 31.5 (0-63) cells/μl and 92.8% were below 50 cells/μl. The CD4+ cell counts of different genus infections were listed from the highest to the lowest as follows: Penicillium spp. (53.5 cells/μl), Aspergillus spp. (24.5 cells/μl), other genera (22 cells/μl), and TM (15 cells/μl) (P<0.05). The primary laboratory abnormalities included elevated erythrocyte sedimentation rate (55.2%), leukopenia (32.9%), leukocytosis (13.3%), anemia (58.7%), and thrombocytopenia (16.1%). After receiving antifungal therapy, 121 patients (84.6%) were cured or improved on discharge, and 22 cases (15.4%) were discharged due to deterioration or died.

CONCLUSIONS: The pathogenic spectrum of filamentous fungal infection in AIDS patients is diverse, but mainly consists of TM and Aspergillus fumigatus; The clinical manifestations lack specificity.

SEVERE ANAEMIA IS ASSOCIATED WITH LATENT TUBERCULOSIS AMONG PEOPLE LIVING WITH HIV

M. Daniel[1,2], L. Osborn[1], J. Gersh[3], A. Warr[4], S. LaCourse[3], K. John[1,5], D. Horne[6,7], KNH-UW Team

[1]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [2]Maseno University, Public Health, Kisumu, Kenya, [3]University of Washington, Medicine, Division of Allergy and Infectious Diseases, Seattle, United States, [4]University of Washington, School of Medicine, Seattle, United States, [5]Kenyatta National Hospital, Reproductive Health, Nairobi, Kenya, [6]University of Washington, Global Health, Seattle, United States, [7]University of Washington/Harborview Medical Center, Medicine, Division of Pulmonary, Critical Care, and Sleep Medicine, Seattle, United States

BACKGROUND: Anaemia is associated with significant adverse health outcomes in people living with HIV (PLHIV) including poor survival, decreased quality of life, and accelerated disease progression to acquired immune deficiency syndrome (AIDS). We assessed prevalence and correlates of severe anaemia in PLHIV participating in a cross-sectional study on evaluation of World Health Organization (WHO) screening tool for tuberculosis (TB).

METHODS: We analyzed baseline data from adult PLHIV who were isoniazid preventive therapy (IPT)-naïve or had completed IPT at least 6 months before enrollment and were receiving HIV treatment in Ahero and Bondo County hospitals in Kenya. A structured questionnaire was used to determine frequency and correlates of anaemia. Blood samples were collected for HIV viral load (VL) and full haemogram, while sputum samples were collected for tuberculosis (TB). Tuberculin skin test (TST) was done to evaluate for latent TB infection (LTBI). We Used the WHO definition of severe anaemia (Hb <8.0g/dl), Correlates of severe anaemia in PLHIV were estimated by prevalence ratios (PR) using multinomial logistic regression.

RESULTS: Fifty-eight percent [225] of study participants were female and the median age was 37 years [IQR 31-45]. Median hemoglobin was 14.3 [IQR 13.1-15.3 g/dL] and 11.7 [IQR 10.1-12.9 g/dL] for males and females respectively. Overall, 41% of participants were anaemic, with 17%, 18% and 6% having mild, moderate and severe anaemia, respectively. Five [1.3%] PLHIV were co-infected with active TB and 126 [32%] with LTBI. In multivariate analysis, male sex [aPR 0.07, 95% CI:0.01-0.51], current employment [aPR 0.42, 95% CI: 0.21-0.83], and number of years being on ART [aPR 0.88 per year, 95% CI: 0.83-0.95] were associated with decreased risk of severe anemia while LTBI [aPR 1.25, 95% CI:1.08-1.44] and erythrocyte sedimentation rate (ESR) [aPR 1.04 per mm/h, 95 % CI: 1.01-1.06] were associated with increased risk of severe anaemia.

CONCLUSIONS: We identified high prevalence of anaemia among PLHIV with active TB or LTBI. Our data suggests potential benefit of screening PLHIV with evidence of LTBI for severe anaemia.

RACIAL/ETHNICAL DISPARITIES IN HCV TESTING AMONG MSM IN HIV CARE

J. Li[1], C. Armon[2], F. Palella[3], E. Tedaldi[4], R. Novak[5], J. Fuhrer[6], G. Simoncini[4], S. Puriton[7], K. Buchacz[8]

[1]CDC, Division of HIV/AIDS Prevention, Atlanta, United States, [2]Cerner Corporation, Kansas City, United States, [3]Northwestern University Feinberg School of Medicine, Chicago, United States, [4]Lewis Katz School of Medicine at Temple University, Philadelphia, United States, [5]University of Illinois College of Medicine, Chicago, United States, [6]Renaissance School of Medicine at Stony Brook University, Stony Brook, United States, [7]Cerner Coroporation, Kansas, United States, [8]CDC, Atlanta, United States

BACKGROUND: Liver-related mortality, primarily due to HCV, is a leading non-AIDS cause of death for persons with HIV (PWH) in the United States (US). National guidelines recommend that sexually active PWH who are men who have sex with men (MSM) be tested for HCV at least annually depending on the presence of high-risk sexual or drug use practices. HCV testing rates vary substantially by race/ethnicity in the general population. We hypothesized that race and ethnicity may also play a role in uptake of HCV testing among HIV-positive MSM.

METHODS: We analyzed medical records data from MSM in the HIV Outpatient Study (HOPS) receiving care at nine US HIV clinics during 01/01/2011-12/31/2018. We excluded participants who had a positive HCV antibody (AB) or HCV RNA (viral load, VL) test before or at baseline. Additionally, we censored observation for participants after their first positive HCV AB or VL test. We evaluated HCV AB testing in each calendar year of follow up among HCV-seronegative MSM. Generalized estimating equations analyses were performed to assess factors associated with receiving an HCV AB test.

RESULTS: Of 1,780 eligible MSM, 1,158 were non-Hispanic (NH) white, 387 NH black, 174 Hispanic, and 61 of other race/ethnicity. Most participants were ≥ 40 years (70.1%), with CD4 count ≥ 350 cells/mm3 (78.2%), and with HIV viral load < 200 copies/mL (77.9%). During 2011-2018, 1,133 (63.7%) men had any HCV AB testing with varying levels by race/ethnicity (71.8% for NH-black, 69.5% for Hispanic, and 63.9% for other race/ethnicity, 60.0% for NH-white, P < 0.001). Annual HCV testing levels during 2011-2018 were the highest for NH-black (34.2%) men, followed by those for men of other race/ethnicity (32.0%), Hispanic (31.9%), and NH-white (28.1%). In multivariable longitudinal analysis, NH-blacks were more likely to undergo an HCV test than NH-whites (OR=1.35; 95% confidence interval =1.13, 1.62). Other factors associated with HCV testing (P ≤ 0.001) included hepatitis B diagnosis and elevated aspartate aminotransferase/alanine aminotransferase levels.

CONCLUSIONS: Low HCV testing rates in all racial/ethnic groups indicate suboptimal performance of recommended HCV screening. The underlying causes of black-white difference in HCV testing need to be further investigated.

PEB0149

PREVALENCE AND PREDICTORS OF TOBACCO USE IN PATIENTS LIVING WITH HIV/HCV CO-INFECTION: FINDINGS FROM A LARGE URBAN TERTIARY CENTER

O. Sims[1], A. Jackson[2], Y. Guo[3], D. Truong[1], H. Mamudu[4]
[1]University of Alabama at Birmingham, Birmingnam, United States, [2]Yale University, New Haven, United States, [3]University of North Carolina Charlotte, Charlotte, United States, [4]East Tennessee State University, Johnson City, United States

BACKGROUND: Although tobacco use is the leading preventable cause of morbidity and mortality in the United States and a co-risk factor for hepatocarcinogenesis in patients with HCV, there is limited data on tobacco smoking behaviors in HCV patients with HIV co-infection (HIV/HHCV). This study aimed to access prevalence and predictors of tobacco use among patients living with HIV/HCV co-infection.

METHODS: Patient report outcomes (PROs) of patients with HIV/HCV co-infection (n=313) who presented for clinical evaluation and treatment of HCV between 2013-2017 at a university-affiliated clinic were analyzed. Patients completed several questionnaires on tobacco smoking, alcohol and substance use, and depression and anxiety. Laboratory and other medical data were extracted from electronic medical records. Binomial logistic regression was used to identify predictors of tobacco smoking.

RESULTS: The mean age was 52±11.1 years, and the majority of patients were African American (56%) and insured (87%). Patients were aware of their HCV diagnosis for 7±7.3 years and aware of their HIV diagnosis for 14 (9.3) years. The prevalence of tobacco use in patients with HIV/HCV co-infection was 48%. Of those who reported number of cigarettes smoked per day, 47% (82/174) and 36% (63/174) smoked ½-1 and 1-2 packs of cigarettes per day. Compared to non-smokers, a higher proportion of tobacco smokers had substance use disorders (29% vs. 44%, p=0.00), and concurrent alcohol and substance use (21% vs. 40%, p=0.000). Tobacco smokers and non-smokers did not differ in any other clinical characteristics. In multivariate analysis, concurrent alcohol and substance use (OR=3.059, p=0.011) was positively associated with tobacco smoking.

CONCLUSIONS: This study identified major disparities in the prevalence of tobacco smoking (among patients with HIV/HCV co-infection) compared to the national use rate (48% vs. 15%), and tobacco smoking was positively associated with alcohol and/or substance use. Findings suggest that tobacco smoking cessation interventions, especially pharmacological alone interventions, may be suboptimal if these respective interventions fail to integrate behavioral approaches to reduce both alcohol and substance use in patients with HCV/HIV co-infection. Otherwise, patients with HIV/HCV co-infection may be at greater risk for hepatocarcinogenesis compared to HIV patients without HCV co-infection.

PEB0150

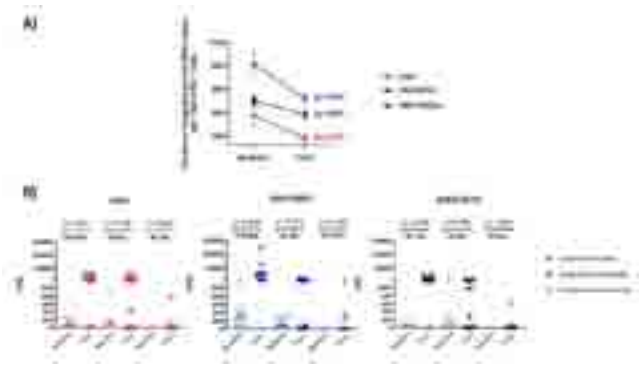
EVOLUTION OF HIV RESERVOIR AND VIRAL SPLICING AFTER THE ELIMINATION OF HCV WITH DAAS IN HIV/HCV PATIENTS

P. Martínez Román[1], C. Crespo Bermejo[1], S. Arca Lafuente[1], M.R. López Huertas[1], I. Cortegano[1], L. Martín Carbonero[2], P. Ryan[3], I. de los Santos[4], J.M. Castro Álvarez[2], M. Gálvez Charro[2], M. Matarranz del Amo[3], J. Sanz Sanz[4], S. Resino[1], A. Fernández Rodríguez[1], M. Coiras[1], V. Briz[1]
[1]Institute of Health Carlos III, Majadahonda, Spain, [2]Instituto de Investigación Sanitaria Hospital de la Paz, Madrid, Spain, [3]Hospital Infanta Leonor, Madrid, Spain, [4]Hospital Universitario de La Princesa, Madrid, Spain

BACKGROUND: Previously, we observed an increase in HIV reservoir size in patients exposed to HCV (HIV+/HCV+ coinfected and HIV+/HCV- spontaneous clearers) compared to HIV+ monoinfected subjects in resting CD4 T cells (rCD4). We also observed an increase in multiple spliced RNA viral transcripts in HCV-exposed patients that could indicate that viral protein regulator Tat was being more actively synthesized leading to a higher yield of new HIV particles. However, the effect of HCV elimination with direct-acting antivirals (DAAs) on HIV reservoir and viral splicing remains unclear.

METHODS: Longitudinal study (52 weeks follow-up) in 50 aviremic patients: 19 HIV+/HCV+, 16 HIV+/HCV- and 15 HIV+ subjects. Using different Alu-LTR PCRs, viral spliced RNA transcripts and the number of proviral DNA copies integrated in rCD4 cells were quantified. Paired samples were analyzed using a generalized mixed linear model.

RESULTS:



[Figure.]

All HIV+/HCV+ patients achieved sustained virological response after taking DAAs. A decrease in HIV proviral DNA was observed at the end of follow-up only in HCV exposed patients: HIV+/HCV- (Baseline: 1354.8 vs Final: 871.1 HIV DNA copies/10e6 cells;p=0.019); HIV+/HCV+ (693.8 vs 551.8; p=0.057) (FigA). All forms of viral splicing had an increased ΔRQ at the end of follow-up (FigB). However, only unspliced RNA transcripts showed a significant increase: HIV+ (251.95x ΔΔRQ; p=0.002); HIV+/HCV- (116.46x; p=0.000); HIV+/HCV+ (170.12x; p=0.000).

CONCLUSIONS:

1) Evolution of HIV reservoir size in previously HCV-exposed patients showed a decrease in the number of proviral DNA copies in rCD4 cells. However, HIV reservoir size remains higher than in HIV+ group.
2) A significant increase in unspliced viral transcripts does not condition the replenishment of the viral reservoir.
3) Our results show that clearance of HCV from HIV-infected patients reinstate the dynamics of HIV reservoir.
Early treatment of HCV in coinfected patients that do not spontaneously clear the infection could suppose a better prognosis of HIV infection in these patients.

PEB0151

COSTS AND CLINICAL OUTCOMES OF A SIMPLIFIED HCV TREATMENT ALGORITHM FOR UKRAINE

K. Chew[1], S. Antoniak[2], Y. Stopolianska[2], M. Freiman[3], T. Barnard[4], C. Chasela[2,5], M. Gandhi[1], I. Sanne[6,2], I. Ivanchuk[7], S. Antonyak[8], V. Tretiakov[9], J. Dible[4], T. Minior[4], C. Cavenaugh[4], F. Marange[2], T. Xulu[2], S. Rosen[10], EQUIP HEALTH

[1]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, United States, [2]Right to Care, EQUIP, Centurion, South Africa, [3]Boston University, Boston, United States, [4]U.S. Agency for International Development, Kiev, United States, [5]University of Witwatersrand, Epidemiology and Biostatistics, Johannesburg, South Africa, [6]University of Witwatersrand, School of Clinical Medicine, Johannesburg, South Africa, [7]100%Life, Kyiv, Ukraine, [8]Gromashevsky Research Institute of Epidemiology and Infection Diseases, Medical Academy of Sciences of, Kiev, Ukraine, [9]Alliance for Public Health, Kyiv, Ukraine, [10]Boston University Boston, MA, USA, School of Public Health, Boston, United States

BACKGROUND: Access to hepatitis C virus (HCV) testing and treatment for key populations is limited in Ukraine. We conducted a demonstration project of an integrated HIV and viral hepatitis testing and HCV treatment strategy using generic ledipasvir/sofosbuvir (LDV/SOF).

METHODS: Eligible HCV viremic adults recruited from key populations at two clinics in Kyiv were treated with LDV/SOF +/- weight-based ribavirin for 12 weeks. Clinical assessments were performed at screening and week 24 and as needed; treatment was dispensed every 4 weeks. The primary outcome was sustained virologic response (SVR)12 weeks after treatment. Program costs in 2018 USD were estimated per patient treated using observed resource utilization, local unit costs, and antiretroviral therapy (ART) costs for HIV+ participants over the 24-week period.

RESULTS: Among 522 participants (79% HCV genotype 1, 19% genotype 3), of whom 85% were people who inject drugs and 52% HIV-positive, nearly all (511, 97.8%) achieved SVR. Only 7 (1.3%) failed therapy, 3 (0.6%) were lost to follow up, and 1 (0.2%) died. The average cost (standard deviation) per patient treated was $678 ($304), assuming generic LDV/SOF and ribavirin pricing ($102/course) and standard quantitative HCV viral load testing ($33.71/test) in the central laboratory in Kyiv. Medications comprised 38% of the average cost/patient, laboratory tests 26%, events (clinic visits, counselling) 10%, and indirect costs 26%. ART accounted for 60% of all drug costs, with HCV medications just 40%. Standard viral load testing cost less than other platforms in the project, but GeneXpert® (Cepheid) HCV at point of care (POC) may cost less ($27.54/successful test) at higher-volume implementation scale.

CONCLUSIONS: Generic LDV/SOF +/- ribavirin provided in public sector clinics produced exceptionally good outcomes at an average cost <$700/patient year, including ART for those with HIV. For budgeting purposes, under the assumption of generic drug pricing and decreased real-world effectiveness (lower SVR), an average cost of $750/patient is likely a reasonable estimate for this intervention for Ukraine, excluding costs for scaling up or maintaining the treatment program, such as procurement, training, management, and oversight. Use of POC GeneXpert® to confirm HCV viremia could increase access to testing and treatment in this setting.

PEB0152

HIGH SVR WITH LEDIPASVIR/SOFOSBUVIR +/- RIBAVIRIN AMONG PWID AND PWH IN UKRAINE

S. Antoniak[1], Y. Stopolianska[1], C. Chasela[1,2], T. Barnard[3], S. Antonyak[4], T. Xulu[1], T. Minior[5], C. Cavanaugh[5], F. Marange[1], K. Chew[6], I. Sanne[1,7,6], EQUIP Health

[1]Right to Care, EQUIP, Centurion, South Africa, [2]University of Witwatersrand, Epidemiology and Biostatistics, Johannesburg, South Africa, [3]U.S. Agency for International Development, School of Public Health, Kiev, Ukraine, [4]Gromashevsky Research Institute of Epidemiology and Infection Diseases, Medical Academy of Sciences of, Kiev, Ukraine, [5]U.S. Agency for International Development, Kiev, United States, [6]Boston University Boston, MA, USA, School of Public Health, Boston, United States, [7]University of Witwatersrand, School of Clinical Medicine, Johannesburg, South Africa

BACKGROUND: Access to hepatitis C virus (HCV) treatment for key populations, including people who inject drugs (PWID) and people with HIV (PWH), is limited in Ukraine. We evaluated an integrated HIV and viral hepatitis testing and HCV treatment strategy using generic ledipasvir/sofosbuvir (LDV/SOF).

METHODS: Key populations (PWID, PWH, men who have sex with men, sex workers, and sexual partners of HCV+ persons) were screened for HCV, HIV, and HBV. Eligible HCV viremic adults were treated with LDV/SOF +/- weight-based ribavirin for 12 weeks. Clinical assessments were performed at screening and week 24 and as needed driven by on study symptoms or events. Treatment was dispensed every 4 weeks. Participants on ribavirin had additional haemoglobin monitoring. Those newly diagnosed with HIV were linked to antiretroviral therapy prior to HCV treatment initiation. The primary outcome was sustained virologic response (SVR) at 12 weeks after treatment.

RESULTS: 868 participants initiated treatment at two sites in Kyiv, Ukraine, 98% HCV treatment naïve, 55% HIV co-infected (67 were newly diagnosed with HIV through the project, of which 6 enrolled in HCV treatment), 0.7% HBV co-infected, 87% PWID, and 8% cirrhotic. Most (64%) were male, with a median age of 39 years. GT1 and 3 were most common (74% and 22%). Six hundred fifty-four (75.3%) participants received LDV/SOF alone and 214 (24.7%) also received ribavirin. 865 (99.7%) completed the treatment course; five were lost to follow-up after treatment completion and 860 were assessed for SVR at 24 weeks. The overall SVR rate was 97% (842/868); 96% for GT3 and PWH (184/191 and 462/482, respectively). There were 80 adverse events, and all of them but one death (due to myocardial infarction) were mild or moderate, with 70 (87.5%) drug related, of which 88.6% (62/70) were due to ribavirin and the rest to LDV/SOF. There were no treatment discontinuations due to adverse events.

CONCLUSIONS: Generic LDV/SOF +/- ribavirin was highly effective amongst PWID and PWH, regardless of HCV genotype, delivered at public health clinics in Kyiv, Ukraine. LDV/SOF may be an effective therapeutic option in settings with limited access to pan-genotypic HCV treatment regimens, but requires the capacity for HCV genotyping.

PEB0153

CREATING A MULTI-SITE HCV CARE CASCADE FOR HIV/HCV CO-INFECTED PERSONS RECEIVING CARE IN 11 CT CLINICS USING DATA TO CARE METHODS

R. Brooks[1], M. Wegener[1], S. Speers[2], L. Nichols[1], C. Rizk[1], T. Valeriano[1], H. Jenkins[2], M. Villanueva[1]
[1]Yale University, New Haven, United States, [2]CT Department of Public Health, Hartford, United States

BACKGROUND: There is currently no available Hepatitis C (HCV) cascade of care for persons with HIV/HCV co-infection for Connecticut. Individual clinics have created localized treatment cascades for their own use, but statewide and/or multi-site care cascades have not been created due to incomplete HCV surveillance data, lack of standardized matching algorithms and inability to determine HCV care status. Such data is important for assessing treatment gaps that prevent achievement of micro-elimination targets.

METHODS: A combination of state-wide health surveillance and local clinical conferencing was used to establish a list of HIV/HCV co-infected individuals obtaining clinical care at 11 HIV clinics from January 2009 - September 2018. Statewide HIV surveillance data (eHARS) was combined with individual clinic rosters to define persons living with HIV (PLWH) who had received HIV care in this time frame. These were matched to the Connecticut HCV surveillance database (CTEDSS) using a validated algorithm. Clinic-specific co-infected patient lists were reviewed by clinic data personnel to determine current HCV treatment status for those deemed treatment eligible (e.g. treatment initiated, SVR documented, untreated but in clinical care) as well as additional determinations such as deceased, incarcerated, relocated, lost to care or transferred. These were used to generate a multi-site HCV cascade of care that was updated over time to reflect changes in treatment status.

RESULTS: A total of 7265 names were on clinic rosters as receiving HIV-related services; 2117 matched to HCV surveillance, representing 1496 unique patients. As of January 1, 2020, patients were: treatment eligible (N=855, 57%), deceased (N=304, 20%), cleared virus spontaneously (N=124, 8%), relocated out of state (N=90, 6%), transferred to non-project facilities (N=96, 6%), antibody negative (N=27, 2%). Among the treatment eligible group: 604 initiated treatment (71%), 591 completed treatment (69%), and 553 had documented SVR (65%).

CONCLUSIONS: This work emphasizes the feasibility of creating a care cascade for HIV/HCV using health department surveillance together with clinic-specific data. The determined SVR rate is better than other published care cascades, including for mono-infected individuals. Patients who have not achieved SVR are a heterogeneous group including individuals lost to care. Further study is needed to better characterize barriers to achieving cure.

OTHER VIRAL HEPATITIS (E.G., A, B, D, E)

PREDICTORS ASSOCIATED WITH BETTER RESPONSE TO JAPANESE ALUMINUM-FREE HEPATITIS A VACCINE TO JAPANESE PEOPLE LIVING WITH HIV: LESSONS FROM THE HEPATITIS A OUTBREAKS IN TOKYO

M. Koga[1], T. Tsutsumi[1], T. Senkouji[1], M. Kubota[1], M. Saito[1], K. Okushin[2], K. Ikeuchi[1], T. Kikuchi[1], E. Adachi[1], T. Koibuchi[1], A. Kawana-Tachikawa[3], K. Hosomich[4], T. Matano[3], H. Yotsuyanagi[1]
[1]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [2]The University of Tokyo, Graduate School of Medicine, Tokyo, Japan, [3]AIDS Research Center, National Institute of Infectious Diseases, Tokyo, Japan, [4]Kanazawa University, Graduate School of Medical Sciences, Knazawa, Japan

BACKGROUND: HAV infections are predominantly seen among MSM in Japan and only limited MSM-LWHIV obtain anti-HAV antibody (16.9%) as of 2017. After the recent outbreak of HAV in Tokyo, the importance of HAV vaccination has been emphasized especially for MSM-LWHIV. Hepatitis A vaccine used in Japan, Aimmugen®, has been licensed and distributed exclusively in Japan. It is lyophilized, whole-virion, inactivated, aluminum-free and recommended to give three doses for the general population, however, it is reported that 85% of recipients acquire seroprotection against HAV after the second doses. We performed retrospective analyses to evaluate the efficacy of two/ three doses and the predictors associated with the response to Aimmugen® in MSM-LWHIV.

METHODS: We retrospectively examined anti-HAV IgG titers who were injected Aimmugen® between January 2018 and October 2019 in IMSUT Hospital, Tokyo, at the baseline and after each dose. The subjects' data including age, the history of AIDS, the duration of ART, BMI, smoking habits, CD4 count, CD4/8 ratio, HIV-RNA at the first vaccination, human leukocyte antigen (HLA) and killer cell immunoglobulin-like receptors association tests were collected.

RESULTS: One hundred forty-one subjects were examined and all were MSM. The titers of anti-HAV IgG were all negative before vaccination. Median age, CD4 count, CD4/8 ratio, were 46 years old, 615/μl, 0.88, respectively. The proportion of subjects with undetectable HIV-RNA was 97.2%. The acquisition rate of protectable anti-HAV IgG titers (>1.0 S/CO) after the second, the third dose was 71.1%, 98.6% respectively. The median of anti-HAV IgG level after the second, the third dose was 2.14 s/co [IQR: 0.87-4.82], 9.96 s/co [6.95-11.6], respectively. In 114 subjects whose anti-HAV IgG titers were tested after the second dose, factors significantly associated with better response were longer duration of ART, higher CD4 count and the possession of *HLA-DPA1*02:01* (p=0.009, 0.02, 0.018, respectively).

CONCLUSIONS: The acquisition of anti-HAV IgG titer of PLWH with the Aimmugen® inoculation greatly varied among individuals. In addition to long sustainable control of HIV replication resulted in an increasing number of CD4 cell counts, possession of *HLA-DPA1*02:01* may play an important role in the improvement of acquired immune systems in PLWH.

PEB0155

HIGH CO-INFECTION WITH HBV, HCV AND SYPHILIS, AND LOW CD4/CD8 RATIO AMONG HIV/AIDS PATIENTS IN GUANGZHOU, CHINA 2014-2017

D. Chen[1], G. Luo[1], L. Li[2], G. Xu[2], Y. Zhou[1], M. Li[1], H. Zou[1,3]
[1]Sun Yat-sen University, School of Public health (Shenzhen), Shenzhen, China, [2]Eighth People's Hospital, Guangzhou, China, [3]Kirby Institute, University of New South Wales, Sydney, Australia

BACKGROUND: Co-infections with HBV, HCV, and syphilis among HIV/AIDS patients are common. CD4/CD8 ratio is of significant importance to immune-recovery. The purpose of our study is to understand co-infection with HBV, HCV and syphilis, as well as CD4/CD8 ratio among HIV/AIDS patients in Guangzhou, China.

METHODS: Data on HIV, HBV, HCV and syphilis, as well as CD4 and CD8 T cell counts were retrieved from the national HIV/AIDS information system in China for HIV/AIDS patients attending the Eighth People's Hospital of Guangzhou in China, a designated hospital specializing in infectious diseases. T-test and rank sum test were used to compare means or medians between two groups. Pearson's Chi-square test and Fisher's exact test were used to compare proportions between two groups. Factors associated with co-infections were assessed using multivariate logistic regression.

RESULTS: 2783 HIV/AIDS patients were included, with a mean age of 38 ± 12 years. 95.1% were Han ethnicity, 87.2% were males and 25.2% were younger than 30 years old. 27.3% were infected with at least one of HBV, HCV and syphilis. The co-infection rates of HBV, HCV and syphilis were 14.0%, 2.9% and 12.6%, respectively. Compared with men who have sex with men (MSM), heterosexual men had a higher rate of HBV co-infection (OR=1.48, 95% CI: 1.14-1.91) and intravenous drug users had a higher rate of HCV co-infection (OR=271.60, 95% CI: 109.22-675.40). The co-infection rate of syphilis in women was lower than that in men (OR=0.15, 95% CI: 0.06-0.37). Median CD4/CD8 ratio was 0.30 (IQR: 0.15-0.40). CD4/CD8 ratio was higher in patients under 30 years than those above 30 years (0.33 vs 0.29, $P < 0.001$).

CONCLUSIONS: Rates of co-infection with HBV, HCV and syphilis were high and differed by age and HIV transmission route. CD4/CD8 ratio among HIV/AIDS patients was low. Screening and treatment of co-infections was of great importance. Efforts are needed to detect HIV-infected people as earlier stage so as to maintain reasonable CD4/CD8 ratio.

PEB0156

SEROLOGIC RESPONSE TO HEPATITIS A VACCINATION AMONG HIV-INFECTED INDIVIDUALS

T. Muramatsu[1], T. Hagiwara[1], A. Ichiki[1], Y. Chikasawa[1], M. Bingo[1], R. Sekiya[1], K. Yokota[1], M. Yotsumoto[1], K. Amano[1], K. Fukutake[1], E. Kinai[1]
[1]Tokyo Medical University Hospital, Laboratory Medicine, Shinjuku, Japan

BACKGROUND: Recently, acute hepatitis A outbreaks caused severe epidemics throughout the world. After the outbreak of hepatitis A among men who have sex with men in Tokyo from 1998 to 1999, we started a hepatitis A vaccination program for HIV-infected patients who are seronegative for protective antibodies.

METHODS: We analyzed the data of the patients who participated in this vaccination program from 2013 to 2019. Three-dose vaccination of lyophilized inactivated aluminum-free hepatitis A vaccine (Aimmugen) was administered for HAV antibody negative HIV-infected patients. Serology samples for hepatitis A virus antibody titers were taken 4–12 weeks later. Anti-hepatitis A virus antibody titers were measured by a chemiluminescent immunoassay. The seroconversion rate was determined, and the influence of several factors including CD4 cell counts, CD4/CD8 ratio, plasma viral load of HIV, smoking status, hepatitis B core antibody, and hepatitis C antibody were evaluated.

RESULTS: Four hundred and sixty-two patients were analyzed in this study. 99.2% were men, 98.9% were Japanese. Median age was 39 (IQR 32-45) years. 270 (58%) were hepatitis B core antibody positive, 15 (3.3%) were hepatitis C antibody positive. 178(38.5%) were active smokers. Median CD4/CD8 ratio was 0.63 (0.46-0.87) and median CD4 cell count was 548.5 (417.2-715.3).

In total, 427 (92.4%) cases turned positive for hepatitis A virus antibody after the initial series of vaccination. Among who did not show serologic response, one patient developed acute hepatitis A. The factor associated with seroconversion was higher CD4/CD8 ratio (per 0.50 increase, adjusted odds ratio, 3.12; 95% confidence interval, 1.25-7.79, p = 0.015).

CONCLUSIONS: Hepatitis A vaccination was effective for HIV-infected patients. Higher CD4/CD8 ratio was associated with higher serologic response to hepatitis A vaccination. We need to promote vaccination to prevent ongoing transmission.

PEB0157

HEPATITIS B CO-INFECTION IN HIV-INFECTED PATIENTS RECEIVING MULTI-DRUG RESISTANT TUBERCULOSIS (MDRTB) TREATMENT AT THE BOTSABELO HOSPITAL IN LESOTHO

L. Oyewusi[1], M. Tamirat[1], M. Stephanie[2], J. Makaka[1], M. Mofolo[1], M. Ndayizigiye[1], K. Seung[3], P. Nkundanyirazo[1], D. Holtzman[1]
[1]Partners in Health Lesotho /Bo-Mphato Litšebeletsong tsa Bophelo, Maseru, Lesotho, [2]Ministry of Health, Maseru, Lesotho, [3]Brigham and Women's Hospital, Medicine, Boston, United States

BACKGROUND: Lesotho is facing a high burden of infectious diseases including HIV and TB. Hepatitis B is known to be highly prevalent in regions with a high burden of HIV and causes liver injuries that often exacerbate the liver toxicity of drug-resistant TB treatment. Previously, there was no documented evidence of any association between hepatitis B and HIV co-infection in Lesotho. Our study aimed to assess the rate of hepatitis B and HIV co-infection among a cohort of Rifampicin Resistant Tuberculosis (RR TB) patients in Lesotho.

METHODS: A cohort of patients with RR TB patients enrolled in endTB observational study in Lesotho from October 2015 to September 2018 was studied. All patients were screened for hepatitis B (Hepatitis B Surface Antigen), HIV, malnutrition, anaemia and alcohol use at baseline and results were captured in patients files and Electronic Medical Record (EMR) system. We used existent aggregated and verified data to assess the proportions of hepatitis B and other co-morbidities in the cohort.

RESULTS: Among the 244 patients enrolled for the observational study, Hepatitis B Surface Antigen positivity rate was 7.4% (18). 94% (17) of patients with hepatitis B co-infection also had HIV co-infection compared to 79% of patients without hepatitis B co-infection. Rates of baseline liver injury were common among participants with and without hepatitis B co-infection (6% in both groups). However, the average baseline values of alanine aminotransferase and aspartate aminotransferase were higher among individuals with hepatitis B co-infection.

CONCLUSIONS: We found a significant rate of hepatitis B co-infection among HIV positive, MDRTB patients. This finding confirms the need for testing HIV positive patients for Hepatitis B and the need to design an algorithm for the management of hepatitis B infection in Lesotho.

PEB0158

BURDEN OF HUMAN PAPILLOMAVIRUS INFECTION AMONG HIV POSITIVE WOMEN IN NORTH CENTRAL NIGERIA: A CROSS SECTIONAL STUDY

M.M. Yakub[1], C.G. Anaedobe[2], A. Fowotade[3], M.M. Manga[4], R.A. Bakare[3], B.A. Abimiku[5]
[1]Federal Medical Center, Department of Medical Microbiology and Parasitology, Keffi, Nasarawa, Nigeria, [2]University of Abuja Teaching Hospital, Department of Medical Microbiology and Parasitology, Gwagwalada, Abuja, Nigeria, [3]University College Hospital, Department of Medical Microbiology and Parasitology, Ibadan, Nigeria, [4]Federal Teaching Hospital, Department of Medical Microbiology and Parasitology, Gombe, Nigeria, [5]University of Abuja Teaching Hospital, Department of Histopathology and Forensic Medicine, Gwagwalada, Abuja, Nigeria

BACKGROUND: Cervical cancer is the second most prevalent cancer among women in Nigeria and infection with high risk human papillomavirus (HPV) genotypes is the major cause of cervical cancer. The risk of acquiring HPV is higher in HIV infected women due to immune suppression and HIV modifying effect on HPV pathogenesis. In Nigeria, women particularly those who are HIV infected are under-represented in the global estimate of HPV infection. There is a dire need to emphasize HPV screening programs for accurate data on its epidemiology and effective control interventions.
METHODS: Between August 2016 and May 2017, 220 HIV-positive women attending the antiretroviral clinic of the Federal Medical Center, Keffi in Nigeria, were enrolled in a cross sectional cohort study. Cervical samples obtained were tested for cervical HPV infection using PCR while HPV genotypes were determined by DNA sequencing. Sociodemographic data were obtained using questionnaires, CD4 count and HIV viral load were retrieved from their case files and data analyzed using SPSS version 20.
RESULTS: Of the 220 HIV-positive women, HPV DNA was detected in 119(54.1%) and high risk HPV in 79(35.9%). Nineteen genotypes in varying combinations were detected with majority 10/19(52.6 %) of the high risk genotype. A total of 25/119 (21%) of the HPV- positive women had multiple HPV genotypes; predominantly of the high risk HPV 22/25 (88%). Among the 214 HIV-positive women with abnormal cytology report, 54(25.3%) had cervical pre-cancerous and cancerous lesions, almost all 53/54(98.2%) were high risk HPV. The risk of being HPV positive was significantly higher among women with CD4 count <200 and HIV viral load > 20,000 copies/ml. No significant association was found with the sociodemographic factors.
CONCLUSIONS: We found that low CD4 count and high HIV viral load are significantly associated with HPV infection. HIV-positive women infected with multiple HPV genotypes or diagnosed with pre-cancerous and cancerous cervical lesions had predominantly the high risk HPV genotypes. Increased HPV /high risk HPV screening and cervical cytology for risk stratification is necessary among HIV positive women.

PEB0159

PREVALENCE AND CHARACTERISTICS OF ANAL PAPILLOMAVIRUS INFECTION IN A COHORT OF HIV-POSITIVE MEN WHO HAVE SEX WITH MEN IN LIMA, PERU

J.A. Collins[1], M. Soria[2], R. Castillo[1], O. Malpartida[1], D. Cerrón[3], J. Ballena[3], R. Illescas[1], for the Almenara Hospital AIDS Working Group
[1]Almenara Hospital, EsSalud, Infectious Diseases Service, Lima, Peru, [2]Almenara Hospital, EsSalud, Cytopathology and Genetics Service, Lima, Peru, [3]Almenara Hospital, EsSalud, Infectious Disease Fellow, Lima, Peru

BACKGROUND: Human papillomavirus (HPV) is associated with anal cancer, which is more common in HIV-positive people. However, there is little data on anal papillomavirus infection in HIV-positive men in our country. We aimed to determine the prevalence and characteristics of anal HPV infection in HIV-positive men who have sex with men (MSM).
METHODS: Prospective cross-sectional observational study of HIV-positive MSM at our center between September 2017 and December 2018. HPV detection and typing was performed using a polymerase chain reaction technique that evaluated 21 genotypes: six low-risk (6, 11, 42, 43, 44 and 81) and 15 high-risk (16, 18, 31, 33, 35, 39, 45, 51, 52, 53, 56, 58, 59, 66 and 68).
RESULTS: We evaluated 224 HIV-positive MSM (mean age: 42 years [SD: 12], mean length of HIV infection: 10 years [SD: 8], mean CD4 cell count: 514 cell/mm3 [SD: 232]). The HPV infection prevalence in the cohort was 71% (159/224). Multi-virus anal infection, i.e. infection with two or more HPV genotypes, occurred in 71% (113/159) of cases. Of these, 76% (86/113) had two to four different genotypes. In the group of mono-viral anal HPV infection the occurrence of high-risk genotypes was 59% (27/46). The most frequent low-risk genotypes were 6 and 11, with 30% each (47/153). The most frequent high-risk genotypes were 16, 33, 52, 58, 31, 39 and 45 with 33% (53/159), 22% (35/159), 21% (34/159), 21% (34/159), 20% (32/159), 20% (32/159) and 19% (30/159) respectively. The frequency of genotype 18 reached 8% (13/159).
CONCLUSIONS: HPV anal infection in HIV-positive MSM is very high in our center. Infection with multiple HPV genotypes is the rule. The distribution of papillomavirus genotypes is similar to that of other series or regions. These findings emphasize the importance of vaccination against papillomavirus in HIV-positive carriers, especially MSM, to prevent anal cancer.

PEB0160

CLINICAL AND LABORATORY ASPECTS OF PATIENTS WITH ASYMPTOMATIC NEUROSYPHILIS AND HIV INFECTION TREATED WITH CEFTRIAXONE: A RETROSPECTIVE COHORT

A..L. De Castro Conde Toscano[1], J.V. Bermudez[1], T. Newman Lobato de Souza[1], E. Prevelato Athaide Filho[1]
[1]Emilio Ribas Infectious Diseases Institute, Day Hospital, São Paulo, Brazil

BACKGROUND: PLHIV have higher rates of persistence of T. pallidum in the CNS even in the early stages of syphilis, leading to higher rates of CNS involvement and its complications. Current recommendations indicate the preferential use of crystalline penicillin for all neurosyphilis presentations. However, ceftriaxone has greater dosage convenience than crystalline penicillin. This study aims to describe data from HIV-infected patients diagnosed with asymptomatic neurosyphilis treated with ceftriaxone at Emilio Ribas Infectious Diseases Institute (IIER).

METHODS: An observational, retrospective study was conducted from 2015-2018 at IIER. Eligibility criteria were age 18+, HIV+; first diagnosis of neurosyphilis; use of ceftriaxone (ten consecutive days). Patients with symptomatic neurosyphilis were excluded. Information analyzed included demographic, previous syphilis occurrence, stage of syphilis, serum findings, CD4 T cell count (CD4+), HIV viral load (HIV-VL), regular use of ART and posttreatment laboratory response. Fisher's exact tests were used for for univariate and binary logistic regression. A p value <0.05 was considered statistically significant.

RESULTS: A total of 149 patients were identified. Sixty-one individuals were included in the final analyzes. Males accounted 96.7% of cases, with mean age of 39 years. The median CD4+ was 629 cells/mm^3 and 80% of participants were on HAART. Twenty-four (39.3%) had previously been diagnosed with syphilis. 86.2% had normalization of serum and/or CSF VDRL titres. Forty-nine (80.3%) patients had control serum VDRL records, form which 38 (77.5%) had adequate titration reduction within 12 months. Thirty-four patients (55.7%) had control CSF VDRL, 27 (79.4%) with adequate response within 12 months.Twenty-one patients achieved CSF cell count reduction. Undetectable HIV-VL was higher (although not statistically significant) in the group with CSF response (90.4%) p = 0.071. Twenty (74.0%) patients with adequate reduction in CSF titre, had a serum control exam. An adequate reduction in serum VDRL was observed in 16 (80%) patients. A similar percentage value (83.3%) was found for adequate serum response among individuals without CSF response.

CONCLUSIONS: In our study, most of our patients were young males, in a work active age and high levels of CD4+. Ceftriaxone allows treatment in Day Hospital regime and might be considered as an alternative to treat neurosyphilis in PLHIV.

PEB0161

INTEGRATING HPV TESTING FOR CERVICAL CANCER SCREENING IN WLHIV IN ZAMBIA

M.J. Chaila[1], J. Matambo[2], D. Ojok[2], M. Phiri[2], D. Chanda[1], S. Chanda[1], S. Sichamba[1], J. Banda[3], S. Kapambwe[1], A. Kabalo[1]
[1]Ministry of Health, Department of Health Promotions, Environment & Social Determinants, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia (CIDRZ), Lusaka, Zambia, [3]Jhpiego, Lusaka, Zambia

BACKGROUND: Zambia has an estimated cervical cancer (CaCx) incidence rate of 66.4/100,0000. CaCx remains the most common cancer accounting for nearly 30% of all cancers diagnosed and cause more cancer deaths. The Ministry of Health (MOH), established the national CaCx screening program in 2006 using Visual Inspection with Acetic Acid (VIA) enhanced with digital cervicography. Recently, WHO made a call to eliminate CaCx through the 90-70-90 approach. The 70 target demands that 70% of eligible women are screened with a high-precision test at 35 and 45 years of age. We present Zambia's progress in integrating HPV testing for CaCx screening in WLHIV.

METHODS: A workshop was held in April 2019 to develop guidelines for HPV testing with support from Jhpiego and the Ministry of Health and Wellness from Botswana. Lessons from Botswana's fessibility study on HPV testing were adapted to fit the Zambian context. The Cobas-4800, GeneXpert and Hologic-Panther were validated at Centre for Infectious Disease Research in Zambia (CIDRZ) Central Laboratory and approved by MOH as primary tools for HPV testing. We present the preliminary findings on HPV testing done at CIDRZ Central Laboratory from November-December 2019 using the Hologic-Panther.

RESULTS: A total of 695 WLHIV submitted self-collected samples from Seven health centres in Lusaka district (Table 1). Two samples were insufficient. Of the 693 remaining samples, 46.9% (n=325) tested positive for HPV. About 13.3% (n=43) tested HPV16 of those that tested positive. Others were co-infections with HPV18/45 at 8.0% (n=26), HPV16/18/45 at 2.8% (n=9) and other high risk HPV at 76% (n=247).

SN	Item	Number	Percentage
1	**Cervical specimen collected**	**695**	**100.0**
	Specimen rejected (insufficient sample)	2	0.3
	Specimen tested	693	100.0
2	**Specimen tested**	**693**	**100.0**
	HPV Positive	325	46.9
	HPV Negative	368	53.1
3	**Genotype**	**325**	**100.0**
	HPV 16	43	13.2
	Co-Infection HPV 18/45	26	8.0
	Co-Infection HPV 16/18/45	9	2.8
	Other high risk HPV	247	76.0

[Table 1. HPV genotype in WLHIV screened for cervical cancer in Lusaka, Zambia]

CONCLUSIONS: It is possible to integrate HPV testing for CaCx screening in WLHIV in a country like Zambia where there is strong government commitment in a coordinated approach with implementing partners and support from other governments within the sub-region. HPV genotyping will help the country identify it's pandemic.

PEB0162

DRAMATIC INCREASE OF MACROLIDE RESISTANCE IN *TREPONEMA PALLIDUM* ISOLATES IN ARGENTINA

N. Morando[1], E. Vrbova[2], A. Melgar[3], R.D. Rabinovich[1], D. Šmajs[2], M.d.l.Á. Pando[1]
[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, Buenos Aires, Argentina, [2]Masaryk University, Department of Biology, Brno, Czech Republic, [3]Universidad de Buenos Aires, Hospital de Clínicas "José de San Martín", Programa de Enfermedades de Transmisión Sexual (PETS), Buenos Aires, Argentina

BACKGROUND: Globally, approximately 94% of *Treponema pallidum* (TPA) clinical isolates belong to the SS14-like group, 6% belong to the Nichols-like group and macrolide resistance ranges from 0 to 100%. A previous study revealed that Argentina has a different distribution pattern with a higher frequency of Nichols-like strains (27%) and low levels of macrolide resistance (14%). Several studies suggested that the molecular epidemiology of TPA is changing, so our goal was to update the information on circulating TPA strains in order to assess strain distribution and macrolide resistance frequency in Buenos Aires.

METHODS: Swab samples from patients with clinical symptoms of syphilis were collected during 2015-2018. DNA was isolated and three loci (TP0136, TP0548, 23S rRNA) were characterized by sequencing-based typing. Strains were classified into two clades based on similarity to reference sequences: Nichols-like and SS14-like. We determined the presence of macrolide resistance-associated mutations (A2058G, A2059G) by examination of the 23S rRNA gene sequence. The distribution of allelic profiles was based on combinations of TP0136, TP0548 and 23S rRNA sequences. Analyses were performed using Fisher´s exact test (IBM SPSS Statistics Base 22.0).

RESULTS: Among 32 swab samples 40.6% were classified as Nichols-like and 59.4% as SS14-like. Macrolide resistance prevalence was found to be 51.7%, being significantly more frequent among SS14-

like samples as compared with Nichols-like samples (70.6% (12/17) vs. 23.1% (3/12), respectively; p=0.0253). Nine distinct allelic profiles were found, four related to the SS14 strain and five related to the Nichols strain. Compared to a previously published study (samples collected in the same setting between 2006-2013, n=41), macrolide resistance significantly increased (51.7% vs. 14.3%, p=0.0012) between the studies. The frequency of Nichols-like strains increased (26.8% vs. 40.6%, p=0.31), but not with statistical significance.

CONCLUSIONS: Even though macrolide resistance isolates were previously detected at a relatively low frequency in Argentina, our results reveal a dramatic increase. Our results are in agreement with international tendencies and underscore the need to pursue further TPA molecular typing studies in Argentina and Latin America.

PEB0163

INCORPORATION OF SCREENING AND TREATMENT FOR SEXUALLY TRANSMITTED INFECTIONS INTO ROUTINE CARE FOR PATIENTS LIVING WITH HIV IN GABORONE, BOTSWANA

S. Dunin De Skrzynno[1], T. Carveth-Johnson[1], A. Wynn[1], N. Moshashane[1], K. Ramontshonyana[1], R. Lebelonyane[1], D. Ramogola-Masire[1], J. D. Klausner[1], C. Morroni[1]
[1]Botswana-UPenn Partnership (BUP), Botswana Sexual and Reproductive Health Research Initiative, Gabarone, Botswana

BACKGROUND: Screening for STIs during HIV care is not routinely offered in many countries and management is carried out based on symptoms, which misses asymptomatic infections. Chlamydia trachomatis (CT) and Neisseria gonorrhoea (NG) are treatable STIs associated with increased risk of HIV transmission. This study assessed the feasibility of incorporating screening for CT/NG into routine HIV care in Botswana, and the prevalence of CT/NG within this high-risk population.

METHODS: A prospective study was held at the HIV specialty clinic in Gaborone, Botswana between February and October 2019. Eligibility criteria included: ≥ 18 years, HIV-infected, and not treated for CT/NG in past month. Patients were recruited during vitals collection prior to being seen by a healthcare provider. Interested and eligible patients were offered informed consent, and were instructed on how to self-collect samples for CT/NG testing using a 4-module GeneXpert®, which allowed for 90-minutes to result.

Participants responded to a questionnaire on sociodemographic and health characteristics. Patients were offered same- day results in person or by telephone. Those who tested positive were given directly observed antibiotic therapy.

RESULTS: Among the 806 patients counselled in the vitals room, 526 (65%) expressed interest in participating. Due to personnel time limitations, 451 (86%) enrolled. Participant median age was 48 years, 66% were women, 98% were on ART, 93% had a recorded viral load, and among those, 95% had a viral load of ≤400 copies/ml. All participants provided self-collected samples, were successfully tested, and received results. Due to the 90-minute wait, most preferred to receive their results by phone (83%). The prevalence of CT/NG was 5%, including 16 with CT-only, 4 with NG-only, and 2 with dual infection. In bivariate comparisons, younger age and being female (7% in females compared to 1% in men) were associated with having CT/NG. Among those infected, 20 (91%) received same-day results, all were treated, including 4 (18%) on the same day as testing. With partner notification, among those infected, 19 preferred to notify partners themselves and 2 preferred not to notify.

CONCLUSIONS: It was feasible to integrate CT/NG testing into routine HIV care as all participants received testing, results, and treatment if appropriate.

PEB0164

EPIDEMIOLOGY OF HUMAN PAPILLOMAVIRUS GENOTYPES AND PREVALENCE OF CERVICAL PRECANCEROUS LESIONS AMONG WOMEN LIVING WITH HIV: RESULTS FROM A PILOT CERVICAL CANCER SCREENING PROGRAM IN UGANDA

S. Ndidde[1], M. Lubega[2], G. Senyama[2], Y. Kamuntu[2], A. Musoke[2], A. Abala[2]
[1]Uganda National Health Laboratory Services, Kampala, Uganda, [2]Clinton Health Access Initiative, Kampala, Uganda

BACKGROUND: There is lack of evidence on distribution of human papillomavirus (HPV) genotypes among women living with HIV (WLHIV) in Uganda. Yet, WLHIV are more likely to be infected with human papillomavirus (HPV) and to have persistent HPV progressing to cervical pre-cancer and/or invasive cervical cancer compared to HIV negative women. Information on epidemiology of high-risk HPV (hrHPV) infections and prevalence of specific HPV genotypes is very vital in mounting an effective response to the growing challenge of cervical cancer.

METHODS: A pilot cervical cancer screening program was conducted between September and December 2019. HPV testing using self-collected vaginal samples was offered to WLHIV aged 25 to 49 attending antiretroviral clinics in 7 high-volume hospitals. Samples were processed using GeneXpert. HPV+ women were referred for Visual Inspection with Acetic acid (VIA) triage, and those having a positive VIA test (precancerous lesions) treated with cryotherapy or thermocoagulation. Data was collected from hospital registers to determine the distribution of HPV genotypes and prevalence of cervical precancerous lesions among HPV positive WLHIV.

RESULTS: Across the 7 pilot sites, 1021 WLHIV were offered screening and 991 (97%) had a valid result. HPV positivity rate was 35% (349). Of the HPV+ women, 48 (14%) were HPV16 positive, 69 (20%) were HPV 18/45 and 235 (64%) had other hrHPV genotypes as a pooled result including HPV 31, 33, 35, 39, 51, 52, 56, 58, 59, 66 and 68. 35 (10%) of the women had multiple infections with hrHPV genotypes.

175 (50%) HPV+ women were linked to care and triaged with VIA and 54 (30%) were found with precancerous lesions, of whom 35 (64%) were treated with cryotherapy or thermocoagulation. Two women were found to be suspicious of cancer and referred for further management.

CONCLUSIONS: HrHPV infections are common among WLHIV, including HPV16 and 18 that cause majority of cervical cancer. A significant proportion of women have infections that progress to cervical pre-cancer. HPV+ WLHIV found to have no lesions need to be proactively followed-up to ensure that non-regressive infections are appropriately managed. Cervical cancer efforts need to intensify screening among WLHIV.

PEB0165

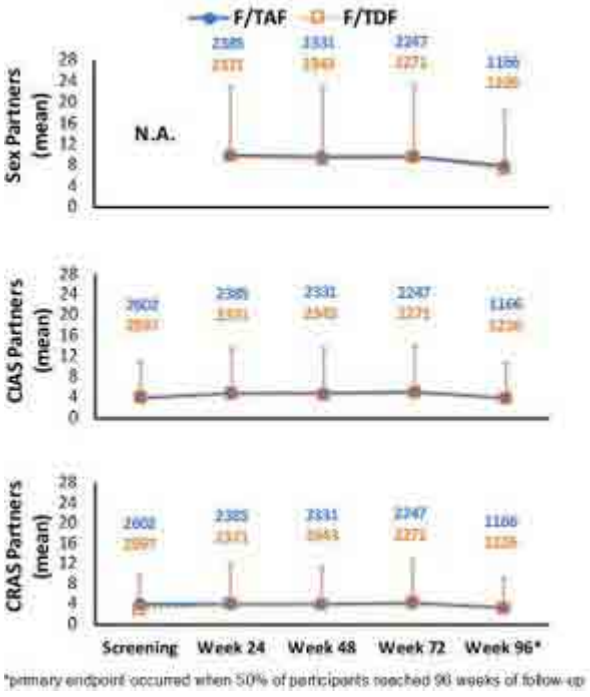
DISCOVER STUDY FOR HIV PRE-EXPOSURE PROPHYLAXIS (PREP): NO EVIDENCE OF RISK COMPENSATION IN PARTICIPANTS TAKING F/TDF OR F/TAF FOR PREP THROUGH 96 WEEKS

P. Shalit[1], K. Mounzer[2], L. Salazar[3], O. Dosekun[4], Y. Shao[5], P. Wong[5], R. Ebrahimi[5], M. Das[5], S. McCallister[5], D.M. Brainard[5], C.C. Carter[5], J. Hindman[5], P. Philibert[6], C. Kerr[7]

[1]Peter Shalit MD, Seattle, United States, [2]Philadelphia FIGHT, Philadelphia, United States, [3]St. Jude Hospital Yorba Linda. D.B.A. St. Joseph Heritage Healthcare, Newport Beach, United States, [4]Imperial College Healthcare NHS Trust, London, United Kingdom, [5]Gilead Sciences Inc., Foster City, United States, [6]Hôpital Européen Marseille, Marseille, France, [7]St. James's Hospital, Dublin, Ireland

BACKGROUND: In DISCOVER, emtricitabine plus tenofovir alafenamide (F/TAF) was non-inferior to F/tenofovir disoproxil fumarate (TDF) for prevention of HIV infection in participants who reported sexual behavior associated with HIV acquisition risk. Here, we report the baseline prevalence and longitudinal trends in HIV sexual risk behaviors during the DISCOVER trial, and assess for risk compensation, defined as an increase in risk behavior due to a reduction in perceived risk.

METHODS: DISCOVER is an ongoing multi-center randomized controlled trial in which 5,335 men who have sex with men (MSM) and transgender women were randomized 1:1 and received F/TAF or F/TDF for PrEP. The primary endpoint occurred when half of participants reached 96 weeks of follow-up. Sexual behavior was assessed by Computer-Assisted Self-Interview questionnaire, including number of Sex Partners, Condomless Insertive Anal Sex (CIAS) Partners, and Condomless Receptive Anal Sex (CRAS) partners. Self-reported sexual behaviors from baseline through the primary endpoint were assessed using descriptive statistics.



[Figure. Longitudinal trends in sexual behaviors in DISCOVER.]

RESULTS: Between Sep 2016-June 2017 participants were randomized and received once-daily blinded tablets of F/TAF (n=2694) or F/TDF (n=2693) plus matched placebo. Baseline demographic, clinical, and risk behavior were balanced between arms. The median age was 34 years, 474 (9%) were black, and 1318 (24%) were of Hispanic or Latinx ethnicity. Most participants (91%) self-identified as gay; 385 (7%) as bisexual, 41 (1%) as heterosexual, and 71 (1%) as trans women. There were no longitudinal changes in the mean number of Sex Partners, Condomless Insertive Anal Sex Partners and Condomless Receptive Anal Sex Partners (Figure). These sexual behavior findings mirror the lack of change in STI rates observed in participants throughout the same timeframe (data not shown).

CONCLUSIONS: In DISCOVER, participants reported a stable number of total and condomless sexual partners through 96 weeks. These data suggest that risk compensation did not occur in DISCOVER.

PEB0166

ANAL CYTOLOGICAL ABNORMALITIES AND HPV DETECTION WITH DIFFERENT PRIMER SETS IN HIV-POSITIVE MEN IN EASTERN INDIA

J. Chakravarty[1], A. Gautam[1], N. Agarwal[1], A. Ghosh[2], M. Rai[1]

[1]Institute of Medical Sciences, Banaras Hindu University, Department of Medicine, Varanasi, India, [2]Institute of Medical Sciences, Banaras Hindu University, Department of Pathology, Varanasi, India

BACKGROUND: Oncogenic Human papillomavirus (HPV) infections are closely associated with anal cancer which is high among human immunodeficiency virus (HIV) infected males. HPV detection rate is affected by choice of consensus primer selection. The aim of this cross-sectional study was to detect Human papillomavirus (HPV) infection and its types by four different consensus primers in HIV positive treatment naïve males attending the ART centre.

METHODS: We screened 102 HIV positive treatment naïve males attending the ART centre between 2016-2017 with anal Pap smear cytology and HPV testing. Four different consensus primer sets MY09/11, GP5+/ GP6+, E6 and E6/E7 were used to amplify broad spectrum HPV types. HPV genotype (16, 18, 31, 35, 52, 58, 66, and 68) was determined by SYBR Green based real-time PCR method. Risk factors were analyzed by using univariate and multivariate logistic regression models.

RESULTS: The overall HPV prevalence was 79.41% (81/102). The detection rate for each primer set was E6/E7 (80%), E6 (67%), GP5+/6+ (60.49%) and MY09/11 (54.32%). The most prevalent HPV types were HPV-16, 18, 31, 35, and 52 (42%, 20%, 12%, 7% and 3% respectively) and multiple HPV types were identified in 36.58% (30/82). Prevalence of anal cytological abnormalities was 54.5% (48/88). HSIL (high-grade squamous intraepithelial lesions) was present in 1.13% (1/88), LSIL (low-grade squamous intraepithelial lesions) in 26.13% (23/88), ASCUS (atypical squamous cells of undetermined significance) in 14.77% (13/88), ASC-H (atypical squamous cells cannot exclude a HSIL) in 12.5% (11/88). Risk factors for anal cytological abnormalities were history of anal intercourse and age <19 yr at first intercourse on multivariate analysis. Among those with abnormal cytology 92% (44/48) were positive for HPV-DNA .

CONCLUSIONS: The prevalence of anal HPV infection and anal cytological abnormalities was high in our population. E6/E7 consensus primer was the most suitable primer for detection of oncogenic HPV.

PEB0167

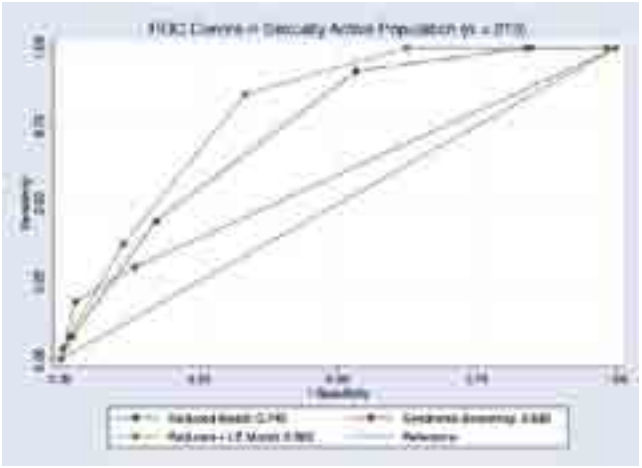
CLINICAL PREDICTION OF *CHLAMYDIA TRACHOMATIS* AND *NEISSERIA GONORRHEA* AMONG ADOLESCENTS AND YOUNG ADULTS LIVING WITH HIV IN ESWATINI

N. Thivalapill[1], C. Jasumback[2,3], Z. Masangane[4], M. Mavimbela[4], N. Mthethwa[5], L. Dlamini[2], B. Lukhele[2], J. Mphaya[6], A. Mandalakas[7], S. Perry[2,7], A. Kay[2,7]
[1]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [2]Baylor College of Medicine Children's Foundation, Mbabane, Eswatini, [3]United States Peace Corps, Extension, Community Health, Mbabane, Eswatini, [4]Eswatini Ministry of Health, Eswatini National Sexual and Reproductive Health Unit, Mbabane, Eswatini, [5]Eswatini Ministry of Health, Eswatini National AIDS Program, Mbabane, Eswatini, [6]UNICEF, Young Child Survival and Development Program, Mbabane, Eswatini, [7]Baylor College of Medicine and Texas Children's Hospital, Department of Pediatrics, Houston, United States

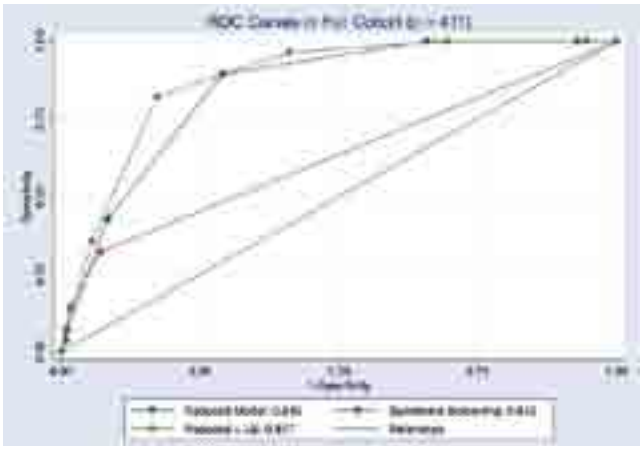
BACKGROUND: Despite poor predictive power, syndromic screening is standard of care for diagnosing sexually transmitted infections (STIs) in low-resource, high HIV-burden settings. Predictive models may augment syndromic screening when diagnostic testing is unavailable.

METHODS: 439 HIV-positive participants, age 15 to 24, were serially recruited from three clinical sites in Eswatini, providing urine, sexual and medical history, and physical examination. STI cases were defined by a positive Xpert result for *Chlamydia trachomatis* or *Neisseria gonorrhea*. A predictive model was estimated through backward-stepwise regression in a training set constituting half of the sexually active population and was assessed in the test set. Models were evaluated with receiver-operator-characteristic curves and diagnosed with c-statistics.

RESULTS: In the sexually active population, syndromic screening had an AUC of 0.589. The reduced model developed in the training set contained five predictors: relationship status, condom usage, sex, age, and recent sexual activity. This reduced model discriminated more efficiently than syndromic screening (AUC: 0.743, p = 0.0094) and similar AUCs were observed in the training (AUC: 0.732) and test set (AUC: 0.752), suggesting minimal overfitting. The model's performance increased when leukocyte esterase (LE) testing was added (AUC: 0.802, p = 0.0052). Model performance was similar for syndromic screening in the full cohort (AUC: 0.612), but improved for both the reduced model (AUC: 0.845) and the model containing LE testing (AUC: 0.877).



[Figure 1.]



[Figure 2.]

CONCLUSIONS: We propose this predictive model to complement syndromic screening or guide patient selection for molecular tests. This approach promises to improve STI diagnosis in HIV positive adolescents and young adults.

PEB0168

A MULTI-COUNTRY COMPARATIVE STUDY OF TWO TREPONEMAL TESTS FOR THE SERODIAGNOSIS OF SYPHILIS AMONGST MEN WHO HAVE SEX WITH MEN (MSM): CHEMO-LUMINESCENT ASSAY VS TREPONEMA PALLIDUM PARTICLE AGGLUTINATION

A. Zorzi[1], M. Cordioli[2], N. Sherriff[3], R. Peeling[4], R. Ballard[5], S.S. Thwin[5], K. Blondeel[5], D. Wlazly[6], G. Homer[7], M.O. Hassan-Ibrahim[7], J. Vera[8], C. Richardson[9], L. Gios[2], I. Toskin[5], M. Mirandola[2,3]
[1]University of Verona, Department of Diagnostics and Public Health, Virology and Microbiology Unit, Verona, Italy, [2]University of Verona, Department of Diagnostics and Public Health, Infectious Diseases Section, Verona, Italy, [3]University of Brighton, School of Environment & Technology, Brighton, United Kingdom, [4]London School of Hygiene & Tropical Medicine, International Diagnostics Centre, London, United Kingdom, [5]World Health Organization |, Department of Reproductive Health & Research, Geneva, Switzerland, [6]Royal Sussex County Hospital Brighton, CIRU Research Laboratory, Brighton, United Kingdom, [7]Royal Sussex County Hospital, Department of Microbiology & Infection, Brighton, United Kingdom, [8]Brighton and Sussex Medical School, Department of Global Health and Infection, Brighton, United Kingdom, [9]Royal Sussex County Hospital, Elton John Centre, Brighton, United Kingdom

BACKGROUND: International guidelines recommend routine screening for syphilis amongst 'high-risk' populations using treponemal and non-treponemal tests. Whilst treponemal tests have high sensitivities and specificities, differences remain regarding interpretation and workload; problematic in laboratory settings with a high turnover of sample processing. The Chemo-Luminescent Assay (CLIA) is a cost-and-time effective automated method for detecting the anti-Treponema pallidum antibody. However, Treponema Pallidum Particle Agglutination (TPPA; a manual procedure) is considered to be the 'gold-standard'. Few studies have adequately compared the performance of these two tests with sufficient positive cases. This study thus compared the performance of these tests CLIA (index) vs. the TPPA (reference test).

METHODS: 1280 asymptomatic MSM were enrolled in Brighton and Verona as part of a larger WHO multi-site study. Ethical approval was obtained. Serum was tested with CLIA (Siemens ADVIA Centaur® Syphilis assay) and TPPA (SERODIA-TP·PA®) following the manufacturers' instructions. Sensitivity, specificity, likelihood ratios (positive/negative), and the Diagnostic Odds Ratio (DOR) were estimated.

RESULTS: CLIA identified 339 (26.31%; CI95% 23.98%-28.79%) positive samples compared to 334 with TPPA (25.91%; CI95% 23.59 - 28.37%). False negative/positive rates were consistent with the manufacturer's declaration. Sensitivity was 99.4% (CI95%: 97.8%-99.9%), whilst specificity was 99.2% (CI95%: 98.4%-99.6%). The area under the ROC curve resulted: .993 (CI95%: .988 - .998). The positive Likelihood ratio was 112 (CI95%: 57.2-218) and negative Likelihood ratio .0076 (CI95%: .0022-.026). The DOR was very high 14781 (CI95%: 3588 - 60887).

CONCLUSIONS: The CLIA showed a high performance compared to the TPPA. The DOR as a global measure of test performance was very high and likely related to the sensitivity and specificity observed. However, considering the study is based on QUADAS principles and with a homogeneous population, results are also likely to be generalisable. These findings suggest that the CLIA automated method (index test) can be a viable, time-saving and cost-efficient testing approach to routine syphilis screening compared to the current more labour intensive TPPA reference test. Results have important implications for considering changes to routine laboratory algorithms for syphilis.

PEB0169

PERFORMANCE OF SELF-COLLECTED SPECIMENS FOR THE DETECTION OF CHLAMYDIA TRACHOMATIS AND NEISSERIA GONORRHOEAE INFECTION

G.M. Vavala[1], M.J. Rotheram-Borus[1], C.C. Bristow[2], C. Goldbeck[1], D. Polanco[1], M. Ocasio[3], J. Fournier[3], A. Romero-Espinoza[1], M.I. Fernandez[4], D. Swendeman[1], S. Comulada[1], S.-J. Lee[1], J.D. Klausner[1], ATN CARES Study Group

[1]University of California, Los Angeles., Los Angeles, United States, [2]University of California, San Diego, La Jolla, United States, [3]Tulane University, New Orleans, United States, [4]Nova Southeastern University, Fort Lauderdale, United States

BACKGROUND: Pharyngeal and rectal chlamydial or gonococcal infections are common in human immunodeficiency virus (HIV) infected patients. The US Food and Drug Administration (FDA) recently approved two diagnostic devices for the detection of rectal and pharyngeal *Chlamydia trachomatis* and *Neisseria gonorrhoeae* infection with clinician-collected swab specimens. Multiple *Chlamydia trachomatis* and *Neisseria gonorrhoeae* testing platforms are FDA-approved for use with self-collected vaginal and urine specimens. FDA approval of self-collected rectal and pharyngeal specimens would benefit patients and streamline screening for providers. We assessed the quality of self-collected specimens for rectal and pharyngeal *Chlamydia trachomatis* and *Neisseria gonorrhoeae* from a large cohort study of participants undergoing chlamydia and gonorrhea screening.

METHODS: Using self-collected specimens, we tested gay, bisexual, and transgender study participants between the ages of 12-24 years in Los Angeles and New Orleans recruited into a large prospective Adolescent Trials Network study for pharyngeal, rectal, and urogenital (urine or vaginal) *Chlamydia trachomatis* and *Neisseria gonorrhoeae* infection (Cepheid Xpert® CT/NG assay). Study interviewers provided verbal instructions on how to self-collect specimens. We used that laboratory assay's Specimen Adequacy Control data (which tests for the presence of human hydroxymethylbilane synthase gene) to calculate the proportion of tests that had detectable human synthase gene by anatomic site.

RESULTS: Our study population was 82.7% male, 12.9% HIV infected, with median age 21 years (IQR 19-23 years). The total sample provided 2,885 self-collected specimens. Human synthase gene was detected in 99.4% (2,868/2,885) of specimens. The proportion of human synthase gene positive specimens by anatomic specimen was 99.6% (891/895) for pharyngeal, 98.8% (1,072/1,085) for rectal, 100% for vaginal (223/223), and 100% (682/682) for urine.

CONCLUSIONS: Self-collected pharyngeal and rectal specimens demonstrated a very high proportion of human gene presence suggesting that self-collection was adequate. *Chlamydia trachomatis* and *Neisseria gonorrhoeae* test manufacturers should pursue additional claims for the FDA approval of self-collected pharynx and rectal specimens.

NEUROLOGIC DISORDERS

PEB0170

FREQUENCY OF DETECTABLE HIV VIREMIA AND IMMUNE SUPPRESSION EPISODES AS DETERMINANTS OF NEUROCOGNITIVE DYSFUNCTION IN UGANDANS WITH CHRONIC HIV INFECTION

A. Ezeamama[1], I. Vega[2], A. Sikorskii[2], S.K. Zalwango[3], M.J. Boivin[1], L.H. Rubin[4], B. Giordani[5]

[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Michigan State University, East Lansing, United States, [3]Kampala Capital City Authority, Kampla, Uganda, [4]Johns Hopkins University, Baltimore, United States, [5]University of Michigan, Ann Arbor, United States

BACKGROUND: Neurocognitive dysfunction (ND), periods of immune incompetence, and HIV viremia remain highly prevalent among persons living with HIV-infection (PLWH) despite effective antiretroviral therapy (cART). Little is known about the relationship between and the frequency of immune suppression and HIV viremia in in relation to ND in cART treated PLWH.

METHODS: Participants included cART treated adolescents (11 - 18 years) n=124) and n=154 adults (22–74 years) PLWH. Absolute CD4 cell-count and viral load measures were obtained from medical records and used to define frequency of immune-suppression episodes (<500, <350 and <200 cells/ul), stable virologic suppression vs. 1 or ≥2 episodes of viremia (low:1-199, moderate:200-999; high:≥1000 copies/ml). Instrumental activities of daily living (ADL) were measured using the Waisman ADL Scale. Eight validated neuropsychological tests were used to derive age- and sex-standardized z-scores for proficiency in motor control, gross motor speed, executive function, processing speed, simple attention, concentration/working memory, and learning. Cognitive domain specific z-scores and ADL <-1.5 were used to define ND severity (not cognitively impaired, asymptomatic neurocognitive impairment and minor/major ND) per Frascatti criteria. Multinomial logistic regression models estimated relationship between the number of viremic and immune suppressed episodes to ND function using Statistical Analysis Software (v.9.4).

RESULTS: Per unit increase in frequency of CD4<500, ND severity increased increased by 28% (OR=1.28, 95%CI: [1.01, 1.62]). Per unit increase in frequency of CD4 <350 and <250 cells/ul the odds of ND severity rose from 64% (95% CI: [1.09-2.48[) to 156% (95%CI: [1.36, 4.82]) among adolescents.

Regardless of age, any viremia vs. stable virologic suppression over time in HIV care was associated with higher ND severity (OR=1.83, 95% CI: [1.17, 2.84[). However, the relationship between ND severity and detectable viremia was most consistent among adults although

the increase in ND odds per unit increases in low (OR=1.83, 95%CI: [1.04, 3.21]) and high (OR=1.85; 95%CI: [1.17, 2.93]) viremia episodes were similar.

CONCLUSIONS: High frequency of immune suppression and detectable HIV viremia are determinants of ND severity among PLWH on cART. Clinical and behavioral interventions to support cART adherence, maintain stable virologic suppression and CD4>500 cells/uL may reduce ND severity in this population.

PEB0171

NEUROCOGNITIVE FUNCTION ASSESSED VIA A SELF-ADMINISTERED TABLET-BASED DIGITAL PLATFORM AMONG PEOPLE WITH HIV SEEKING ADULT CLINICAL CARE

L.H. Rubin[1], K. Althoff[2], J. Severson[3], T. Marcotte[4], A. Best[3], L. Eldred[5], N.C. Sacktor[6], J.-B. Fuchs[5], R.D. Moore[5]
[1]Johns Hopkins University, Neurology, Epidemiology, Psychiatry, Baltimore, United States, [2]Johns Hopkins University, Epidemiology, Baltimore, United States, [3]Digital Artefacts, LLC, Iowa City, United States, [4]University of California San Diego, Psychiatry, San Diego, United States, [5]Johns Hopkins University, Medicine, Baltimore, United States, [6]Johns Hopkins University, Neurology, Baltimore, United States

BACKGROUND: Despite increasing use of effective antiretroviral therapy (ART), clinically significant neurological complications persist among people with HIV (PWH), with the most common being neurocognitive impairment (NCI). However, cognitive screening is not routinely conducted in HIV clinics.

METHODS: A self-administered tablet-based digital platform was used to cross-sectionally assess the prevalence of NCI among consenting adults seeking HIV care in the Johns Hopkins Bartlett HIV Practice from January 29, 2019 to December 30, 2019. Four neuropsychological (NP) tests were developed and programmed into an iPad-based suite of NP measurement tools called BrainBaseline Assessment of Cognition and Everyday Functioning (BRACE) by Digital Artefacts/UCSD: 1) Trail Making Tests (TMT)-Part 1 measuring attention/concentration; 2) TMT-Part 2 measuring executive function; 2) Stroop Color Test measuring processing speed; and 4) Visual-spatial Learning Test (VSLT) measuring visual-spatial learning. NCI on each test was defined as a T-score ≤40. A global NP function score was estimated by averaging T-score performance of the four outcomes with impairment defined as a mean T-score ≤40. A sub-group of participants completed a comprehensive NP battery concurrently to quantify the validity of the iPad-based tests. Sociodemographic, clinical, and co-morbidity diagnosis data were abstracted from electronic medical records of participants.

RESULTS: Four hundred and four PWH (mean age 53.6, SD=10.7 years; 72% >50 years of age; 82% Black; 58% male, 99% on ART; 90% with HIV-1 RNA < 500 copies/ml; mean CD4 count=652, SD=350) completed the four NP tests via BBC (mean completion time=12 min; SD=3.2), of whom 61 also had an NP battery. All four tests had lower means than the cut-off for NCI (TMT-1: 34%, TMT-2: 44%, Stroop: 40%, VSLT: 17%); the global NP function score indicated 25% of participants were impaired. The correlation between the gold standard NP test battery and global NP function via the iPad-based assessment in the subgroup of 61 was 0.634 (P<0.001).

CONCLUSIONS: BRACE estimated burdens of NCI in PLWH similar to the gold standard NP test battery, suggesting the validity of this easy-to-use tool in the clinical setting. Even in PWH on treatment, the burden of NCI is substantial and will continue to impact the care of adults with HIV.

[1]Lausanne University Hospital, Infectious Diseases, Lausanne, Switzerland, [2]Lausanne University Hospital, Laboratory of Neuroimmunology, Research Centre of Clinical Neurosciences, Department of Clinical Neurosciences, Lausanne, Switzerland, [3]University Hospital of Geneva, Department of Neurology, Geneve, Switzerland, [4]University Hospital of Geneva, HIV Unit, Infectious Diseases Division, Department of Medicine, Geneve, Switzerland, [5]Bern University Hospital, Department of Infectious Diseases, Bern, Switzerland, [6]Bern University Hospital, Deparment of Neurology, Bern, Switzerland, [7]Universitätsspital Zurich, Department of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland, [8]Universitätsspital Zurich, Department of Neurology, Zurich, Switzerland, [9]Kantonsspital Bruderholz, Department of Medicine, Basel, Switzerland, [10]Universitätsspital Basel, Infectious Diseases and Hospital Epidemiology Department, Basel, Switzerland, [11]University Center for Medicine of Aging, Memory Clinic, Basel, Switzerland, [12]Kantonsspital St. Gallen, Infectious Diseases and Hospital Epidemiology Division, St. Gallen, Switzerland, [13]Neurology Clinic St. Gallen, St. Gallen, Switzerland, [14]Ospedale Regionale di Lugano, Infectious Diseases Division, Lugano, Switzerland, [15]Ospedale Civico di Lugano, Deparment of Neurology, Lugano, Switzerland, [16]Lausanne University Hospital, Service of Neurology, Department of Clinical Neurosciences, Lausanne, Switzerland

BACKGROUND: The Neurocognitive Assessment in the Metabolic and Aging Cohort (NAMACO) study previously reported a neurocognitive impairment (NCI) prevalence of 39.8% among 981 HIV positive patients in Switzerland, of whom 25.4% had asymptomatic neurocognitive impairment (ANI), 0.8% mild neurocognitive disorder (MND), 0.6% HIV-associated dementia (HAD) and 13.0% non-HIV-associated NCI. The current study examined the neurocognitive diagnosis at two years from baseline.

METHODS: The NAMACO study is an ongoing prospective, longitudinal, multicentre and multilingual (German, French, Italian) study embedded within the Swiss HIV Cohort Study. Patients ≥ 45 years old (mean age 59.3 years, 81% male, 91% Caucasian, 96% with HIV-1 RNA <50 copies/ml) were recruited and assessed with standardized neuropsychological tests performed by neuropsychologists at baseline (between 2013 and 2016) and then at a two-year follow-up. NCI was diagnosed using Frascati criteria.

RESULTS: At the two-year follow-up, 722 patients (of 981, 73.6%) were evaluated. Among these 722 patients, overall NCI prevalence was 37.4%: 24.1% with ANI, 1.1% with MND, 0.6% with HAD and 11.4% with non-HIV-associated NCI (Table 1).

	Diagnosis at two-yer follow-up				
Diagnosis at baseline of the 722 patients	NNF	ANI	MND	HAD	Non-HIV-associated NCI
NNF (N= 480, 66.4%)	403 (83.96%)	57 (11.9%)	3 (0.6%)	0	17 (3.54%)
ANI (N=152, 21.02%)	41 (26.97%)	101 (66.5%)	1 (0.6%)	0	9 (5.92%)
MND (N=7, 0.98%)	0	1 (14.3%)	3 (42.9%)	1 (14.3%)	2 (28.6%)
HAD (N=3, 0.41%)	0	0	1 (33.3%)	2 (66.6%)	0
Non-HIV-associated NCI (N=80, 11.07%)	10 (12.5%)	15 (18.75%)	0	1 (0.8%)	54 (67.5%)
Total	454 (62.88%)	174 (24.1%)	8 (1.1%)	4 (0.6%)	82 (11.4%)

[Table 1. Prevalence of NCI diagnosis among NAMACO patients at two-year follow-up]

Among 152 patients with ANI at baseline, 27% improved to normal neurocognitive function (NNF), 66.5% remained with ANI, and 5.9% developed non-HIV-associated NCI. Patients unimpaired at baseline developed NCI in 16.04% of cases, with ANI being the most common diagnosis (11.9%).

CONCLUSIONS: In this cohort of well-treated patients, ANI remained the most common NCI diagnosis. Overall, we observed a general stability in neurocognitive diagnosis among HIV patients, with a tendency towards improvement. Patient factors associated with ANI prognosis will be presented.

PEB0173

TRYPTOPHANE METABOLITES PREDICT NEUROCOGNITIVE IMPAIRMENT AND SIDE EFFECTS DURING EFAVIRENZ

G. Lapadula[1], E. Bresciani[2], I. Baldisserotto[2], F. Bai[3], E. Focà[4], A. Di Biagio[5], M. Rossi[1], A. d'Arminio Monforte[6], F. Castelli[4], A. Calcagno[7], G.M. Migliorino[1], Swear Study Group
[1]"San Gerardo" Hospital, Clinic of Infectious Diseases, Monza, Italy, [2]University of Milano-Bicocca, Milan, Italy, [3]Azienda Ospedaliera San Paolo, Milan, Italy, [4]University of Brescia, Brescia, Italy, [5]San Martino Hospital, Genoa, Italy, [6]University of Milan, Milan, Italy, [7]University of Turin, Turin, Italy

BACKGROUND: Tryptophan metabolites have been suggested as possible markers of HIV-associated neurocognitive (NC) disorders. We assessed the association of kynurenic (K) and quinolic acid (Q) with a wide spectrum of central nervous system (CNS) alterations during treatment with tenofovir/emtricitabine/efavirenz (TDF/FTC/EFV).

METHODS: We conducted a substudy of a RCT assessing NC function among patients switching from TDF/FTC/EFV to TDF/FTC/rilpivirine (RPV). At screening, patients underwent a battery of tests exploring 6 NC domains, quality of sleep, presence of depression, anxiety and CNS side effects. Those enrolled were randomized 1:1 to continue TDF/FTC/EFV or switch to TDF/FTC/RPV and repeated all assessments 24 weeks after randomization. Plasma K and Q were measured at the same time-points, along with immune-inflammatory markers neopterin, MCP-1 and sCD163. T-test was used to compare log-transformed marker levels between patients with or without NC impairment (ie, z-scores below -1 in ≥2 domains), depression, anxiety, sleep disturbances or significative CNS side effects. Correlations between markers and NC performances were assessed using Pearson correlation.

RESULTS: 112 patients were included. Upon screening, median K and Q were 726 (IQR:505-1067) and 32 (21-46) ng/ml; median Q/K ratio was 0.04 (IQR:0.02-0.08). Levels of MCP-1 directly correlated with K (r=0.29, P=0.002) and inversely with Q (r=-0.34, P<0.001) and Q/K (R=-0.4, P<0.001). K was significantly higher K among patients with depressive symptoms (P=0.02) and significant CNS side effects (P=0.09). Surprisingly, lower Q (P=0.075) and Q/K (P=0.041), but not K levels, were associated with NC impairment.

In particular, patients with impaired memory and executive function had significantly lower Q (P=0.028 and 0.020) and Q/K (P=0.087 and P=0.029). Q and Q/K levels were directly correlated with memory (r=0.25, P=0.007 and r=0.23, P=0.016), executive function (r=0.20, p=0.033 and r=0.21, p=0.027) and language z-scores (r=0.21, p=0.028). 68 patients (33 on EFV and 35 on RPV) were evaluated after 24 weeks. K and Q did not significantly change in either arm, whereas MCP-1 and neopterin slightly increased after switching to RPV (P= 0.045 and P=0.029). Changes in marker levels did not correlate with z-scores changes.

CONCLUSIONS: Among patients under effective antiretroviral treatment, plasma levels of trypotophan metabolites may predict NC function and neuropsychiatric side-effects.

DEPRESSION AND OTHER PSYCHIATRIC MANIFESTATIONS

PEB0174

ASSOCIATION BETWEEN DEPRESSIVE SYMPTOMS AND ADHERENCE AMONG ADOLESCENTS LIVING WITH HIV IN THE REPUBLIC OF CONGO

M.H. Ekat[1], M. Yotebieng[2], V. Leroy[3], C. Mpody[4], R. Becquet[5]
[1]Ambulatory Treatment Center of Brazzaville, Brazzaville, Congo, [2]Einstein University, New - York, United States, [3]Université de Toulouse, Toulouse, France, [4]Ohio State University, Ohio, United States, [5]Université de Bordeaux, ISPED, Bordeaux, France

BACKGROUND: The increasing availability of antiretroviral therapy (ART) worldwide is yet to result in decreasing HIV-related mortality among adolescents (10 - 19 years old) living with HIV (ALHIV) in part because of poor adherence. The poor adherence might itself be due to high level of depression. We assess the prevalence of depressive symptomatology and it's associated with adherence among ALHIV receiving ART care in Brazzaville and Pointe Noire, Republic of Congo (RoC).

METHODS: Adolescents aged 10-19 years, on antiretroviral therapy (ART), followed in the two Ambulatory Treatment Centers (ATC) in Brazzaville and Pointe Noire, RoC were included in this cross-sectional study. From April 19 to July 9, 2018. Participants were administered face to face interviews using a standardized questionnaire that included the nine-item Patient Health Questionnaire (PHQ-9). Participants who reported failing to take their ART more than twice in the 7 days preceding the interview were classified as non-adherent. Bivariate and multivariable log-binomial models were used to estimate the prevalence ratio (PR) and 95% confidence interval (95%CI) assessing the strength of association between predictors and presence of depressive symptoms (PHQ-9 score ≥9).

RESULTS: Overall, 135 adolescents represented 50% of ALHIV in active care at the two clinics were interviewed. Of those, 67 (50%) were male, 81 (60%) were 15-19 years old, 124 (95%) had been perinatally infected, and 71 (53%) knew their HIV status. Depressive symptoms were present in 52 (39%) participants and 78 (58%) were adherent. In Univariate analyses, the prevalence of depressive symptoms was relative higher among participants who were not adherent compared to those who were (73% vs 33%; PR:2.20 [95%CI:1.42-3.41]). In multivariate analysis, after adjustment for report of been sexually active, alcohol drinking, age category (10-14 and 15-19), not in school, loss of both parents, the association between depression and adherence was strengthened (PR: 2.06 [95%CI:1.23-3.45]).

CONCLUSIONS: The prevalence of depressive symptoms in adolescents living with HIV is high and was strongly associated with poor adherence even after adjustment of potential confounders. Efforts to scale-up access to screening and management of depression among ALHIV in sub-Saharan is needed for them to realize the full of ART.

PEB0175

MENTAL HEALTH BARRIERS TO PARENTING AMONG MOTHERS LIVING WITH HIV IN ZIMBABWE

L. Sherr[1], H. Mebrahtu[1], F. Cowan[2,3], R. Chingono[3], V. Simms[4], Z. Mupanbireyi[3], A. Rehman[4], E. Matsikire[3], R. Malaba[5], P. Ndlovu[5], H. Weiss[4]
[1]University College London, Global Health, London, United Kingdom, [2]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom, [3]Centre for Sexual Health HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [4]London School of Hygiene & Tropical Medicine, MRC Tropical Epidemiology Group, Faculty of Epidemiology and Population Health, London, United Kingdom, [5]World Education Inc./Bantwana, MRC Tropical Epidemiology Group, Harare, Zimbabwe

BACKGROUND: HIV presents challenges to parenting beyond HIV prevention. We assessed a parenting intervention for mothers living with HIV in a cluster-randomised trial with no evidence of a difference in child development by trial arm but showed maternal mental health was poor. We present secondary analyses exploring how mother's mental health changes over time and its impacts on childhood cognition.

METHODS: Mother-infant dyads in 30 clusters in two Zimbabwe rural districts, were provided a one-year parenting and income/savings intervention or control. Suicidal ideation, and common mental health disorders (CMD) were assessed using validated measures (Edinburgh Postnatal Depression Scale;Shona Symptom Questionnaire) and child cognitive development was assessed using the Mullen Scales. We categorised suicidal ideation and common mental disorders measured twice, one-year apart, to generate four groups: chronic (indicated at both times), well (not indicated at either time), deteriorating (indicated at follow up only), improving (indicated at baseline only). We used mixed effects linear regression to examine the effect of mother's mental health category on infant cognitive outcomes adjusted for trial arm.

RESULTS: Mental health was assessed in 485 biological mothers at both baseline and one-year follow-up. Suicidal ideation was indicated in 171/562 (30%) mothers at baseline and 132/485 (27.2%) mothers after one-year, with n=86;17.7% chronic, n=287;59.2% well, n=46;9.5% deteriorating and n=66;13.6% improving. Baseline suicidal ideation was associated with younger maternal age, unmarried status, reported moderate to severe hunger, elevated parental stress and postnatal depression symptoms. CMD was indicated in 40.1% well, 25.5% chronic, 19.7 deteriorating and 14.8% improving. Infants of mothers with emerging maternal suicidal ideation showed poorer child cognitive outcomes (Adjusted mean difference [aMD]:-7.1;95% CI:-11.5 to-2.7;p=0.03).Children of caregivers with chronic CMD(n=131,25.5%) had lower receptive language scores (aMD:-2.81, 95%CI -5.1 to -0.6;p=0.05) compared to well mothers (n=206, 40.1%).

CONCLUSIONS: Prevalence of maternal mental health morbidity were high and fluctuated over time, possibly interacting with effectiveness of parenting interventions Maternal suicidal ideation and common mental health disorders are associated with lower infant cognition. A family approach with mental health provision may be urgently needed to maximise parenting and ensure the best long term outcomes for children born into HIV affected families.

MALIGNANCIES (AIDS AND NON-AIDS)

PEB0176

PATIENT AGE AND CERVICAL LESION SEVERITY BY HIV-STATUS: THE FIRST 13 MONTHS OF VIA AND CRYOTHERAPY/THERMOCOAGULATION IMPLEMENTATION IN NAMIBIA

L. Muzingwani[1], G. O'Bryan[2], A. Ensminger[2], A. Boylan[3], M. Kashali[4], L. Eckert[5], E.-L. Kafidi[1], N. Forster[1], G. O'Malley[2]
[1]International Training and Education Center for Health (I-TECH), Windhoek, Namibia, [2]International Training and Education Center for Health (I-TECH), University of Washington, Department of Global Health, Seattle, United States, [3]U.S. Centers for Disease Control and Prevention (CDC), Windhoek, Namibia, [4]Namibian Ministry of Health and Social Services (MoHSS), Windhoek, Namibia, [5]University of Washington, Departments of Obstetrics and Gynecology and Global Health, Seattle, United States

BACKGROUND: Recommendations for cervical cancer screening initiation in HIV-positive women vary internationally with little published data available on which to base those recommendations. In March 2018, the Namibian Ministry of Health and Social Services finalized cervical cancer prevention guidelines setting first screening for HIV-positive women at age 20 years because of high HIV prevalence (15.7%) and younger sexual debut (mean: 16 years). Analysis of program data compared visual inspection with acetic acid (VIA)-positivity at age of first screening by HIV status to inform screening initiation recommendations.

DESCRIPTION: We analyzed program data from the first 13 months (October 2018–October 2019) of VIA and cryotherapy and thermocoagulation implementation in the Khomas region, and from the first three months (July–September 2019) from 6 expansion regions. We compared rates of VIA-positivity by age at self-reported first ever screening, and lesion severity by HIV status. Chi-square tests were used to assess statistical significance.

LESSONS LEARNED: Of the 3,172 women who completed screening, 499 (16%) had pre-cancer lesions and 31 (1%) had suspected cancer. Among the women screened, 1,374 (43%) were HIV-positive. For all ages, HIV-positive women had VIA-positivity rates significantly higher (19% vs. 15%, p=<0.01) and the proportion with large lesions ineligible for cryotherapy or thermocoagulation was significantly higher compared to HIV-negative women (7% vs. 3%, p=<0.01) (Tables 1–2). Of the 279 women below 24 years of age (15–24) who completed screening, 56 (20%) had pre-cancer lesions, a higher VIA-positivity rate than any other age group. Among women 20–24 years, the VIA-positivity rate was 23% in HIV-positive women compared to 19% in HIV-negative women.

	Age (years)

HIV-positive	98	1,276	1,374	
HIV-negative	58	1,631	1,689	χ2= 21.44
Total	156	2,907	3,063	p= <0.01

[Table 2. VIA-positivity and cryotherapy/thermocoagulation ineligibility by HIV status at first screening in Namibia (Oct. 2018–Sep. 2019)]

CONCLUSIONS/NEXT STEPS: Young HIV-positive women in Namibia had high VIA-positivity. Age-stratified cancer incidence data could distinguish human papillomavirus infections likely to self-clear from true pre-cancer lesions in young women. Additionally, cost-benefit analysis of potential overtreatment and cancer cases averted in young women could guide resource allocation.

PEB0177

CERVICAL CANCER SCREENING: EXPERIENCE FROM THE CAMEROON BAPTIST CONVENTION HEALTH SERVICES WOMEN HEALTH PROGRAM

D.M. Bonghaseh[1], M. Simon[2], K. Nulah[3], F. Manjuh[4]
[1]Etoug-Ebe Baptist Hospital, Women's Health Department, Yaounde, Cameroon, [2]CBC Health Services, Reproductive Health, Bamenda, Cameroon, [3]CBC Health Services, Database Manager, Bamenda, Cameroon, [4]CBC Health Services, Women's Health Supervisor, Yaounde, Cameroon

BACKGROUND: Cervical cancer is one of the most common malignancies affecting women of reproductive age in Cameroon. Its incidence has seen a great increase since the start of the HIV epidemic and it is a major cause of morbidity and mortality in women living with HIV/AIDS. Prevention and early detection through massive low-cost screening campaigns is key to improving quality of life and increasing survival

DESCRIPTION: The Women's Health Program (WHP) of the Cameroon Baptist Convention Health Services was set-up in 2007 with 1 screening site. The "see and treat" method was adopted to ensure continuity of care and the average cost of screening was set at USD 5.92. Visual Inspection with Acetic acid (VIA) /Visual Inspection with Lugol's Iodine (VILI) was the main screening method and positive lesions were treated with cryotherapy or Loop Electrosurgical Excition procedure (LEEP) meanwhile biopsy was done for suspected cases of malignancy. In order to improve on the detection of pre-cancerous lesions, new technologies such as a portable colposcope with a better magnification linked to a mobile application integrated into a Samsung device is currently used as the main screening method. The program has been expanded to 12 screening sites and all the screening procedure is performed by trained nurses.

LESSONS LEARNED: Since 2007, 85847 women have been screened for cervical cancer in the WHP. VIA was positive in 6568 (7.7%) cases of all women screened. HIV was positive in 9443 (9.1%) women and VIA was positive in 1139 (12.1%) HIV positive women. A decreasing trend of VIA positivity in HIV positive women was also recorded from 26.8% in 2007 to 12.7% in 2018. These results highlight the success of a low-cost nurse-led program for the prevention, detection, and management of cervical cancer in both HIV positive and HIV negative women.

CONCLUSIONS/NEXT STEPS: We recommend the widespread application of VIA in all health facilities in Cameroon, in order to scale-up cervical cancer screening and promote early detection and management. We also recommend further longitudinal studies to be carried to evaluate the effectiveness of the "see and treat" method in preventing future development of cervical cancer in Cameroon.

PEB0178

ASSOCIATIONS OF VIREMIA AND ANTIRETROVIRAL THERAPY DURATION WITH VIA POSITIVITY IN MALAWI: A RETROSPECTIVE ANALYSIS

S. Lewis[1], M. Mphande[2], B.A. Banda[2], H. Sigauke[2], T. Gumbo[2], A. Amberbir[1,2], A. Moses[2], S. Gupta[1,2], R.M. Hoffman[1], C. Moucheraud[3]
[1]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, United States, [2]Partners in Hope, Lilongwe, Malawi, [3]University of California, Los Angeles, Fieldings School of Public Health, Los Angeles, United States

BACKGROUND: HIV-positive women face a particularly high cervical cancer burden. HIV severity (e.g., low CD4 count, clinical stage) has been shown to impact cervical cancer risk, however, there is less evidence on how additional factors such as viral load suppression and antiretroviral therapy (ART) duration and regimen influence risk. We describe results from a cervical cancer screening program based at a free ART clinic in Malawi, and explore the association between HIV clinical characteristics and screening positivity.

METHODS: Data were collected at an urban, PEPFAR-USAID supported HIV treatment site in Malawi that provides free cervical cancer screening (visual inspection with acetic acid [VIA]) and same-visit removal of abnormal cells (using thermocoagulation) or referral for complicated cases. Retrospective data from the cervical cancer screening and ART registries were analyzed to investigate the association between viral load, ART duration and regimen, and body mass index (BMI) on VIA positivity. Associations were assessed through multivariate logistic regression adjusted for age and year of VIA screening.

RESULTS: Between May 2017 and October 2019, 1308 HIV-positive women underwent first-time cervical cancer screening. Most women were between 25-49 years old (74%) and 99.5% were on ART with a median treatment duration of 7.1 years (IQR: 4.4-9.2). Five percent of women (n=65) screened VIA-positive. Factors associated with positive VIA included a viral load of ≥ 1000 copies/mL within one year of screening (aOR=2.66, 95% CI: 1.33-5.31); ART for less than 5 years (aOR=1.90, 95% CI: 1.05-3.42); and treatment with a protease-based ART regimen (aOR=1.94, 95% CI: 0.78 – 4.83) (Table 1).

[Table 1. Association between HIV clinical characteristics and VIA positivity (n=971)]

CONCLUSIONS: HIV-positive women with a high viral load and shorter duration on ART were more likely to have abnormal VIA. Elucidating cervical cancer risk factors for women with HIV can help inform screening strategies tailored to women based on risk, with more frequent screening and careful follow-up for women at highest risk.

CARDIOVASCULAR DISEASE

PREVALENCE AND PREDICTORS OF HYPERTENSION STRATIFIED BY HIV STATUS IN KISUMU, KENYA

J. Mogaka[1,2], S. Masyuko[1,3], T. Temu[1], M. Sharma[1], J. Zifodya[4], J. Kinuthia[2], A. Osoti[5], A. Njoroge[1], A. Otedo[3], B. Chohan[1], D. Nakanjako[6], S. Page[1], C. Farquhar[1]

[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]Ministry of Health, Nairobi, Kenya, [4]Tulane University, New Orleans, United States, [5]University of Nairobi, Nairobi, Kenya, [6]Makerere University, Kampala, Uganda

BACKGROUND: Few studies have assessed the prevalence of hypertension among people living with HIV (PLWH) on long term antiretroviral therapy (ART) after the test and treat strategy was implemented in Sub-Saharan Africa (SSA). Death from cardiovascular disease is increasing in SSA, with untreated hypertension a likely contributor. We sought to compare the prevalence and risk factors associated with hypertension among PLWH to the HIV negative individuals.

METHODS: In a cross-sectional study design, we enrolled PLWH on long term ART (≥ 6 months) and HIV-negative adults ≥ 30 years, seeking routine services at the Kisumu County Hospital, between 2017 and 2018. Hypertension was classified as systolic blood pressure ≥ 140mmHg, diastolic blood pressure ≥ 90mmHg and/or previous diagnosis of hypertension. Logistic regression was used to evaluate the association between hypertension and HIV status adjusting for age, gender and traditional cardiovascular risk factors.

RESULTS: We enrolled 300 PLWH and 298 HIV-negative men and women. The median (interquartile range) age was 45 (40-53) years among PLWH and 40 (31-55) years for HIV-negative participants. Among PLWH, average duration on ART treatment was 8 years with 96% of them having achieved viral suppression. The prevalence of hypertension was lower among the PLWH compared to HIV negative persons (33% vs 44%; p<0.01). After adjustment for age, sex, and traditional CVD risk factors, PLWH were 42% less likely to have hypertension than HIV-negative participants [adjusted odds ratio (aOR) 0.58; 95% confidence interval (CI) 0.40-0.83]. Other factors that were associated with hypertension in the overall cohort included older age ≥ 40 years [aOR 2.59; 95% CI 1.73-3.87] and BMI of ≥ 25kg/m^2 [aOR 2.02; 95% CI 1.25-3.26]. No significant association was observed between ART duration, nadir or current CD4 T cell count with hypertension among PLWH after additionally adjusting for HIV related characteristics.

CONCLUSIONS: There was lower prevalence of hypertension in PLWH than HIV negative individuals in this study from the SSA region. Further exploration of potential factors that contribute to these differences is critical to targeting future interventions.

BACKGROUND: HIV-infected individuals are at increased risk of cardiovascular disease (CVD). Previous studies have demonstrated this increased risk is related to HIV infection, side effects of antiretroviral therapy (ART), and conventional CVD risk factors. This study describes the HIV-infected population in Colombia who were naive for ART, and their associated CVD risk factors and comorbidities.

METHODS: We conducted a multicenter, retrospective cohort study in 26 HIV clinics from the Colombian HIV group (VIHCOL). Patients aged ≥ 18 years, who were naïve to ART, and had at least six months of follow up were included. Data collection was performed using the software REDCap. Preliminary analysis of these data was conducted using R software.

RESULTS: A total of 1,371 patients were included; 1,138 (83.0%) identified as male, median age was 30 years (IQR 24-40). Median baseline viral load and TCD4 lymphocyte count were 46,996.5 copies/mm3 (IQR 10,12-181,500) and 281 cells/mm3 (IQR 133-433) respectively. Existing comorbidities included hypertension (n=51, 3.7%), dyslipidemia (n=330, 24.1%), diabetes mellitus (DM, n=13, 0.9%), and chronic kidney disease (CKD, n=12, 0.9%). Mean baseline BMI was 22.8 kg/m2; 48 (3.5%) individuals were classified as obese. Tobacco smoking in the past six months was reported by 240 (17.5%) patients. Mean follow-up time was 32.3 months. By the end of follow up, 70.0% (n=960) had an undetectable viral load. During the study period, there were 39 (3.0%) incident cases of hypertension, three (0.2%) of DM, and 14 (1.0%) of CKD. Mean BMI increased to 23.9 kg/m2 (p<0.001). Mean low-density lipoprotein (LDL) level increased from 92.1 to 99.5md/dl (p<0.001), and triglycerides from 145.6 to 158.0mg/dl (p=0.021). Five patients had a non-fatal cardiovascular event (1.3 per 1,000 person-years). Four patients died (1.1 per 1,000 person-years).

CONCLUSIONS: In this cohort of Colombian HIV-infected patients, metabolic comorbidities are less frequent than those described in high-income countries, which may be a result of the younger median age at enrollment and the follow-up time. However, there is a high prevalence of modifiable risk factors for CVD such as smoking and dyslipidemia in this population, which may be the target of interventions. Next steps include further analysis of these longitudinal data.

PEB0181

PATTERNS OF ANTIRETROVIRAL USE AND IMMUNOLOGIC CORRELATES IN THE REPRIEVE TRIAL AT STUDY ENTRY

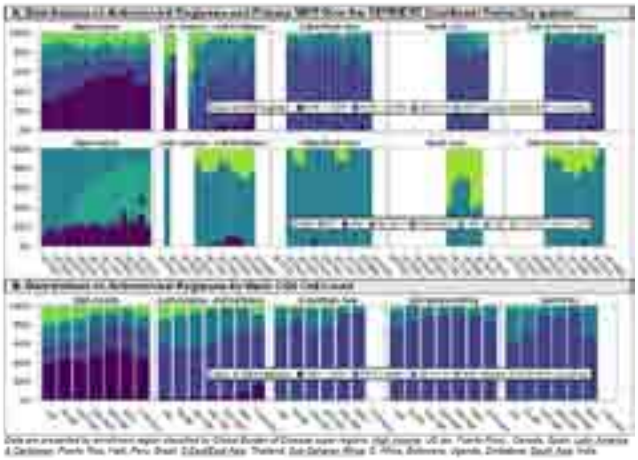
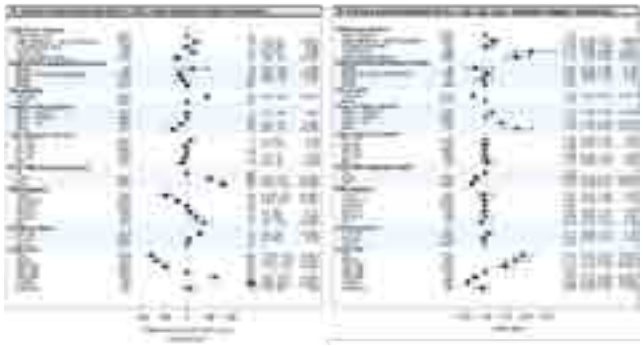
BACKGROUND: REPRIEVE is an international randomized trial of pitavastatin calcium versus placebo to prevent major adverse cardiovascular events in people with HIV (PWH) on antiretroviral therapy (ART). We present patterns of ART use and immunologic correlates at study entry.

METHODS: REPRIEVE enrolled PWH age 40-75 years on ART for ≥180 days, with a CD4 count >100 c/mm^3 and low-moderate CVD risk. ART use was summarized by key demographics within global burden of disease super regions; adjusted linear and logistic regression examined associations with CD4 counts and CD4:CD8.

RESULTS: 7,770 participants enrolled between 2015-2019. Median (Q1,Q3) age-50 years (45,55); female sex-31%; black race-43%, Asian race-15%; BMI>25 kg/m^2-56%; Current/former smokers-49%. Median CD4 count-620 cells/mm^3 (447,826) and undetectable HIV viral load-88%. Median duration of prior ART use-9.5 years (5.3,14.8). Overall, 40% were taking NRTI+NNRTI; 35% taking NRTI+INSTI; 15% were taking NRTI+PI; and 10% other combination ART. ART use varied noticeably by region (Figure 1 Panel A), with shifts in ART during enrollment (Figure 1 Panel A). ART selection varied by nadir CD4 (Figure 1 Panel B). In adjusted analyses, entry CD4 and CD4:CD8 (Figure 2) were associated with geographic region, sex, ART selection, duration of ART, and nadir CD4; CD4 was also associated with BMI and smoking status.





CONCLUSIONS: There were substantial variations in ART use by geographic region and over time that likely reflect local availability of specific medications, changes in treatment guidelines and provider/patient preferences. The CD4 and CD4:CD8 analyses provide interesting signals that may provide valuable insights regarding immune function and outcomes in PWH.

BACKGROUND: There is evidence that epicardial adipose tissue (EAT) volume correlates with the severity of coronary artery disease. Little is known regarding EAT in older people living with HIV (PLHIV) in Asia. We assessed EAT among PLHIV and matched HIV uninfected participants older than 50 years, to identify factors associated with EAT.

METHODS: We conducted a cross-sectional study of 339 consecutive older PLHIV (age≥50 years) compared to 144 HIV uninfected participants frequency matched by sex and age in 5-year intervals, in Bangkok, Thailand. Participants underwent a non-contrast cardiac CT scan to assess coronary artery calcium (CAC) score from Mar 2016-June 2017. EAT was measured in the same CT images. All cardiac CT and EAT measurements were read by 1 trained radiologist and confirmed by 1 specialized radiologist, both blinded to patient care and HIV status. Multivariate linear regression analyses were used to investigate factors associated with the EAT among PLHIV.

RESULTS: Patient's mean age was 56.9 + 5.8 years, 63% were men,15% had diabetes mellitus, 31% had hypertension and 13% current smokers. 16 % had CAC>100. Median duration of ARV was 16 years with 97% had HIV RNA< 50 copies/ml and median CD4 of 617 cells/mm^3. Median EAT was significantly higher in PLHIV [99 (IQR 75-122 cm^3)] than the negative controls [93 (IQR 69-117 cm^3)], p=0.009. From a

multivariate regression model, factors independently associated with EAT were age (coefficient =1.61, 95% CI=1.04–2.18), p<0.001), waist circumference (coefficient = 1.28, 95% CI = 0.66–1.91), p<0.001), HIV infection (coefficient =19.88, 95% CI=11.88–27.88), p<0.001), triglyceride (coefficient 0.04, 95%CI=0.01-0.07,p=0.009) and having hypertension (coefficient 8.37 (95%CI=1.35–15.4); P=0.02). In PLHIV, EAT was strongly associated with age (coefficient = 1.93, 95% CI = 1.20–2.66), p<0.001), abnormal waist circumference (male>90 cm, female > 80 cm) (coefficient = 13.91, 95% CI = 1.15–26.67), p=0.03) and lipodystrophy (coefficient =12.4, 95% CI = 2.69–22.12), p=0.012), after adjustment for other confounders.

CONCLUSIONS: In this group of elderly PLHIV on long-term ART with high rates of viral suppression, EAT was significantly higher than HIV-uninfected individuals and it was independently associated with central fat accumulation and lipodystrophy.

PEB0183

INCREASED IL1-β PRODUCTION DURING CHRONIC HIV-INFECTION; A ROLE FOR INNATE REPROGRAMMING

W.A. van der Heijden[1], L. Van de Wijer[1], F. Keramati[2], M. Jaeger[1], R. ter Horst[1], C. Dinarello[1,3], M.G. Netea[1,4], A.J. van der Ven[5], Q. de Mast[5]

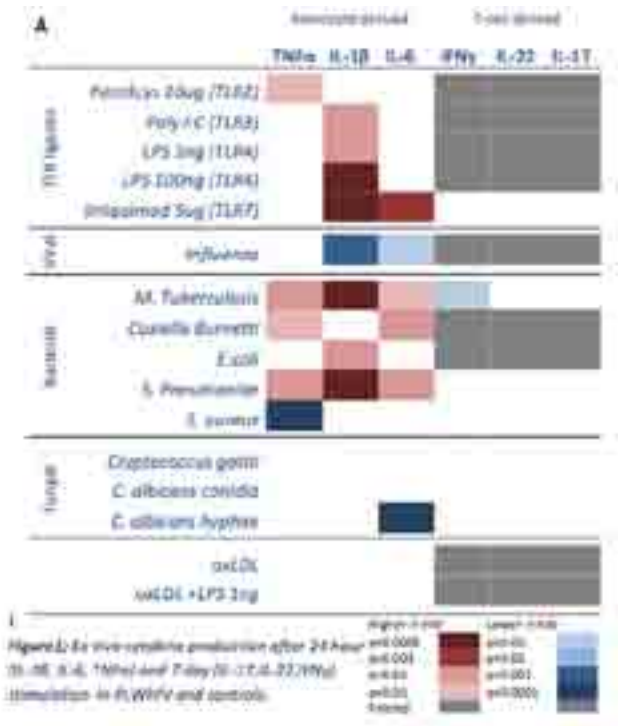
BACKGROUND: Chronic inflammation and immune dysfunction play a key role in the development of non-AIDS related comorbidities. The aim of our study was to explore new pathways for this immune dysregulation by comparing specific antigen immune responses between people living with HIV(PLWHIV) and uninfected controls.

METHODS: PLWHIV on stable antiretroviral therapy(cART) and controls simultaneously were enrolled including an age-sex matched control group in the second sampling. We performed PBMC stimulation to assess ex vivo cytokine production after bacterial, fungal and viral stimulation. We used a linear regression model with age, sex, BMI and seasonality as covariates to compare both cohorts. All p-values are FDR-corrected.

RESULTS: The median (IQR) duration of known HIV-infection and cART-use were 8.1(9.3) and 6.5(7.9) years. PLWHIV (n=211) were more often male (91% vs 61%) than controls. Upon stimulation (Figure 1), PLWHIV showed a pro-inflammatory profile in monocyte-derived cytokines, especially IL1β after imiquimod (TLR7), LPS and Mycobacterium tuberculosis (all p<0.0001) stimulation. This IL-1β production correlated with systemic inflammation (sCD14,r=0.33,p<0.0001). This increase was stable, after subsequent sampling using an age-sex matched control group. The priming of the IL1β pathway and intrinsic changes in monocytes were confirmed using transcriptome analysis (Figure 2)



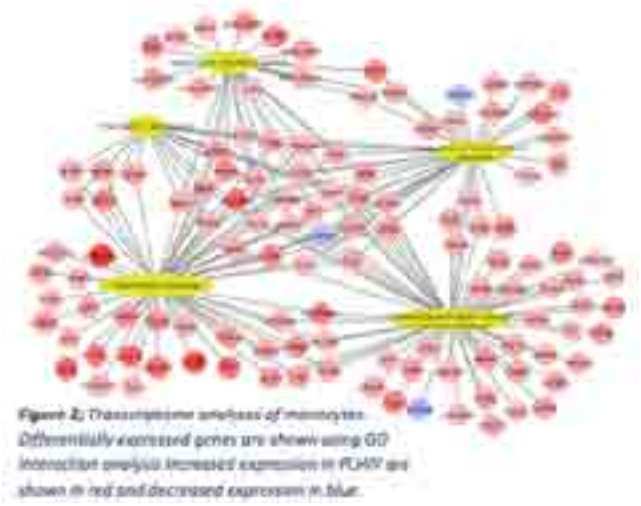


Figure 2: Transcriptome analysis of monocytes. Differentially expressed genes are shown using GO interaction analysis. Increased expression in PLWHIV are shown in red and decreased expression in blue.

CONCLUSIONS: Our findings show that PLWHIV on stable cART have a strong increase in the production of monocyte-derived cytokines (especially IL-1β), but not of lymphocyte-derived cytokines. This stable increase in cytokine production capacity in PLWHIV suggests priming of the innate immune compartment or trained immunity. Our findings highlight the relevance for the innate immune system as a potential therapeutic target for inflammation-related comorbidities during chronic HIV infection.

PEB0184

ASSOCIATION OF ANTIRETROVIRAL THERAPY WITH MYOCARDIAL DEFORMATION IN ANTIRETROVIRAL THERAPY-NAIVE HIV-INFECTED PATIENTS

H.S. Toh[1], C.-T. Liao[2], W.-T. Chang[2], H.-J. Tang[3], Z.-C. Chen[2], Y.-H. Li[2], J.-C. Li[2], H.-C. Ku[4], W.-P. Chen[4]
[1]Chimei Medical Center, Department of Intensive Care Medicine, Tainan City, Taiwan, Province of China, [2]Chi Mei Medical Center, Division of Cardiology, Department of Internal Medicine, Tainan City, Taiwan, Province of China, [3]Chi Mei Medical Center, Division of Infectious Diseases, Department of Internal Medicine, Tainan City, Taiwan, Province of China, [4]Chi Mei Medical Center, Infection Control Center, Tainan City, Taiwan, Province of China

BACKGROUND: People living with HIV are found to have more myocardial deformation change, and myocardial deformation has been used to detect early cardiovascular disease (CVD). Although antiretroviral therapy (ART) can lower the risk of CVD, its effect on the myocardial strain remains unclear. This study aims to investigate whether myocardial deformation change is reversible after the initiation of ART in ART-naive population.

METHODS: This prospective cohort study enrolled asymptomatic ART-naive HIV-infected patients from August 2017 to August 2018 in a medical center of Taiwan. Simultaneously, patients with regular ART were also recruited for comparison. 2D speckle-tracking echocardiography (2DSTE) was performed during enrolment and repeated after six months to measure the left ventricular (LV) myocardial strain. Abnormal LV global longitudinal strain (LVGLS) was defined as greater than -15%. A greater absolute number of LVGLS represents better myocardial deformation.

RESULTS: A total of 20 ART-naive (aged 28.2 ± 6.6 years) and 132 ART-experienced (aged 38.6 ± 11.5 years) patients were recruited. Surprisingly, the ART-naive group had a higher prevalence of abnormal LV myocardial deformation, comparing to ART-experienced group (15.0% vs. 6.1%). After six months of ART, the prevalence of abnormal LV myocardial deformation for the ART-naive group dropped to 10.5%, while 6.4% of the experienced group had abnormal myocardial deformation. The LVGLS changes of ART-naive and experienced group were -0.9 ± 4.1% and 0.1 ± 3.4% respectively.

Data	ART-experienced (n = 132)	ART-naive (n = 20)
CD4 (/mm^3), mean ± SD	534.6 ± 245.0	403.9 ± 245.1
Viral load < 200 copies/mm^3, n (%)	126 (95.5)	0
LV ejection fraction (%), mean ± SD	66.2 ± 5.6	63.5 ± 4.6
LVGLS (%), mean ± SD	-19.0 ± 2.5	-17.0 ± 3.5
LVGLS > -15%, n (%)	8 (6.1)	3 (15.0)
After 6 months	ART-experienced (n = 125)	ART-naive (n = 19)
LVGLS (%), mean ± SD	-18.1 ± 3.4	-18.4 ± 2.8
LVGLS > -15%, n (%)	8 (6.4)	2 (10.5)
Difference in LVGLS	-0.9 ± 4.1%	0.1 ± 3.4%

[Table]

CONCLUSIONS: This is the first cohort study using 2DSTE to evaluate the effect of ART on myocardial deformation in HIV-infected patients. We found that myocardial deformation is likely to be reversed after the initiation of ART. The result emphasizes the importance of early ART initiation on CVD. However, the long term effect of ART remains a question and we expected further analysis of this ongoing cohort could provide more evidence on the effect of ART on CVD in the future.

PEB0185

IS HYPERTENSION MORE PREVALENT IN HIV PATIENTS? A CROSS-SECTIONAL STUDY FROM RWANDA

B. Niyongabo[1], S. Tuyishime[1], J. Kamwesiga[1], B. Asiimwe-Kateera[1], J. Gonzalez Perez[1], J. van den Hombergh[2]
[1]AIDS Healthcare Foundation, Kigali, Rwanda, [2]AIDS Healthcare Foundation, Los Angeles, United States

BACKGROUND: Hypertension (HTN) is major risk factor for cardiovascular disease among HIV infected patients. Highly active antiretroviral therapy (ART) has greatly reduced the morbidity and mortality related to HIV/AIDS. Association of hypertension (HTN) with HIV infection and initiation of ART has not been sufficiently evaluated in our context.

METHODS: A cross-sectional study was conducted at three AHF supported sites in Kigali. Patients older than 21 years,resident in Kigali area and followed up in the three facilities were offered to participate in the study. A questionnaire on life style and risk factors for hypertension was administered and clinical files were used to get additional information. Patients were selected using matched age and sex to identify HIV negative controls in the same community. The study was conducted between December 2014 and June 2015. Hypertension was defined as a systolic blood pressure (BP) ≥ 140 mmHg and/or diastolic BP ≥ 90 mmHg taken at 2 different occasions. In descriptive analysis, proportions were compared using chi square. Logistic regression was used to identify factors independently associated with hypertension.

RESULTS: 835 clients were included in the study. 68% were female, 38% were ≥ 40 years, and 31% were unemployed. 30% of participants were overweight or obese. 31% were HIV negative, 30% HIV positive ART-naïve, 39% HIV positive on ART and 92% were WHO clinical stage 1. The prevalence of hypertension was 20% in HIV positive patients not on ART, 16% in patients on ART and 13% in HIV-negative controls. In the multivariate regression analysis, HIV positive not on ART (Odds Ration [OR] 1.73, [95% CI]:1.04-2.89, p=0.035) versus HIV negative, unemployment (OR 2.54, 95% CI 1.13-5.72, p=0.024), and age 40-49years (OR 2.85, 95% CI 1.51-5.37, p=0.001 were associated with an increased risk of hypertension.

CONCLUSIONS: In line with previous studies, we found that risk of hypertension increases with age. Routine monitoring of Blood Pressure needs to be reinforced in national guidelines for People living with HIV especially in those above 40 years. Income generating activities should be availed consistently to address hypertension risks in people living with HIV in Rwanda.

PEB0186

WHO HEARTS TREATMENT PROTOCOL FACILITATES INTEGRATION OF HYPERTENSION MANAGEMENT INTO HIV CARE AND IMPROVES BLOOD PRESSURE CONTROL AT THE LARGEST HIV CLINIC IN UGANDA

M. Muddu[1], I. Kimera[1], R. Ssennyonjo[1], R. Katwesigye[1], A. Katahoire[2], S.P. Kigozi[3], F. Semitala[2], J. Schwartz[4], I. Ssinabulya[5]
[1]Makerere University Joint AIDS Program (MJAP), Care and Treatment, Kampala, Uganda, [2]Makerere University College of Health Sciences, Kampala, Uganda, [3]Infectious Disease Research Collaboration (IDRC), Kampala, Uganda, [4]Yale School of Medicine, New Haven, United States, [5]Uganda Heart Institute, Kampala, Uganda

BACKGROUND: Persons Living with HIV (PLHIV) receiving antiretroviral therapy have increased risk of cardiovascular disease (CVD). Integration of services for hypertension (HTN), the primary CVD risk factor, into HIV clinics is recommended in Uganda. At Makerere University Joint AIDS program (MJAP's) HIV Centre of Excellence (COE) providing ART to over 16500 PLHIV, HIV control as shown by viral suppression is at 97%. Paradoxically, among PLHIV who have HTN, only 23% were receiving appropriate anti-hypertensive treatment despite a high prevalence of HTN of 21%. The purpose of the project was to integrate screening and treatment of HTN into HIV care at Mulago ISS clinic.

DESCRIPTION: This implementation science project started in August 2019. We aimed to screen 100% of all PLHIV for HTN, initiate HTN treatment in at least 90% of HTN patients and achieve BP control of 50% at one year. The implementation package included: training 36 health care providers on WHO HEARTS guideline for CVD, patient education and counseling on HTN/HIV by HIV peer counselors, one page HTN treatment protocol, adopting WHO data collection tools as well as HTN targets (50% of HTN PLHIV with BP ≤ 140/90), providing medicines for HTN (Amlodipine, Valsartan and Hydrochlorothiazide) at no cost to patients and task shifting HTN screening to HIV peer counselors and treatment to nurses and clinical officers.

LESSONS LEARNED: At three months, all the 16400 PLHIV were screened for HTN with a prevalence of HTN of 24% and baseline HTN control of 27%. A total of 1063 hypertensive PLHIV are enrolled into integrated HTN/HIV treatment. HTN control overall is 64% at 3 months and is 74% among clients who have completed 4 months of treatment. The HIV care cascade continued to perform well despite HTN/HIV integration at 92%, 91% and 97% of the UNAIDS 90-90-90 goals.

CONCLUSIONS/NEXT STEPS: A quarter of adult PLHIV have HTN. Simple, stepwise treatment protocols are effective for HTN control and facilitate task shifting of HTN screening and treatment. Continuous supply of anti-hypertensive medicines is necessary for effective integration. There is need to expand HTN/HIV integration efforts since integration does not interfere with but rather leverages the HIV program gains.

PEB0187

CARDIOVASCULAR RISK ESTIMATION IS SUB-OPTIMAL ACROSS TWO HIV COHORTS

V. Triant[1], A. Lyass[2], L. Hurley[3], L. Borowsky[1], R. Ehrbar[2], M. Silverberg[3], J. Massaro[2], R. D'Agostino[2]
[1]Massachusetts General Hospital, Boston, United States, [2]Boston University, Boston, United States, [3]Kaiser Permanente, Oakland, United States

BACKGROUND: Persons living with HIV (PLWH) confront an elevated risk of cardiovascular disease (CVD) that may not be accurately predicted by established CVD risk prediction functions. We assessed the performance of two established CVD risk prediction functions in two clinically and geographically discrete HIV cohorts.

METHODS: CVD risk scores were calculated for PLWH in the Kaiser Permanente Northern California (KPNC) HIV Cohort and the Partners HIV Cohort, using the Framingham function for coronary heart disease (CHD) and the American College of Cardiology/American Heart Association (ACC/AHA) atherosclerotic CVD (ASCVD) function. Outcomes were myocardial infarction (MI) or coronary death for the Framingham function and MI, stroke or coronary death for the ASCVD function. Within each cohort and for each function, we assessed discrimination and calibration separately among men and women.

RESULTS: There were 7918 individuals in the KPNC Cohort and 2212 in the Partners Cohort. Event numbers, incidence rates, and median risk scores are shown in the Table.

Framingham CHD	N	Years Follow-up Median (Q1, Q3)	Events	Incidence Rate (per 1000 Person Years)	Risk Score Median (Q1, Q3)	C-statistic	Chi-square (p)
Partners Women	536	10.7 (5.3, 15.1)	32	5.90	0.012 (0.006, 0.029)	0.693	38.98 (p<0.0001)
Partners Men	1676	11.3 (5.9, 14.8)	97	5.59	0.030 (0.017, 0.052)	0.689	175.0 (p<0.0001)
KPNC Women	809	4.4 (1.5, 8.7)	7	1.66	0.012 (0.005, 0.025)	0.844	N/A
KPNC Men	7109	3.8 (1.5, 8.0)	116	3.34	0.026 (0.015, 0.045)	0.735	252 (p<0.0001)
ACC/AHA ASCVD	**N**	**Years Follow-up Median (Q1, Q3)**	**Events**	**Incidence Rate (per 1000 Person Years)**	**Risk Score Median (Q1, Q3)**	**C-statistic**	**Chi-square (p)**
Partners Women	318	8.3 (3.7, 13.2)	46	16.59	0.018 (0.009, 0.042)	0.670	6.46 (p=0.167)
Partners Men	1144	10.0 (4.7, 13.4)	144	13.46	0.037 (0.020, 0.070)	0.689	51.9 (p<0.0001)
KPNC Women	552	5.0 (1.7, 8.9)	22	7.33	0.015 (0.008, 0.033)	0.743	0.16 (p=0.694)
KPNC Men	5207	4.0 (1.6, 8.2)	211	8.05	0.033 (0.017, 0.064)	0.719	53.6 (p<0.0001)

[Table]

Discrimination, assessed using c statistic, was suboptimal for men and women in Partners for both functions, moderate for men in KPNC for both functions and moderate for women in KPNC for the ASCVD function. Calibration was poor for men in both cohorts for both functions and for women in Partners for the Framingham function. A chi-square p value could not be calculated for women in KPNC for the Framingham function due to a small number of events.

CONCLUSIONS: These data confirm and expand upon initial findings that established CVD risk prediction functions do not provide a good fit for HIV populations, particularly among men. Differences in model performance by gender underscore the need for both HIV-specific and gender-specific functions. Development of such models will enhance the care of aging PLWH.

BONE DISEASE

PEB0188

BONE ACCRUAL IN CHILDREN WITH PERINATALLY ACQUIRED HIV COMPARED TO HEALTHY CHILDREN

D. Jacobson[1], W. Yu[1], S. Brummel[1], H. Kalkwarf[2], S. Shiau[3], E. McFarland[4], K. Patel[5], W. Borkowsky[6], J. Chen[7], A. Mirza[8], L. DiMeglio[9], for the Pediatric HIV/AIDS Cohort Study
[1]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [2]Cincinnati Children's Hospital, Department of Pediatrics, Cincinnati, United States, [3]Rutgers University, Department of Biostatistics and Epidemiology, Piscataway, United States, [4]University of Colorado School of Medicine, Department of Pediatrics, Aurora, United States, [5]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [6]New York University Langone Medical Center, Department of Pediatrics, New York, United States, [7]Drexel University School of Medicine, Department of Pediatrics, Philadelphia, United States, [8]University of Florida, Jacksonville, Department of Pediatrics, Jacksonville, United States, [9]Indiana University School of Medicine, Department of Pediatrics, Indianapolis, United States

BACKGROUND: Low bone mineral density (BMD) has been reported in children living with perinatally-acquired HIV (CPHIV), but few studies compared slopes of bone accrual in CPHIV to healthy children.
METHODS: Among CPHIV in the U.S.-based Pediatric HIV/AIDS Cohort Study, we performed whole body (WB) and spine (SP) dual energy X-ray absorptiometry (DXA) at baseline (age 7-16 years), 2 years post-baseline, and >4 years post-baseline if Tanner 5 not reached at second DXA. Outcomes included BMD (g/cm^2) and bone area (BA, cm^2) of the WB and SP. We calculated Z-scores for WB- and SP-BMD in CPHIV for age, race (Black vs non-Black), and sex using reference curves from the longitudinal Bone Mineral Density in Childhood Study of healthy children. We fit weighted linear mixed effects models with a random slope for each child to compare BMD Z-scores across actual age by cohort, adjusted for height Z-score (HZ), and compare WB-BA and SP-BA, adjusted for sex, race, and HZ. We tested for differences in slopes over age by cohort (effect modification).
RESULTS: After weighting, baseline age, sex, and race were similar between the 172 CPHIV and 1321 healthy children. Final Z-score models assume similar slopes between cohorts. The mean difference (95% confidence interval), adjusted for HZ, in WB-BMD Z-score (-0.50 [-0.80, -0.20]) was consistently lower across age in CPHIV vs healthy children. SP-BMD Z-score was lower across age in CPHIV without adjustment for HZ, but higher (0.32 [0.03, 0.61]) in CPHIV adjusted for HZ. Slopes differed across cohorts for BA. CPHIV had slower accrual in WB-BA (slope difference: -24.74 [-34.42, -15.07]) and SP-BA (slope difference: -0.42 [-0.70, -0.13]) before 14 years. After 14 years, accrual in WB-BA (slope difference: 13.97 [-1.48, 29.42]) and SP-BA (slope difference: 0.39 [-0.08, 0.85]) was slightly faster in CPHIV. However, both adjusted mean WB-BA and SP-BA tended to be lower overall in CPHIV.
CONCLUSIONS: Across age, CPHIV had deficits in BMD and BA at most sites compared to healthy children. The exception was higher SP-BMD Z-score across age in CPHIV, perhaps explained by BA accrual deficit for height. Data are needed on CPHIV followed to adult height and peak bone mass.

PEB0189

THE IMPORTANCE OF BONE MASS DISCORDANCE IN THE DIAGNOSIS OF OSTEOPOROSIS IN PEOPLE LIVING WITH HIV

P. Vizcarra[1], J. Gallego[1], M.J. Vivancos[1], R. Ron[1], J. Martínez Sanz[1], J.L. Casado[1]
[1]Hospital Universitario Ramón y Cajal, Infectious Diseases, Madrid, Spain

BACKGROUND: Bone mass discordance between lumbar spine and femoral neck can change the prevalence of osteoporosis, though no data on its significance and characteristics are available for people living with HIV (PLHIV).
METHODS: Longitudinal study of 865 consecutive PLHIV included after a dual X-ray absorptiometry (DXA) scan. Bone mass discordance was defined as different T-score categories at lumbar spine and femoral neck: major discordance (osteoporosis versus normal), minor discordance (osteoporosis versus osteopenia, or osteopenia versus normal).
RESULTS: Of 865 individuals (mean 44.5 years, female 27%), 381 (44%) presented bone mass discordance (major, 2%; minor, 42%), mainly due to lower lumbar spine-bone mineral density (BMD). Of all individuals with osteoporosis at lumbar spine, 78% had no diagnosis of osteoporosis at femoral neck. Thus, the prevalence of osteoporosis changed from 4% when both sites were considered for diagnosis to 21% using the lowest T-score at any site. Discordant PLHIV with lower femoral neck-BMD were older (P<0.01), had lower BMI (P<0.01), higher prevalence of chronic kidney disease (P=0.08), hyperparathyroidism (P=0.08), and HCV coinfection (P=0.07) compared to discordant individuals with lower lumbar spine-BMD. Noteworthy, HIV-related factors such as low CD4+ T-cell counts (P=0.05), longer duration of HIV infection (P<0.01) and longer time on antiretroviral therapy (P=0.03) were more frequent among discordant PLHIV with lower femoral neck-BMD. Complete data to estimate the 10-year risk of fracture by Fracture Risk Assessment (FRAX) tool were available for 208 individuals. The FRAX score was significantly higher among discordant PLHIV with lower femoral neck-BMD versus those with lower lumbar spine-BMD (2.44% versus 1.79%, P=0.04, +36% for major osteoporotic fracture; 0.73% versus 0.31%, P<0.01, +135% for hip fracture).
CONCLUSIONS: Bone mass discordance was highly prevalent among PLHIV, affecting the overall diagnosis of osteoporosis and modifying the estimated risk of fracture. HIV-related factors and secondary causes of osteoporosis explained the presence of bone mass discordance.

PEB0190

CD4 NADIR AND CD4/CD8 RATIO ARE ASSOCIATED WITH BONE REMODELLING

N. Squillace[1], M. Rossi[1], F. Sabbatini[1], A. Soria[1], P. Vitiello[1], E. Colella[1], P. Columpsi[1], G.M. Migliorino[1], G. Lapadula[1]
[1]ASST-MONZA, San Gerardo Hospital, Infectious Diseases Unit, Monza, Italy

BACKGROUND: Bone turn-over markers and Bone Loss were associated with immune reconstitution in HIV infection. The aim of our study was to assess the association between plasma markers of bone remodeling (BM), as Beta cross-laps (CTX), bone alkaline phosphatase (bALP) and Osteocalcin (OC), and CD4 cell count (CD4) , and CD4/CD8 ratio. The secondary aim was to evaluate the association between bone density and Immune-status.
METHODS: A cross sectional study including HIV-positive patients under antiretroviral treatment, with available dosage CTX, bALP and OC between 2011 and 2019. When a recent DEXA scan was available

bone mineral density (BMD) at hip (F) and lumbar spine (L) were expressed as T-scores. Non-normally distributed variables were log transformed. Correlations between BM and immune-markers were assessed using Pearson correlation analysis. Similarly, Spearman correlation analysis and linear regression were used to assess possible association between BMD and the same covariates.

RESULTS: 1005 patients were included. 756 (75.2%) were male, with a mean age of 48 yrs [Interquartile range (IQR) 41-54]; 891 (88.7%) acquired HIV infection by sexual route. Their median CD4 was 578 cell/micrL (IQR 397-780), and CD4/CD8 ratio 0.6 (IQR 0.4-0.9); CD4 nadir 236 cell/micrL (IQR 108-399). DEXA scan was available for 473 patients. Median bone marker levels were as follows: CTX 440 pg/ml (IQR 291-602), bALP 14.6 mcg/L (IQR 11.1-19.3), OC 23 ng/ml (IQR 18-30). F T-score was -1.4 (IQR -2.1 - -0.8), whilst L T-score -1.3 (IQR -2.1 - -0.5).

Using multivariable linear regression analysis, nadir CD4 (per 100 cells, est 0.011, P=0.005) and CD4/CD8 ratio (est. -0.08, P<0.001) were significantly associated with log10 CTX levels, patients with lower CD4 nadir had significantly lower levels of bALP (per 100 cells, est. -0.011, P<0.001)while , CD4/CD8 ratio resulted to be inversely associated with levels of OC (est -0.04, P=0.006).

CONCLUSIONS: A history of severe immune-depression and current low CD4/CD8 are associated with high levels of bone formation markers (bALP and OC) while only current low CD4/CD8 ratio is associated with increased levels of bone resorption markers.

BACKGROUND: Chronic kidney disease (CKD) is one of the important comorbidities among people living with HIV (PLHIV). Although several CKD risk prediction models are available, their use in clinical settings has been limited. We validated the Data collection on Adverse events of anti-HIV Drugs (D:A:D) full- and short-risk score models for CKD in two Asian PLHIV databases.

METHODS: PLHIV with baseline estimated glomerular filtration rate (eGFR) >60 mL/min/1.73m^2 were included from the TREAT Asia HIV Observational Database (TAHOD) for validation of the D:A:D full-risk score model and TAHOD Low Intensity Transfer (TAHOD-LITE) for the D:A:D short model. Those with <3 eGFR measurements from baseline or previous exposure to nephrotoxic antiretrovirals were excluded. CKD was defined as two eGFR values ≤60 mL/min/1.73 m2 at least 3-months apart. Kaplan-Meier methods were used to estimate the probability of CKD development. Calibration of full- and short-risk score models Lwas estimated by calculating the Area Under the Receiver Operator Characteristic (AUROC) curve.

RESULTS: We included 5701 participants from TAHOD (full model validation) and 9791 from TAHOD-LITE (short model validation). The majority of participants were male (70%), >50% had nadir CD4 count ≤200 cells/mm3 and nearly 70% had baseline eGFR >90 ml/min/1.73m^2. The crude incidence rate of CKD was 0.81 (95% CI 7.3-8.9) per 100 person-years of follow-up (PYFU) during a median of 8.2 years follow-up in TAHOD, and 1.05 (95% CI 9.6-11.4) per 100 PYFU during a median of 4.9 years follow-up in TAHOD-LITE. There were 90, 99, and 202 CKD events among low-, medium-, and high-risk groups in TAHOD and 106, 147, and 267 CKD events among these groups in TAHOD-LITE. The progression rates for CKD at 10 years in TAHOD were 2.7%, 8.9% and 26.1% for low-, medium- and high-risk groups, and 3.5%, 11.7% and 32.4% in TAHOD-LITE. The AUROC curve for CKD risk score in the full model was 0.81 and 0.83 in the short model.

CONCLUSIONS: D:A:D CKD full- and short-risk score models well predicted CKD events in Asian PLHIV populations. These risk prediction models might be useful tools to assist clinicians in identifying individuals at high risk of developing CKD.

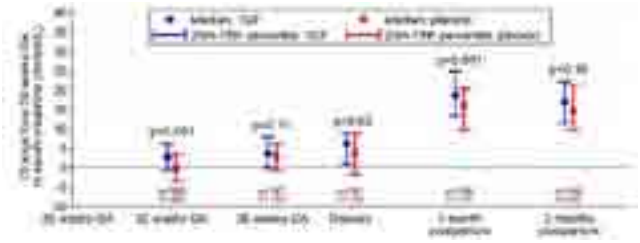
BACKGROUND: Renal safety data on tenofovir disoproxil fumarate (TDF) in HIV-uninfected pregnant women remain limited. We analyzed the evolution of several renal safety parameters using data and serum and urine samples from a randomized, double-blind, placebo-controlled clinical of TDF for the prevention of mother-to-child transmission of hepatitis B virus (HBV) in HBV mono-infected pregnant women in Thailand (iTAP study, NCT01745822).

METHODS: 331 women received either (1:1) 300 mg of TDF (n=168) or a matching placebo (n=163) once daily from 28 weeks gestational age (GA) to 2 months postpartum. Serum creatinine was measured

at 28, 32 and 36 weeks GA, delivery and 1 and 2 months post partum. Tubular dysfunction was defined by the presence at 2 months postpartum of at least two of these parameters: tubular maximum phosphate reabsorption to estimated glomerular filtration rate ratio <0.8 mmol/L, urine total protein to creatinine ratio >30 mg/mmol and urine glucose ≥10 mg/dL.

RESULTS:



[Figure 1. Change in serum creatinine from baseline during pregnancy and postpartum period in women randomized to TDF arm (blue) and women randomized to pacebo arm (red). Comparisons using Wilcoxon-Mann-Whitney test.]

At 28 weeks GA (baseline), the median (IQR) weight was 61 (56 to 70) kg, height 157 (153 to 160) cm, and serum creatinine 45 (41 to 53) µmol/L. Changes in creatinine levels from baseline to 32 weeks GA, delivery and 1 month post-partum were significantly higher in the TDF arm versus placebo (Figure 1). At 2 months postpartum, 1 of 123 women (1%) on TDF had tubular dysfunction versus 0 of 129 (0%) on placebo (Fisher's exact test: p=0.49). No kidney-related adverse events reached DAIDS Grade 3-4 nor warranted TDF discontinuation.

CONCLUSIONS: In HIV-negative, HBV-infected Asian women, TDF from 28 weeks GA to 2 months postpartum was not associated with an increase risk of tubular dysfunction despite a slight increase in creatinine level. These findings were similar to that observed in PrEP users and complement our knowledge of TDF safety in HIV-negative pregnant women such as those receiving daily TDF/emtricitabine PrEP.

METABOLIC, LIPID AND ENDOCRINE COMPLICATIONS (INCLUDING LIPODYSTROPHY)

PEB0193

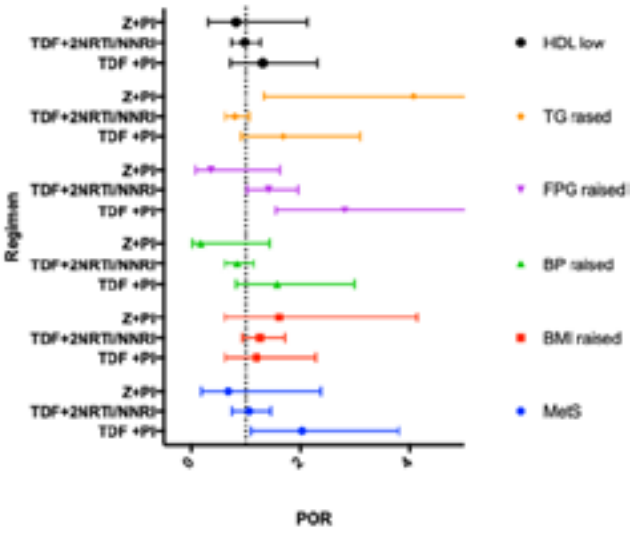
A STUDY OF EFFECT OF ANTI-RETROVIRAL THERAPY (ART) REGIMEN ON METABOLIC SYNDROME (METS) IN PEOPLE LIVING WITH HIV/AIDS (PLHIV) IN INDIA: A COMPREHENSIVE POST HOC ANALYSIS

A. Singh[1], V.K. Sashindran[1]
[1]Armed Forces Medical College, Department of Internal Medicine, Pune, India

BACKGROUND: Treatment guidelines for ART have recently undergone a major change in India. The primary ART regimen is now Tenofovir (TDF) based. As the ART programme in India has now been available for almost 15 years, an increasing number of patients are on second-line therapy which is protease-inhibitor (PI) based. While the association of dyslipidemia with nucleoside reverse transcriptase (NRTI) based regimens in India is well-reported, the effect of TDF or PIs on the same has not been studied much. This study looked at the impact of ART regimen on MetS in people living with HIV/AIDS (PLHA) .

METHODS: This study was a post hoc analysis of unpublished dissertation data in a cross-sectional prevalence study conducted in ART clinics in a tertiary care hospital in India between Dec 2016 and Nov 2018. A total of 1208 PLHA on ART were enrolled in this study. Data was obtained through personal interviews and records. ART constituted the exposure and outcomes included occurrence of MetS, obesity, hypertriglyceridemia, low HDL-c, and deranged blood sugars. Chi square test, Mann Whitney U test, logistic regression analysis was done and Prevalence Odds Ratio (POR) was calculated.

RESULTS: The overall prevalence of MetS was 21.3%. This study found that the TDF based PI regimens had a two fold risk of MetS against patients of HIV on other ART regimens (Fig 1). Also this risk was significantly higher than both TDF based non PI regimens and Non TDF based PI regimens.



[Fig 1.]

CONCLUSIONS: Thus patients on TDF based PIs had a significantly higher prevalence of MetS. This has significance in the present and future scenario of HIV therapy in India which relies heavily on TDF as a backbone of ART and is seeing increased use of PIs .

WEIGHT GAIN

PEB0194

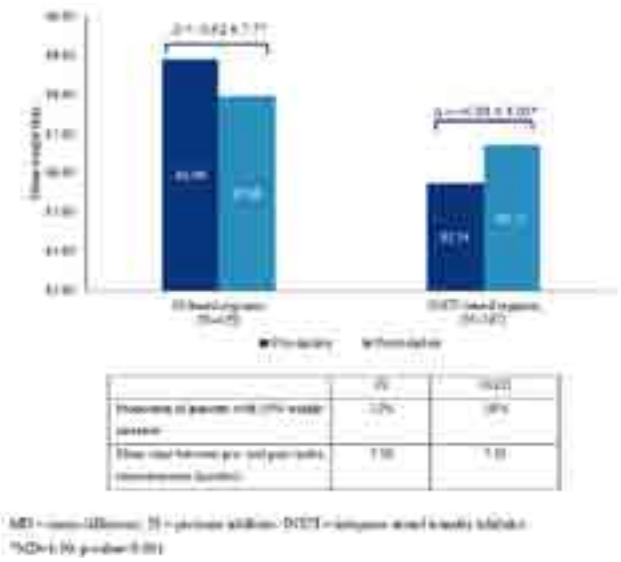
WEIGHT/BODY MASS INDEX (BMI) GAINS FOLLOWING INITIATION OF INTEGRASE STRAND TRANSFER INHIBITOR (INSTI) VERSUS PROTEASE INHIBITOR (PI) AMONG PEOPLE LIVING WITH HUMAN IMMUNODEFICIENCY VIRUS (PLWH) IN THE UNITED STATES

W. Chow[1], P. Donga[1], A. Côté-Sergent[2], C. Rossi[2], P. Lefebvre[2], M.-H. Lafeuille[2], B. Emond[2], H. Hardy[1]
[1]Janssen Scientific Affairs, LLC, Titusville, United States, [2]Analysis Group, Inc., Montreal, Canada

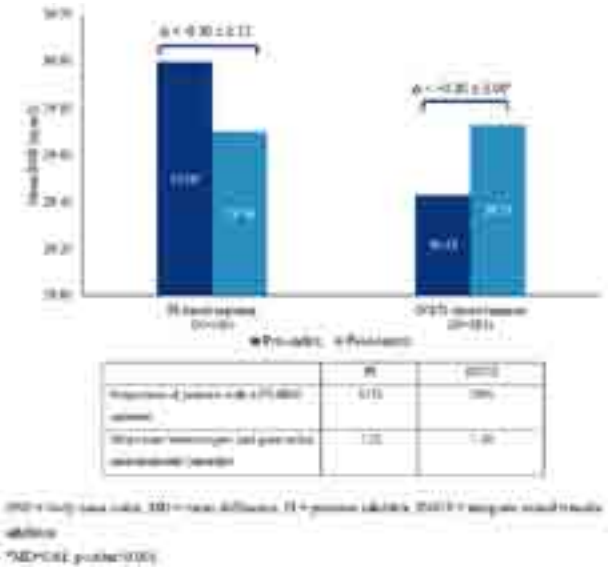
BACKGROUND: Growing evidence suggests that INSTIs may be associated with weight gain among PLWH; as a result, US-based treatment guidelines were updated to reflect such findings and raise clinicians' awareness. This real-world study compared change in weight/BMI between insured US patients initiating a PI or INSTI.

METHODS: A retrospective longitudinal study was conducted using linked claims and electronic medical records from Decision Resources Group's Real World Data Repository (7/17/2017-6/1/2019). Adult PLWH initiating a PI or INSTI on or after 7/17/2018 (index date) were included. Baseline characteristics during the 12-month pre-index period were balanced using inverse probability of treatment weighting (IPTW). Proportion of patients with weight/BMI increases ≥5% and mean weight/BMI change from pre- to post-index were evaluated. Outcomes were compared using odds ratios (ORs) and mean differences (MDs).

RESULTS: Following IPTW, 20367 patients (9993 PI and 10374 INSTI) were included. Baseline characteristics were well-balanced (mean age=50 years; ~30% females in both cohorts). Pre- and post-index weight/BMI measurements were available in 429/430 PI patients and 397/383 INSTI patients. Mean time between index and follow-up measurements was ~7 months. The proportion of patients with a weight/BMI gain ≥5% was lower in the PI (12%/11%) than the INSTI (18%/20%) cohort (OR [≥5% weight gain]=0.61; p=0.014; OR [≥5% BMI gain]=0.51; p<0.001). Mean weight/BMI gain was significantly higher (MD=1.90/0.61) in the INSTI than in the PI cohort (Figure 1 and 2 respectively).



[Figure 1. Mean change between pre- and post- index weight for PI and INSTI cohorts]



[Figure 2. Mean change between pre- and post- index BMI for PI and INSTI cohorts]

CONCLUSIONS: Results confirm previous evidence demonstrating higher weight/BMI gain in patients initiating INSTIs relative to PIs. Clinical considerations for selecting treatment options are warranted.

PEB0195

SO MUCH TO LOSE: A REVIEW OF 25 BARIATRIC SURGERY CASES IN PEOPLE LIVING WITH HIV (PLWH) AT AN URBAN, RYAN WHITE-FUNDED HIV CLINIC

M. Gareca[1]
[1]*Lehigh Valley Health Network, Infectious Diseases, Allentown, United States*

BACKGROUND: Combination antiretroviral therapy (cART) has transformed the lives of PLWH but has been associated with weight gain, obesity and related comorbidities. Bariatric surgery is utilized commonly to manage obesity, but data remains limited regarding possible impacts on cART related to altered gastrointestinal anatomy. We evaluated outcomes following bariatric surgery in a cohort of PLWH at an urban, Ryan White-funded HIV clinic.

METHODS: 28 PLWH who underwent bariatric surgery were identified retrospectively. Medical records were abstracted for demographics, HIV viral load (VL), CD4, cART, weight, BMI, GFR, hemoglobin A1c and number of medications taken for comorbidities (diabetes [DM], hypertension [HTN], hyperlipidemia) at baseline and up to 36 months post-surgery. For missing data, last observation was carried forward but not beyond the current post-surgery interval. Reasons for virologic rebound, cART changes and post-operative complications were also analyzed.

RESULTS: 25 of 28 PLWH with at least 12 months follow-up were analyzed (2 without baseline data, 1 with recent surgery were excluded). At baseline, patients were mainly female (76%) with mean age of 46 (24-61) and BMI of 43.7 kg/m2 (32-67) and underwent sleeve gastrectomy (60%) or Roux-en-Y (40%). Mean BMI decreased 28.6% at 12 months and was maintained through 36 months. Seven experienced virologic rebound (VL>200) during follow-up, 3 due to post-surgery complications (2 nausea, 1 dysphagia), and 4 with nonadherence. All re-suppressed except one (nonadherence). 7 patients had DM at baseline. Mean DM medication use per patient declined 80% by 12 months and 91% by 36 months. Nausea and acid reflux were common. 2 patients briefly switched to liquid cART due to dysphagia. No deaths, opportunistic or post-operative infections occurred.

N=25	Baseline	12 Months	*p*-value
Weight, mean (kg)	119.4	84.3	<0.001
BMI, mean (kg/m^2)	43.7	31.2	<0.001
CD4, mean (cells/mm^3)	722	706	0.704
Percentage w/ HIV VL <20 copies/mL	92%	92%	NS
HTN Medication Count, mean	1.78	0.67	<0.001
Lipid Medication Count, mean	1.33	0.33	0.041
Patients with Diabetes (N=7)	**Baseline**	**12 Months**	***p*-value**
Hemoglobin A1c, mean (%)	8.19	5.91	0.009
DM Medication Count, mean	2.14	0.43	0.011

CONCLUSIONS: We demonstrate that bariatric surgery in PLWH is an option to reduce body weight and improve outcomes of obesity-related comorbidities while not compromising virologic control. Post-operative issues impacting cART adherence can be managed effectively.

PEB0196

IMPACT OF WEIGHT GAIN ON PRESCRIBING BEHAVIOR FOR HIV PATIENTS ON INTEGRASE INHIBITOR REGIMENS USING REAL WORLD DATA

S. Gubernick[1], M. Denarie[2], K. Laessig[1], W. He[3], C. Kollipara[3], G. Srivastava[4], G. Dias-Lalcaca[5]
[1]IQVIA, Plymouth Meeting, United States, [2]IQVIA, R&D Solutions, Plymouth Meeting, United States, [3]IQVIA, Advanced Analytics, Plymouth Meeting, United States, [4]IQVIA, US Analytics Managed Services, Plymouth Meeting, United States, [5]IQVIA, Strategy/Life Sciences, Plymouth Meeting, United States

BACKGROUND: Integrase inhibitors [InSTIs] are widely considered safe and effective treatments for HIV; however, weight gain in patients on InSTIs is now being seen. We hypothesize that weight gain in patients on InSTIs does not substantively change prescribing habits, but patients who gain the most weight are likely to be switched off InSTIs.

METHODS: We leveraged IQVIA ambulatory EMR data, a fully anonymized data set covering roughly 100 million patients going back to 2006 with approximately 22 million patients per annum. Patients were selected based on their HIV positive diagnosis. This retrospective observational cohort study was conducted on HIV patients selected starting January 2013 and observed through August 2019.

RESULTS: We identified 31,841 patients on InSTIs during the selection period. 28,895 remained after removing those treated with both InSTIs and PIs [protease inhibitors] at the index date. Ultimately, our study cohort yielded 4,585 patients having both baseline and follow-up visit weights. 61.4% of patients gained weight, and of those, 80% underwent switch. Most switching occurred within the InSTI class, followed by InSTIs to PIs, then InSTIs to NNRTIs [non-nucleoside reverse transcriptase inhibitors]. Switches to PIs slightly increased as weight gain increased from 0-30 pounds, while the reverse was true for switches to NNRTIs. In patients gaining > 30 pounds, the lion's share of switching was intra-InSTI. The mean time to first switch was 1.34 years for females, 1.35 years for males. 94% of patient switching was associated with weight gains of 0 to 19 pounds, and surprisingly only 75% of patients gaining > 30 pounds switched. Across all patients, the mean weight gain to first switch was 7.6 pounds.

CONCLUSIONS: This study revealed that only 49% of InSTI patients who gained weight switched their antiretroviral therapy. Most switching was within the InSTI class, even in those who gained the most weight, disproving a portion of our hypothesis. Switching between classes was modest. We acknowledge that factors other than weight gain can account for switching. Future analyses will focus on which InSTIs were associated with the most weight gain across gender, age, time to switch and concomitant usage with tenofovir alafenamide.

PEB0197

WEIGHT GAIN ASSOCIATED WITH ANTIRETROVIRAL THERAPY IN HIV-INFECTED INDIVIDUALS IS AFFECTED BY MULTIPLE FACTORS

L. Wei[1], X. Song[1], Y. Li[1], Y. Han[1], Z. Qiu[1], T. Li[1], W. Cao[1]
[1]Peking Union Medical College Hospital, Department of Infectious Disease, Beijing, China

BACKGROUND: Weight gain during antiretroviral therapy (ART), which is strongly associated with metabolic issues, has been a concern in patients live with HIV (PLWH). It has been related to use of antiretroviral medications especially integrase inhibitors in many populations. However, disease status at diagnosis may have significant impact on the baseline weight and its change overtime, especially in late presenters. In this study, we investigated dependent factors of weight gain in Chinese PLWH.

METHODS: A retrospective observational study was conducted in adult PLWHs (aged over 18 years) enrolled in Peking Union Medical College Hospital during Jun 2007 to Aug 2018. Patients' weight at baseline, one year and two years of ART were collected and analyzed in treatment-naïve individuals. We compared the weight gain data among different regimens and used linear regression models to assess weight change, adjusted for age, race, baseline CD4 count, CD4/CD8 ratio, viral load, and opportunistic infection status.

RESULTS: A total of 334 patients were included in this study, with 65 starting INSTI-based regimens (35 using DTG and 28 using RAL). 92% of these patients were male and the median age was 42 (IQR 33-50). On average, the INSTI group experienced greater weight gain of 4.6kg and 5.7kg at one-year and two-year follow-up, respectively, compared with 1.3kg and 1.6kg of those using non-INSTI regimens. Significant differences were observed in weight change of PLWH with different levels of CD4/8 ratio (<0.15, >=0.15), CD4 counts (<125, >=125), or opportunistic infection status, indicating that weight gain following ART initiation was also determined by pre-treatment stage of HIV infection.

Weight change in INSTI group stratified by clinical characteristics

Clinical Characteristics	Mean (IQR) Change in Weight (kg) at 1-year followup	p value	Mean (IQR) Change in Weight (kg) at 2-year followup	p value
Baseline CD4 cell (cells/mm3)				
CD4<=125 (n=17,7)	8.5(2-12)	0.0029	9.2(0-15.5)	0.1681
CD4>125 (n=46,30)	3.2(0-6)		4.9(2-7)	
Baseline CD4/CD8 ratio				
CD4/CD8<=0.15 (n=16,9)	8.8(2.5-13.5)	0.0028	8.9(1-17)	0.032
CD4/CD8>0.15 (n=47,28)	3.2(0-6)		4.3(1.5-6.5)	
Opportunistic infection when start INSTI regimen				
Y (n=8,4)	10.8(6-16.5)	0.0038	16.1(12-20)	0.0019
N (n=55,33)	3.7(0-6)		4.5(1-7))	

[Table.]

CONCLUSIONS: Weight gain associated with ART in treated naïve Chinese patients is affected by multiple factors. In addition to regimen-specific influences, important baseline factors should be taken into consideration when evaluating the weight gain associated with ART.

PEB0198

TENOFOVIR ALAFENAMIDE (TAF) DOES NOT INCREASE WEIGHT IN PEOPLE LIVING WITH HIV (PLWH)

K.M. Natali[1], J. Fallon[2], D. Puntiel[3], M. Metrus[3], A. Al-Dairi[3], C. Abirami Balasubramaniapandian[3], J. Slim[4]
[1]Saint Michael's Medical Center, Department of Pharmacy Services, Newark, United States, [2]Saint Michael's Medical Center, Research Department, Newark, United States, [3]Saint Michael's Medical Center, Medical Education, Newark, United States, [4]Saint Michael's Medical Center, Division of Infectious Diseases, Newark, United States

BACKGROUND: Obesity, which is associated with comorbid conditions, is becoming one of the most common ailments encountered in PLWH in our inner-city clinic in Newark, NJ. The increased use of Integrase inhibitors (INI) has been implicated as an underlying cause for this epidemic, and some studies have suggested that TAF may contribute as well.
Most of those studies, however, examined antiretroviral therapy (ART) naïve patients, in which weight gain could represent a recovering immune system.
METHODS: This was a retrospective, observational cohort study in virologically suppressed (VS) patients who switched ART. Virologic suppression was defined as HIV RNA < 200 copies/mL for at least 12 weeks on pre-switch ART regimen, that persisted for at least 24 weeks after switch.
We evaluated mean change in weight at 24 weeks after switch. We analyzed those who switched from a non-TAF containing regimen (nTAF) to nTAF (group 1) or to a TAF regimen (group 2); also, those who switched from a TAF containing regimen to TAF (group 3), or to nTAF (group 4). The one-way ANOVA test was used for statistical analysis of the primary endpoint.
RESULTS: Among the 350 patients eligible for inclusion, 64% were Male and 36% were Female. The majority of patients were Black (59%) and the mean age was 53 years (SD + 12). Weight at 24 weeks was evaluated in the 4 groups: group 1 (n = 127), group 2 (n=150), group 3 (n = 51), and group 4 (n=22). Mean changes in weight were +0.97 kg for group 1, -0.03 kg for group 2, -0.22 kg for group 3, and +0.67 kg for group 4. Mean change in weight at 24 weeks was statistically similar between groups (p = 0.81).
CONCLUSIONS: Our study showed that PLWH who are VS on a nTAF regimen did not gain weight in the first 24 weeks after switching to a TAF containing regimen, as well as those who switched from TAF to nTAF did not lose weight. This is reassuring, but requires confirmation with prospective, longer term trials, taking into consideration the backbone of the regimen.

PEB0199

WEIGHT CHANGE BEFORE AND AFTER SWITCHING THERAPY TO TENOFOVIR ALAFENAMIDE (TAF) IN VIROLOGICALLY SUPPRESSED (VS) PERSONS

K.M. Natali[1], J. Fallon[2], D. Puntiel[3], M. Metrus[3], A. Al-Dairi[3], C. Abirami Balasubramaniapandian[3], J. Slim[4]
[1]Saint Michael's Medical Center, Department of Pharmacy Services, Newark, United States, [2]Saint Michael's Medical Center, Research Department, Newark, United States, [3]Saint Michael's Medical Center, Medical Education, Newark, United States, [4]Saint Michael's Medical Center, Division of Infectious Diseases, Newark, United States

BACKGROUND: While Protease inhibitors (PIs), and more recently, integrase-strand-transfer inhibitors (INSTIs) have been associated with an increase in weight, there is a paucity of data examining the effect of regimens with TAF-based (TAFb) backbones. Moreover, there is little literature describing the effect on weight in patients switched to TAF-based backbone regimens with the same background agent
METHODS: This was an observational, retrospective study conducted at an inner-city clinic in Newark, NJ. We evaluated change in weight 24 weeks before the switch to baseline (time of switch) and baseline to 24 weeks after the switch in VS patients who were switched to a TAFb regimen with the same background agent. Background agents included PIs, INSTIs, or non-nucleoside reverse transcriptase inhibitors (NNRTIs). VS was defined as HIV RNA < 200 copies/mL at least 24 weeks before and through 24 weeks after switching regimen.
RESULTS: There were 70 patients identified who met inclusion criteria, 40 of which were Male and 30 were Female. The majority of patients were Black (57%), their mean age was 51 years (SD + 13). Mean change in weight 24 weeks pre-TAFb regimen switch compared to 24 weeks post-TAFb regimen switch was evaluated for the following groups: PI-based (n = 3), NNRTI-based (n = 27), and INSTI-based (n = 40). In the PI-based group, mean change in weight 24 weeks pre-TAFb switch and 24 weeks post-TAFb switch was +2.7 kg and -2.5 kg respectively, however the sample size was too small for statistical analysis. There was no difference in mean change in weight pre-TAFb and post-TAFb switch in the NNRTI-based group (-0.7 kg vs +2.3 kg [p = 0.28]). There was, however, a statistically significant difference in mean change in weight pre-TAFb and post-TAFb switch in the INSTI-based group (+0.26 kg vs –1.23 kg [p = 0.029]).
CONCLUSIONS: Our study suggests that patients who are VS, do not gain weight when the backbone is switched to a TAFb regimen, and may possibly loose weight if the background is an INSTI. If this finding is validated in a larger sample size, it may add another benefit of switching to TAFb backbone.

PEB0200

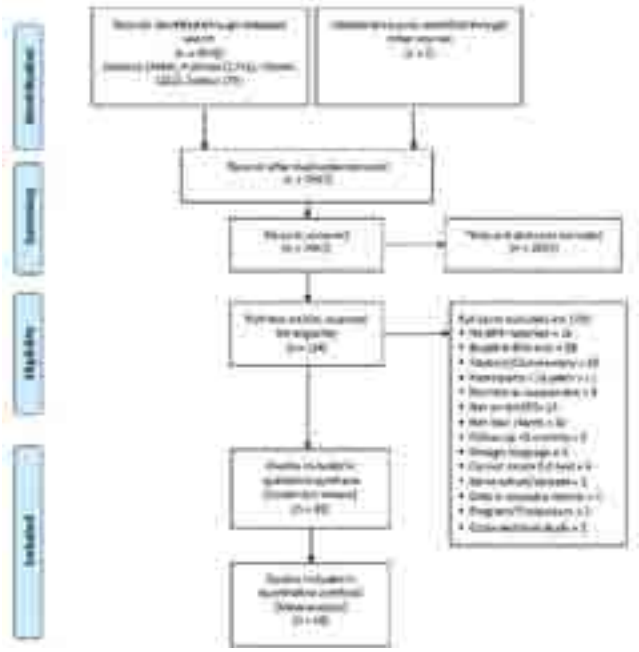
CHANGES IN BODY MASS INDEX AMONG PEOPLE LIVING WITH HIV WHO ARE NEW ON HIGHLY ACTIVE ANTIRETROVIRAL THERAPY: A SYSTEMATIC REVIEW AND META-ANALYSIS

J. Olawepo[1], J. Pharr[1], C. Cross[2], A. Kachen[1], B. Olakunde[1], R. Kabir[3], F. Sy[1]
[1]School of Public Health, University of Nevada Las Vegas, Las Vegas, United States, [2]School of Medicine, University of Nevada Las Vegas, Las Vegas, United States, [3]School of Integrated Health, University of Nevada Las Vegas, Las Vegas, United States

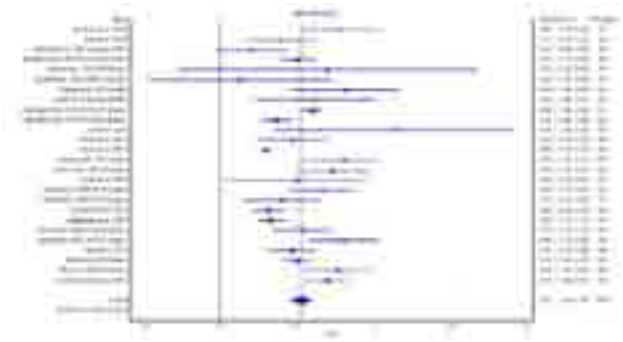
BACKGROUND: In the era of highly active antiretroviral therapy (HAART), obesity is increasingly being reported among people living with HIV (PLHIV). In this study, we reviewed published literature on body mass index (BMI) changes among treatment-naïve adult PLHIV who started HAART and remained on treatment for at least six months.

METHODS: Using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guideline, four databases were searched in February 2018, and results of included studies were synthesized to describe the BMI trend among PLHIV on treatment.

RESULTS:



[Figure 1. PRISMA Flow Diagram]



[Figure 2.]

The search generated 4948 studies, of which 30 were included in the qualitative synthesis and 18 were eligible for the meta-analysis. All the studies showed an increase in group BMI. HAART was associated with increase in BMI (pooled effect size [ES] = 1.58 kg/m^2; 95% CI: 1.36, 1.81). The heterogeneity among the eighteen studies was high (I^2 = 85%; p <.01). Subgroup analyses showed pooled ES of 1.54 kg/m^2 (95% CI: 1.21, 1.87) and 1.63 kg/m^2 (95% CI: 1.34, 1.91) for studies with follow-up ≤1 year and >1 year, respectively. We conclude that the greatest gain in BMI is in the initial 6-12 months on treatment, with minor gains in the second and subsequent years of treatment.

CONCLUSIONS: Finally, care providers working with PLHIV should take note of possible changes in BMI and the potential implications of a rising BMI on the health of their clients especially with regards to the clustering of other chronic diseases and cardio-metabolic risk factors associated with obesity and overweight.

PEB0201

RISK OF WEIGHT GAIN (WG) ACCORDING TO TYPE OF SWITCHING STRATEGY IN A LARGE COHORT OF HIV-INFECTED INDIVIDUALS WITH STABLE SUPPRESSED HIV-RNA

University of Modena and Reggio Emilia, Modena, Italy, [10]Department of Medical, Surgical and Experimental Sciences, University of Sassari, Sassari, Italy, [11]ASST Santi Paolo e Carlo, University of Milan, Clinic of Infectious and Tropical Diseases, Department of Health Sciences, Milan, Italy

BACKGROUND: There is rising evidence that INSTIs may be associated with WG in ART-naïve patients. Data on WG in virologically suppressed patients switching to INSTIs are still limited.

METHODS: ART-treated patients in the Icona Foundation Cohort with stable viral suppression (<200 copies/mL), no history of virological failure who switched for the first time over 2009-2019 to ART regimen with anchor drug belonging to a drug class (INSTI or PI/b or NNRTI) to which they were currently naïve (baseline), were included. Primary endpoint was to evaluate WG defined as an increase of ≥3 kg or ≥5% or BMI over 2 units from baseline (Outcome 1).

A more stringent WG definition (≥10% weight increase or BMI ≥30 from baseline), identifying "greater gainers" and treatment-emergent obesity, was also used (Outcome 2).

Sensitivity analysis, excluding patients with BMI≥30 or ≤18.5 at baseline or receiving TAF, was performed. Follow-up accrued until to change/stop of drug class or last observation. Inverse Probability Weighted Cox regression was used to estimate causal HR of WG, adjusting for the main confounders (Table).

RESULTS: 720 patients (male 79%; Caucasian 94.5%) included, 348 (48%) switching to INSTI, 138 (19%) to PI/b and 234 (33%) to NNRTI. WG occurred in 320/720 patients by Outcome 1 and in 109/660 by Outcome 2, with incidence rate of 24.4 [95%CI21.9-27.2] and 7.3 [6.0-8.8] per 100 PYFU, respectively. Causal HR of WG for INSTIs versus other drug-classes did not show any significant difference (Table). In the sensitivity analysis, only using Outcome 2, an increased risk of WG for INSTIs compared to NNRTIs was observed (Table).

[Table. Crude and adjusted hazard ratios (AHR) of experiencing weight gain (WG) after switching to a new ARV drug-class according to two different outcome definitions from fitting a weighted Cox regression model.]

CONCLUSIONS: No clear evidence of WG after switching to INSTIs was observed in overall population. However, an increased risk of greater WG (≥10%) or obesity was found in those switching to INSTIs compared to NNRTIs when considering normal/overweight patients not receiving TAF.

PEB0202

GREATER WEIGHT GAINS FOUND IN ART-EXPERIENCED NIGERIAN PATIENTS SWITCHING TO DTG THAN IN EFV-BASED PATIENTS AT 18-MONTHS FOLLOW-UP

J. Campbell[1], O. Abudiore[2], J. Harwell[3], C. Middlecote[4], I. Amamilo[2], J. Conroy[5], W. Eigege[2], N. Otubu[2], J. Jiboye[2], F. Lufadeju[2], C. Amole[4], O. Wiwa[2], O. Agbaji[6], D. Anweh[7], S. Akanmu[8]
[1]Clinton Health Access Initiative, Analytics and Implementation Research Team, Boston, United States, [2]Clinton Health Access Initiative, Abuja, Nigeria, [3]Clinton Health Access Initiative, Clinical Sciences Team, Boston, United States, [4]Clinton Health Access Initiative, HIV Access Program, New York, United States, [5]Clinton Health Access Initiative, HIV Access Program, Kampala, Uganda, [6]University of Jos, Department of Medicine, Jos, Nigeria, [7]Federal Medical Centre Makurdi, Markurdi, Nigeria, [8]University of Lagos, College of Medicine, Lagos, Nigeria

BACKGROUND: Weight gain is associated with dolutegravir (DTG) use. At 6 (6m) and 12 months (12m) follow-up we found underweight and normal body-mass-index (BMI) patients gained weight in Nigerian adult patients switching to DTG. Here we extended our analysis to 18 months (18m) and compared findings to patients receiving efavirenz-based ART.

METHODS: We included NNRTI-intolerant patients that switched to TDF/3TC/DTG (TLD) starting July 2017, and 18m follow-up was completed by July 2019. Records were extracted for TDF/3TC/EFV (TLE) patients, with a minimum of 6 months of ART experience, at the same facilities and time window.

We analyzed weight and BMI changes at 6m, 12m, and 18m using generalized estimating equations adjusted for facility clustering using SAS9.4.

RESULTS: 271 patients were enrolled in the original DTG study. 206 were ART-experienced with a baseline and at least one other weight data point. 187(69%) had baseline and 18m weights. 63% were female, median age was 47. 95% were virally suppressed at switch (n=168), the mean weight was 62kg and 61% had normal baseline BMI. In the TLE arm, 380 patients had baseline and at least one other weight data point. 72% were female, median age 42 and mean baseline weight 63kgs.

Absolute weight gains were found at 18m in both TLD and TLE patients: 3.9kg (p<0.01) and 2.1kg (p<0.01), respectively, with a significant difference of 1.8kg between arms(p=0.02).

Additionally, there was an increase in percentage weight gain in both arms: TLD-3%(6m), 5%(12m), and 7%(18m) (p<0.01 for all) TLE-2%(6m), 3%(12m), and 4%(18m) (p<0.01 for all). The percentage difference between arms was significant at 6m(1.6%, p=0.01) and 18m(3%, p<0.01). Isolating normal baseline BMI, there was a difference across arms in absolute weight gain at 18m only(p=0.03). No significant difference was found for overweight and obese BMI(p>0.4 for all).

CONCLUSIONS: We found weight gain in both the TLD and TLE patients at 18m, however the weight gain was greater in the TLD group signifying that discussions of healthy lifestyle is important for all patients. We did not find TLD-associated weight gain among overweight and obese patients, suggesting that withholding TLD from this cohort requires further research and may be unnecessary.

PEB0203

EFFECT OF DOLUTEGRAVIR ON WEIGHT IN PERSONS LIVING WITH HIV IN HAITI

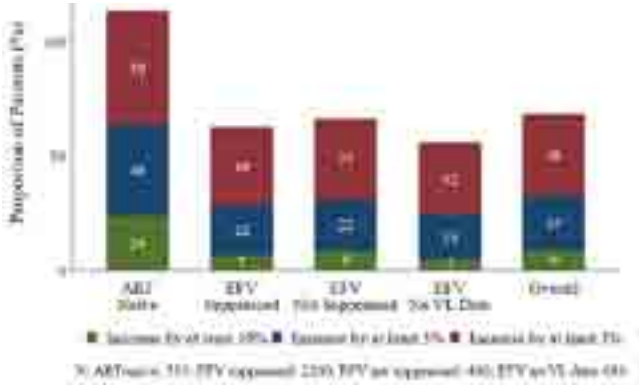
P. Severe[1], A. Sanchez-Chico[2], A. Dai[2], C. Bellot[1], G. Ceus[1], L.D. Mathurin[1], A. Clervil[1], S. Koenig[3], P. Cremieux[2], J.W. Pape[1]
[1]GHESKIO Centers, Port-au-Prince, Haiti, [2]Analysis Group, Inc., Boston, United States, [3]Brigham and Women's Hospital, Boston, United States

BACKGROUND: Dolutegravir (DTG) is being rapidly scaled-up due to its high potency, low cost, and favorable tolerability. However, recent studies have reported associated weight gain. We studied this relationship in a real-world setting among persons living with HIV in Haiti.

METHODS: Between November 2018 and September 2019, 3954 patients started DTG (ART-naïve or switching from efavirenz [EFV]-based regimen) and had ≥3 months follow-up with ≥2 weight measurements at GHESKIO, the largest HIV-services provider in the Caribbean. We analyzed weight change (from -30/+15 days of DTG initiation to latest measurement) and potential predictors.

RESULTS: 515 patients (13%) were ART-naïve, 2260 (57%) switched from EFV with HIV-1 RNA (VL) <200 copies/mL, 496 (13%) with VL ≥200 copies/mL, and 683 (17%) without VL data at switch. 2060 (52%) were female; median baseline age was 45 (IQR: 35–53).

Median time on DTG was 6 months (IQR: 4–8). Median weight gain was 1.0 kg (IQR: -1.0–3.0) overall; 1.8 kg (IQR: -1.0–5.0) among ART-naïve patients; and 0.9 kg (IQR: -1.0–3.0), 0.3 kg (IQR: -2.0–2.7), and 0.8 kg (IQR: -1.0–2.5), among patients switching from EFV (suppressed, not suppressed, and without VL data, respectively).



[Figure. Proportion of weight gain by ART category at start of Dolutegravir]

Factors positively associated with ≥10% weight gain were, among ART-naïve patients, lower weight (OR: 2.54; 95% CI: 1.67–3.87), ages 30–50 (OR: 1.95; 95% CI: 1.09–3.48), and time on DTG (OR: 1.12; 95% CI: 1.02–1.23); and among EFV patients, lower weight (OR: 2.06; 95% CI: 1.51–2.81), female sex (OR: 2.06; 95% CI: 1.50–2.82), and time on DTG (OR: 1.25; 95% CI: 1.16–1.34), with viral suppression negatively associated (OR: 0.68; 95% CI: 0.48–0.98).

CONCLUSIONS: One-tenth of patients starting DTG in Haiti gained ≥10% weight. Gains were greater among ART-naïve patients than those switching treatments (see Figure) and among low-weight and not-suppressed patients, supporting a return-to-health.

HEPATIC COMPLICATIONS (E.G., NASH)

PEB0204

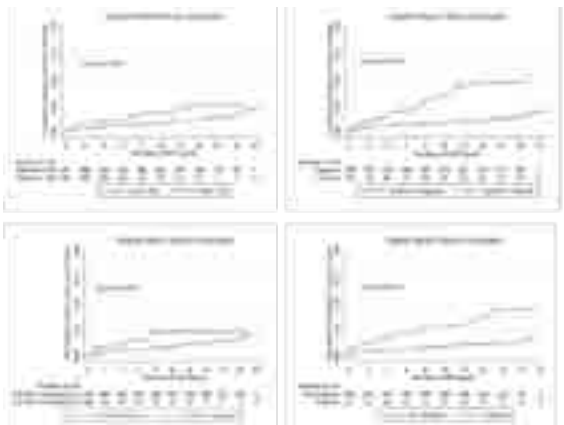
DIABETES MELLITUS IS ASSOCIATED WITH INCIDENT LIVER CIRRHOSIS IN PEOPLE LIVING WITH HIV IN THAILAND: A PROSPECTIVE COHORT ANALYSIS

T. Ueaphongsukkit[1,2], W.M. Han[1], S. Gatechompol[1,3], J. Sophonphan[1], S.J. Kerr[1,4,5], S. Ubolyam[1], S. Phonphithak[1], P. Tangkijvanich[6], A. Avihingsanon[1,3], HIV-NAT 006/207 study team
[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Tuberculosis Research Unit, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [4]Biostatistics Excellence Centre, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [5]The Kirby Institute, University of New South Wales, Sydney, Australia, [6]Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

BACKGROUND: Liver disease has emerged as a common non-AIDS related mortality among people living with HIV(PLHIV). We determined the incidence of liver cirrhosis and its associated risk factors among PLHIV on long-term combination antiretroviral therapy(cART) in Thailand from 1996-2019.

METHODS: Patients were included if they had a pre-treatment ALT, AST and platelet count measurement at cART initiation and at least one additional ALT, AST and platelet count available during the follow-up. Liver cirrhosis was defined as having APRI score >1.5 or FIB4 score >3.25 or liver stiffness measurement by transient elastography>12.5 kPa or a clinical diagnosis of cirrhosis. HBV and HCV co-infections were defined by positive HBsAg and positive anti-HCV. Factors associated with incident liver cirrhosis were analysed using Cox regression models.

RESULTS: Among 1,069 PLHIV (67%males) included, 124(12%) developed liver cirrhosis over a median of 7.1(3.9-13.3) follow-up years (incidence,1.5 per 100 person-years [PYS] during 8,225 PYS). The median age and median CD4 count at cART initiation were 32 years and 240 cells/uL, respectively. Prevalence of HBV and HCV-coinfection were 16% and 9%. During follow-up, 5.2% and 23% developed diabetes mellitus and lipodystrophy. Figure 1 shows the probability of liver cirrhosis.



[Figure 1. Cumulative incidence of liver cirrhosis stratified by CD4 count, anti-HCV status, HIV-RNA and diabetes mellitus]

Factors independently associated with liver cirrhosis (adjust hazard ratio [aHR] (95% CI)) were: HCV co-infection (4.7, 2.9-7.63, p<0.001), current HIV-RNA ≥50 copies/mL (2.21 (1.15-4.23), p=0.02; vs. <50 copies/mL), lipodystrophy (2.7 (1.41-5.17), p=0.003), HDL-cholesterol ≤40mg/mL (2.25 (1.39-3.65), p=0.001; vs. >40mg/dL) and diabetes mellitus (2.98 (1.56-5.7), p<0.001) were independently associated with incident liver cirrhosis in multivariate Cox model. Mortality among cirrhosis (5.7%) and non cirrhosis (3.8%) was comparable but ASCVD score was higher among cirrhosis (4.9 vs 2.4, p<0.001).

CONCLUSIONS: Liver cirrhosis contributes an important comorbidity in PLHIV from an Asian setting. Screening and management of co-infections and non-AIDS comorbidities such as metabolic diseases are important to reduce burden of liver diseases among PLHIV.

PEB0205

RACE AND GENDER AS PREDICTORS OF LIVER STEATOSIS IN PEOPLE LIVING WITH HIV IN THE MIAMI ADULT STUDIES ON HIV (MASH) COHORT

C. Teeman[1], J. Hernandez[1], Y. Huang[1], J. Bastida[1], N. Gonzalez[1], J. Tamargo[1], A. Johnson[1], J. Jasmin[1], L. Seminario[1], S. Martinez[1], A. Campa[1], R. Ehman[2], M. Baum[1], J. Chen[3,3]
[1]Florida International University, Dietetics and Nutrition, Miami, United States, [2]Mayo Clinic, Department of Radiology, Rochester, United States, [3]Mayo Clinic, Department of Health Science Research, Rochester, United States

BACKGROUND: Several studies have previously reported an increased risk of liver steatosis and metabolic complications in people living with HIV (PLWH). However, the role of race and gender in the development of steatosis is still not completely understood. The objective of this study was to investigate the relationship between race, gender, and liver steatosis in an HIV mono-infected population.

METHODS: Two hundred and eleven HIV mono-infected individuals were included in the current study. Liver fat percentage was calculated from magnetic resonance elastography (MRE) and blood draw procedures were completed after an overnight fast. Liver steatosis was defined as >3.5% liver fat. Insulin resistance was measured via the Triglyceride-Glucose Index (TyG). Statistical analysis included Pearson Chi-square, student t-test, and multiple logistic regression.

RESULTS: The sample was comprised of 49 White, 146 Black, and 16 unspecified participants, with 92 women and 119 men were analyzed. The prevalence of steatosis by race was 49% in White participants, 24.7% for Black participants, and 25% among unspecified participants. The prevalence of steatosis in Women was 28.3% and 31.9% in Men. White participants had a mean triglyceride level of 167.79 ± 83.90 compared to 121.52 ± 92.53 (P=0.002) in Black participants despite no difference in BMI, total energy, protein, carbohydrate, or fat intake (all P-values > 0.250). Triglyceride levels were not different between Men and Women (P=0.116). Univariate analysis showed White participants had an increased risk of liver steatosis compared to Black participants (OR=2.93 (1.49-5.76), P=0.001), but no difference between men and women (P=0.581). Multivariate logistic analysis resulted in White participants still being at a greater risk of liver steatosis (OR=2.61 (1.21-5.65), P=0.015), additionally BMI (P=0.012) and TyG Index (P<0.001) were also independently associated with higher risk of liver steatosis. Gender was not significantly associated with steatosis (P=0.718).

CONCLUSIONS: White participants had higher fasting triglyceride levels and were 2.61 times more likely to have liver steatosis than Black participants but there was no difference by gender. The latter

finding contradicts previous studies warranting further investigations into lifestyle and genetic factors that may help explain the role of race and gender in the development of liver steatosis.

PEB0206

ASSOCIATIONS BETWEEN DIET QUALITY, THE INTESTINAL MICROBIOME, AND LIVER FIBROSIS IN PEOPLE LIVING WITH HIV (PLWH) IN THE MASH COHORT

H. Martin[1], S. Martinez[1], V. Stebliankin[2], J. Tamargo[1], A. Campa[1], G. Narasimhan[2], M. Baum[1]
[1]Florida International University, Department of Dietetics and Nutrition, Miami, United States, [2]Florida International University, Bioinformatic Research Group, Miami, United States

BACKGROUND: Liver disease is a common comorbidity and a leading cause of mortality in PLWH. PLWH have also been shown to have poor diet quality and measurable differences in intestinal microbiome composition. This study's objective was to investigate the interrelationships between diet quality, intestinal microbiome composition, and liver fibrosis in PLWH.

METHODS: A cross-sectional prospective pilot study of 50 HIV+ adults on antiretroviral therapy was completed which enrolled participants from the Miami Adult Studies on HIV (MASH) cohort based in Miami, FL. Demographic data, HIV viral load, CD4 cell count, aspartate aminotransferase, alanine aminotransferase, and 24-hour recalls were obtained from the MASH cohort study. Diet quality was measured using the USDA Healthy Eating Index-2015 (HEI). Microbiome composition was measured via 16S rRNA gene sequencing obtained from fecal samples. Liver fibrosis was measured using the Fibrosis-4 Index (FIB-4). Participants were divided into two groups based on FIB-4<1.45 and FIB-4 ≥1.45. T-tests, chi-square, one sample t-test, spearman correlation, and partial least squares discriminant analysis (PLS-DA) were conducted.

RESULTS: The mean age was 55±6.81 years, 58% were male, 68% were Non-Hispanic African American, and 68% had an annual income of <$12,500. Mean CD4 cell count was significantly lower in the FIB-4 ≥1.45 group (P=0.007). The mean total HEI score for the sample was 45.67±11.54, which was significantly lower than the mean total HEI score of the US population (P<0.0001). Dairy consumption (P=0.0057) and dairy HEI score (P=0.0364) were significantly higher in the FIB-4 <1.45 group. Intestinal microbiome features that separated the FIB-4 ≥1.45 group from the FIB-4 <1.45 group using PLS-DA included the bacterial genus *Haemophilus*, associated with respiratory diseases and the oral microbiome.

CONCLUSIONS: Dairy consumption has been associated with oral health and shown to have a hepatoprotective effect. Additionally, poor oral health is related to liver disease progression. A higher abundance of *Haemophilus* within the higher FIB-4 score group was found, and this finding has also been demonstrated in other liver disease-related studies. These findings may suggest mechanisms of actions and potential for interventions in PLWH.

PEB0207

IS NAFLD THE SAME DISEASE IN HIV INFECTED PATIENTS?

S. Policarpo[1,2], M. V Machado[3], C. B Simões[3], A. Cracium[3], H. Cortez-Pinto[3,1]
[1]Faculdade de Medicina Universidade de Lisboa, Laboratório de Nutrição, Lisboa, Portugal, [2]Hospital Santa Maria - CHULN, Serviço de Dietética e Nutrição, Lisboa, Portugal, [3]Hospital Santa Maria - CHULN, Serviço de Gastrenterologia, Lisboa, Portugal

BACKGROUND: Non-Alcoholic Fatty Liver Disease (NAFLD) is a growing comorbidity in HIV-infected population, in association with the obesity pandemic. We aimed to determine the prevalence and epidemiology of NAFLD in HIV patients and to compare it with non-infected NAFLD patients.

METHODS: HIV patients without known liver disease followed at an Infectious Disease outpatient clinic in a tertiary university hospital were included. Clinical and anthropometric data were collected. Patients with opportunistic diseases, hospital admission in the previous 3 months and on hepatotoxic drugs were excluded. HIV patients were screened for NAFLD and HIV-NAFLD patients were compared with non-HIV NAFLD patients from the Hepatology Outpatient Clinic.

RESULTS: 157 patients were referred; 32 declined participation and 13 patients were excluded due to identification of hepatitis C infection and/or excessive alcohol intake; 83 patients were included in this analysis, mostly Caucasian (72%;n=60), males (65%;n=54), with mean age 53±12years (24-90years), TCD4+≥ 500cel/mm3 (78%;n=65), all with undetectable viral load. 68 patients had BMI≥25kg/m2. Less than 20% of patients presented abnormal liver enzymes, but 53% had NAFLD (n=44). The prevalence of abnormal aminotransferases was similar in HIV patients regardless of the presence of NAFLD. Using a fibroscan device, mean controlled attenuation parameter (CAP) was 282±44; Elastography showed F2-F3 fibrosis in 23% (n=10) and F4 in 9%(n=4). FIB4 could not predict liver cirrhosis and elastography did not correlate with steatosis severity. HIV-NAFLD presented higher BMI vs. HIV non-NAFLD (27.5±4.2 vs. 25.1±4.4kg/m2;p=0.031). Compared to 67 non-HIV NAFLD patients, gender and age were similar, but HIV-NAFLD patients were leaner (BMI 27.5±4.2 vs. 31.3±5.6kg/m2;p<0.001) and presented lower AST levels (24±9 vs. 45±29IU/L;p<0.001), ALT (30±19 vs. 63±46IU/L;p<0.001) and GGT (62±35 vs. 101±75IU/L;p<0.001). HIV-NAFLD patients more frequently presented advanced fibrosis compared to non-HIV NAFLD patients (32 vs. 9%;p<0.001).

CONCLUSIONS: The preliminary results of this ongoing study suggest that NAFLD is highly frequent in compensated HIV patients, and present more frequently with advanced fibrosis as compared to non-HIV NAFLD patients, despite lower BMI and lower liver enzymes. In fact, non-invasive scores did not seem to accurately discriminate advanced fibrosis in HIV-NAFLD patients.

MENTAL HEALTH AND HIV

PEB0208

HIV AND SERIOUS MENTAL ILLNESS

V. Ntlantsana[1], U. Chhagan[1], Y. Asmal[1], E. Karim[1], M. Sibiya[1], B. Chiliza[1], S. Paruk[1], A. Tomita[2]
[1]University of KwaZulu-Natal, Psychiatry, Durban, South Africa, [2]KwaZulu-Natal Research Innovation and Sequencing Platform (KRISP), University of KwaZulu-Natal, Durban, South Africa

BACKGROUND: HIV has been associated with poorer outcomes in patients with psychosis. We aimed to describe the mental health profile of HIV infected adults presenting with first episode psychosis (FEP) in a high HIV prevalence setting in South Africa.

METHODS: We recruited adult patients (18-45 years) presenting with FEP to five psychiatric units in the eThekwini Municipality, KwaZulu-Natal Province. We used the Positive And Negative Symptoms Scale to assess the severity of psychotic symptoms, the WHO Quality of Life (WHOQOL)-BREF to measure quality of life and the Alcohol, Smoking and Substance Involvement Screening test (WHO ASSIST) for substance use. Sociodemographic and trauma exposure information was collected

RESULTS: Sixty-six participants were recruited mean age 26 years (SD 8, IQR 19-33), 65% (n=43) were male. Mean age at presentation was 24 and 30 years for males and females respectively, with males being significantly younger than females (p=0.002).

HIV prevalence was 26% (n=17). After controlling for age, males were 6.6 times more likely to be HIV infected than females, p=0.0001 and increasing age was associated with an increased likelihood of being HIV positive.

HIV infected patients reported poor physical and psychological quality of life compared with those not infected (p=0.01)

There was no significant difference between the severity of psychotic symptoms between HIV infected and uninfected participants (p=0.4).

Eighty percent (n= 53) reported lifetime traumatic events and there was no difference between trauma exposure by gender and HIV status, p= 0.7 and p=0.3 respectively.

Lifetime use of tobacco, alcohol and cannabis was reported at 58%, 46%, and 31% respectively. All tobacco and cannabis users were assessed to need intervention while 63% of alcohol users were found to be in need to intervention for use.

CONCLUSIONS: The study shows that in an already marginalised group of people with serious mental illness, HIV infection is associated with with an additional burden of a lower quality of life. The study also bring to attention an important subgroup with increased vulnerability to HIV, that of males with serious mental illness. For the elimination of HIV by 2030 to be achieved, focused interventions targeting high-risk groups in society need to be developed.

PEB0209

SUICIDAL THOUGHTS AND ATTEMPTS AMONG HIV-POSITIVE TRANS WOMEN IN TRANSAMIGAS STUDY, SÃO PAULO, BRAZIL

P. Galdino Cardin de Carvalho[1], L. Fasciolo Maschião[1], G. Santa Roza Saggese[1], T. Félix Pinheiro[1], I. Leite Concílio[1], C. Spindola Luciano[1], K. Bassichetto[1], S. A Lippman[2], J. Sevelius[2], H. Gilmore[2], M.A. Veras[1], NUDHES - LGBT + HUMAN RIGHTS AND HEALTH STUDY GROUP
[1]Faculty of Medical Sciences of Santa Casa de São Paulo, Public Health, São Paulo, Brazil, [2]University of California, San Francisco, Department of Medicine, San Francisco, United States

BACKGROUND: Transgender women living with HIV face a complex set of psychosocial challenges in access to and adherence to HIV care, including stigma and discrimination. In general, trans people have higher rates of emotional health challenges related to experienced stigma, such as depression, resulting in increased levels of self-injury behaviour and suicidality (suicidal thoughts, suicide attempts and suicide rates) compared to the cisgender population. This analysis aims to investigate the prevalence of suicidal thoughts and attempts, and associated factors among HIV-positive trans women in the TransAmigas study in São Paulo, Brazil.

METHODS: TransAmigas was a 9-month randomized peer-navigation intervention based on the Gender Affirmation Model, specifically developed for the trans population. Between May and December 2018, interviewer-administered questionnaires were applied to 113 HIV positive, 18+ transgender women at study enrollment. Bivariate and multivariate Poisson regression models were employed to analyze lifetime suicidal attempt association with transphobic violence experiences, emotional health, substance use and sociodemographic variables, such as unstable housing, that is defined as living on the street, in a shelter or at work.

RESULTS: The majority of participants reported previous suicidal thoughts 69 (61.1%), 45 (39.8%) reported previous attempted suicide, and 13 (11.5%) attempted suicide in the previous 12 months. In a multivariate model adjusted for age, ethnicity, education and income, having suffered transphobic sexual violence (aPR 1.75; CI95% 1.09 - 2.80) and unstable housing (aPR 2.09; CI95% 1.29 - 3.36) were associated with having attempted suicide at least once in a participant's lifetime. Self-evaluation of emotional health and illicit substance use were not significantly associated with suicidality.

CONCLUSIONS: Suicidality is a critical health concern among transgender people and investigating risk factors of suicide among HIV-positive transgender women may inform the development of preventative interventions. The association between suicidality and experience or anticipation of violence or discrimination suggests the preponderance of social and structural factors in the health of this population. These results reinforce the importance of understanding the life trajectories of the populations we serve and addressing these in work to facilitate access to care.

PEB0210

DEPRESSION AND ASSOCIATED FACTORS AMONG ART PATIENTS IN UKRAINE

K. Dumchev[1], T. Kiriazova[1], M. Germanovych[2], C. Parrish[3], N. Puttkammer[3]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine, [3]University of Washington, Seattle, United States

BACKGROUND: Mental health disorders among PLHIV have an immense detrimental impact on initiation of and adherence to ART and progression to AIDS, leading to poorer health outcomes and mortality. Until very recently, this issue has been neglected by HIV service providers in Ukraine globally, representing a lost opportunity for more efficient HIV response. In this study we assessed prevalence of depression and its association with other health outcomes.

METHODS: This study is a secondary analysis of data from a survey of ART patients at 23 largest HIV clinics in 11 priority regions of Ukraine. A random sample was recruited at each facility to measure adherence, physical and mental health, side effects and treatment satisfaction. CES-D scale was used to assess depression. Clinical data were extracted from an electronic medical record system.

RESULTS: Of the 473 surveyed patients, 44.8% were males, average age was 40.5 years. Moderate or severe depression (CES-D score >=10) was detected in 93 (19.7%) patients. There was significant correlation of the depression score with recent injecting drug use (Pearson's r=0.178, p<0.001), lifetime history of injecting drug use (r=0.194, p<0.001), age (r=0.146, p=0.001), SF-12 physical health score (r=-0.512, p<0.001), treatment satisfaction score (r=-0.337, p<0.001), number of side effects (r=0.540, p<0.001), more recent missed doses (r=0.174, p<0.001), HCV diagnosis (r=0.185, p=0.016), TB (r=0.142, p=0.026), higher CD4 count (r=-0.134, p=0.008). Prevalence of moderate or severe depression was higher among those who experienced ART dropout (55.6% compared to 20.1%, p=0.01). There was no significant association with gender, clinical stage at diagnosis, alcohol intake, and viral suppression.

CONCLUSIONS: The study found a substantial level of depression among ART patients in Ukraine. Our findings confirmed the adverse impact of depression on HIV treatment adherence and outcomes, and the contribution of co-morbidities (such as HCV, TB, drug use) to the burden of mental illness. Integration of mental health services in HIV clinics should become a priority for programs aiming to achieve high level of adherence and the third "90" of the UNAIDS targets.

AGEING WITH HIV (INCLUDING POLYPHARMACY AND FRAILTY)

PEB0211

EVALUATION OF THE IMPLEMENTATION OF A COMPREHENSIVE HIV AND AGING PROGRAM IN A LARGE URBAN HIV CLINIC: THE GOLDEN COMPASS PROGRAM

M. Greene[1], J. Myers[2], J. Tan[2], C. Blat[3], P. Hsue[4], M. Shiels[5], M.L. Hicks[5], W. Olson[5], J. Grochowski[5], J. Oskarsson[5], D. Havlir[5], M. Gandhi[5]
[1]University of California San Francisco, Medicine - Geriatrics, San Francisco, United States, [2]University of California San Francisco, Medicine - Prevention Science, San Francisco, United States, [3]University of California San Francisco, Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [4]University of California San Francisco, Medicine - Cardiology, San Francisco, United States, [5]University of California San Francisco, Medicine - HIV, ID, and Global Medicine, San Francisco, United States

BACKGROUND: Older adults living with HIV face an increased risk of comorbid and geriatric conditions as well as unique psychosocial issues. We present findings from the initial evaluation of an innovative care model for older people living with HIV (PLHIV), called the Golden Compass Program, at the Ward 86 HIV Clinic at San Francisco General Hospital.

METHODS: Golden Compass, a comprehensive HIV and aging program- which includes co-located cardiology and geriatrics clinics, pharmacy support, exercise and brain health classes, and support groups- was initiated in January 2017 at Ward 86 to address the needs of PLHIV aged ≥50 years. The implementation science framework RE-AIM (*Reach, Effectiveness, Adoption, Implementation, and Maintenance*) was used to guide the evaluation of the program after the first 1.5 years.

RESULTS: From 1/2017-6/2018, 200 adults aged ≥50 years participated in 1 or more components of Golden Compass, corresponding to an estimated *reach* of approximately 20% of eligible patients at Ward 86. Providers, staff, and patients indicated high acceptability of the program; patients and providers were satisfied with both clinics and classes. Co-location of services and specific pharmacy and geriatric assessments, such as those for mobility, were especially valued in both groups. Among patients, connections gained through participation in classes was important (*effectiveness*). Overall *adoption* by providers was high and the program has been *implemented* and *maintained* largely as originally designed. Areas for improvement included outreach to older women and challenges of framing aging services to patients without accompanying stigma.

CONCLUSIONS: The Golden Compass program at Ward 86 is one of the first HIV and aging programs in the U.S. and evaluation of its success via implementation science methodology showed moder-

ate reach, but high effectiveness, adoption, implementation and maintenance. Next steps for Golden Compass include expanding the reach of the program, examining longer-term outcomes, and replicating its model in other settings.

PEB0212

LONG TERM IMPACT OF ABACAVIR AND TENOFOVIR (TDF OR TAF) ON BLOOD TELOMERE LENGTH

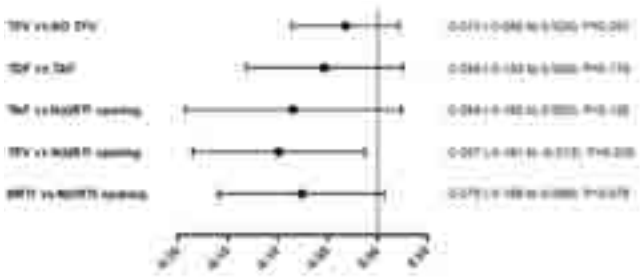
R. Montejano[1], N. Stella-Ascariz[1], B. Alejos[2], R. De Miguel[1], J. Rodriguez-Centeno[1], J.I. Bernardino[1], J.M. Castro[1], M. Mayoral[1], J. Cadiñanos[1], M.L. Montes[1], E. Valencia[1], L. Martin-Carbonero[1], B. Rodes[1], F. Arnalich[1], J.R. Arribas[1]

[1]Hospital Universitario La Paz - IdiPAZ, Madrid, Spain, [2]Institute of Health Carlos III, Madrid, Spain

BACKGROUND: Tenofovir (TFV) disoproxil fumarate (TDF) or abacavir (ABC) produced smaller gains in blood telomere length (TL) after 2 years of follow-up in our cohort of aviremic HIV-infected adults. We now report the impact of ABC and TDF or tenofovir alafenamide (TAF) in blood TL after 4 years of follow-up.

METHODS: Prospective cohort of aviremic HIV+ participants. We compared blood TL (qPCR) in participants receiving nucleoside reverse transcriptase inhibitors (NRTI), TFV (TDF or TAF) or nucleos(t)ide reverse transcriptase inhibitors (NtRTI)-sparing regimens throughout the 4 years of follow-up. Variables independently associated with TL were evaluated using a backward stepwise procedure. We assessed differences by treatment group adjusting by potential confounders.

RESULTS: 132 participants. Male: 76,5%, Caucasian: 92%, at year 4 of follow-up mean age: 53.3 years, mean duration of known HIV infection: 21 years, mean CD4, CD8 and CD4/CD8: 727, 677 cells/μL and 1.2, median blood TL(IQR): 0.95(0.845, 1.07), NtRTI use: TFV 50 (TDF 23, TDF switched to TAF 27), NRTI 61(ABC 59, AZT 2) and NtRTI-sparing 21 (boosted protease inhibitors [bPI] monotherapy 14, bPI+lamivudine 3, others 4). Crude association between independent factors and longer blood TL at 4 years: younger age (p=0.001), female (p<0.001), shorter time since HIV diagnosis (p=0.003), higher CD4/CD8 (p=0.03), lower %CD8 (p=0.009), higher CD4 (p=0.052). Adjusted associations with longer blood TL at 4 years: younger age (p=0.021), female (p=0.002), shorter time since HIV diagnosis (p=0.003) and lower %CD8 (p=0.054). An estimative analysis of the impact of type of ART on blood TL adjusted by age, sex, %CD8, %CD4 and time since HIV diagnosis, showed that, compared to participants receiving NtRTI-sparing regimens, participants receiving TFV (-0.097, p=0.025) or NRTI (-0.075, p=0.076) had shorter blood TL.



[Figure. Mean difference in telomere length after 4 years by treatment group]

CONCLUSIONS: After 4 years of follow-up, longer blood TL was associated with younger age, female sex, shorter duration of HIV infection and treatment with NtRTI-sparing regimens.

PEB0213

AGING WITH HIV: USING TREATMENT CASCADES TO IDENTIFY GAPS IN THE PROVISION OF CARE TO PEOPLE LIVING WITH HIV (PLWH)

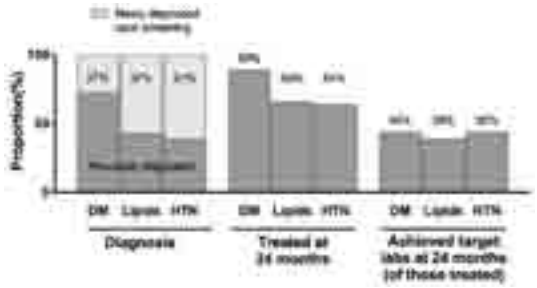
R. Rajasuriar[1,2], C. Meng Li[2,3], F. Jie Ying[4], D. Raj[2], W. Pui Li[1,2], I. Azwa[1,2], S.F. Syed Omar[1,2], A. Kamarulzaman[1,2]

[1]University of Malaya, Faculty of Medicine, Kuala Lumpur, Malaysia, [2]Centre of Excellence for Research in AIDS, University of Malaya, Kuala Lumpur, Malaysia, [3]University Malaya Medical Centre, Medicine, Kuala Lumpur, Malaysia, [4]University of Malaya, Faculty of Pharmacy, Kuala Lumpur, Malaysia

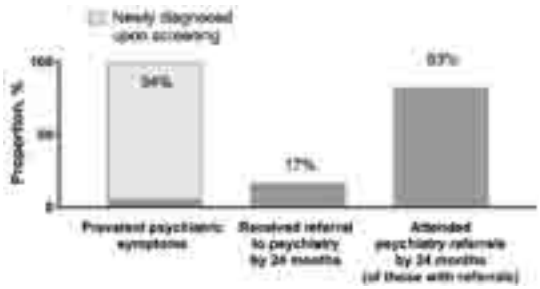
BACKGROUND: The rapidly growing epidemic of non-communicable diseases (NCDs) including mental health among aging PLWH has put a significant strain on the provision of health services in many HIV clinics. We constructed care cascades for specific NCDs and mental health among PLWH attending our centre to identify potential areas for programmatic improvement.

METHODS: This was a follow-up study of participants recruited in the Malaysian HIV & Aging study (2014-2016) at the University Malaya Medical Centre (n=336). Participants on suppressive antiretroviral therapy for a minimum of 12 months were invited to participate. At study entry, all participants underwent screening for diabetes (DM), hypertension (HTN) and dyslipidemia; and completed assessments using the depression, anxiety and stress scale (DASS-21). Screening results were recorded in medical charts and clinical management provided as per standard of care. A subsequent review of medical records was performed at 24 months following study completion among participants who remained on active follow-up. Treatment pathways for NCD treatment (drug or lifestyle modification) and psychiatric referrals were assessed based on local practice guidelines to construct the care cascade.

RESULTS: 333 participants (83% male; median age=47 years) completed follow-up at 24 months and 329 had complete laboratory/pharmacy records for NCD management. The prevalence of diabetes was 13%, dyslipidemia 88% and hypertension 44% while 45% presented with moderate-extremely severe symptoms of depression, anxiety and/or stress requiring psychiatric referrals. Treatment cascades were as follows;



[Figure. Treatment cascade for non-communicable diseases (NCDs)]



[Figure. Treatment cascade for symptoms of depression, anxiety and stress]

CONCLUSIONS: Systematic screening must be introduced to identify NCDs, particularly mental health, followed by proper linkage and referrals for management of screen positive cases.

PEB0214

PREVALENCE AND SEVERITY OF NEUROCOGNITIVE DYSFUNCTION IN AGE, SEX AND DEMOGRAPHICALLY MATCHED PEOPLE WITH HIV AND COMMUNITY DWELLING HIV-UNINFECTED UGANDAN SENIORS

A. Ezeamama[1], A. Sikorskii[1], A. Bellino[2], M.J. Boivin[1], N. Nakasujja[3], M. Ssonko[4], D. Guwatudde[5], I. Vega[2], L.H. Rubin[6], B. Giordani[7]
[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Michigan State University, East Lansing, United States, [3]Makerere University, School of Medicine, Kampala, Uganda, [4]Mildmay Uganda Ltd., Kampala, Uganda, [5]Makerere University, School of Public Health, Kampala, Uganda, [6]Johns Hopkins University, Baltimore, United States, [7]University of Michigan, Ann Arbor, United States

BACKGROUND: In the era of effective antiretrovirals, the burden of neurocognitive dysfunction (ND) among older people living with HIV (PLWH) in Africa-the region with the highest HIV burden remains understudied.

METHODS: PLWH in Uganda 50+ years (n=112) were enrolled from a tertiary health center and matched to HIV-uninfected community controls (n=107) by age (± 5 years), sex and village of residence. Eight neuropsychological tests were internally standardized by age and sex to performance by community controls and used to define proficiency in motor control, gross motor speed, executive function, processing speed, simple attention, concentration/working memory, and learning. Instrumental activities of daily living (ADL) were measured using the Waisman ADL Scale. Multi-domain neurocognitive impairment and ADL z-scores <-1.5 were used to define ND severity (not cognitively impaired, asymptomatic neurocognitive impairment (ANI) and minor/major ND) per Frascatti criteria. Multinomial logistic regression models estimated HIV-serostatus differences on ND severity after adjusting for a number of non-HIV comorbid diseases, educational status (≥advanced level, some/completed ordinary level vs. ≤primary) and above vs. ≤average score on the Hope Scale using Statistical Analysis Software (v.9.4).

RESULTS: ANI and major/minor ND were present in 12.5% (n=14) and 41.1% (n=46) respectively among older PLWH. Among HIV-uninfected controls, ANI and major/minor ND were present in 7.5% (n=8) and 22.4% (n=24), respectively. Compared to HIV-uninfected individuals, older PLWH were at a higher odds of ND severity (OR = 2.97, 95% CI: 1.67, 5.29). Increasing number of non-HIV comorbid conditions(OR=1.34, 95% CI: 1.00, 1.79) was positively associated with ND severity. Regardless of HIV-serostatus and comorbidity, higher education (some/completed ordinary level vs. ≤primary education (OR=0.48, 95% CI: 0.24, 0.92) and above vs. ≤average self-reported hope score were both associated with lower ND odds (OR=0.44, 95% CI: 0.25, 0.78).

CONCLUSIONS: Despite treatment, older PLWH experience higher rates and greater severity of ND relative to HIV-uninfected peers. However, higher education and greater self-reported hope were each cognitively sparing regardless of HIV-serostatus. This suggest that multi-modal interventions that enhance knowledge and buttress psychosocial resiliency maybe useful adjunct complements of benefit for reducing ND among older Ugandans regardless of HIV-infection.

PEB0215

COMPARISON OF THE FRAILTY SCORE AND THE POOLED COHORT EQUATIONS IN PREDICTING CARDIOVASCULAR DISEASE AMONG PERSONS WITH HIV

S. Kelly[1], K. Wu[2], K. Tassiopoulos[2], K. Erlandson[3], S. Koletar[4], F. Palella[5], ACTG A5322 Study Team
[1]Vanderbilt University Medical Center, Nashville, United States, [2]Harvard School of Public Health, Boston, United States, [3]University of Colorado School of Medicine, Denver, United States, [4]The Ohio State University Wexner Medical Center, Columbus, United States, [5]Northwestern University Feinberg School of Medicine, Chicago, United States

BACKGROUND: The 2013 Pooled Cohort Equations (PCE) for estimating 10-year atherosclerotic cardiovascular disease (ASCVD) risk has underestimated cardiovascular disease (CVD) events among people with HIV (PWH). Frailty is associated with multiple adverse health consequences and was associated with incident CVD in our cohort. We evaluate whether the addition of frailty modifies PCE's ability to estimate CVD risk among aging PWH.

METHODS: Participants in the AIDS Clinical Trials Group (ACTG) A5322 who had baseline PCE and frailty data were included. Frailty score was measured on a 0-5 scale, with frailty defined as ≥3 components of weight loss, fatigue, low activity, weakness, and slowness. The primary outcome was incident CVD (acute coronary syndrome, unstable angina, peripheral arterial disease, cerebrovascular accident, need for invasive coronary intervention). Inverse probability-weighted logistic regression models for incident CVD were fit with (a) PCE alone and (b) PCE and frailty scores together; the area under the curve (AUC) for both models were compared to assess how the addition of frailty modified the predictive ability of PCE.

RESULTS: The analysis included 999 A5322 participants (age ≥40 years at enrollment): 48 experienced incident CVD during the study period, and 71 were censored due to lack of follow-up data. Baseline 10-year ASCVD risk scores, frailty status and frailty scores are presented in Table 1. The AUC=0.738 for the PCE-only model. With frailty score added, the AUC was unchanged (0.733). In the model including both PCE and frailty score, both variables predicted CVD risk (PCE: odds ratio [OR]=1.08, 95% confidence interval [CI]=1.05-1.10, p=<0.001; frailty score: OR=1.28, 95% CI=0.99-1.65, p=0.06).

	Total (N=999)	Persons with incident CVD (N=48)	Persons without incident CVD (N=880)	Censored (N=71)
10-year ASCVD risk score, median (Q1, Q3)	4.9% (2.6%, 9.9%)	12.0% (5.0%, 25.7%)	4.8% (2.4%, 9.1%)	5.2% (3.1%, 10.1%)
Frailty status, N (%) frail	61 (6%)	6 (13%)	55 (6%)	0 (0%)
Frailty score, median (Q1, Q3)	0 (0, 1)	1 (0, 2)	0 (0, 1)	0 (0, 1)

ASCVD = atherosclerotic cardiovascular disease; CVD = cardiovascular disease
Covariates included in the PCE (assessed at entry) include: age, sex, race/ethnicity, body mass index, smoking status, diabetes history, hypertensive medication use, fasting total cholesterol, fasting high-density lipoprotein, fasting low-density lipoprotein, systolic blood pressure, and diastolic blood pressure.

[Table 1: Baseline 10-year ASCVD score, frailty status, and frailty score]

CONCLUSIONS: Addition of frailty did not modify the predictive ability of PCE. PCE independently predicts future CVD risk in this cohort of older PWH, as does frailty score, though marginally. While no CVD risk estimator has yet been validated among PWH, for aging PWH with marginal CVD risk, incorporation of the frailty score into clinical practice may provide additional or adjunctive CVD risk estimation.

PEB0216

OLDER ADULTS WITH HIV ARE NOT ALL THE SAME. DATA FROM THE HIV-FUNCFRAIL COHORT

F. Branas[1], A. Antela[2], M. Torralba[3], J. Vergas[4], M.J. Galindo[5], P. Ryan[6], F. Dronda[7], M. Ramirez[8], C. Busca[9], I. Machuca[10], M.J. Bustinduy[11], A. Cabello[12], M. Sanchez-Conde[7]

Irycis, Madrid, Spain, [8]Hospital Universitario Gregorio Marañon, Madrid, Spain, [9]Hospital Universitario La Paz, Madrid, Spain, [10]Hospital Universitario Reina Sofía, Cordoba, Spain, [11]Hospital Universitario Donostia, San Sebastian, Spain, [12]Fundacion Jimenez Diaz, Madrid, Spain

BACKGROUND: More than 50% of the people with HIV are older than fifty years. Data about this population are still scarce and mainly focused on comorbidity instead of physical function, frailty and quality of life. HIV-FUNCFRAIL Cohort is one of the four European Cohorts of older HIV adults, launched in 2018. Our main objective in this work was to know the characteristics of older adults with HIV in terms of comorbidity, polypharmacy, frailty, physical function and other geriatric syndromes.

METHODS: Longitudinal prospective cohort study. Patients from the "HIV-FUNCFRAIL: Multicenter spanish cohort to study frailty and physical function in older adults with HIV" were included. Eleven centers participated. We recorded sociodemographic data, comorbidities and variables related to HIV infection. All the patients underwent a Comprehensive Geriatric Assessment (CGA): frailty (frailty phenotype, physical function (FAC, Barthel index, SPPB, gait speed, falls), cognitive (MOCA test), mood (GDS-SF), social status and quality of life were measured.

RESULTS: 563 patients were included. Median age was 56.2 (53.7–60.6). 25.8% were women. At baseline median CD4 count was 672.5 (473.5 – 904.5). Viral load was undetectable in 91.2%. 30% of the patients had > 4 comorbidities and 21.8% had polypharmacy. Results of the CGA are shown in Table 1.

	N=563
FAC 5 (%). Able to walk independently	97.5
Barthel Index 100 (%).	97
Falls in the las year (%)	16.6
Short Physical Performance Battery < 9 (%)	17.7
Frailty (%)	
Frail	5.8
Prefrail	51.5
Robust	42.6
Gait speed < 0.8m/sg	5.4
VACS. 5 year risk of mortality (Median IQR)	7.8 (5.8-11.3)
MOCA score < 20 (%)	12.6
SF-GDS Geriatric Depression Scale >9 (%)	11.7
Not satisfied with his/her life %	27.7
Pain (%)	40
Living alone (%)	35.5
No social contacts (%)	27.7
No social support (%)	31.3

[Table 1.]

In the multivariate analysis frailty was associated with: year of HIV diagnosis <1996 (OR 0.26; 0.10-0.65); polypharmacy (OR 6.42; 2.73-15.09); MOCA score <20 (OR 3.05; 1.23-7.57) and SF-GDS score >9 (OR 7.34; 2.88-18.73).

CONCLUSIONS: Older adults with HIV are a heterogeneous group with many differences regarding physical, cognitive and social status, frailty and quality of life. It is important to detect those who are more vulnerable to design specific approaches.

OTHER ART COMPLICATIONS AND ADVERSE REACTIONS

PEB0217

TO DOSE-ADJUST OR NOT TO DOSE-ADJUST: 3TC DOSE IN RENAL IMPAIRMENT

K. Mounzer[1], L. Brunet[2], C. Wyatt[3], J. Fusco[2], V. Vannappagari[4], A. Tenorio[4], M. Shaefer[4], L. Ragone[4], R. Hsu[5,6], G. Fusco[2]
[1]Philadelphia FIGHT, Philadelphia, United States, [2]Epividian, Durham, United States, [3]Duke University, Department of Medicine, Durham, United States, [4]ViiV Healthcare, Research Triangle Park, United States, [5]AIDS Healthcare Foundation, New York, United States, [6]NYU Langone Medical Center, New York, United States

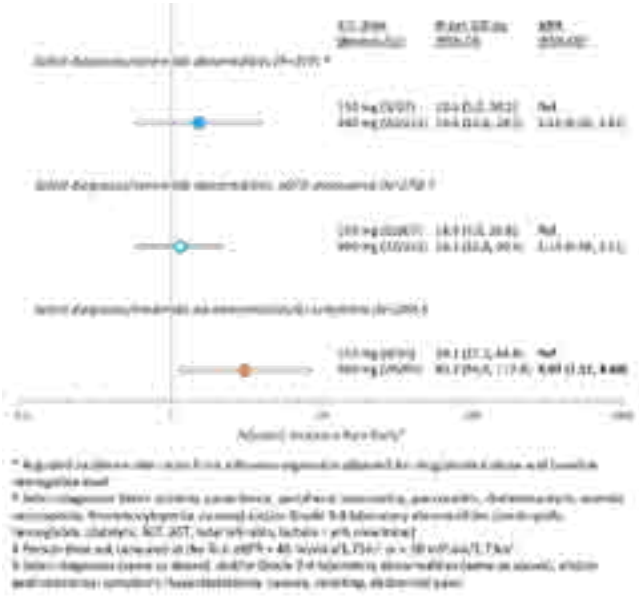
BACKGROUND: Current guidelines suggest 3TC dose adjustment for people living with HIV (PLWH) with decreased renal function, which may prevent fixed-dose combination use. We assessed the risks associated with the full (300mg) vs adjusted 3TC dose (150mg) in PLWH with decreased estimated glomerular filtration rate (eGFR).

METHODS: PLWH initiating 3TC for the first time with an eGFR ≥30 and ≤49 ml/min/1.73m^2 were identified in the OPERA cohort. Person-time was censored at 3TC discontinuation/dose change, loss-to-follow-up, death, 31Mar2019, or first out-of-range eGFR. The association between 3TC dose and incident composite events (Figure) was assessed among PLWH without prevalent events with Poisson regression adjusted for drug/alcohol abuse and hemoglobin. In a sensitivity analysis, person-time was not censored at first out-of-range eGFR.

RESULTS: PLWH on 150mg 3TC were sicker than those on 300mg (Table). There was no statistically significant difference in select diagnoses/severe lab abnormalities with 300mg 3TC vs 150mg 3TC (main analysis aIRR: 1.51; 95% CI: 0.59, 3.92; sensitivity analysis aIRR: 1.14, 95% CI: 0.59, 2.21) [Figure]. However, a statistically significantly higher rate of select diagnoses/moderate lab abnormalities/gastrointestinal symptoms was observed with 300mg vs 150mg 3TC (aIRR: 3.07, 95% CI: 1.12, 8.40) [Figure].

	3TC Daily Dose: 150 mg, n=103	3TC Daily Dose: 300 mg, n=436
Age, median (IQR)	54 (48, 61)	54 (47, 60)
Female, n (%)	40 (39)	119 (27)
Black, n (%)	67 (65)	202 (46)
Log10 Viral load, median (IQR)	2.1 (1.3, 4.5)	1.7 (1.3, 2.9)
eGFR, median (IQR)	39.9 (36.4, 45.5)	43.3 (38.4, 46.5)
Drug/alcohol abuse, n (%)	28 (27)	79 (18)
Low hemoglobin (female: <8.5g/dL; male: <9g/dL)	17 (17)	28 (6)
Prevalent Composite Unintended Events 1 (select diagnoses, Grade 3-4 lab abnormalities)	36 (35)	124 (28)
Prevalent Composite Unintended Events 2 (select diagnoses, Grade 2-4 lab abnormalities, gastrointestinal symptoms)	79 (77)	351 (80)

[Table. Characteristics at ART initiation]



[Figure. Incidence rates and rate ratios for unintended events by 3TC dose]

CONCLUSIONS: Among PLWH with decreased eGFR, there was no statistically significant difference in the risk of select diagnoses/severe lab abnormalities by daily 3TC dose, but an increased risk of GI symptoms/moderate lab abnormalities was detected with the full dose. 3TC dose adjustment may be unnecessary with eGFRs 30-49, although clinical judgement is key in weighing risks and benefits.

PEB0218

RACIAL DISPARITIES IN HOSPITALIZATIONS AMONG PERSONS LIVING WITH HIV (PLWH) IN THE US AND CANADA, 2005-2015

T. Davy-Mendez[1], S. Napravnik[1], J.J. Eron[1], S.R. Cole[1], D. van Duin[1], D.A. Wohl[1], B. Hogan[2], J.G. Fleming[3], M.A. Horberg[4], J.N. Martin[5], N.G.A. Nanditha[6], P.F. Rebeiro[7], M.J. Silverberg[8], K. Gebo[2], S.A. Berry[2], for the North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD) of IeDEA

[1]UNC Chapel Hill, Chapel Hill, United States, [2]Johns Hopkins University, Baltimore, United States, [3]Fenway Health, Boston, United States, [4]Mid-Atlantic Permanente Research Institute, Rockville, United States, [5]UCSF, San Francisco, United States, [6]UBC, Vancouver, Canada, [7]Vanderbilt University, Nashville, United States, [8]Kaiser Permanente Division of Research, Oakland, United States

BACKGROUND: Among PLWH, racial/ethnic differences in antiretroviral use and risk of comorbidities may lead to differences in hospitalization rates. We examined hospitalization rates by race/ethnicity among US and Canadian PLWH.

METHODS: We followed PLWH aged ≥18 years in care between 2005 and 2015 in six NA-ACCORD cohorts. We used modified Clinical Classifications Software to categorize the primary discharge diagnosis of hospitalizations. We calculated crude annual rates and used Poisson regression with GEE to estimate incidence rate ratios (IRR):

(1) examining linear calendar time trends stratified by race/ethnicity, and;

(2) comparing rates between racial/ethnic groups.

Adjusted models included calendar year, gender, HIV risk group, and annually-updated age, CD4, and HIV viral load.

RESULTS: Among 28,057 included patients (125,724 person-years), 32% were Black, 41% White, 16% Hispanic, and 80% cisgender men. One-quarter (n=7503) were hospitalized, contributing 21,230 total hospitalizations. Trends in crude all-cause hospitalization rates were -3% annually (95% CI -5, -2) for White, -5% (-7, -4) for Black, and -5% (-7, -3) for Hispanic patients; in 2015, crude rates were 11.9 (95% CI 10.7-13.3), 16.6 (14.8-18.7), and 11.6 (9.7-13.8) per 100 person-years, respectively. After adjusting, in each racial/ethnic group, rates were stable over time. Compared to Whites, all-cause hospitalization rates were higher for Black (adjusted IRR 1.18, 95% CI 1.07-1.29) but not Hispanic patients (0.97, 0.88-1.07). In cause-specific adjusted analyses (Table), Hispanic and Black patients had higher hospitalization rates than Whites for AIDS-defining illnesses (ADI), and Black patients had higher rates for cardiovascular, renal/genitourinary, and endocrine/metabolic hospitalizations.

Diagnostic Category	Number of hospitalizations (%)	Adjusted IRR (95% CI) Black vs White	Adjusted IRR (95% CI) Hispanic vs White
Non-AIDS-defining infection	5263 (25%)	1.08 (0.96-1.22)	0.94 (0.82-1.09)
Cardiovascular	2134 (10%)	1.43 (1.10-1.85)	0.97 (0.76-1.23)
Liver/gastrointestinal	1817 (9%)	0.94 (0.76-1.16)	1.10 (0.88-1.37)
Psychiatric	1699 (8%)	0.92 (0.72-1.17)	0.81 (0.58-1.14)
Non-AIDS-defining cancer	1411 (7%)	0.85 (0.66-1.08)	0.93 (0.69-1.26)
AIDS-defining illness	1232 (6%)	1.31 (1.02-1.69)	1.41 (1.10-1.82)
Injury	1112 (6%)	1.00 (0.81-1.25)	0.76 (0.60-0.96)
Renal/genitourinary	1076 (5%)	2.49 (1.97-3.15)	1.33 (0.95-1.85)
Endocrine/metabolic (including diabetes)	992 (5%)	1.81 (1.37-2.39)	1.16 (0.82-1.64)

[Table]

CONCLUSIONS: Adjusting for demographics, CD4, and viral load, Black and Hispanic patients had higher hospitalization rates than Whites for ADI, and Black patients had higher hospitalization rates for all-cause and several other causes. Hospitalization disparities might be partly attributable to delayed care-seeking due to socioeconomic factors, or to differences in diabetes, chronic kidney disease, and other chronic diseases.

PEB0219

EVALUATION OF HEALTH-RELATED QUALITY OF LIFE OF PEOPLE LIVING WITH HIV IN TAIWAN

L.Y. Chen[1], H.Y. Chang[1], Y.Z. Lou[1], P.Y. Wu[1], Y.C. Su[2], W.C. Liu[2], Y.C. Chuang[2], K.Y. Lee[2], C.W. Huang[2], H.Y. Sun[2], C.C. Hung[2]

[1]National Taiwan University Hospital, Center of Infection Control, Taipei City, Taiwan, Province of China, [2]National Taiwan University Hospital, Department of Internal Medicine, Taipei City, Taiwan, Province of China

BACKGROUND: Antiretroviral therapies containing integrase strand transfer inhibitors (INSTIs) have been recommended regimens in Taiwan since 2016, where HIV-positive patients receiving antiretroviral therapy have increased from 73% in 2015 to 90% in 2019, and viral suppression has increased from 87% in 2015 to 94% in 2019. Good health-related quality-of-life has been proposed as the fourth 90 target by UNAIDS. We aimed to investigate the current status of physical and mental symptoms among these virally suppressed patients in Taiwan.

METHODS: A prospective survey was conducted at an outpatient department of a university hospital to include patients with HIV suppression (<200 copies/mL) who were receiving stable antiretroviral therapy. A 20-item self-reported HIV symptom index questionnaire interview was conducted to inquire into the physical and mental symptoms. For each symptom, a five-point scale is used to score responses, as follows: (0) no symptom; (1) has symptom, but does not

bother; (2) has symptom and bothers a little; (3) has symptom and bothers; (4) has symptom and bothers a lot. Medical records were reviewed to collect information on demographic and clinical characteristics.

RESULTS: Of all 340 patients who completed the questionnaire interview, 330 (97.1%) were male, with a median age of 36.8 years (range 19.5-88 years) and 39 (11.5%) aged over 50 years. The median known duration of HIV diagnosis was 7.1 years (range, 0.09-28), with 235 (69.1%) being five years or more. Of these patients, 313 (92.1%) were on INSTI-containing regimens. The average number of reported symptoms was 5.8 (SD, 5.2), and 215 (63.2%) patients reported at least one bothersome symptom. "Fatigue/loss of energy" was the most common symptom reported by 166 patients (48.8%), followed by "trouble remembering" (164, 48.2%), and "difficulty sleeping" (143, 42.1%); 95 (28%) reported "difficulty sleeping" to be bothersome.

CONCLUSIONS: A brief, self-reported questionnaire is a simple approach to measuring HIV symptoms for planning of integrated clinical management in the successful, long-term management of HIV infection. While modern antiretroviral therapies have improved linkage to care, ART initiation, and achievement of viral suppression, more efforts are needed to improve the health-related quality of life among people living with HIV.

PEB0220

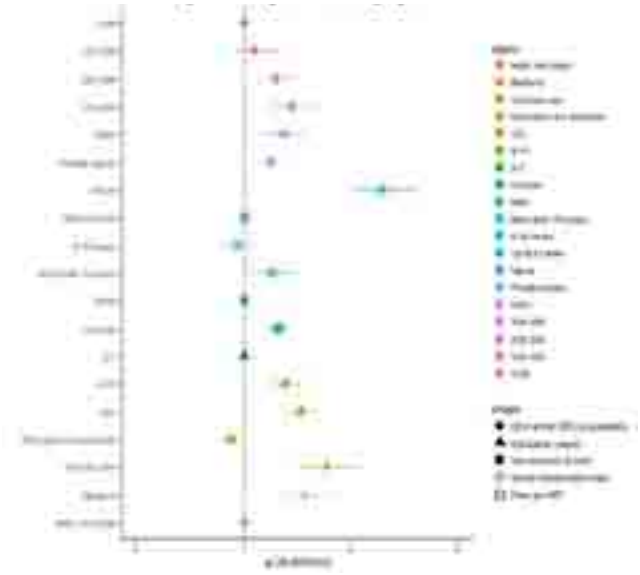
FACTORS ASSOCIATED WITH SELF-REPORTING OF ADVERSE EVENTS IN BRAZIL: RESULTS FROM A REAL-LIFE COHORT OF PLHIV USING DTG-CONTAINING REGIMENS

A.R.P. Pascom[1], L.N. da Silveira[1], F.F. Fonseca[1], G.F.M. Pereira[1], C.J.B. Batista[1], M.A. de Freitas[1]
[1]Ministry of Health of Brazil, Department of Diseases of Chronic Condition and STI, Brasilia, Brazil

BACKGROUND: Brazil offers universal and free HIV care and treatment for all people living with HIV (PLHIV). Since January/2017, the Ministry of Health of Brazil (MoH) has included DTG in its antiretroviral portfolio and, in April/2017, implemented an active pharmacovigilance (PV) to monitor adverse events (AE) among PLHIV using DTG-containing regimens (DTG-CR). AE occurrences are reported by PLHIV through a specific form. In this study, we aim describe factors associated with self-reporting an AE in a real-life cohort of PLHIV aged 18yo and using DTG-CR.

METHODS: We analyzed programmatic data from the pharmacovigilance system, which gathers information on AE occurrence reported by PLHIV using DTG-CR. PV information was collected by pharmacists at the second DTG pick-up. Logistic regression models were used to assess factors associated to the likelihood of PLHIV self-report an AE.

RESULTS: We included 275,251 people aged 18yo and over who filled the pharmacovigilance form. Median age was 38yo(IQR:29-49), 72% were men and overall AE prevalence was 1.3%. The main factors associated to PLHIV self-reporting an AE in the multivariable analysis were: starting ART with a DTG-CR (aOR:2.29;CI95%:2.01-2.61); 12+ years of education (aOR:1.53;CI95%:1.37-1.71); residence in a city with low/very low SVI (aOR:1.77;CI95%:1.51-2.08); higher CD4 counts at first DTG prescription; and being a woman (aOR:1.32; CI95%: 1.23-1.42).



[Figure. Forest plot of adjusted odds ratio (aOR) for self-reporting an AE among PLHIV using DTG-containing regimens]

CONCLUSIONS: Our study showed low prevalence of AE in Brazil in a cohort of PLHIV using DTG-CR, in accordance to what has been observed in clinical trials. Factors associated with self-perception seem to play a very important role in AE reporting by PLHIV, since we observed that PLHIV in favorable social context seem to perceive more an AE than those in most unfavorable settings. More studies are needed to better understand the contribution of individual factors on self-perception of AE and, therefore, on AE reporting.

PEB0221

MEDICATION BURDEN AND ADVERSE DRUG REACTIONS DURING THE INITIAL SIX MONTHS OF ANTIRETROVIRAL TREATMENT

A. Cama[1,2], G. Huerta[1,2], E. Gonzalez[1,2], P. Legua[1,2]
[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru

BACKGROUND: The association between the number of non-antiretroviral drugs ("medication burden") with adverse drug reactions (ADR) in the first six months of antiretroviral treatment (ART), along the effects of ADR on adherence and viral suppression, was evaluated at our HIV referral center in Lima, Peru.

METHODS: From November 2016 to December 2017, we conducted a prospective cohort study with follow-up to 24 weeks after ART initiation. The main exposure was medication burden, defined by number of non-antiretroviral drugs; ART adherence was measured by a validated questionnaire (SMAQ) and the HIV program results were used for viral suppression. ADR were detected at each study visit and by charts reviews. We present descriptive and bivariate analyses.

RESULTS: The median age of 268 participants was 29.6 years (IQR 24.4;36.5); 83.9% were men, 31 (11.6%) were ART experienced and 26 (9.7%) were on TB treatment at enrollment. Major depression was reported by 22.8%, alcoholism in 20.5% and illegal drug use in 13.4%. The principal ART regimens were TDF+3TC+EFV (40.7%) and AZT+3TC+EFV (36.2%); 48.5% used at least one non-ART drug, in participants older than 30 years the percentage was 56.6%. The main use of non-ART drug was for TB therapy (34.3%) and prophylactic drugs for opportunistic infections (25.7%). The frequency of ADR was 70%, including gastrointestinal (32.1%), sleep disturbances (16.6%)

and skin lesions (10.7%); 76.8% has severity 1 and 18.5% severity 2. In a total follow-up of 9153 persons-week, the incidence rate of ADR was 0.22 [95% CI: .019-.025]). Only 47.9% reported being adherent in all visits but 84% were adherent in visits on the first month of treatments and 81.6% in the visits after five months. Viral suppression between 3 to 9 months was 52.3%. Overall, the appearance of ADR was not associated with medication burden, neither ADR with adherence, but we found a trend in ADR appearance with total adherence.

CONCLUSIONS: An association between medication burden and ADR was not found, nevertheless a high frequency of ADR and suboptimal levels of adherent to ART and viral suppression were found.

PEB0222

DOLUTEGRAVIR-RELATED ADVERSE EVENTS: RESULTS FROM THE ACTIVE PHARMACOVIGILANCE IMPLEMENTED IN BRAZIL

F. Fernandes Fonseca[1], L. Silveira[1], M. Freitas[1], G. Pereira[1], C. Batista[1], J. Monteiro[1], V. Lima[1], A. Beber[1], A. Guarabyra[1], G. Mosimann[1], A.R. Pascom[1]
[1]Brazilian Ministry of Health, Department of Chronic Conditions Diseases and Sexually Transmitted Infections, Brasilia, Brazil

BACKGROUND: Antiretroviral treatment in Brazil is universal and free of charge for all people living with HIV (PLHIV). Following the introduction of DTG as first line therapy in national guidelines in 2017, the Ministry of Health of Brazil (BMoH) implemented a strategy of active pharmacovigilance (PV) to monitor adverse events (AE) among PLHIV using DTG-containing regimens (DTG-CR). Brazil has one of the biggest cohorts of PLHIV using DTG-CR in the world and the PV system aimed to contribute to the safety data on the use of DTG in a real-life cohort. This study aimed to estimate AE prevalence and to describe the most common AE observed in the country.

METHODS: The antiretroviral (ARV) national database registers virtually all treatment prescriptions and comprises a self-reported PV form. The PV information is primarily collected by pharmacists from the second DTG prescription and by October/2019 covered 92% of PLHIV using DTG-CR. We conducted a descriptive analysis of most frequent AE and the estimated prevalence rate of AE and severe AE occurrence. All registered PLHIV using DTG-CR aged above 18yo who filled the PV form from January 2017 to October 2019 were included in this analysis.

RESULTS: 276,602 adult PLHIV using DTG-CR were included in the analysis; median age was 38yo (IQR:29-49) and 72% were men. 3,521 PLHIV reported any AE, with an overall AE prevalence of 1.3% (CI95%= 1.23%-1.31%). The prevalence rate of severe AE was 0.07% (CI95%= 0.06%-0.08%), with only one severe AE reported as being persistent. Most common AE were nausea (876;0.32%), headache (600;0.22%), diarrhea (566;0.20%), skin disorders (460;0.17%) and insomnia (397;0.14%). Depression was reported by 73 (0.03%), weight gain by 49 (0.02%), weight loss by 29 (0.01%) and hyperglycemia by six people.

CONCLUSIONS: This study of a real-life cohort showed a low prevalence of self-reported AE associated with the use of DTG-CR in Brazil, which is in accordance to what has been observed in randomized controlled trials. This analysis did not support evidence of a possible concern about depression, nor weight gain or hyperglycemia. PV has been an important tool to support public health decisions on ART recommendations in the country.

MEASURING THERAPY TOLERANCE THROUGH PROMS AS PART OF ROUTINE CLINICAL HIV CARE: EVALUATING TWO YEARS OF EXPERIENCE

G.E. van den Berk[1], D. Ait Moha[1], J.E. Stalenhoef[1], K. Brinkman[1], N. van der Meche[1], P. Oosterhof[2]
[1]OLVG, Internal Medicine, Amsterdam, Netherlands, [2]OLVG, Department of Pharmacy, Amsterdam, Netherlands

BACKGROUND: Combination antiretroviral therapy (cART) has become more efficient and more tolerable over the years although therapy intolerance can still negatively influence health related quality of life (hrQoL). In OLVG we introduced a questionnaire in our daily clinical HIV practice to measure patient related outcomes (PROs). These could lead to interventions in the care process in order to improve hrQoL of our patients. To our knowledge no validated therapy tolerance questionnaire exists yet. Therefore we formulated one question regarding therapy tolerance with a focus on side-effects. Also, we started registering switch of cART routinely. In this study we evaluated (1) the usefulness (the "actionability") of this therapy tolerance question included in our hrQoL-questionnaire and (2) whether there was a link between therapy tolerance and therapy switch.

METHODS: Yearly all patients attending OLVG HIV center in Amsterdam are asked to fill in the routine hrQoL-questionnaire before consultation. Patients are offered a smartphone app that connects to their electronic health record (EHR). A visual analog scale is used for the therapy tolerance question: 'to what extend do you experience side effects form your HIV medication? (1 = not at all to 10 = the worst ever). This first analysis reports on how many patients did fill in the questionnaire, what scores were obtained and if poor tolerability scores results into therapy switch.

RESULTS: In 2018-2019, a total of 1713/3641 patients (47%) with access to the EHR answered the therapy tolerance question. A score of 3 or lower was reported in 11.7% in 2018 and 11.9% in 2019; a score of 8 or higher in 28.3 % in 2018 and 35.9% in 2019. In 3.6% of cases with a low side effect score (3 or lower), cART was switched due to toxicity versus a 12.5% switch due to toxicity in the group with high side effect scores of 8,9 or 10.

CONCLUSIONS: Preliminary data shows that higher therapy tolerance scores lead to more ART toxicity switches (12.5% vs 3.6%) although the effect is lower than anticipated. Final analysis will contain kind of cART used and file investigation whether tolerance scores have been discussed with the patient.

OTHER NON-COMMUNICABLE DISEASES

PILOT TRIAL OF A NOVEL BEHAVIORAL ACTIVATION/PROBLEM SOLVING SMOKING CESSATION INTERVENTION FOR PEOPLE LIVING WITH HIV IN BOTSWANA

B. Tsima[1], P. Moedi[2], J. Maunge[3], K. Mochangane[3], M. Kgogwane[3], T. Mudojwa[3], W. Bilker[4], R. Ashare[5], R. Schnoll[5], R. Gross[5]
[1]University of Botswana, Family Medicine and Public Health, Gaborone, Botswana, [2]Princess Marina Hospital, Gaborone, Botswana, [3]Botswana UPenn Partnership, Gaborone, Botswana, [4]University of Pennsylvania, Philadelphia, United States, [5]University of Pennslyvania, Philadelphia, United States

BACKGROUND: Tobacco use is prevalent among HIV infected individuals. In resource constrained settings, pharmacological smoking cessation interventions are infeasible due to their high cost. There is a need to develop and evaluate behavioral interventions to address the unique challenges of tobacco use in the HIV infected populations in these settings. We aimed to assess the feasibility and acceptability of the Behavioral Activation/Problem Solving for Smoking Cessation (BAPS-SC) intervention to determine whether it should be tested in an adequately powered randomized controlled trial.

METHODS: We merged Behavioral Activation Therapy (BAT) with the principles of Problem Solving Therapy to create a novel 5-session counseling model to address the unique challenges of tobacco cessation among those with HIV. Feasibility measures included the rate of enrollment among those eligible and the retention rate and descriptive analysis of intervention acceptability. Our secondary outcome was 7-day point smoking prevalence abstinence, confirmed with breath carbon monoxide (CO).

RESULTS: A total of 128 individuals were screened over eight weeks with 50 deemed eligible and 40 enrolled (80%). Retention at week 12 was 53% (21/40). The 7-day point prevalence abstinence, co-confirmed, at week 12 was 37.5% (15/40). All respondents indicated that they would recommend BAPS-SC to other smokers who want to quit and would be willing to participate in the program again up to the point of exit if they did not stop smoking.

CONCLUSIONS: A full scale RCT comparing BAPS-SC with usual practice is warranted to evaluate the efficacy of this novel intervention in these settings.

PEB0225

PREVALENCE OF LOW LEAN MASS IN PEOPLE LIVING WITH HIV ON ANTIRETROVIRAL THERAPY

P. Vizcarra[1], M.J. Vivancos[1], A. Abad[1], J. Gallego[1], J. Martínez Sanz[1], R. Ron[1], J.L. Casado[1]
[1]Hospital Universitario Ramón y Cajal, Infectious Diseases, Madrid, Spain

BACKGROUND: Low lean mass (LLM) may affect physical function and is associated with adverse events. We assessed the prevalence of LLM in people living with HIV (PLHIV) on antiretroviral therapy, the associated factors, and the influence of using different definitions.

METHODS: Cross-sectional study of 607 consecutive PLHIV included after a whole-body dual X-ray absorptiometry (DXA) scan. We defined LLM based on the following criteria and cut-offs: 1) appendicular lean mass index (ALMI) criteria according to European cut-off (EWGSOP, <7.26 kg/m^2 in men; <5.5 kg/m^2 in females), 2) ALMI criteria according to the NHANES cut-off (<6.19 kg/m^2 and <4.73 kg/m^2, respectively), and 3) ALMI/body mass index criteria (ALMI/BMI, <0.9 kg/m^2 and <0.63 kg/m^2, respectively).

RESULTS: The overall mean age was 44.6 years, and 28% were females. The mean (range) ALMI was 7.4 (4.75-11.16) kg/m^2 in males, and 5.83 (3.85-8.52) kg/m^2 in females. Applying the European criteria, 46% of males and 32% of females presented LLM. Additionally, the prevalence of LLM varied considerably according to the cut-off and criteria applied: NHANES, 10%; ALMI/BMI, 44% (Table). The highest values of ALMI were observed in the fourth decade, although the prevalence of LLM using European criteria was high in all age strata. In both sexes, the ALMI was negatively and weakly correlated with age (males: rho=-0.12, P=0.01; females: rho=-0.16, P=0.04), while there was no correlation with the duration of HIV infection or antiretroviral treatment. In males, this index was positively correlated with lymphocyte T-CD4+ count at inclusion and its improvement from nadir. Furthermore, the ALMI was correlated with BMI (males: rho=0.22, P<0.01; females: rho=0.46, P<0.01), total fat (males: rho=0.57, P<0.01; females: rho=0.32, P<0.01), and trunk and limbs fat.

	ALMI -EWGSOP criteria	ALMI -NHANES criteria	ALMI/BMI criteria
Total (n=607)	42%	10%	44%
Males (n=437)	46%	10%	44%
Females (n=170)	32%	8%	43%

CONCLUSIONS: LLM was highly prevalent in PLHIV under antiretroviral therapy in all age strata, with lower rates in the fourth decade. Nevertheless, the prevalence of LLM and the relationship between lean mass and body fat differed considerably according to the criteria and cut-offs applied.

PEB0226

LEVELS OF MATRIX METALLOPROTEINASES (MMPS) IN HIV-INFECTED CHILDREN AND ADOLESCENTS WITH AIRWAY OBSTRUCTION

E. Sovershaeva[1], D. Bowen[2], L.-M. Yindom[2], T. Flaegstad[3], J.Ø. Odland[4], R. Ferrand[5]
[1]The Arctic University of Norway, Department of Community Medicine, Tromsø, Norway, [2]University of Oxford, Oxford, United Kingdom, [3]The Arctic University of Norway, Clinical Medicine, Tromsø, Norway, [4]Norwegian University of Science and Technology, Community Medicine, Trondheim, Norway, [5]London School of Hygiene and Tropical Medicine, Infectious Disease, London, United Kingdom

BACKGROUND: Chronic lung complications, predominantly airway obstruction, are common in children growing up with HIV. HIV impairs host defence mechanisms in the lung, maintains chronic inflammation and facilitates lung fibrosis. Matrix metalloproteinases (MMPs) are enzymes involved in remodeling of extracellular matrix proteins that may contribute to lung fibrosis progression. In this study, we aimed to investigate the relationship between plasma levels of several MMPs and presence of airway obstruction in HIV-infected children.

METHODS: All participants were recruited at a public hospital in Harare, Zimbabwe. HIV-infected individuals on antiretroviral therapy aged 6-19 years provided blood samples. Clinical history was collected and spirometry was performed in order to define airway obstruction (FEV1 z-score <-1 without reversibility). The plasma levels of MMP 1, 3, 7, 8, 10, 12 were measured using Multiplex assay panel. Linear and logistic regression analyses were performed in order to examine to which extent levels of MMPs differed between study groups. The levels of MMPs were log-transformed prior to analyses. Analyses were adjusted for age, sex and stunting.

RESULTS: In total 296 HIV-infected participants were enrolled: 241 with airway obstruction and 55 with normal lung function. 34% of HIV-infected children with airway obstruction had prior tuberculosis (TB) compared to 14.5% of HIV-infected with normal lung function (p=0.005). Higher levels of MMP 1, 7, 10 were significantly associated with presence of airway obstruction in adjusted logistic regression analysis. Moreover, levels of MMP 1, 7, 8, 10 were associated with lower FEV1 z score in adjusted linear regression analysis. Notably, prior TB was a significant predictor of higher MMP 10 level in adjusted linear regression analysis.

CONCLUSIONS: Our findings support a role for certain MMPs in HIV-associated chronic lung impairment. Further studies are warranted in order to investigate the potential utility of them as an early plasma marker of lung damage in HIV-infected population.

PEB0227

DELAYS IN SOLID ORGAN TRANSPLANT EVALUATION AMONG HIV-INFECTED PATIENTS

G. Ambaraghassi[1], H. Cardinal[2], C. Fortin[1], M.-C. Fortin[2], P. Ferraro[3], J. Malaise[4], V. Martel-Laferrière[1], M. R. Pâquet[2], C. Poirier[5], D. Rouleau[1]
[1]Centre Hospitalier de l'Université de Montréal, Microbiologie Médicale et Infectiologie, Montreal, Canada, [2]Centre Hospitalier de l'Université de Montréal, Néphrologie, Montreal, Canada, [3]Centre Hospitalier de l'Université de Montréal, Chirurgie Thoracique, Montreal, Canada, [4]Centre Hospitalier de l'Université de Montréal, Chirurgie Générale, Montreal, Canada, [5]Centre Hospitalier de l'Université de Montréal, Pneumologie, Montreal, Canada

BACKGROUND: Solid organ transplantation (SOT) has shown to confer increased survival benefits to HIV-infected patients with terminal organ failure. Nonetheless, HIV-infected patients suffer from equal access and disparities in SOT. In this study, we compared the duration to complete SOT evaluation for HIV-infected and non-HIV-infected patients.

METHODS: The study was conducted at the Centre Hospitalier de l'Université de Montréal. Data was collected retrospectively through the TRANSHIV cohort for HIV-infected patients as well as the kidney and lung transplant registries for non-HIV infected patients. Patients were recruited if referral date to the SOT team was available. Time spans were calculated between the referral date, the registration date on the waiting list and the SOT date. Any withdrawal of the waiting list or SOT refusal was registered along its reason. Adjusted hazard ratios (HR) were calculated using Cox regression for time spans according to HIV status.

RESULTS: We identified 15 HIV-infected and 230 non-HIV-infected patients. HIV-infected patients spent an average of 869,3 days between the referral date to the SOT evaluation and the registration date on the waiting list while non-HIV-infected patients passed an average of 437 days. Likelihood of shorter time spent for SOT assessment up to the registration date on the waiting list was 61% lower for non-HIV-infected patients than for HIV-infected patients (adjusted HR, 0,39; 95% CI, 0,23 to 0,67; p = 0,0001). Average time spent between the waiting list and the SOT was 467,2 and 444,2 days respectively for HIV-infected and non-HIV-infected patients (adjusted HR, 0,89; 95% CI, 0,52 to 1,53; p = 0,6653). In the HIV group, reasons for temporary or permanent withdrawal of the waiting list include occurrence of a new lung nodule (n = 2), CD4 < 200 cells/ul (n = 1) and the need of semi-urgent surgery (n = 2).

CONCLUSIONS: Our finding highlights disparities in terms of delay of time in the SOT evaluation process up to the registration on the waiting list for HIV-infected candidates. HIV status did not affect the time on the waiting list to the SOT. Additional studies are required to further understand why HIV status prolongs SOT assessment time.

CO-MORBIDITIES AND ART COMPLICATIONS IN KEY POPULATIONS

PEB0228

HIGH ABSTINENCE RATES FROM A SMOKING CESSATION PROGRAM EMBEDDED WITHIN AN HIV CLINIC

M. McKellar[1], A. Sivashanmugam[2], E. Langhans[2], K. Keicher[1], L. Thomas[2], J. Dirkes[3], K. Dicks[1], J. Davis[2]
[1]Duke University, Division of Infectious Diseases, Durham, United States, [2]Duke University, Center for Smoking Cessation, Durham, United States, [3]Duke University, Center from Smoking Cessation, Durham, United States

BACKGROUND: Smoking rates for people living with HIV (PLWH) are 2-4 times higher than within the general US population, and smoking-related diseases are the leading cause of death in PLWH. PLWH face multiple barriers to quitting including high rates of co-morbid psychiatric illnesses and low socioeconomic status (SES). To address this, the Duke Center for Smoking Cessation and Division of Infectious Diseases (ID) partnered to develop a specialized smoking cessation program embedded within the Duke HIV Clinic.

METHODS: Patients referred to the Duke ID Smoking Cessation Clinic located in the Duke HIV Clinic in Durham, NC, were seen by both an advanced practice provider from the Duke Center for Smoking Cessation and a behavioral provider at the HIV clinic. Here, we report data on patient demographics, HIV history, cigarette use, nicotine dependence, and pre- and post-treatment smoking abstinence confirmed by carbon-monoxide breath testing.

RESULTS: Between December 2017 to April 2019, 62 PLWH were seen at the Duke ID Smoking Cessation Clinic. Demographic outcomes include: 74% male, 57% African American, 94% non-Hispanic, 52% publicly insured, 19% uninsured, and 75% with an annual income <$50,000. Among these patients, 93% had current CD4 counts >200 cells/mm^3, and 87% had undetectable HIV-1 viral loads (<50 copies/mL). Mean baseline cigarettes per day was 16.22 (SD=8.38), expired carbon monoxide level was 18.02 parts per million (ppm) (SD 11.68), pack years was 25.03 (SD=17.91), and the Fagerstrom Test for Nicotine Dependence was 4.31 (SD=2.25). Since its initiation, 400 smokers were referred to this program; 62 (16%) completed an initial visit, and 32 (52%) completed at least 1 follow-up visit. Among persons with data available on a quit attempt, 37% demonstrated smoking abstinence confirmed by expired breath carbon monoxide < 7 ppm.

CONCLUSIONS: Our approach - a smoking cessation program embedded within an HIV clinic - is serving an important need. Patients at this clinic were mostly black males with well-controlled HIV, low SES, moderate nicotine dependence, and high-level cigarette use. Those who attended a follow-up visit showed a high smoking abstinence rate. More work needs to be done on recruitment and retention to increase enrollment and engagement in a difficult-to-treat population.

ART IN ACUTE, FIRST- AND SECOND-LINE THERAPIES

PEB0229

THE BICSTAR PROSPECTIVE COHORT: REAL-WORLD EFFECTIVENESS, SAFETY AND TOLERABILITY OF BICTEGRAVIR/EMTRICITABINE/TENOFOVIR ALAFENAMIDE (B/F/TAF) IN ROUTINE CLINICAL PRACTICE IN PEOPLE LIVING WITH HIV (PLWH)

O. Robineau[1], S. Esser[2], C. Spinner[3], C. Stephan[4], J. Brunetta[5], J. De Wet[6], A. Wong[7], B. van Welzen[8], J. Lambert[9], S. Schreiber[10], M. Heinzkill[10], H. Ramroth[11], S. Sahali[12], H. Tossonian[13], A. Torres Cornejo[14], N. Marshall[15], R. Haubrich[16], D. Thorpe[11]

BACKGROUND: The purpose of this ongoing, observational cohort study in PLWH is to evaluate the effectiveness, safety and tolerability of B/F/TAF in routine clinical practice.

METHODS: Enrollment of antiretroviral treatment (ART)-naïve (TN) and ART-experienced (TE) PLWH is ongoing. This interim analysis at 6 months (6M) includes pooled data from sites in Germany (20), France (19), Canada (6), Netherlands (1) and Ireland (1). Study outcomes included HIV-1 RNA (missing data, B/F/TAF discontinuation=excluded analysis, no imputation), drug-related (DR) adverse events (AEs), weight changes and treatment persistence (% participants still on B/F/TAF at 6M).

RESULTS: A total of 613 HIV-1 infected participants (97 TN, 516 TE) started B/F/TAF and were included in the analysis at time of data cut-off. Most were male (90%), Caucasian (85%), and 43% aged ≥50 years. Prevalence of ongoing comorbidities at baseline was high (71% overall; 52%, TN; 75%, TE) including neuropsychiatric disorders (25%), arterial hypertension (18%), hyperlipidemia (18%) and cardiovascular disorders (10%). Main reasons for switch were ART simplification (60%), patient preference (35%) and side effects on previous ART (27%). Of those participants with available plasma viral load (VL) data at 6M (n=527), 89% (74/83) and 94% (418/444) TN and TE participants, respectively, had VL <50 copies/mL; 96% (80/83) and 98% (436/444) had VL <200 copies/mL. VL data were unavailable for n=86 participants. No participant developed treatment emergent resistance that reduced susceptibility to B/F/TAF. Persistence with B/F/TAF was high at 6M (95%), with 5% (n=28; 1 TN and 27 TE) discontinuing B/F/TAF prior to 6M (mostly due to DRAEs [n=19] which were neuropsychiatric symptoms in 12 participants [1 TN and 11 TE]). No participants discontinued B/F/TAF due to renal or bone DRAEs. Overall, DRAEs and DR serious AEs (DRSAEs) were reported in 11% (n=67) and 0.5% (n=3) participants, respectively. Most common DRAEs were gastrointestinal (4%) and psychiatric symptoms (3%); DRSAEs (all in TE) were depression (n=2), gastrointestinal (n=1). Median (Q1-Q3) weight change from baseline was +3kg (0-6) in TN (n=60), and +0.6kg (-0.8-3) in TE (n=338).

CONCLUSIONS: Real-world effectiveness, safety, tolerability and persistence of B/F/TAF at 6M were demonstrated in this observational cohort including older participants with ongoing comorbidities.

PEB0230

VERY HIGH BASELINE HIV VIREMIA IMPAIRS EFFICACY OF NNRTI-BASED ART: A LONG-TERM OBSERVATION IN TREATMENT-NAÏVE PATIENTS

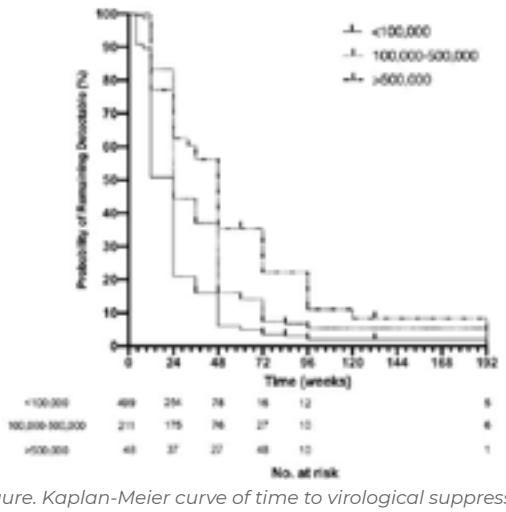
S. Chen[1], T. Li[1], W. Cao[1], Y. Han[1], X. Song[1], Y. Li[1], T. Zhu[1]

[1]Peking Union Medical College Hospital, Department of Infectious Diseases, Beijing, China

BACKGROUND: It was not completely clear whether a very high pre-therapy viral load (≥500,000 copies/ml) can further impair the virological response and risk of virological failure, especially in the long run.

METHODS: A retrospective study based on data from multicentral cohorts in China was performed. We enlisted untreated HIV-infected adults recruited between18 and 65 years old, who received China's first-line NNRTI-based regimen upon recruitment. All patients had baseline HIV-RNA levels over 500 copies/ml, showed good adherence, and were followed for at least 24 weeks. Patients were stratified according to their baseline HIV-RNA level: <100,000 copies/ml, 100,000-500,000 copies/ml and ≥500,000 copies/ml. Virological suppression was defined as the first HIV-RNA <50 copies/ml which lasted for six months. Virological failure included incomplete viral suppression (HIV-RNA ≥200 copies/mL with no recorded viral suppression within 24 weeks of treatment) and viral rebound (confirmed HIV RNA level ≥50 copies/mL after virologic suppression). Kaplan–Meier analysis and Cox proportional hazard model were used to compare time to virological suppression. Logistic regression was used to evaluate odds to virological failure.

RESULTS: 758 pre-treatment HIV patients were enlisted. The median follow-up time was 144 weeks (IQR 108-276 weeks). Most patients (68.2%) were given TDF+3TC+EFV regimen. By week 48, rates of virological suppression in three groups (<100,000, 100,000-500,000 and ≥500,000 copies/ml) were 94.1%, 85.0%, and 63.8%, respectively (p<0.001). Very high baseline HIV viremia over 500,000 copies/ml were found to be independently associated with delayed virological suppression (≥500,000 vs. <100,000, adjusted RH 0.455; 95% CI, 0.32-0.65; p <0.001) as well as incomplete viral suppression (≥500,000 vs. <100,000, adjusted OR 9.104, 95% CI, 3.050-27.175; p <0.001).



[Figure. Kaplan-Meier curve of time to virological suppression based on baseline HIV-RNA stratum. Log-rank p<0.05]

CONCLUSIONS: Very high levels of pre-treatment HIV-RNA were significantly related with delayed efficacy of NNRTI-based ART and increased risk of treatment failure. Those with high baseline viremia should be considered to start with more potent regimens.

PEB0231

CD4:CD8 RATIO NORMALIZATION WITH MODERN ANTIRETROVIRAL REGIMENS

A. Zhabokritsky[1], L. Szadkowski[1], C. Cooper[2], D. Kelly[3], N. Machouf[4], Z. Brumme[5], M. Loutfy[1], A. McClean[5], R. Hogg[5], S. Walmsley[1], CANOC
[1]University of Toronto, Toronto, Canada, [2]University of Ottawa, Ottawa, Canada, [3]Memorial University of Newfoundland, St. John's, Canada, [4]Clinique de Médicine Urbaine du Quartier Latin, Montréal, Canada, [5]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

BACKGROUND: HIV infection leads to selective depletion of CD4+ T cells and an increase in CD8+ T cells resulting in an inverted CD4:CD8 ratio, which often persists despite antiretroviral therapy (ART) and is associated with AIDS and non-AIDS related morbidities. Studies previously reported <15% ratio normalization. Current treatment guidelines emphasize early initiation of ART, which is feasible given more tolerable drugs and single-tablet regimens; both of which improve treatment adherence. We hypothesize that treatment naïve patients starting ART in the modern era have shorter time to CD4:CD8 normalization relative to historical values.

METHODS: Retrospective analysis of the Canadian Observational Cohort (CANOC), a collaboration of HIV-infected individuals initiating combination ART between 2000 and 2016. Participants starting on 2 Nucleoside Reverse Transcriptase Inhibitors (NRTIs) with either Integrase Strand Transfer Inhibitor (INSTI), non-NRTI (NNRTI) or Protease Inhibitor (PI) on or after January 1, 2011 with a pre-treatment CD4:CD8 ratio <1.0 were included. Participants were censored if they switched to a different ART class for ≥2 months. Kaplan Meier estimates were used to describe time to CD4:CD8 ratio normalization (CD4:CD8 ratio ≥1.0 on 2 consecutive measures ≥30 days apart). Multivariable proportional hazards models were used to estimate the association between ART class and time to CD4:CD8 normalization.

RESULTS: 2519 participants were included and followed for a median [IQR] 1.99 [0.92, 3.45] years. Median [IQR] age was 39 [31, 48], 54.4% identified as Caucasian, 13% as Black and 32.7% as other. At the start of ART, median CD4 count was 340 [200, 490] with a CD4:CD8 ratio of 0.36 [0.21, 0.53]. 675 (26.8%) participants normalized their CD4:CD8 ratio with a 0.28 (95%CI 0.26, 0.30) probability of achieving normalization within 2 years. After adjusting for age, baseline CD4 count, viral load and risk factor, there was no significant difference in time to normalization based on ART class (HR [95%CI] = 1.03 [0.83, 1.28] for NNRTI and 1.02 [0.81, 1.28] for PI vs. INSTI).

CONCLUSIONS: In this large Canadian cohort, CD4:CD8 ratio normalization was higher than previously reported values, but no ART class effect was identified. Whether this is associated with lower rates of comorbidity or improved survival requires further study.

PEB0232

SECOND-LINE DOLUTEGRAVIR OR PROTEASE INHIBITOR FOR ADULTS WITH HIV IN RURAL HAITI WITH VIROLOGIC FAILURE ON A FIRST-LINE NNRTI-BASED REGIMEN WITHOUT AVAILABLE GENOTYPE

G. Constant[1], A. Richterman[2,3], R. Blondel Charles[1], J. Bernard[1], F. Edmond[1], A. Beckett[4], F. Leandre[1]
[1]Zanmi Lasante, Croix-des-Bouquets, Haiti, [2]Brigham and Women's Hospital, Infectious Diseases, Boston, United States, [3]Massachusetts General Hospital, Center for Global Health, Boston, United States, [4]Partners In Health, Boston, United States

BACKGROUND: In patients experiencing virologic failure on first-line NNRTI-based regimens, changing to dolutegravir is non-inferior to lopinavir/ritonavir (both with two NRTIs) if one of the NRTIs is known to be fully active. While boosted PIs combined with NRTIs have been shown to effectively suppress HIV even with no predicted NRTI activity, it is unknown whether this is the case for dolutegravir. Because of this, the optimal second-line ART strategy is unknown for patients failing first-line ART in settings where genotype is unavailable.

METHODS: We conducted a retrospective study of Haitian adults with HIV who had virologic failure on a first-line NNRTI-based regimen and were changed to either dolutegravir or a PI with two NRTIs at 11 rural Ministry of Health clinics supported by Partners In Health / Zanmi Lasante. We abstracted demographic and clinical information from the electronic record and used a multivariable logistic regression model to identify factors associated with subsequent virologic suppression.

RESULTS: We identified 378 patients who changed ART after experiencing virologic failure on a first-line NNRTI from 7/2015-10/2019, 212 (56%) of whom were female with a median age of 41 (IQR 30-50). 137 (33%) changed to DTG, and 241 (64%) to a PI. There were 96/137 (64%) changed to dolutegravir and 54/241 (22%) to a PI who did not change NRTIs, and among these 94% received TDF and 3TC. Only 4 patients (1%) were receiving tuberculosis treatment. Subsequent viral load testing was available for 279 patients (74%), with virologic suppression in 40/65 (62%) changed to dolutegravir and 75/214 (35%) to a PI. In our multivariable model, switching to dolutegravir and age were independently associated with subsequent virologic suppression (Table).

	Adjusted Odds Ratio	95% CI
Switch to DTG (vs PI)	2.91	1.53-5.54
Changing NRTIs	1.28	0.72-2.31
Age (per five year increase)	1.15	1.06-1.24
Female	1.24	0.75-2.09

Table. Multivariable model of factors associated with subsequent virologic suppression

CONCLUSIONS: This study suggests that changing to dolutegravir is a superior strategy compared to changing to a PI for patients experiencing virologic failure on a first-line NNRTI without an available genotype, even if NRTIs are not changed. This study is limited by differential subsequent viral load testing available between dolutegravir and PIs.

PEB0233

WEIGHT CHANGE AMONG TREATMENT NAIVE WOMEN INITIATING DOLUTEGRAVIR IN THE ARIA STUDY

S. Walmsley[1], C. Orrell[2], M.J. Perez Elias[3], J.-M. Molina[4], B. Jones[5], B. Wynne[6], R. Grove[7], A. Tenorio[6], L. Curtis[7], J. van Wyk[5], A. Buchanan[6], C. Man[6]

[1]University of Toronto, Toronto, Canada, [2]University of Cape Town, Cape Town, South Africa, [3]Del Hospital Ramón y Cajal, Madrid, Spain, [4]St-Louis Hospital, Paris, France, [5]ViiV Healthcare-UK, Brentford, United Kingdom, [6]ViiV Healthcare, Research Triangle Park, United States, [7]GlaxoSmithKline, Uxbridge, United Kingdom

BACKGROUND: INSTIs and dolutegravir (DTG) have been associated with weight gain in recent studies, being more pronounced among women of African heritage and when combined with tenofovir alafenamide. We describe weight changes in HIV-1 infected women taking dolutegravir/abacavir/lamivudine (DTG/ABC/3TC) in the ARIA study.

METHODS: ARIA was a randomised, open-label, non-inferiority study conducted in 12 countries. Treatment-naive adult women were randomised to receive DTG/ABC/3TC (DTG group) or atazanavir/ritonavir + tenofovir disoproxil + emtricitabine (ATZ group). The primary endpoint was the proportion of participants with VL<50 c/ml. Utilising weight data retrospectively obtained from the central laboratory a post-hoc regression analysis, adjusted for baseline factors, was conducted for weight and BMI to Week 48.

RESULTS: 495 women were randomised and treated; 248 DTG, 247 ATZ. Median age was 37 years; 41% DTG group and 44% ATZ group were of African heritage. Mean baseline weight and BMI were similar; DTG: 70.1kg; 26.8 kg/m^2; ATZ: 71.8 kg, 27.3 kg/m^2. At week 48, adjusted mean change in weight: 2.61kg DTG group (n=208), 1.41kg ATZ group (n=192), difference = 1.20kg, 95% CI: 0.10, 2.30; p=0.0328. Adjusted mean change in BMI to week 48: 1.01kg/m^2 DTG group, 0.56kg/m^2 ATZ group, difference = 0.45kg/m^2, 95% CI: 0.02, 0.88; p=0.0388. Increases in weight of 10% or more were experienced by 18% of the DTG group and 15% of the ATZ group. Treatment emergent obesity was observed in 8% DTG group and in 6% ATZ group at week 48. Weight increase in the DTG group was significantly higher (p<0.05) as compared to the ATZ group in the following subgroups: baseline CD4<=350 cells/mm^3, baseline VL>100,000 copies, age ≥37 years, BMI>25kg/m^2 and women of white race. Among race subgroups, increases in weight were largest among women of African heritage in both groups, however the between group difference was relatively small (0.99kg) and not statistically significant (p=0.2594).

CONCLUSIONS: Initiation of DTG/ABC/3TC was associated with moderate (1.20kg) but significantly higher weight gain as compared to the ATZ group over 48 weeks. The proportion of women experiencing a 10% or more increase in weight or treatment emergent obesity was similar between treatment groups.

ART IN HIGHLY TREATMENT-EXPERIENCED PERSONS

PEB0234

CLINICAL OUTCOMES OF HEAVILY TREATMENT EXPERIENCED INDIVIDUALS IN THE OPERA COHORT

R. Hsu[1,2], J. Fusco[3], C. Henegar[4], V. Vannappagari[4], C. Llamoso[5], L. Brunet[3], P. Lackey[6], G. Pierone[7], G. Fusco[3]

[1]NYU Langone Health Center, Internal Medicine, New York, United States, [2]AIDS Healthcare Foundation, New York, United States, [3]Epividian, Durham, United States, [4]ViiV Healthcare, Research Triangle Park, United States, [5]Viiv Healthcare, Branford, United States, [6]Signature Healthcare, Charlotte, United States, [7]Whole Family Health Center, Fort Pierce, United States

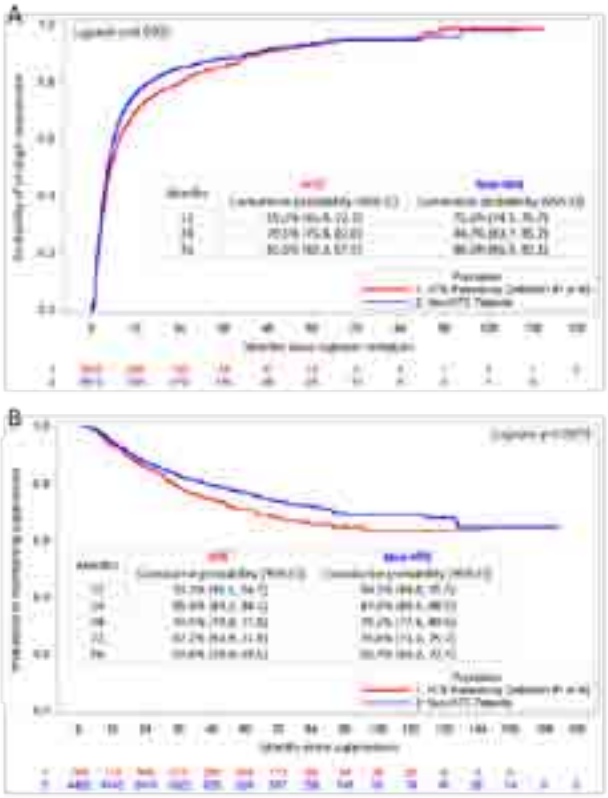
BACKGROUND: Multi-class resistance, intolerance, or interactions with long-term antiretroviral therapy (ART) results in unique ART combinations for the heavily treatment experienced (HTE) people living with HIV (PLWH). Few studies have evaluated long-term outcomes of HTE PLWH.

METHODS: PLWH in care in the OPERA Cohort on 12/31/2016 were identified as HTE (on their ≥3rd core agent class or on a regimen suggestive of HTE [Figure]) or non-HTE (ART-experienced on a three-drug regimen, not meeting the definition of HTE) and followed through study end (12/31/2018). Baseline was the start of the 12/31/2016 regimen. Baseline comparisons were made with Pearson Chi-Square or Wilcoxon Rank Sum tests. Time to virologic suppression, failure, regimen changes, and death were assessed using Kaplan-Meier methods and log-rank tests.

RESULTS: HTE PLWH (n=2,277) were older, with higher viral load, lower CD4 count, and more comorbidity than non-HTE (n=21,906) [Table]. Of individuals unsuppressed (≥50 copies/mL) at baseline, HTE PLWH were less likely to achieve suppression (24-month cumulative probability: 79.5%, 95% CI: 76.8, 82.0) than non-HTE PLWH (84.7%, 95% CI: 83.7, 85.7) [Figure A]. Among those who achieved suppression during follow-up, HTE PLWH were less likely to remain suppressed (24-month: 85.9%, 95% CI: 83.2, 88.2) than non-HTE PLWH (87.5%, 95% CI: 86.5, 88.5) [Figure B]. Death (1.6% HTE; 0.7% non-HTE p=0.0002) and changes in regimen discontinuation (45.3% HTE; 41.3% non-HTE p<0.0001) were more frequent among HTE.

	HTE Population N=2,277	Non-HTE Population N=21,906	p-value
Age, median (IQR)	49.5 (42.0, 55.8)	43.7 (32.9, 52.2)	**<.0001**
Female, n (%)	431 (18.9%)	3615 (16.5%)	**0.0068**
Black Race, n (%)	906 (39.8%)	8612 (39.3%)	0.0610
Hispanic Ethnicity, n (%)	572 (25.1%)	5626 (25.7%)	0.2142
MSM, n (%)	1190 (52.3%)	12798 (58.4%)	**<.0001**
Years since HIV Diagnosis, median (IQR)	15.3 (7.0, 21.8)	7.1 (2.5, 14.5)	**<.0001**
Viral Load log^{10} copies/mL, median (IQR)	2.0 (1.3, 4.2)	1.3 (1.3, 2.0)	**<.0001**
CD4 Count cells/uL, median (IQR)	412 (209, 636)	587 (396, 801)	**<.0001**
Any comorbid condition, n (%)	1823 (80.1%)	15132 (69.1%)	**<.0001**

[Table. Baseline characteristics of HTE vs. Non-HTE]



* HTE: heavily treatment experienced, defined as individuals on their 4th line of ART (discontinued agents from ≥3 core agent classes prior to current regimen) or on a regimen suggestive of HTE (dolutegravir BID, darunavir BID, etravirine, ENSTI+PI, maraviroc, or enfuvirtide

[Figure. Cumulative probability of (A) achieving suppression (<50 copies/mL) among viremic (VL≥50 copies/mL) at regimen initiation, and (B) maintaining suppression (<200 copies/mL) among PLWH who achieved suppression after regimen initiation]

CONCLUSIONS: HTE PLWH were at greater risk of virologic failure, changes in regimen and death than non-HTE PLWH, suggesting additional therapeutic options are needed for this vulnerable population.

REGIMEN SIMPLIFICATION AND SWITCH STUDIES

PEB0235

REAL LIFE STUDY WITH DUAL THERAPY IN A HIV-1 TREATMENT EXPERIENCED PORTUGUESE COHORT

R. Correia[1], A. Carvalho[2,3]
[1]Universidade do Minho, Braga, Portugal, [2]Hospital de Braga, Braga, Portugal, [3]Escola de Medicina da Universidade do Minho, Braga, Portugal

BACKGROUND: There are scarce data on dual therapies for HIV infection in real life clinical practice. We investigated the effectiveness and safety of the association of lamivudine with dolutegravir or with a protease inhibitor in virologically controlled patients treated with triple antiretroviral therapy (cART).

METHODS: This cohort of 149 HIV-1 infected Portuguese patients included all patients who changed their usual ART between July 2015 and July 2018 to dolutegravir with lamivudine (DTG/3TC) or to a boosted protease inhibitor with lamivudine (PI/b/3TC), regardless of reason, provided they were 18 years of age or older, without chronic hepatitis B or known resistance-conferring mutations for any of the antiretrovirals used, under stable cART for at least 6 months and with a viral load <50 copies/ml.

RESULTS: A total of 149 patients were included, 77 under DTG/3TC and 72 under PI/b/3TC. Overall 72% were men, aged between 23 and 84 years. Most (69%, n=89) had been on cART for at least 5 years and had a median TCD4 lymphocyte count of 593 cells/ml (IQR=67-1347). Approximately 90% of all patients completed 48 weeks of treatment successfully, 90.9% in the DTG/3TC group and 88.9% in the PI/b/3T group. Of five virological failures only one, in a patient under DRV/3TC, was attributed to a clinically significant mutation (M184V). Overall, the median LTCD4 increased significantly to 660 cells/ml (p<0.001) while the CD4/CD8 ratio remained unchanged when compared to baseline. Variations in alanine aminotransferase were not significant. Glomerular filtration rate had a significant initial decrease in patients who started dolutegravir but later stabilized.

CONCLUSIONS: Virological efficacy was maintained with the dual therapy regimens studied, with a slight improvement in immune status. These dual therapy regimens proved to be effective and safe in HIV-1 infected virologically controlled patients. This strategy reduces toxicities as well as costs associated with HIV treatment. These findings should be confirmed in larger randomized controlled trials.

PEB0236

PERSONS LIVING WITH HIV (PLWH) IN JAPAN ON 2-DRUG REGIMEN REVEAL MORE COMPLEX PATIENT PROFILES THAN THAT OF A 3-DRUG REGIMEN COHORT

D. Ruzicka[1], M. Kamakura[1], N. Kuroishi[1], N. Oshima[2], M. Yamatani[1], B. Crawford[3], K. Tsukada[4], S. Oka[4]
[1]MSD K.K., Medical Affairs, Tokyo, Japan, [2]MSD K.K., Clinical Development, Tokyo, Japan, [3]Syneos, Tokyo, Japan, [4]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan

BACKGROUND: Regimen simplification to 2-drugs might address potential issues regarding tolerability, adherence, toxicity and drug-drug-interactions. Current treatment patterns/patient profiles of 2-drug regimens (2DR) are unclear and might identify areas of unmet need.

METHODS: We conducted a retrospective, observational database study using a Japanese hospital claims database extracting data from 2008 until 2019. Demographics, comorbidities, comedication and current antiretroviral treatment (ART) of patients >= 18 years receiving 2DR were assessed and compared to a 3-drug regimen (3DR) cohort.

RESULTS: 2% of PLWH on ART (n=4092) were identified on a 2DR (n=94, 87% male). They were older (mean 54.4 vs. 43 years), had a higher Charlson Comorbidity Score, higher percentage of AIDS and took more comedications compared to the 3DR cohort (n=3998, 93% male). The most utilized 2DR were PI+INSTI (33%), NNRTI+INSTI (32%), PI+NRTI(12%) and INSTI+NRTI (12%). 71% (n=67) of the 2DR cohort used an NRTI-sparing (complete avoidance of NRTI) approach. Over time there was a distribution shift from PI+INSTI to NNRTI+INSTI in the NRTI-sparing group and a shift from PI+1NRTI to INSTI+1NRTI in the partial-NRTI-sparing group. A slight decrease of NRTI-sparing regimens can be observed from 76% (2008-2014) to 70% (2016-2018).
Major observed chronic comorbidities are given in the table.

	2-Drug (n=94)		3-Drug (n=3998)		P-value
	N	%	N	%	
Hypertension	50	53.2%	765	19.1%	<0.0001
Any Diabetes	48	51.1%	874	21.9%	<0.0001
Mild liver disease	41	43.6%	1333	33.3%	0.0371
Lipid disorders	40	42.6%	712	17.8%	<0.0001
Psychiatric disorders**	39	41.5%	1448	36.2%	0.2936
Renal disease	32	34.0%	192	4.8%	<0.0001
Chronic pulmonary disease	28	29.8%	942	23.6%	0.1607
Bone Disorders	17	18.1%	251	6.3%	<0.0001

[Table]
**Mania, depression, anxiety, psychosis, insomnia

CONCLUSIONS: PLWH on 2DR have complex disease backgrounds and require attention by treating physicians.
The majority of patients on 2DR are on an NRTI-sparing regimen, and their very complex patient profiles indicate that reducing toxicities or avoiding DDI of current NRTIs is a current major treatment trend, when considering any 2DR. Recently NRTI-sparing strategy seems to decrease slightly driven by a decrease of PI-INSTI and whether this will decrease more with approval of new 2DR needs to be observed.

PEB0237

DURABILITY OF DUAL ANTIRETROVIRAL REGIMENS AND FACTORS ASSOCIATED WITH DISCONTINUATION IN THE CLINICAL PRACTICE

P. Vizcarra[1], M. Monsalvo[1], M.J. Vivancos[1], A. Moreno[1], A. Abad[1], R. Ron[1], J. Martínez Sanz[1], T.C. Velasco[1], U. Ansa Urroz[1], J.L. Casado[1]
[1]Hospital Universitario Ramón y Cajal, Infectious Diseases, Madrid, Spain

BACKGROUND: Long-term data about dual antiretroviral regimens (DR) are scarce. We assessed the durability of switching to DR in people living with HIV.
METHODS: We prospectively analyzed individuals with HIV-RNA ≤50 copies/mL switching to DR during 2015-2019. The outcome of interest was treatment discontinuation (TD) due to treatment failure (TF; non-adherence/loss of follow-up or virological failure: HIV-RNA ≥200 copies/mL or 2 consecutive HIV-RNA >50 copies/mL), toxicity/intolerance, simplification, or drug-drug interactions.
RESULTS: Overall, 352 DR were initiated in 292 individuals (mean 53 years, female gender 29.5%). The main DR were dolutegravir plus rilpivirine (33%), boosted darunavir plus lamivudine (29%), and boosted darunavir plus dolutegravir (16%, Table).
The initial DR was discontinued in 102 (29%) cases during a median follow-up of 52 months (interquartile range 41-68, 1688 person-years). The main causes of TD were drug-drug interactions (10%), simplification (7%), toxicity/intolerance (5%; 3% gastrointestinal, 2% neurological), and TF [5%; 4.7% due to non-adherence, and only 0.3% (1 case) due to virological failure]. The probabilities of all-cause TD at 1, 3 and 5 years were 3%, 7%, and 12%, respectively. Furthermore, the probabilities of TF excluding non-virological reasons at 1, 3 and 5 years were 1%, 2%, and 4%, respectively. After discontinuing the DR, 22% switched to a single-tablet regimen. In a Cox multivariate analysis, male gender (hazard ratio, HR, 0.5, 95% confidence interval, CI, 0.3-0.9), a DR consisting of dolutegravir plus rilpivirine (HR 0.4, 95%CI 0.2-0.8), and a lower number of pills in current regimen (HR 0.6, 95%CI 0.4-0.8) were associated with lower hazard of TD.

	Total (n=352)	Dolutegravir + rilpivirine (n=117)	Boosted darunavir + dolutegravir (n=55)	Boosted protease inhibitor + raltegravir (n=41)	Boosted darunavir + non-nucleoside reverse transfer inhibitor (n=23)	Etravirine + raltegravir (n=14)	Boosted darunavir + lamivudine (n=102)
Age [years], mean (range)	53 (31-85)	55 (31-85)	52 (33-66)†	53 (36-73)	53 (35-73)	55 (46-78)*	52 (31-76)†

Duration of HIV infection [months], median (interquartile range)	247 (177-298)	254 (175-298)	279 (223-323)	259 (204-298)	251 (159-317)	258 (207-346)	211 (160-279)
Total duration of antiretroviral therapy [months], median (interquartile range)	185 (138-235)	211 (152-241)	221 (155-262)	201 (127-252)	217 (125-252)	215 (176-250)	177 (117-211)‡

[Table]
†= P-value <0.05, and ‡ P-value <0.001 compared with dolutegravir + rilpivirine.

CONCLUSIONS: In this study in a clinical setting with long-term follow-up, DR were highly effective with only one case of virological failure (<1%). Indeed, 81% of TD were related to non-virological reasons, mainly due to drug-drug interactions or simplification.

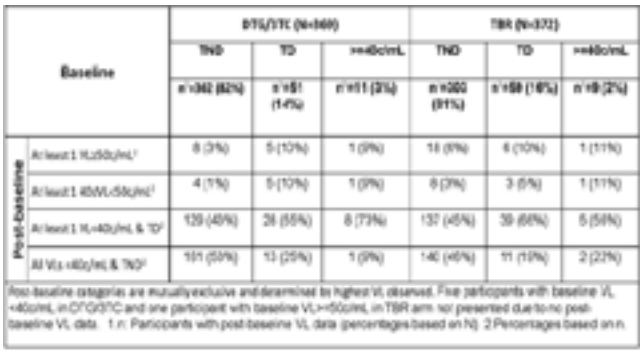
PEB0238

COMPARISON OF VIRAL REPLICATION AT <40C/ML FOR 2-DRUG REGIMEN (2DR) OF DOLUTEGRAVIR/ LAMIVUDINE (DTG/3TC FDC) VERSUS 3-DRUG REGIMEN (3DR) BASED ON TENOFOVIR ALAFENAMIDE (TAF) (TBR) IN THE TANGO STUDY

R. Wang[1], J. Wright[2], M. Ait-Khaled[3], T. Lutz[4], O. Osiyemi[5], M. Gorgolas[6], R. Razeek[2], M. Virk[2], M.C. Nascimento[3], A. Tenorio[1], M. Underwood[1]
[1]ViiV Healthcare, RTP, United States, [2]GlaxoSmithKline, Stockley Park, United Kingdom, [3]ViiV Healthcare - UK, Brentford, United Kingdom, [4]Infektio Research, Frankfurt, Germany, [5]Triple O Research Institute PA, West Palm Beach, United States, [6]Jiménez Díaz Foundation University Hospital, Madrid, Spain

BACKGROUND: TANGO Week48 results for HIV-1-infected adults receiving TBR with HIV-1 RNA <50c/mL demonstrated switching to DTG/3TC was non-inferior to continuing TBR using a 4% non-inferiority margin for Snapshot virologic failure. The Abbott RealTime HIV-1 assay measures viral load (VL) from 40c/mL to 10,000,000c/mL, and provides qualitative target detected (TD) or target not detected (TND) outcomes for VL<40c/mL. We assessed the proportion of participants with TD/TND through Week48 for 2DR versus 3DR.

METHODS: Participants were randomized 1:1 to receive 2DR or 3DR. Participant proportions with VL<40c/mL and TND status were analysed by visit (Snapshot analysis) through Week48. Classification of participants into VL>=50c/mL, 40<=VL<50c/mL, or TD/TND (when VL<40c/mL) was performed on baseline and post-baseline outcomes.
RESULTS: At Week48, similar proportions of participants had TND in the 2DR and 3DR arms (79% [291/369] vs 76% [284/372], respectively, adjusted difference 2.5%, 95% CI -3.5%, 8.5%) by Snapshot, and at each visit: baseline (83% vs 81%), Weeks 4 (78% vs 78%), 8 (75% vs 79%), 12 (81% vs 77%), 24 (77% vs 81%), and 36 (79% vs 79%). Of the participants with TND at baseline, proportions with TND at all visits through Week48 were 53% in 2DR and 46% in 3DR arm, and similar between arms in other post-baseline VL categories (Table1). Seven participants had pre-existing, archived mutation mixture M184M/V or M184M/I, and all had Week48 VL<50c/mL, with 3/4 of these participants receiving 2DR vs 2/3 receiving 3DR having TND at baseline and through Week48.



[Table 1. Changes in quantifiable and non-quantifiable VL levels by baseline VL category through Week 48

CONCLUSIONS: Similar proportions of participants were TND at baseline and at all visits through Week48 (Snapshot analysis) for both arms, and across TD/TND categories per baseline VL classification. Post-baseline incident viremia (>=40c/mL) appeared more commonly associated with baseline TD than baseline TND. Using the more stringent TND threshold (Snapshot), there was no difference in proportions between DTG/3TC 2DR and TBR 3DR at Week48.

PEB0239

PATIENT'S SATISFACTION IN THE CONTEXT OF A DUAL THERAPY AND A SIMPLIFIED, PATIENT-CENTRED MONITORING STRATEGY FOR MANAGEMENT OF HIV INFECTION: A SWISS NON-INFERIORITY, RANDOMIZED, CONTROLLED, CLINICAL TRIAL (SIMPL'HIV)

A. Marinosci[1], D. Sculier[1], G. Wandeler[2], M. Stoeckle[3], E. Bernasconi[4], D. Braun[5], P. Vernazza[6], M. Cavassini[7], K. Metzner[5], L. Decosterd[7], M. Buzzi[1], H. Gunthard[5], P. Schmid[6], S. Yerly[1], A. Limacher[8], M. Egger[8], A. Calmy[1]
[1]Hôpitaux Universitaires de Genève, Infectious Diseases, Geneva, Switzerland, [2]Bern University Hospital, Infectious Diseases, Bern, Switzerland, [3]University Hospital of Basel, Infectious Diseases, Basel, Switzerland, [4]Lugano Regional Hospital, Infectious Diseases, Lugano, Switzerland, [5]University Hospital of Zurich, Infectious Diseases, Zurich, Switzerland, [6]Kantonspital St. Gallen, Infectious Diseases, St. Gallen, Switzerland, [7]University Hospital of Lausanne, Infectious Diseases, Lausanne, Switzerland, [8]Clinical Trials Unit, Bern, Switzerland

BACKGROUND: Treatment simplification can reduce pill burden and improve quality of life in HIV-infected patients, while minimizing costs and potential toxicity. Monitoring optimization and decentralization of health care can contribute to improve patient perception on the quality of services. We evaluated patient satisfaction in the Swiss randomized controlled clinical trial SIMPL'HIV by treatment arms.
METHODS: SIMPL'HIV is a non-inferiority, randomized, controlled, clinical trial conducted among treatment experienced HIV-infected adults in Switzerland. Participants were randomized 1:1:1:1 to switch to dolutegravir (DTG) + emtricitabine (FTC) or to continuing combination antiretroviral therapy (cART), and to patient-centred monitoring (PCM) vs continuation of 3-monthly surveillance. Patient-centred monitoring included annual immunological and safety monitoring, telephone calls, posting of medication, and decentralized venepuncture. We previously demonstrated non-inferiority of the dual therapy arm compared to cART by maintaining HIV-RNA below 100 copies through 48 weeks. Monitoring and treatment satisfaction were assessed using a visual analog scale (VAS) ranging from 0 to 100 points at week 48. Study satisfaction was evaluated by questionnaire at week 48.
RESULTS: Ninety-three participants were randomized to the DTG+FTC arm (48 to PCM and 45 to 3-monthly surveillance), and 94 to the cART arm (47 to the PCM and 47 to 3-montly surveillance). Mean nadir CD4 count was 259 cells/mm3 (SD 187); 17% were female. Monitoring and treatment satisfaction were above 80 points in both treatment arms, as was study satisfaction, with no significant difference between arms. Only 25.8% of patients in the DTG+FTC arm and 31.9% in the cART arm required additional visits outside of the study plan, majority of which consisted of non-HIV-related clinical visits. At study termination, 85.6% of participants in the dual therapy arm and 32.2% in the cART arm opted for DTG+FTC or the newly recommended EACS dual therapy of DTG/lamivudine.
CONCLUSIONS: Treatment simplification and patient-centred monitoring approach resulted in high patient's satisfaction in both treatment arms. Post-trial data was encouraging of simplified treatment with more than half of patients opting for dual therapy. Further studies should focus on collating evidence of cost-effectiveness and impact on Quality of Life of optimized monitoring and treatment strategies.

PEB0240

FACTORS ASSOCIATED WITH VIROLOGICAL FAILURE (VF) IN HIV-1 SUBJECTS RECEIVING DOLUTEGRAVIR MONOTHERAPY (DTG-M) AS MAINTENANCE THERAPY: A META-ANALYSIS OF INDIVIDUAL PATIENTS DATA (IPDMA)

A.L. Fournier[1], L. Hocqueloux[2], D. Braun[3], T. Turk[3], R. Kouyos[3], F. Raffi[4], E. Martinez[5], B. Rijnders[6], C. Rokx[6], H.F. Günthard[3], J.-J. Parienti[1]
[1]CHU de Caen, Infectious diseases, Caen, France, [2]CH Orléans, Orléans, France, [3]Centre for Infectious Diseases, Zurich, Zurich, Switzerland, [4]CHU de Nantes, Nantes, France, [5]Hospital Germans Trias i Pujol, Barcelona, Spain, [6]Erasmus University Medical Center, Rotterdam, Netherlands

BACKGROUND: DTG-m is not recommended as a maintenance strategy in current antiretroviral therapy guidelines. However, most of the subjects receiving DTG-m in randomized controlled trials (RCTs) did not experience a VF. Thus, our aim was to determine independent predictors of VF with DTG-m maintenance and to evaluate DTG-m in subgroups stratified by these risk factors.
METHODS: A European collaboration was conducted to perform IPDMA. All RCTs where virologically controlled HIV-1 infected participants were randomized to receive DTG-m or combined antiretrovi-

ral therapy (cART) were included. The primary end-point was time to VF, defined as a confirmed viral load >50 copies/mL at or before week 48 (>200 copies/mL plasma before or at week 24 in DOMONO). We computed uni- and multivariate Cox models among subjects randomized to DTG-m. We then estimated the risk difference of VF and 95% confidence interval (CI) between DTG-m and cART by subgroups with available data.

RESULTS: IPD of 416 subjects enrolled in the Early-Simplified (n=101), DOMONO (n=95), DOLAM (n=62) and MONCAY (n=158) trials were collected. Overall, 16/227 (7.0%) in the DTG-m arm had VF versus 0/189 in cART arm, absolute difference 7.0%; 95% CI [-4% to -11%], p=0.007 by the log-rank test. In the DTG-m arm, independent predictors of VF were: CD4 cells nadir <350/mm^3 (Hazard Ratio, 14.2; 95% Confidence Interval [1.8 to 109.4]; p=0.01); baseline HIV DNA ≥2.7log/10^6 PBMCs (3.3; [1.2 to 9.4]; p=0.02) and the presence of a plasma PCR signal at baseline (3.9; [1.3 to 11.5]; p= 0.01). The subgroup analyses of the VF difference (D) are shown in the Table.

	Triple cART arm (n/N)	Monotherapy arm (n/N)	D [95%CI] ; Fisher exact test
Nadir CD4 <350/mm^3	0/95	13/110	-0.12 (-0.06;-0.19) ; p<0.001
Nadir CD4≥ 350/mm^3	0/63	1/86	-0.01 (0.05;-0.06) ; p>0.99
HIV DNA at baseline ≥ 2,7 log/10^6 PBMCs	0/14	11/36	-0.31 (-0.06;-0.47) ; p=0.022
HIV DNA at baseline <2.7 log/10^6 PBMCs	0/66	3/97	-0.03 (0.03; -0.09) ; p=0.28
Presence of a PCR signal at baseline	0/28	5/32	-0.16 (-0.01; -0.32) ; p=0.05
Absence of a PCR signal at baseline	0/130	8/64	-0.05 (-0.01; -0.09); p=0.01

[Table]

CONCLUSIONS: This is the first IPDMA of VF in DTG-m. Adjusting for HIV-DNA reservoir and presence of PCR signal at baseline, nadir CD4 <350/mm^3 was the strongest predictor of VF with DTG-m. Moreover, the efficacy of DTG-m versus cART maintenance differed according to the nadir CD4. A too low nadir CD4 for inclusion may explain the failure of DTG-m in some RCTs.

PEB0241

VIROLOGICAL EFFICACY AND TOLERABILITY OF DUAL THERAPY MAINTENANCE WITH DOLUTEGRAVIR PLUS LAMIVUDINE IN HEAVILY TREATMENT EXPERIENCED HIV-INFECTED PATIENTS: FOUR YEARS DATA FROM DOLULAM STUDY

J. Reynes[1], B. Montes[2], E. Tuaillon[2], N. Meftah[1], C. Fernandez[1]
[1]Montpellier University Hospital, Infectious Diseases, Montpellier, France, [2]Montpellier University Hospital, Virology, Montpellier, France

BACKGROUND: We evaluated the dual therapy with dolutegravir (DTG) and lamivudine (3TC) in virologically suppressed individuals with a long exposure to ARV and even with previous experience of resistance to 3TC. We present the data after 4 years of follow up.

METHODS: DOLULAM is a prospective cohort study. Patients on a stable antiretroviral regimen with plasma HIV RNA (VL) < 50 copies/mL, without resistance to integrase inhibitors, switched to DTG 50 mg plus 3TC 300 mg once daily. Reasons of therapy discontinuation included treatment-related adverse events, virological rebound (defined as persistent low level viremia (LLV) with VL between 50 and 200 c/mL), virological failure (defined as a single VL >200 c/mL) and patient's or physician's decision.

RESULTS: We enrolled 27 adults (20 men, 7 women; all whites). Baseline (BL) characteristics (median or %): age: 59 years, weight: 73 kg, zenith VL > 100 000 copies/ml: 56%, nadir CD4 :167/mm3, CD4 : 601/mm3 , HIV DNA load: 2,93 log10 copies/106 PBMC. Patients had been taking ARV for a median of 215 (range 22-329) months and the last regimen (TDF: 48%, PI/r : 81%, RAL : 26%) for a median of 51 (13-108) months. Ten (37%) patients had a history of genotypic test prior switch with M184V mutation.

After a follow up of 4 years, no patient experienced virological failure or severe adverse event, or was lost to follow-up. We observed 4 treatment discontinuations: 3 patients wanted to stop during the first 6 months (2 for fatigue, one for anxiety after blip), one patient interrupted at month 33 after 18 months of LLV without emergence of mutation of resistance.

Median changes between BL and 4 years were for weight : 0 kg (extremes -7, + 6 kg; no obesity), CD4: -47/mm3, ratio CD4/CD8: + 0,14, HIV DNA : -0,31 log10 copies/106 PBMC (IQR -0,01, -0,50), eGFR: - 2,5 mL/min/1,73 m2(IQR - 11,3 , + 1,7).

CONCLUSIONS: These results suggest that, in this population of heavily treatment-experienced patients without or with history of M184V mutation, dolutegravir plus lamivudine dual therapy is an effective and durable strategy of maintenance.

PHARMACOKINETICS/PHARMACODYNAMICS/ PHARMACOGENOMICS AND THERAPEUTIC DRUG MONITORING

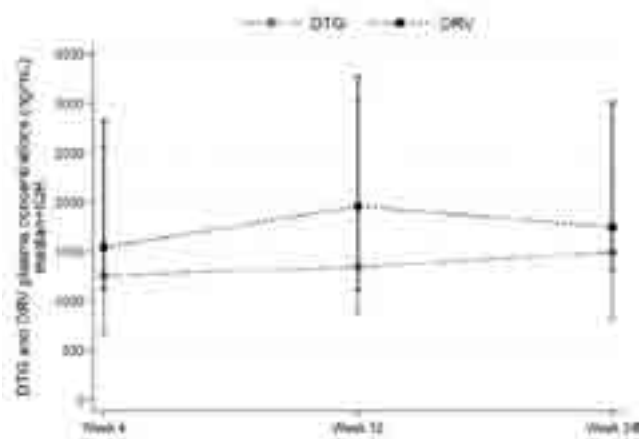
SUFFICIENT PLASMA LEVELS WITHIN 24 WEEKS OF ANTIRETROVIRAL HIV THERAPY OF DOLUTEGRAVIR COMBINED WITH BOOSTED DARUNAVIR: A PHARMACOLOGIC SUBGROUP ANALYSIS OF THE DUALIS STUDY

S. Weidlich[1], C. Boeseke[2], J. Schneider[1], H. Klinker[3], A. Zink[4], A. Balogh[5], E. Wolf[5], H. Bidner[6], C.D. Spinner[1]
[1]Technical University Munich, School of Medicine, University Hospital rechts der Isar, Department of Medicine II, München, Germany, [2]Bonn University Hospital, Department of Medicine I, Bonn, Germany, [3]University of Wuerzburg Medical Center, Department of Medicine II, Division of Infectious Diseases, Würzburg, Germany, [4]Technical University Munich, School of Medicine, University Hospital rechts der Isar, Department of Dermatology and Allergology, Munich, Germany, [5]MUC Research, Clinical Research Organisation (CRO), Munich, Germany, [6]Technical University of Munich, Munich Study Center, Clinical Research Organisation, Munich, Germany

BACKGROUND: A combination of dolutegravir (DTG) and ritonavir-boosted darunavir (DRV/r) demonstrated non-inferiority as switch-option in virologically suppressed people-living-with-HIV (PLWH).

METHODS: We present a prespecified pharmacokinetic sub-analysis of a pharmacokinetic sub-study of the prospective, randomized, non-blinded DUALIS-study (Eudra-CT:2015-000360-34). Virologically suppressed PLWH were randomized and either remaining on DRV/r in combination with 2 NRTIs (3DR) or being switched to DTG 50 mg and DRV/r 800/100 mg once-daily (2DR). Samples for PK-analysis in the interventional 2DR arm were obtained after 4, 12 and 24 weeks at a single time-point. Plasma-levels were determined using high-performance-liquid-chromatography (HPLC).

RESULTS: A total of 57 subjects (50 male, 7 female) with a median (IQR) age of 45 (37-51) years and a body-mass-index of 24.3 (22.6-26.2) were included in the sub-study. HIV RNA was <50 cps/mL in 98.1%, 96.3% and 96.3% at week 4, 12 and 24 respectively. Full treatment compliance was reported for DRV in 75.4%, 87.5% and 89.3% and DTG in 78.9%, 87.5% and 89.3% at week 4, 12 and 24, respectively. The median (IQR, interquartile range) differences between last intake of the study medication and sampling at weeks 4, 12 and 24 were 20.6 (8.1-24.0), 18.3 (5.8-23.5) and 18.3 (8.9-23.0) hours, respectively. Median (IQR) levels at weeks 4, 12 and 24 were 1543 (1123-2832) ng/mL, 1961 (1111-3279) ng/mL and 1751 (1314-3008) ng/mL for DRV and 1258 (662-2256) ng/mL, 1345 (870-3021) ng/mL and 1494 (816-2274) ng/mL for DTG (Figure 1).



[Figure 1.]

Plasma concentrations were 0-82 -fold (week 4), 3-79 -fold (week 12) and 4-98 -fold (week 24) above the protein-adjusted IC90 (64 ng/mL) for DTG and 0-45 -fold (week 4), 2-33 -fold (week 12) and 1-42 -fold (week 24) above the protein-adjusted EC90 (200 ng/mL) for DRV, respectively.

CONCLUSIONS: The presented pharmacologic data support the suitability of the 2DR combination DTG plus DRV/r.

PEB0243

PHARMACOGENOMICS AND PHARMACOKINETICS OF EFAVIRENZ 400MG IN TREATMENT-NAIVE HIV-INFECTED PATIENTS: A 48-WEEKS OUTCOME OF A LOWER DOSE ART REGIME STUDY IN CHINA

R. Chen[1], J. chen[1], J. Xun[1], Z. Hu[2], Q. Huang[3], H. Lu[1]
[1]Shanghai Public Health Clinical Center, Fudan University, Shanghai, China, [2]The Second Hospital of Nanjing, Nanjing University of Chinese Medicine, Nanjing, China, [3]Yunnan AIDS Care Center (YNACC), Yunnan Provincial Infectious Disease Hospital, Kunming, China

BACKGROUND: Pharmacogenomics and pharmacokinetics (PK) data of efavirenz (EFV) have been widely reported. However, the pharmacogenetics characters of a lower dose(400mg) efavirenz has rarely been reported.

METHODS: Treatment-naive HIV-Infected patients from 3 sites in China were randomly assigned(1:1) to receive either a lower dose anti-retroviral regimen comprised of TDF (200 mg) plus efavirenz (400 mg) and lamivudine, or the standard dose regimen. Relationships between single nucleotide polymorphisms (SNP: rs28399499, rs35303484, rs8192709, rs36118214, rs3745274, rs4803419, rs2279343, rs2279345, rs776746, rs3842, rs1045642 and rs2307424) and EFV PK with plasma HIV-RNA plasma viral load (pVL) and central nervous system (CNS) and rash adverse reactions (ADRs) at 48 weeks were explored. Blood samples were collected for detection of mid-dose interval concentration (C12) of EFV at 8 weeks after treatment.

RESULTS: Overall, 184 participants (14 women) received at least one dose of TDF+3TC+EFV and were included in the pharmacogenomics analysis. Allele frequency had no difference between the standard and lower dose groups. There was no significant relationship between EFV pharmacogenomics and ADRs of CNS. 171 blood samples were collected for plasma concentration detection. In the standard-dose group, CYP2B6 516G>T T/T(p=0.014) , CYP2B6 785A>G G/G(p<0.001), CYP2B6 18492C>T C/C(p<0.001) and ABCB1 3435C>T T/C(p=0.027) were all associated with higher plasma EFV levels. However, these were not seen in the lower dose group. 166 participants received HIV RNA pVL detection at week 48. No relationship was found between pharmacogenomics and antiviral efficacy. Patients with a bodyweight < 60 kg had significantly higher EFV C12 compared with those with weight ≥ 60 kg when using 600mg EFV but not 400mg EFV.

CONCLUSIONS: The effect of pharmacogenomics and body weight on the plasma concentration of EFV was significant in the 600mg group, but not in the 400mg group. The reduced dose of EFV is more suitable for people living with HIV.

PEB0244

PHARMACOKINETIC AND PHARMACOGENETIC ASSOCIATIONS BETWEEN EFAVIRENZ-BASED REGIMENS AND NEUROCOGNITIVE PERFORMANCE IN PEOPLE LIVING WITH HIV IN NIGERIA

J. Nwogu[1], M. Gandhi[2], A. Owen[3], S. Khoo[3], B. Taiwo[4], A. Olagunju[5], B. Berzins[4], H. Okochi[6], R. Tallerico[6], K. Robertson[7], C. Babalola[1]
[1]University of Ibadan, Pharmaceutical Chemistry, Ibadan, Nigeria, [2]University of California San Francisco, Division of HIV, Infectious Diseases, and Global Medicine, San Francisco, United States, [3]University of Liverpool, Department of Molecular & Clinical Pharmacology, Liverpool, United Kingdom, [4]Northwestern University, Division of Infectious Diseases and Center for Global Health, Chicago, United States, [5]Obafemi Awolowo University, Pharmacy, Ife, Nigeria, [6]University of California San Francisco, Department of Bioengineering and Therapeutic Sciences, Schools of Pharmacy and Medicine., San Francisco, United States, [7]University of North Carolina School of Medicine, Chapel Hill, Department of Neurology, North Carolina, United States

BACKGROUND: Efavirenz (EFV) is recommended as a component of alternative first-line regimens for HIV treatment and is commonly prescribed in Nigeria due to its efficacy and availability. EFV use is associated with neuropsychiatric side effects, which may include poor neurocognitive performance (NP).

Here, we evaluated single nucleotide polymorphisms (SNPs) in genes important for EFV disposition and examined them in association with plasma concentrations, hair concentration, and neurocognitive performance.

METHODS: HIV-positive adults receiving 600mg EFV (N=93, 70.3% female) were genotyped for 7 SNPs in CYP2B6, NRII3 and ABCB1. EFV was quantified in dried blood spots (DBS) and hair using liquid-chromatography-tandem-mass-spectrometry (LC-MS/MS). Plasma EFV concentrations were then calculated using a previously validated equation [DBS[EFV]/(1-hematocrit)*protein binding]. Participants were also administered a neurocognitive battery of 10 tests (7 domains) that assessed total neurocognitive functioning. Linear regression and Independent t-test were used to assess associations between SNPs, Log10 transformed EFV concentrations in hair and

plasma, as well as differences in mean concentrations by genotype. Associations between SNPs, EFV concentrations, and NP were also assessed using correlation.

RESULTS: Strong correlation (r = 0.64, P<0.001) was observed between plasma and hair EFV concentrations. The median (IQR) hair EFV concentrations was 6.85ng/mg (4.56-10.93). CYP2B6 516G>T, rs3745274 (P<0.001) and CYP2B6 983T>C, rs28399499 (P=0.001) were each associated with hair EFV concentrations. The median (IQR) hair concentrations was 5.80ng/mg (4.34-8.45) for those with 516GG, 6.38ng/mg (4.61-11.15) for 516GT and 11.0ng/mg (4.91-24.85) for 516TT. Similarly, 516G>T (P< 0.001) and 983T>C (P=0.009) were significantly associated with plasma EFV concentrations. The median (IQR) EFV plasma concentrations were 1790ng/ml (1423.59-2341.31) for 516GG and 5094ng/ml (4480.93-8506.28) for 516TT. Contrary to other findings, total neuropsychological performance was significantly associated with plasma EFV concentrations (r=0.23, P=0.043) and 983T>C genotype (r=0.38, P<0.0005). In addition, a weak positive correlation was observed between NP and hair concentration (r = 0.12, P=0.290). No other genetic associations were evident.

CONCLUSIONS: This study demonstrated an approximately 3-fold and 2-fold higher EFV plasma and hair concentrations respectively within CYP2B6 516T homozygotes compared to G homozygotes. Higher efavirenz concentrations were associated with better neurocognitive performance, requiring further study to elucidate the relationship between adherence, adverse effects and outcomes.

BACKGROUND: ART adherence is necessary for virologic suppression (VS). Antiretroviral (ARV) hair concentrations reflect drug uptake from the systemic circulation over weeks-months, providing a time-averaged exposure measure. We previously reported results from ACTG-A5288, a strategy trial in RLS which included a cohort of individuals failing second-line PI-based ART, but with susceptibility to ≥1 NRTI and no LPV resistance, who remained on the PI-based regimen. We evaluated associations among hair ARV concentrations, self-reported adherence and virologic outcome in this cohort.

METHODS: Participants in the cohort on 2NRTIs with ATV (n=69) or LPV (n=112), each boosted with RTV, who provided hair samples for evaluating ARVconcentrations at 12, 24, 36 and 48 weeks, were included. Hair was analyzed for ATV, LPV and RTV using validated liquid-chromatography-tandem-mass-spectrometry assays. Participants self-reported percentage of doses taken in the month prior. Virologic Failure (VF) was confirmed HIV-1 RNA≥1000 copies/mL at 24 through 48 weeks.

RESULTS: Among 181 participants, 61% were female. Median age: 39y; CD4 count: 167 cells/uL; HIV-1 RNA: 18,648 copies/mL. Ninety-one (50%) experienced VF. At 12 weeks, median hair concentrations were 2.20 ng/mg for ATV, 2.78 for LPV, and 0.33 for RTV, with little change through 48 weeks. At weeks 12, 24, 36 and 48, 57% to 67% of participants self-reported 100% dosing, with weak correlation ($r_s \leq 0.10$) between self-reported adherence and hair concentrations of each ARV. Correlations between hair concentrations of each drug and HIV-1

RNA at weeks 24 and 48 ranged from −0.53 to −0.74, but correlations between self-reported adherence and HIV-1 RNA were weaker, ranging from −0.08 to −0.24. Individuals with VF had significantly lower ARV hair concentrations than those achieving suppression (Table).

Drug	Week	VF by 48 wks (n=91)	Suppressed: no VF by 48 wks (n=90)	p-value
RTV (n=181), ng/mg	12	0.22 (0.06-0.50)	0.58 (0.27-0.79)	<0.001
	24	0.12 (0.03-0.37)	0.69 (0.46-0.89)	<0.001
ATV (n=69), ng/mg	12	1.34 (0.34-2.64)	3.08 (1.33-4.45)	0.007
	24	0.83 (0.11-3.20)	3.70 (2.84-5.22)	<0.001
LPV (n=112), ng/mg	12	1.05 (0.23-3.18)	4.81 (2.39-6.69)	<0.001
	24	0.79 (0.13-2.66)	5.70 (2.75-8.61)	<0.001

[Table: Median (IQR) drug concentrations for people experiencing versus not experiencing VF]

CONCLUSIONS: Among people experiencing VF on second-line ART with limited resistance, PI concentrations in hair, but not self-reported adherence, were strongly associated with subsequent virologic outcome. These findings argue for incorporating objective adherence metrics into the evaluation of ART failure in RLS.

PEB0246

ROLE OF CYTOCHROME CYP2B6 POLYMORPHISMS ON NEVIRAPINE PLASMA LEVELS AND CLINICAL OUTCOMES. A PROSPECTIVE STUDY AMONG HIV-1 INFECTED PATIENTS RECEIVING ART TREATMENT IN NAIROBI KENYA

M. Ngayo[1], S. B Tanui[2], F. G. Onyambu[3], B. Guyah[2]
[1]Kenya Medical Research Institute, CMR, Nairobi, Kenya, [2]Moi Teaching and Referral Hospital, Eldoret, Kenya, 2Department of Biomedical Sciences, Maseno University, Maseno Kenya, Nairobi, Kenya, [3]Department of Biomedical Sciences, Maseno University, Maseno Kenya, Nairobi, Kenya

BACKGROUND: Genetic variation in cytochrome P450 2B6 (CYP2B6) influences nevirapine (NVP) plasma levels and certain clinical parameters. In this prospective cohort study, we evaluated the role of CYP 516G>T and 983T>C on nevirapine plasma levels and clinical responses among HIV infected population in Nairobi Kenya

METHODS: Blood samples at baseline and month 6 were obtained from 228 consenting HIV- seropositive adult receiving nevirapine-based antiretroviral therapy (ART) in Nairobi and a detailed sociodemographic questionnaire was administered. The NVP plasma levels were determined at month 6 samples using liquid chromatography tandem mass spectrometry (LC/MS/MS). Selected clinical parameters were evaluated at baseline and month six. Associations between polymorphism at CYP 516G>T and 983T>C, plasma nevirapine concentration and clinical parameters were analysed by regression.

RESULTS: Participants with the homozygous mutant for CYP2B6 516TT had higher mean NVP plasma levels (5335.9ng/mL; n = 29) compared to those with heterozygous 516GT (4985.5 ng/mL; n= 74) and wild type 516GG (3725.8 ng/mL; n=104) genotypes (P = 0.001). Participants heterozygous for CYP2B6 983TC genotype had higher mean NVP plasma levels (4748.9ng/mL; n=80) compared to participants the wild-type CYP2B6 TC (4161.5 ng/mL; n=127) genotypes (p=0.046). Multiple linear regression analysis shows CYP2B6 516G>T polymorphism accounted for a significant reduction in viral load levels while increased CD4+ cell level (p=0.039). On the contrary CYP2B6 983T>C genotypes was not associated with significant change on NVP plasma, CD4+ cell and viral load levels. Both the CYP 2B6 516G>T and 983T>C genotypes did not affect virologic response or toxicity.

CONCLUSIONS: Our findings show CYP2B6 genotypes predicted NVP plasma levels as well as immunological and virological outcomes 6 months into ART treatment. Pharmacogenetic testing may be important in guiding individualization of HIV management aimed at improving treatment outcomes in Kenya.

PEB0247

MATERNAL AND NEONATAL EFFECTS OF ANTIRETROVIRAL THERAPY WITH EFAVIRENZ IN PREGNANT WOMEN WITH HUMAN IMMUNODEFICIENCY VIRUS

H. Barbi[1], H. Milanez[2]
[1]Unicamp College of Medical Sciences, Campinas, Brazil, [2]Unicamp College of Medical Sciences, Tocogynecology, Campinas, Brazil

BACKGROUND: Our aim was to determine the rate of adverse effects on antiretroviral therapy (ART) containing Efavirenz (EFV) both among pregnant women and their respective newborn, such as malformations, laboratory changes and prematurity.

METHODS: Observational, cohort, retrospective study. It consisted of a cohort of HIV-infected pregnant women and their exposed newborns attended at CAISM-UNICAMP from 2000 to 2018. We included 116 HIV-infected women who were divided in two groups: group 1, women who had their ART changed during pregnancy; and group 2, women who used ART containing EFV all pregnancy. The results of both groups were compaired in the end.

RESULTS: In group 1 was found no neural tube malformations, two cases of hemangioma, one of esophageal atresia and the other of pyelocalitic dilation. The average age of women was 31,2+-5,8 years; average parity was 1,6+-1,3 births and 81,7% of viral undetection. In group 2, one case of cerebral ventriculomegaly associated with congenital toxoplasmosis, two cases of macrocrania without CNS structural changes; the average age was 31,3+-5,7 years, average parity was 2,1+-1,3 births and 82% of viral undetection. Thus, we observed a low occurrence of malformations associated with medication, with data similar to the occurrence of the general population (~2 to 3%); and a low occurrence of maternal and neonatal adverse effects regarding hematological changes in group 2. In group 1, there was a higher occurrence of metabolic effects associated with the use of protease inhibitors rather than exposure to EFV, as the change was preferentially performed for use of Lopinavir / ritonavir, substances withdrawn from the ARV drug trade due to high occurrence of associated metabolic effects, but which was the preferred regimen recommended for pregnant women in Brazil until 2015.

CONCLUSIONS: Were observed a low occurance of maternal and neonatal adverse effects, mainly in group 2, since most of women of group 1 had their ART changed to a therapy containing protease inhibitors. Thus, the use of EFV in the ART regimen in pregnant women in our service was associated with low occurrence of malformations and other adverse effects, confirming it is a secure drug and still a possibility during pregnancy.

DRUG INTERACTIONS

PEB0248

POLYHERBACY AMONG PEOPLE LIVING WITH HIV IN RESOURCE LIMITED SETTINGS: IMPLICATION FOR DRUG-HERB INTERACTIONS

Z. Sabe[1], E. Lemlemu[2], A. Koye[3]
[1]CDT-Africa, Addis Ababa University, Addis Ababa, Ethiopia, [2]Debre Markos University, Social Science, Debre Markos, Ethiopia, [3]Hule Pharmacy, Addis Ababa, Ethiopia

BACKGROUND: Herbal medicine serves as the primary health care option for 70-90% of the African population due to limited access to mainstream health services. Currently, there is no evidence available on use of combined herbal medicines (polyherbacy) in people living with HIV and how this may impact treatment outcome including drug-herb interactions. As such, the aim of this study was to determine the prevalence of polyherbacy in people living with HIV in Ethiopia and motivations for consumption of these products.

METHODS: This study employed interviewer administered questionnaire for data collection. A sample of 412 participants living with HIV and aged 18 years or above were recruited from five primary hospitals located in Addis Ababa, between July and September 2019. Both descriptive statistics and logistic regression models were used to analyse the data and investigate the association between herbal medicine use and socio-demographic factors.

RESULTS: Four hundred participants (mean age 32.4 years) completed the questionnaire. Nearly all participants (n = 398, 99.5%) used herbal medicine in the past 12 months. The prevalence of polyherbacy among the respondents was 86% (n = 344), with 56.5% (n = 226) taking five or more concomitant herbal preparations in the past 12 months. Being female (OR, 3.1; 95%CI, 1.4-6.68; p=0.004), having no formal education (OR, 6.5; 95%CI, 3.4-13.44; p<0.001), and low income (OR, 3.0; 95%CI, 1.54-5.33; p<0.001) were associated with use of polyherbacy. Main reasons for herbal medicine use were to improve physical strength, immunity, sleep quality, appetite, and emotional wellbeing. Most participants (n = 376, 94%) did not disclose with the use of polyherbacy with health professionals. The main reason for non-disclosure was that they were not asked about the use of herbal medicine by health professionals.

CONCLUSIONS: The finding suggests that there might be risk of potential herb-herb and drug-herb interaction leading to adverse health outcomes among people living with HIV in poor settings. Providing health education about the consequences of polyherbacy will be imperative to reduce potential herb-antiretroviral medication interactions. However, further research is required to ascertain the potential herb-drug interactions and harmful health outcomes of polyherbacy in these patients.

PEB0249

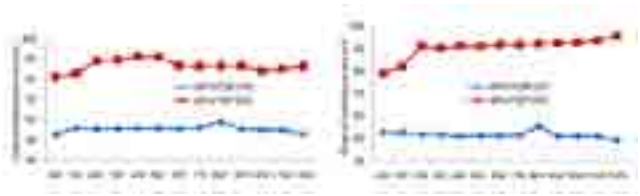
OUTCOMES OF METHADONE MAINTENANCE THERAPY COMBINED WITH RIPIVIRINE/EFAVIRENZ IN TREATMENT-NAIVE HIV-INFECTED PATIENTS: A PILOT STUDY

H. Li[1], C. Yang[1], S. Huang[1], X. Dong[1]
[1]Yunnan Infectious Disease Hospital, Kunming, China

BACKGROUND: Methadone maintenance treatment (MMT) is one of the most effective therapies for opiate addiction, and significantly reduces the use of heroin and other opiates. IDUs enrolled in the MMT may show decreased criminal activities or risk of HIV acquisition, with more likely improved quality of life and socioeconomic status.To evaluate the effect of MMT combined with ripivirine (RPV) based regimens in drug use of HIV individuals.

METHODS: This study was conducted with prospective, open-label, controlled, drug-drug interaction trial in a single center for 24 weeks. Participants on stable MMT were randomly divided into two groups administered RPV/TDF/3TC (RPV-based) and EFV/TDF/3TC (EFV-based), respectively. Adjustment doses of methadone were monitored for 12 weeks, and HIV-1 RNA was used to evaluate the effects of antiretroviral therapy at week 24. Acute opioid withdrawal-, drug craving questionnaire- and MOS-HIV- scales were used to assess study outcomes.

RESULTS: 22 and 18 cases of HIV-infected drug users were recruited in RPV-based and EFV-based groups, respectively. 31 cases had completed monitoring and clinical evaluation at week 24. In RPV-based and EFV-based groups, 32% and 56% patients had methadone dose adjustment, respectively, indicating a significantly lower rate in RPV-based group. The rates of individuals with HIV RNA levels from 50-500 copies/ml were 94% (RPV-based group) and 90% (EFV-based group). The drug craving questionnaire scale scores decreased in both groups, with no change after 3 weeks of combination treatment. After one week of treatments, acute opioid withdrawal scale scores were increased in both groups, with no significant difference between the two groups.



[Figure 1. Methadone doses demands in the RPV and EFV-based groups]

CONCLUSIONS: Concomitant administration of RPV is not significantly affect methadone dose adjustment and could decrease withdrawal symptoms caused by methadone dose adjustment. These results indicate that the RPV-base regimen may be used as first line treatment in IDUs with HIV-infection.

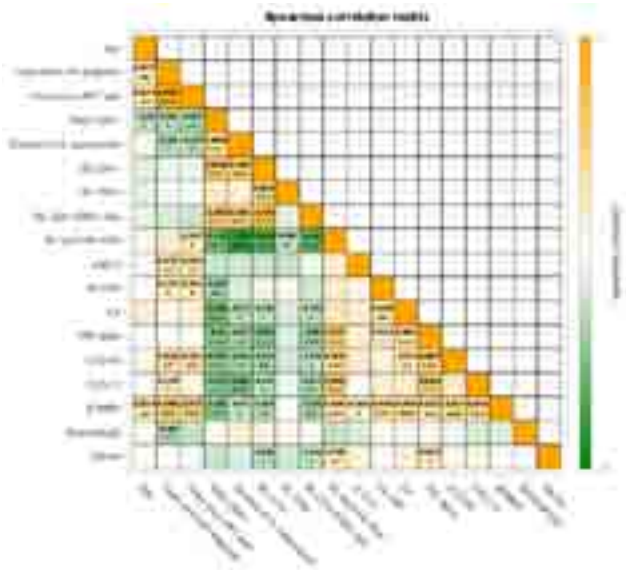
ANTIRETROVIRAL DRUG RESISTANCE

PEB0250

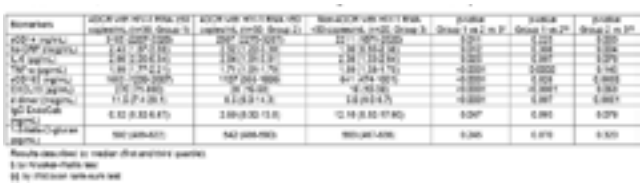
INFLAMMATION, IMMUNE ACTIVATION AND MICROBIAL TRANSLOCATION IN PERSONS LIVING WITH FOUR-CLASS DRUG RESISTANT HIV: DATA FROM THE PRESTIGIO REGISTRY

V. Spagnuolo[1,2], T. Clemente[1], R. Caccia[2], L. Galli[2], A. Poli[2], G. Sterrantino[3], R. Gagliardini[4], B. Rossetti[5], S. Rusconi[6], M.M. Santoro[7], M. Zazzi[8], P. Cinque[2], A. Castagna[1,2], on behalf of the PRESTIGIO Study Group
[1]Vita-Salute San Raffaele University, Faculty of Medicine and Surgery, Milan, Italy, [2]IRCCS Ospedale San Raffaele, Division of Infectious Diseases, Milan, Italy, [3]University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy, [4]IRCCS National Institute for Infectious Diseases L. Spallanzani, Rome, Italy, [5]Azienda Ospedaliero-Universitaria Senese, Infectious Diseases Unit, Siena, Italy, [6]University of Milan, Infectious Diseases Unit, DIBIC Luigi Sacco, Milan, Italy, [7]University of Rome "Tor Vergata", Department of Experimental Medicine, Rome, Italy, [8]University of Siena, Department of Medical Biotechnology, Siena, Italy

BACKGROUND: Four-class drug resistant (4DCR) persons living with HIV (PLWH) are a fragile population with a 22% probability of AIDS- or non-AIDS events or death for any cause over 48 months. No data on biomarkers of inflammation, immune activation and microbial translocation are available for this population.
METHODS: Cross-sectional study on three different groups of PLWH on antiretroviral therapy (ART):
- 4DCR (defined as harbouring a four-class drug resistant virus (NRTI, NNRTI, PI, INSTI)) with HIV-1 RNA ≥ 50 copies/mL (group-1; n=30);
- 4DCR with HIV-RNA <50 copies/mL (group-2; n=30);
- non-4DCR with HIV-RNA <50 copies/mL (group-3; n=20).
Groups were matched by age (±5 years), sex, smoking habit.
Markers of inflammation (hs-CRP, IL-6, TNF-alpha, d-dimer), immune activation (sCD163 and CXCL13) and microbial translocation (sCD14, endotoxin core IgG (EndoCAb IgG) and 1-3-β-D-glucan (BDG)) were measured using specific ELISA kits. Linear correlations were assessed by Spearman correlation analysis.



*[Figure 1. Correlation matrix of inflammation, immune activation and microbial translocation biomarkers and PLWH characteristics. Only significant correlation coefficients are reported (*p<0.05, **p<0.01, ***p<0.001). In the color bar, the yellow side denotes the positive correlations, while green represents the negative correlations.]*



[Table 1. Inflammation, immune activation and microbial translocation biomarkers among the 80 PLWH included in the analysis.]

RESULTS: Eighty subjects were evaluated: median age was 51.7 (IQR=45.9-55.2) years, 86% male, 60% smokers, on ART since 17.8 (IQR=8.0-23.7) years, 472 (IQR=237-766) CD4+cells/mm3, nadir CD4+ 156 (IQR=47-260) cells/mm3; HIV-1 RNA was 3.78 (IQR=2.1-4.69) log-10copies/mL in group-1. Multiple correlations (Figure 1) were detected among inflammation, immune activation and microbial translocation biomarkers (Table 1) and patient characteristics.
CONCLUSIONS: PLWH harbouring a multi-drug resistant virus, also when virologically undetectable, showed a higher degree of inflammation (hs-CRP, d-dimer), immune activation (sCD163, CXCL13) and microbial translocation (sCD14), compared to the non-4DCR group. A longer history of HIV infection and treatment and a worse immunovirological profile were associated with an increased inflammatory status.

PEB0251

VIRAL C-TERMINAL REGION P7 – P6GAG GAG POLYMORPHISMS AND PROTEASE DRUG RESISTANCE MUTATIONS PROFILE IN HIV-1 INFECTED PATIENTS FAILING PROTEASE INHIBITORS COMBINATION THERAPY

G. teto[1], D. Takou[1], J. Fokam[1], B. Dambaya[1], A. Nka[1], M.M. Santoro[2], V. Colizzi[3], C.-F. Perno[4], A. Ndjolo[5]
[1]CIRCB, Virology, yqounde, Cameroon, [2]University of Rome Tor Vergata, Virology, Rome, Italy, [3]University of Rome Tor Vergata, Immunology, Rome, Italy, [4]University of Milan, Virology, Milan, Italy, [5]CIRCB, ORL, Yaounde, Cameroon

BACKGROUND: HIV Gag mutations was reported to confer PI resistance in B subtypes but little is known about non-B. Understanding the role of P7–P6gag and characterize relevant mutational patterns, could help to reduce failures to PI.
METHODS: We conducted at CIRCB a cross-sectional study on 334 individuals (96 on PI). Resistance mutations (RMs) were analyzed in the protease using Stanford algorithm. Mutations were identified in P7–P6gag cleavage sites (CS) (P7/P1 and P1/P6gag) and non-CS of each sequence using HXB2 and BioEdit. Each Gag sequence was analyzed for the presence of P7–P6gag RMs known or not to be associated with resistance to PIs. Samples containing a mixture of wild type and mutant were scored as mutants. Statistical analysis was performed using GraphPad Prism 6 and p ≤ 0.05 was considered significant.
RESULTS: We compared PI exposed patients to not exposed in P7–P6gag CS and non-CS. In CS we found RMs given as exposed/not exposed frequencies: I437V 0%/0.84%; L449P 73.9%/ 80%; P453L 9.37%/3.36% with the respective p 0.861;0.675;0.04 in P7/P1 CS for the first RM and P1/P6gag CS for the others. In non-CS, we found V467E 84.37%/92.47% (p=0.607) and two new mutations with high entropies Q476K 79.16%/0.84% and E477Q 79.16%/0% (p< 0.0001). Among the 96 (44.31% men, Mean age [IR]=41.21±12.66 [7-70] yrs.), 76 were failing PI with RMs (38.63% M46I, 7.95% I47IV/V/A, 4.54% I50L, 12.5% I54IM/M, 14.77% L76V, 4.54%, V32F11.36% V82S/T/A/F, 21.59% I84V and 5.68%

L90M). We found the prevalence of RMs in P7– P6gag in patients with PI-RMs as compared to those with no PI-RMs. Mutations in term of PI-RMs/no PI-RMs were: P453L 55.5%/44.4%; Q476K 43%/55.26%; E477Q 42.10%/53.94% all with p>0.05. No P7–P6gag RMs was linked to a particular subtype: CRF02_AG (63%), G (4%), F2(4%), A (17%), D (2.63%), CRF11_cpx (11.3%) or CRF09_cpx (1.3%) (p≥0.05).

CONCLUSIONS: We revealed, two new, not yet described, potentially important mutations Q476K, E477Q in P7–P6gag non-CS of non-B Gag, that could have clinical implications. They showed no Subtypes or PI-RMs impact. However, further phenotypic analyses and clinical correlates of drug failure will be needed before such information is suitable for amending existing resistance algorithms..

PEB0252

USE OF BICTEGRAVIR/EMTRICITABINE/TENOFOVIR ALAFENAMIDE (B/F/TAF) BEYOND THE PRESENCE OF THE M184V MUTATION

K.M. Natali[1], M. Mutyala[2], A. Khasanova[3], H.R. Jimenez[4,5], J. Slim[2]
[1]Saint Michael's Medical Center, Department of Pharmacy Services, Newark, United States, [2]Saint Michael's Medical Center, Division of Infectious Diseases, Newark, United States, [3]Saint Michael's Medical Center, Medical Education, Newark, United States, [4]Rutgers, The State University of New Jersey, Ernest Mario School of Pharmacy, Piscataway, United States, [5]St. Joseph's University Medical Center, Department of Pharmacy Services, Paterson, United States

BACKGROUND: While B/F/TAF is FDA approved for patients without known resistance to its components, recent data suggests that the presence of M184V/I may not affect its potency. There is little data, however, evaluating its role in patients with M184V in addition to other NRTI and/or INSTI mutations.

METHODS: We conducted a retrospective, observational study of patients receiving B/F/TAF at two inner-city clinics in Newark and Paterson, NJ. We reviewed available resistance testing that was taken prior to B/F/TAF initiation for clinically significant NRTI and or INSTI mutations. The Stanford University HIV Drug Resistance Database was utilized to identify such mutations. Patients were eligible if they were receiving only B/F/TAF for ART regimen, and if they were maintained on it for at least 24 weeks.

RESULTS: A total of 2478 patients were reviewed, 697 of which were receiving B/F/TAF; of those, 54 were eligible for analysis and had known M184V. Thirty-nine had the M184V mutation alone, 15 had M184V plus other clinically significant NRTI and/or INSTI mutations; eight Male and seven Female, the majority were Black (65%) and their mean age was 57 years (SD ± 11). All patients had an undetectable viral load (VL) at the time of B/F/TAF initiation. Baseline resistance mutations were as follows: M184V + TAM(s) (86%), M184V + other NRTI mutation (7%), M184V + INSTI mutation (7%). The method for resistance testing varied: proviral DNA genotype (53%) vs. traditional genotype (47%). The mean duration of B/F/TAF therapy was 12 months. All patients maintained virologic suppression (HIV RNA < 20 copies/mL), with the exception of one patient with a blip of 80 copies/mL, while on B/F/TAF therapy.

CONCLUSIONS: Because B/F/TAF is a convenient single tablet regimen, patients and providers may be tempted to use it as a switch regimen in those who may have had resistance in the past and currently have an undetectable VL on a regimen that requires a change due to drug-drug or drug-food interaction. Although our study is encouraging for those patients, it is critical to have long term follow up and a larger sample size before generalizing its use in patients with multiple NRTI and/or INSTI mutations.

PEB0253

HIGH EFFICACY AFTER SWITCHING TO INTEGRASE STRAND TRANSFER INHIBITORS (INSTI) IN PLWH WITH UNDETECTABLE VIREMIA AND PAST VIROLOGICAL FAILURE WITH OR WITHOUT RESISTANCE

R. Gagliardini[1], P. Lorenzini[1], D. Armenia[2,3], G. Passavanti[1], S. Cicalini[1], A. Vergori[1], F. Forbici[4], A. Bertoli[3], V. Borghi[5], C. Mussini[5], V. Malagnino[6], F. Ceccherini-Silberstein[3], M. Andreoni[6], C.F. Perno[4], A. Antinori[1], M.M. Santoro[3]
[1]INMI L. Spallanzani IRCCS, Rome, Italy, [2]Saint Camillus International University of Health Sciences, Rome, Italy, [3]University of Rome 'Tor Vergata', Department of Experimental Medicine, Rome, Italy, [4]INMI L. Spallanzani IRCCS, Laboratory of Virology, Rome, Italy, [5]Azienda Ospedaliero Universitaria di Modena, Modena, Italy, [6]University of Rome 'Tor Vergata', Clinical Infectious Diseases, Rome, Italy

BACKGROUND: In PLWH with previous virological failures (VF) or resistance, data on optimisation of antiretroviral therapy (ART) with INSTI-regimens are limited. High virological efficacy was demonstrated with DTG+2NRTI in patients with residual NRTI activity and with BIC/TAF/FTC in patients suppressed; few data are available for other INSTI-based options.

METHODS: In this retrospective multi-centre study we analyzed ART-treated PLWH with virological suppression (<50 copies/ml) and at least a previous VF with an available genotype, who had switched to an INSTI-containing regimen. Primary endpoint: viral rebound (VR, confirmed HIV-RNA >=50 c/mL). We estimated incidence ratio (IR) of VR according to a) genotypic susceptibility score (GSS); b) high resistance level to NRTI [K65R/E/N, >= 3 TAM, insT69]. Weighted Cox regression model was fitted to estimate HR of VR, after controlling for confounding variables.

RESULTS: 654 patients included: 30% females, age 52 (IQR 47-56), nadir CD4 116 cells/mmc (40-227), years of viro-suppression 3.2 (1.3-7.4). VR was detected in 120 patients over 1,387 person-year-follow-up (PYFU). IR of VR was comparable throughout the stratifications: a) 8.2 x 100 PYFU (95%CI 5.9-11.3) in patients with GSS <2 and 8.9 x 100 PYFU (7.1-11.0) in patients with GSS >=2; b) 8.8 x 100 PYFU (7.2-10.8) in patients with high resistance level to NRTI and 8.2 x 100 PYFU (5.7-11.8) in patients with no/low resistance to NRTI. Patients in 1° generation INSTI-containing regimens had IR of VR of 10.1 x 100 PYFU (8.1-12.6), those in 2° generation INSTI 6.5 x 100 PYFU (4.7-8.9). By multivariate analysis, patients with GSS>=2 had a lower risk of VR (aHR 0.60, 0.31-1.14), but not statistically significant in the overall population (Table), except for INSTI+NRTI or NNRTI (aHR 0.18, 0.04-0.93, p=0.041). Similar results were obtained with the other definition of resistance.

Viral Rebound	HR 95%CI	p-value	AHR 95%CI	p-value
GSS>=2 vs <2, overall population	0.67 (0.39-1.14)	0.141	0.60 (0.31-1.14)	0.119
GSS>=2 vs <2, 1° generation INSTI + 2NRTI	0.93 (0.41-2.10)	0.852	0.68 (0.28-1.67)	0.399
GSS>=2 vs <2, 2° generation INSTI + 2NRTI	1.36 (0.57-3.25)	0.485	1.55 (0.47-5.08)	0.473
GSS>=2 vs <2, INSTI + NRTI or NNRTI	0.21 (0.05-0.84)	0.028	0.18 (0.04-0.93)	0.041
GSS>=2 vs <2, INSTI + boosted PI	0.58 (0.29-1.14)	0.114	1.15 (0.44-3.02)	0.772
GSS>=2 vs <2, 1° generation INSTI regimen	0.53 (0.27-1.03)	0.063	0.51 (0.21-1.20)	0.122
GSS>=2 vs <2, 2° generation INSTI regimen	1.01 (0.50-2.04)	0.986	0.87 (0.28-1.98)	0.742

[Table]

CONCLUSIONS: After switching during virological suppression, INSTI regimens maintained high rate of virological success even in heavily treatment-experienced patients and with low GSS and/or pre-existing NRTI resistance.

PEB0254

PREVALENCE AND RISK FACTORS OF PRE-EXISTING NNRTI RESISTANCE AMONG SUPPRESSED PLWH IN B/F/TAF SWITCH STUDIES

K. Andreatta[1], R. Acosta[1], M.L. D'Antoni[1], M. Willkom[1], H. Liu[1], R. Martin[1], S. Chang[1], L. Wei[1], S. Collins[1], H. Martin[1], K.L. White[1]
[1]Gilead Sciences, Inc., Foster City, United States

BACKGROUND: Historical preference for NNRTIs as third agents in ART, low barrier to NNRTI resistance (-R) development, and persistence and transmission of relatively fit HIV containing NNRTI-R substitutions have resulted in a high prevalence of NNRTI-R in PLWH. Studies 1844, 1878, 4030, and 4580 demonstrated the safety and efficacy of switching stably suppressed HIV-1-infected adults to bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) and assessed baseline drug resistance in study participants. In this analysis, we investigated the prevalence of pre-existing NNRTI-R and associated risk factors among participants in these four clinical trials.

METHODS: Pre-existing drug resistance was assessed by historical genotypes and/or retrospective proviral DNA genotyping (GenoSure Archive® assay, Monogram Biosciences). Stepwise selection was used to identify potential risk factors for NNRTI-R in a multivariate logistic regression model with variables including participant demographics and baseline characteristics, HIV disease measures, ART history, and other pre-existing HIV drug resistance substitutions.

RESULTS: Baseline genotypic data were available for 1995 participants. Primary NNRTI-R, NRTI-R, and PI-R substitutions were detected in 22% (448/1995), 17% (339/1995), and 10% (208/1995), respectively. The NNRTI-R substitution K103N was detected in 12% (232/1995), rilpivirine (RPV)-associated substitutions (L100I, K101E/P, E138A/G/K/Q/R, V179L, Y181C/I/V, Y188L, H221Y, F227C, or M320I/L) were detected in 10% (196/1995), and other NNRTI-R substitutions (V106A/M, V108I, Y188C/H, G190A/E/Q/S, or P225H) were detected in 7% (144/1995). Previously undocumented NNRTI-R was detected by proviral genotyping in 14% (289/1995). Altogether, 38% (754/1995) of participants were previously treated with NNRTIs, and 7% (145/1995) were on an NNRTI-based regimen at baseline. By multivariate model, factors independently associated with pre-existing NNRTI-R included black race, baseline age <50 years (versus ≥50 years), pre-existing NRTI-R, M184V/I, or PI-R, and prior treatment with protease inhibitors or raltegravir, but not prior NNRTI treatment (potentially due to transmitted resistance or incomplete medical history). Pre-existing RPV-R was associated with CD4 counts <500 cells/mL, prior raltegravir treatment, and pre-existing NRTI-R.

CONCLUSIONS: NNRTI-R was the most frequently observed resistance class in these studies. The high prevalence of NNRTI-R among suppressed PLWH and the risk factors associated with NNRTI-R underscore the importance of comprehensive resistance assessments and medical history prior to switching to RPV or other NNRTI containing regimens.

NRTI MUTATIONS SCENARIO IN EUROPE: HOW THEY HAVE CHANGED AND THEIR IMPLICATION IN HIV PREVENTION AND THERAPY

D. Moschese[1], F. Lombardi[1], A. Borghetti[2], A. Sönnerborg[3,4], E. Barchi[5], C. Devaux[6], F. Garcia[7], R. Paredes[8], E. Heger[9], S. Rusconi[10], F. Incardona[11,12], S. Di Giambenedetto[1,2], EuResist Network Study Group
[1]Catholic University of Sacred Heart, Safety and Bioethics Department - Infectious Diseases Section, Rome, Italy, [2]Fondazione Policlinico "Agostino Gemelli" IRCCS, Rome, Italy, [3]Karolinska Institutet, Department of Laboratory Medicine - Division of Clinical Microbiology, Stockholm, Sweden, [4]Karolinska Institutet, Department of Medicine Huddinge - Division of Infectious Diseases, Stockholm, Sweden, [5]Santa Maria Nuova Hospital, Department of Infectious Diseases, Reggio Emilia, Italy, [6]Luxembourg Institute of Health, Luxemburg, Luxembourg, [7]Hospital Universitario San Cecilio, Clinical Microbiology Service, Granada, Spain, [8]IrsiCaixa AIDS Research Institute, Badalona, Spain, [9]University of Cologne, Institute of Virology - Faculty of Medicine and University Hospital of Cologne, Cologne, Germany, [10]University of Milan, Department of Biomedical and Clinical Sciences "Luigi Sacco", Milan, Italy, [11]EuResist Network, Rome, Italy, [12]InformaPRO, Rome, Italy

BACKGROUND: In recent years, NRTIs-based strategies for both the prevention and dual therapy of the HIV infection have been spreading in Europe and worldwide.

Many clinicians have been skeptical about the widespread application of such protocols because of its unshielded use of NRTIs outside of the standard three-drug cART, thus exposing the patients to potential therapeutic failure or HIV acquisition due to NRTI-resistant strains.

Aim of the study is to explore the overall prevalence of NRTI mutations and its changes over the years.

METHODS: To explore the prevalence of NRTI mutations we analyzed a total of 29.547 sequences retrieved from the early 90s to 2018 from the EuResist Integrated Database. Mutations to NRTI consisting of major and minor ones were identified from the IAS-USA 2019 list.

RESULTS: We identified 9.090 isolates that showed at least one mutation to NRTIs, assessing the overall prevalence at 31%.NRTI mutations appeared early in the history of HIV with a prevalence of around 44%, gradually increasing over the first years of ART reaching a peak of 57% in the early 2000s, then progressively decreasing until reaching its lowest (7%) in 2015-2018.

When focusing on specific mutations, the M184V/I appeared to be the most frequent one with 5.795 isolates harboring it (20%); it showed a similar temporal trend with a peak in prevalence in 2003-2004 (36%) followed by a decrease in the recent period (4% in 2015-18). Specifically, 3.831 patients carried this specific mutation. When divided by countries, the same pattern has been found in all the participating centers (Italy, Spain, Luxemburg, Portugal, Sweden, and Germany).

An exiguous number (5,1%) of transmitted mutations were found while the majority of them were acquired (94,9%).

CONCLUSIONS: Prevalence of NRTI mutation has been declining over the years, showing a peak in the mid-2000s and reaching its minimum in recent years. As for the most frequent mutation, M184 appeared to be the most important one in terms of prevalence. A similar trend can be found in all of the countries included in the analysis, thus the application of new NRTI-based strategies both for prevention and treatment should not be actively discouraged.

PEB0256

DURABILITY OF SECOND-LINE ANTI-RETROVIRAL THERAPY AND PREDICTORS OF VIRAL REBOUND AMONG HIV PATIENTS ON SECOND-LINE ART IN AN HIV SPECIALIST CLINIC IN UGANDA: A 10-YEAR RETROSPECTIVE COHORT

I. Lumu[1,2,3], C. Sekaggya[1], J. Musaazi[1], S. Tomini[2], B. Castelnuovo[1]
[1]Infectious Diseases Institute, Makerere University College of Health Sciences, Kampala, Uganda, [2]University of Liverpool, School of Medicine, Liverpool, United Kingdom, [3]University of Edinburgh, College of Medicine and Veterinary Medicine, Edinburgh, United Kingdom

BACKGROUND: It is projected that up to 19.6% of patients on ART in Sub-Saharan Africa will need second-line treatment by 2030, but the durability of such therapy has not been well studied. This study investigated the durability of second-line ART and the factors associated with the viral rebound in patients on second-line ART in Uganda.

METHODS: A retrospective review of electronic records of patients initiated on second-line ART in an adult HIV clinic. Patients that had taken second-line for ≥6 months between 2007 and 2017 were included. Patients were followed until they experienced a viral rebound (Viral load ≥200copies/ml). Cumulative probability of viral rebounds and factors associated with viral rebound were determined using Kaplan-Meier methods and Cox proportional hazard models respectively.

RESULTS: 1101 participants were enrolled. At base-line, 96% reported good adherence, 64% were female, the median age was 37 years (IQR 31-43), median duration on first-line ART was 3.7 years (IQR 2.7-6.7), and the median CD4 and viral load were 128 cells/ul (IQR 58-244) and 45978 copies/ml (IQR 13827-139583) respectively. During the 4454.17 personal-years, the incidence density of viral rebound was 79.70 (95% CI 71.83- 88.44) per 1000 person-years. The probability of a viral round at 5 and 10 years was 0.34, 95% CI (0.31 -0.37) and 0.5250, 95% CI (0.46 -0.60) respectively. The durability of second-line ART estimated as the median survival without a viral rebound was 9.47 years. Older age categories were protective against viral rebound, but a high switch viral load ≥100,000copies/ml was associated with viral rebound aHR 1.5, p-value < 0.001, 95% CI (1.20- 1.86). Also, later calendar years were associated with viral rebound aHR1.51, 95% CI (1.15-1.99), p-value< 0.003 for 2011-2014 and aHR 2.83, p-value< 0.001, 95% CI (2.00-4.01) for 2015-2017.

CONCLUSIONS: The study affirms that among patients with good adherence in Uganda, second-line regimens are durable, and 50% of patients switched to second-line survive for 9.5 years without experiencing a viral rebound. Meanwhile, a high switch viral load and later calendar year are significantly associated with a viral rebound, suggesting a need for closer follow-up of at-risk individuals in order to maximise the durability of second-line ART.

PEB0257

BASELINE NRTI RESISTANCE IN SUPPRESSED PARTICIPANTS DID NOT LEAD TO VIRAL BLIPS ON BICTEGRAVIR/EMTRICITABINE/TENOFOVIR ALAFENAMIDE (B/F/TAF) OR DOLUTEGRAVIR (DTG)+F/TAF THROUGH WEEK 48 IN STUDY 380-4030

R. Acosta[1], H. Liu[2], S. Collins[3], H. Martin[3], K. White[1]
[1]Gilead Sciences, Inc., Clinical Virology, Foster City, United States, [2]Gilead Sciences, Inc., Biostatistics, Foster City, United States, [3]Gilead Sciences, Inc., Clinical Research, Foster City, United States

BACKGROUND: Study 4030 was the first study to prospectively investigate switching to bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) in virologically suppressed participants with a history of treatment failure and/or known or suspected pre-existing NRTI resistance (NRTI-R). In this study, switching to B/F/TAF was non-inferior to dolutegravir (DTG)+F/TAF, and high rates of virologic suppression were maintained with no treatment-emergent resistance, regardless of pre-existing NRTI-R. Here, we investigated viral blips through 48 weeks of treatment.

METHODS: 565 suppressed participants switched from DTG+F/TAF or DTG+F/tenofovir disoproxil fumarate to B/F/TAF or DTG+F/TAF. Pre-existing NRTI-R was classified into three groups: 1) K65R/E/N or ≥3 TAMs including M41L or L210W (±M184V), 2) any other NRTI-R, or 3) no known or suspected NRTI-R. A blip was a post-baseline HIV-1 RNA value ≥50 c/mL preceded and followed by HIV-1 RNA <50 c/mL. Participants with at least one on-treatment post-baseline HIV-1 RNA value were included in the blip analysis. HIV-1 RNA and last observation carried forward (LOCF) outcome data through week 48 were used.

RESULTS: Of the 562 participants in this analysis, 15 (2.7%) experienced a blip through week 48 with similar blip frequencies between treatment arms (8/283 B/F/TAF; 7/279 DTG+F/TAF). Of the 15 participants with blips, 13 were in the no NRTI-R category, 1 had 3 TAMs and M184I on B/F/TAF, and 1 had M184V on DTG+F/TAF. Only 1 participant had >1 blip (2 blips, B/F/TAF, and no pre-existing NRTI-R). Of the 16 total blip events in the study, 11 were low-level (50-199 c/mL) and 5 were ≥200 c/mL. The proportions of participants with blips <200 c/mL or ≥200 c/mL were similar between treatment arms. At week 48 by LOCF, 14 of the 15 participants with blips had HIV-1 RNA <50 c/mL, and 1 on B/F/TAF had HIV-1 RNA ≥50 c/mL but resuppressed at the next visit. No participant with blips qualified for genotypic and phenotypic testing for emergent resistance.

CONCLUSIONS: Viral blips were infrequent and similar among participants switching to B/F/TAF or DTG+F/TAF, and baseline NRTI-R did not result in a higher rate of blips. Blips did not lead to virologic failure or resistance development using these triple therapy regimens.

PEB0258

HIV DRUG RESISTANCE (HIVDR) IN HAITI: IMPACT ON FUTURE GUIDELINES

S. Koenig[1], J. Wu[2], S. Pierre[3], J.E. Mathon[3], G. Julmiste[3], C. Bellot[3], P. Severe[3], A. Apollon[3], E. Dumont[3], V. Guillaume[3], J. Bernadin[3], R.I. Verdier[3], A. Marcelin[3], P. Crémieux[2], M.M. Deschamps[3], J.W. Pape[3], V. Rouzier[3], S. Avila[4], C.G. Morales[4], B. Liautaud[3], G. Reyes-Terán[5]
[1]Brigham Women Hospital, Boston, United States, [2]Analysis Group, Inc., Boston, United States, [3]GHESKIO Centers, Port-au-Prince, Haiti, [4]Centre for Research in Infectious Diseases of the National Institute of Respiratory Diseases, Mexico City, Mexico, [5]Mexican National Institutes of Health, Ministry of Health, Mexico City, Mexico

BACKGROUND: We assessed drug resistance in a sample of adult patients at GHESKIO in Port-au-Prince, Haiti to inform treatment guidelines. Until November 2018, when dolutegravir became available, 92% of patients had been treated with non-nucleoside reverse transcriptase inhibitor (NNRTI)-based regimens.

METHODS: From September 2018 to July 2019, we conducted HIV genotypes for 817 patients ≥15 years of age using convenience sampling. Of these, 392 were presumably ART-naïve, 226 had failed first-line NNRTI, and 199 had failed a second-line regimen. The median age was 36 years (IQR: 29, 45) and 480 (58.8%) were female. Resistance of at least low level was defined by the Stanford HIV Drug Resistance Database score: ≥ 15.

RESULTS: Pre-treatment efavirenz (EFV) resistance was detected in 21.9% of ART-naïve patients (17.6% in males [n=148] and 24.6% in females [n=244]). Rilpivirine (RPV), doravirine (DOR), and etravirine (ETR) resistance were detected in 11.5%, 8.2%, and 6.4% (see Table 1). Among patients failing a first-line NNRTI regimen, EFV, RPV, and DOR resistance were detected in 81.4%, 46.5%, and 58.0%, respectively. Among patients failing a second-line regimen, EFV, RPV, and DOR resistance were detected in 65.8%, 38.2%, and 41.2%, respectively.
PI resistance was detected in 8.0% of patients failing second-line ART. DTG resistance was detected in 0.4% of first-line NNRTI failure patients.

Treatment Group (≥ 15 yo; n = 817)	EFV	DOR	RPV	ETR	Any NRTI	TDF	AZT	ABC	3TC/FTC	TDF & 3TC	Any PI	DTG
PDR (n = 392)	21.94%	8.16%	11.48%	6.38%	7.40%	3.57%	2.30%	6.12%	6.12%	3.57%	2.30%	0.00%
First-Line NNRTI Failure (n = 226)	81.42%	57.96%	46.46%	34.96%	49.56%	30.97%	4.42%	49.12%	48.67%	30.53%	2.65%	0.44%
Second-Line Failure (n = 199)	65.83%	41.21%	38.19%	23.62%	36.18%	14.57%	15.08%	33.67%	31.66%	12.56%	8.04%	0.00%

[Table. At Least Low-Level Resistance (Score of ≥15 by Stanford HIV Drug Resistance Database)]

CONCLUSIONS: Rates of efavirenz resistance in Haiti are among the highest in the world; thus, EFV should not be used unless ART resistance testing is available. Caution is necessary with the use of other NNRTIs, due to cross-resistance. This must be considered in the use of RPV for long-acting ART. The TDF/3TC/DTG regimen is likely to be effective for first-line ART, but close follow-up is necessary if this regimen is used for NNRTI failures, due to high rates of NRTI resistance. ART resistance testing would be optimal to guide therapy for patients failing second-line ART.

PEB0259

NON-NUCLEOSIDE INHIBITORS-ACQUIRED HIV RESISTANCE IN MEXICO: IS THERE DORAVIRINE CROSS-RESISTANCE?

J.P. Ramirez Hinojosa[1], I.A. Flores[1], J.J. Calva[1], CORESAR
[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Infectious Diseases, Mexico City, Mexico

BACKGROUND: During the last decade, NNRTI (EFV and NVP) have been the most frequently used third component of first-line ART in Mexico´s roll-out national program. There is a need to assess potential benefits of new generation drugs as components of deep salvage regimens. We determined the rate of a new generation NNRTI doravirine (DOR) acquired resistance-associated mutations (DOR-RAM) among patients with background of virologic failure under exposure to NNRTI containing ART regimen in a national cohort in Mexico.

METHODS: A sample of HIV infected patients whose physician requested a salvage treatment recommendation from an official peer advisory comittee at the national program runned by the Ministry of Health was studied. Elegible patients were those with history of virologic failure under an NNRTI containing regimen and a HIV genotypic resistance test (gen-RT). Rate of DOR-RAM was determined, and the low, intermediate or high-level of resistance to DOR according to Stanford University HIV Drug Resistance Database algorithm was assessed.

RESULTS: A total of 1,397 cases with prior NNRTI history and an available gen-RT were analysed. 712 patients were under NN exposure during genRT performance (group 1) 680 were not (group 2) and 5 cases had incomplete data. The following Stanford Resistance scores for DOR were found: Low level (23.4% in Group 1, 15.1% in group 2), Intermediate (26.4% in group 1, 12.2% in group 2), High level (15.8% in group 1, 10% in group 2). Intermediate to High level resistance affecting both ETV and DOR were found in 19.8% in group 1, and 7.5% in Group 2. In the group 1: 17.5% were found to be fully susceptible to ETV but with high level resistance to DOR and 21.2% with low level resistance to DOR but high level resistance to ETV.

CONCLUSIONS: HIV variants harboring DOR-RAM are selected after virologic failure to EFV or NVP. Overall, high level resistance to DOR was found in less than 16%. Although there is no formal experience with Doravirine use as component of salvage regimens, this new NNRTI may have a potential beneficial role and could be used in patients with ETV compromise.

LONG-ACTING AGENTS AND OTHER DRUG DELIVERY SYSTEMS (E.G., INJECTABLES, IMPLANTS, MICRONEEDLE PATCHES)

PEB0260

FEASIBILITY OF IMPLEMENTING LONG-ACTING INJECTABLE ANTI-RETROVIRAL THERAPY TO TREAT HIV: A SURVEY OF HEALTH PROVIDERS FROM THE 13 COUNTRIES PARTICIPATING IN THE ATLAS-2M TRIAL

D. Kerrigan[1], M. Murray[2], T. Sanchez Karver[3], A. Mantsios[4], N. Walters[5], K. Hudson[6], E. Kaplan-Lewis[7], F. Pulido[8], A. Bassa[9], D. Margolis[6], N. Galai[3]
[1]American University, Washington DC., United States, [2]Independent Consultant, London, United Kingdom, [3]Johns Hopkins University, Baltimore, United States, [4]Independent Consultant, New York City, United States, [5]GSK, London, United Kingdom, [6]ViiV Healthcare, Raleigh, United States, [7]Ican School of Medicine at Mount Sinai, New York City, United States, [8]Hospital Universitario 12 de Octubre, Madrid, Spain, [9]Mzansi Ethical Research Centre Middelburg, Middelburg, South Africa

BACKGROUND: Long-acting (LA) injectable antiretroviral therapy (ART), with cabotegravir (CAB) and rilpivirine (RPV), was found to be non-inferior to daily oral ART in Phase 3 trials for efficacy, with high levels of patient acceptability, tolerability and satisfaction. Limited information on provider experiences with LA ART exists, which is critical to inform real world implementation.

METHODS: An online survey was sent to 449 health providers from the 13 countries participating in the Phase 3b ATLAS-2M trial of the administration of CAB LA + RPV LA every 2 months (Q2M) compared to every month (Q1M). A total of 329 providers (73%) responded to the survey. Based on formative qualitative research conducted in prior Phase II trials, we developed aggregate measures of logistical barriers, clinical concerns and patient benefits related to LA ART. Multivariable regression models were developed to identify factors related to LA ART feasibility in the context of routine clinical care including the aforementioned aggregate measures, as well as geographic and provider related variables.

Multivariable logistic regression model of the overall feasibility of monthly LA ART	AOR	95% CI
Region (ref: Europe): North America Latin America Asia/Pacific Africa	 1.4 0.7 1.4 2.9***	 0.79, 2.30 0.22, 2.27 0.73, 2.84 1.87, 4.35
Role in clinic (ref: physician): Nurse/physician assistant Research staff/pharmacist	 1.1 0.8	 0.73, 1.55 0.51, 1.29
Prior trial involvement (ref: 1-2 trials): 3+ clinical trials	 1.6	 0.76, 3.32
Barriers score	0.8**	0.70, 0.94
Concerns score	1.0	0.95, 1.09
Benefits score	1.1**	1.03, 1.13
***=p<0.001; **=p<0.01; *=p<.05		

[Table. Multivariable logistic regression model of the overall feasibility of monthly LA ART]

RESULTS: A majority of providers indicated that it would be very feasible (62.8%) or somewhat feasible (32.1%) to administer monthly LA ART in their clinics. Feasibility scores were higher for delivering LA ART every 2 months versus every month (mean 28.3 vs. 26.9; p-value <0.001). In multivariable logistic regression, providers from sub-Saharan Africa had significantly higher odds of perceived overall feasibility of monthly LA ART (aOR 2.9, 95% CI 1.9-4.4) compared to those from other regions, as did those reporting a greater number of LA ART patient benefits (aOR 1.1, 95% CI 1.0-1.1) compared to those reporting less benefits. Providers reporting a greater number of logistical barriers associated with patients returning to clinic appointments had a significantly lower odds of perceived feasibility of LA ART (aOR 0.8, 95% CI 0.7-1.0) compared to those providers reporting less logistical barriers.

CONCLUSIONS: Clinical and operational guidelines, training, human and material resources, and patient support systems will be essential to optimize the implementation of LA ART outside of clinical trials in routine care settings.

PEB0261

PATIENT-REPORTED OUTCOMES THROUGH WEEK 48 OF ATLAS-2M: A STUDY OF LONG-ACTING CABOTEGRAVIR AND RILPIVIRINE ADMINISTERED EVERY FOUR OR EIGHT WEEKS

V. Chounta[1], E.T. Overton[2], A. Mills[3], S. Swindells[4], P.D. Benn[1], S. Vanveggel[5], R. van Solingen-Ristea[5], Y. Wang[6], K.J. Hudson[7], M. Shaefer[7], D.A. Margolis[7], K. Smith[7], W. Spreen[7]
[1]ViiV Healthcare (UK), Brentford, United Kingdom, [2]University of Alabama at Birmingham, Birmingham, United States, [3]Men's Health Foundation, Los Angeles, United States, [4]University of Nebraska Medical Center, Omaha, United States, [5]Janssen Pharmaceutica NV, Beerse, Belgium, [6]GlaxoSmithKline, Collegeville, United States, [7]ViiV Healthcare (US), Research Triangle Park, United States

BACKGROUND: ATLAS-2M (NCT03299049), a Phase 3b clinical study, demonstrated non-inferior antiviral activity of cabotegravir (CAB) long-acting (LA) + rilpivirine (RPV) LA dosed every 8 weeks (Q8W) versus every 4 weeks (Q4W) over 48 weeks in suppressed ART-experienced persons living with HIV. Patient-reported outcomes (PROs) from ATLAS-2M are presented.

METHODS: PRO endpoints included treatment satisfaction (HIV Treatment Satisfaction Questionnaire [HIVTSQs]), treatment acceptance (ACCEPT© questionnaire), treatment preference (preference questionnaire), and acceptability of injections (Perception of Injection questionnaire [PIN]). HIVTSQs and ACCEPT© results were stratified by prior CAB+RPV exposure (pre-planned analysis).

RESULTS: 391/1045 (37%) participants in ATLAS-2M had received CAB+RPV prior to study entry. In participants without prior CAB+RPV exposure, a large increase from baseline was reported in treatment satisfaction in both LA arms, with Q8W dosing statistically significantly favored at Weeks 24 and 48 (Table). Marked improvements from baseline were observed in the General Acceptance domain of the ACCEPT© questionnaire in both LA arms, but were not statistically significant between groups (Table). Participants with prior CAB+RPV exposure reported high treatment satisfaction (Table) and acceptance values at baseline that were maintained over time.
Statistically significant improvements in the Acceptance of Injection Site Reactions domain of the PIN questionnaire were observed from Week 8 to Weeks 24 and 48 for Q8W and Q4W (Table).
Participants without prior CAB+RPV exposure and with recorded preference responses who received Q8W dosing preferred this regimen over oral CAB+RPV (98%; 300/306). Among those with prior Q4W exposure, 94% (179/191) preferred Q8W dosing versus Q4W (3%; 6/191) or oral CAB+RPV (2%; 4/191). The most common reasons supporting their preference were administration frequency and convenience.

Outcome, Intent-to-treat–exposed population	Q8W without prior CAB+RPV exposure n=327	Q4W without prior CAB+RPV exposure n=327	Adjusted difference Q8W – Q4W	p-value for adjusted diff.	Q8W with prior CAB+RPV exposure n=195	Q4W with prior CAB+RPV exposure n=196	Adjusted difference Q8W – Q4W	p-value for adjusted diff.
Baseline total HIVTSQs score,* mean (SD)	57.7 (9.2)	56.7 (9.3)	N/A	N/A	62.2 (5.4)	62.0 (6.7)	N/A	N/A
Adjusted mean change from baseline in total HIVTSQs score by visit (95% CI adjusted mean):								
Week 24	5.1 (4.4, 5.8)	4.0 (3.3, 4.7)	1.1	**0.036**	0.6 (–0.0, 1.2)	0.5 (–0.1, 1.1)	0.1	0.871
Week 48	4.9 (4.0, 5.7)	3.1 (2.3, 4.0)	1.7	**0.004**	0.4 (–0.3, 1.2)	–0.1 (–0.8, 0.7)	0.5	0.344
Adjusted† mean change from baseline in General Acceptance score‡ (ACCEPT) by visit (95% CI adjusted mean):								
Week 24	5.8 (3.2, 8.5)	4.2 (1.5, 6.8)	1.7	0.379	–0.4 (–3.0, 2.2)	–1.0 (–3.5, 1.6)	0.5	0.772
Week 48	6.8 (4.3, 9.3)	5.7 (3.2, 8.1)	1.1	0.525	–1.0 (–3.9, 2.0)	–1.9 (–4.8, 1.1)	0.9	0.659
	Q8W N=522	**p-value for Week 24/48 vs. Week 8**			**Q4W N=523**	**p-value for Week 24/48 vs. Week 8**		
Acceptance of Injection Site Reactions,§ (PIN) mean (SD):								
Week 8	1.9 (0.9)				1.9 (0.9)			
Week 24	1.8 (0.8)	**0.004**			1.8 (0.8)	**0.002**		
Week 48	1.7 (0.9)	**<0.001**			1.8 (0.9)	**<0.001**		

*Scores can range from 0 (minimum; very dissatisfied) to 66 (maximum; very satisfied).
†Adjusted by baseline score, sex at birth, age, race (white, non-white).
‡The Acceptance/General score is based on participant responses to three items: overall treatment acceptance, the balance between advantages and disadvantages, and whether the treatment is worth taking in the long-term. All items are assessed on Likert-like scales.
§Scores can range from 1 to 5. Higher scores represent a lower acceptance of injection site reactions.

[PEB0261 Table. Outcome, intent-to-treat-exposed population.]

CONCLUSIONS: Q4W and Q8W LA dosing provided high treatment satisfaction and acceptance scores, with patients preferring Q8W dosing over both oral and Q4W therapies. The PRO data, along with safety and efficacy data, support the therapeutic potential of monthly or two-monthly CAB+RPV and highlight participants' preference for LA therapy over daily oral dosing.

PEB0262

WILLINGNESS TO USE INJECTABLE ANTIRETROVIRAL THERAPY (ART) AMONG WOMEN WHO DISENGAGE FROM PREVENTION OF MOTHER-TO-CHILD TRANSMISSION PROGRAMMES IN UGANDA

E. Laker Odongpiny[1], A. Arinaitwe[1], V. Nakate[2], J. Kyenkya[3], M. Lamorde[1], F. Cresswell[1,4,5], C. Waitt[6], D. Meya[3], A. Kiragga[3]
[1]Infectious Diseases Institute, Prevention,Care and Therapy, Kampala, Uganda, [2]Infectious Diseases Institute, Reseach, Kampala, Uganda, [3]Infectious Diseases Institute, Research, Kampala, Uganda, [4]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [5]MRC-UVRI and LSHTM Uganda Research Unit, Enteebe, Uganda, [6]University of Liverpool, Department of Molecular and Clinical Pharmacology, Liverpool, United Kingdom

BACKGROUND: Prevention of mother-to-child transmission (PMTCT) programmes in sub-Saharan Africa continue to have high rates of disengagement from HIV care. The fear of HIV status disclosure by discovering pill bottles at home is a major contributing factor to disengagement. Injectable ART (long acting cabotegravir/rilpivirine) has proven to be efficacious in clinical trials and is discreet, offering a potential solution to this problem. We investigated the knowledge and willingness to use injectable ART among women disengaged from the PMTCT programme in Uganda.

METHODS: Women were considered disengaged if they had not visited the HIV clinic within 90 days of the last scheduled appointment. Community tracing by trained nurse counselors used locator information obtained at enrollment in care. Using structured-questionnaires, opinions relating to injectable ART, including willingness to use it, were collected using a 3-point Likert scale. Logistic regression analysis was performed to determine predictors of willingness to use injectable ART.

RESULTS: Among a total of 1023 women registered between 2017 – 2019 under the PMTCT programmes in Kampala and Wakiso districts, 385 (38%) had disengaged from care and 22% (83/385) were successfully traced and interviewed. The median age was 26 years (IQR; 23-29), 88% (73/83) had a live infant and 66% (55/83) were living with their partner. Only 25% (21/83) had heard of injectable ART. However, 72% (60/83) of women had experience with using other injectable drugs/implants, mainly injectable contraceptives (70%; 42/60). The majority (69%; 57/83) felt that using ART tablets increased disclosure risk. Over half, (55%, 46/83) were very willing to use injectable ART, 40% (33/83) were somewhat willing and four (5%) were not willing. Those who did not associate ART tablets with disclosure risk were less willing to consider injectable ART (adjusted OR 0.21; 95% CI 0.06-0.71; P=0.013).

CONCLUSIONS: We report low levels of knowledge about injectable ART in our study population. There was high willingness to use injectable ART relating to fears that ART tablets caused potential for HIV status disclosure. Injectable ART could be a solution for women that have challenges with disclosure; it may potentially increase retention in care and warrants further investigation in this setting.

PEB0263

COMPASSIONATE USE OF LONG ACTING (LA) CABOTEGRAVIR (CAB) AND RILPIVIRINE (RPV) FOR PATIENTS IN NEED OF PARENTERAL ANTIRETROVIRAL THERAPY

R. D'Amico[1], R. Moodley[2], E. Van Landuyt[3], R. Van Solingen-Ristea[3], B. Baugh[4], V. Van Eygen[3], S. Min[1], A. de Ruiter[2], A. Cutrell[1], M. Shaefer[1], C. Foster[5], D. Chilton[6], S. Allard[7], D. Margolis[1]

[1]ViiV Healthcare, Research Triangle Park, United States, [2]ViiV Healthcare - UK, Brentford, United Kingdom, [3]Janssen Pharmaceuticals, Beerse, Belgium, [4]Janssen Pharmaceuticals - US, Raritan, United States, [5]Imperial College NHS Healthcare Trust, London, United Kingdom, [6]Guys and St Thomas NHS Healthcare Trust, London, United Kingdom, [7]HIV Reference Center Universitair Ziekenhuis Brussel, Brussels, Belgium

BACKGROUND: During the clinical development of CAB + RPV LA, physicians could apply for compassionate use (CU) under a global Named Patient Program supported and overseen by ViiV Healthcare and Janssen. Major entry criteria included need for parenteral therapy, absence of primary mutations in integrase or reverse transcriptase and established retention in care.

METHODS: Data were obtained from standardized CU application and quarterly clinical updates. Data were quality controlled by two ViiV physicians. Patients received a loading dose of CAB (600mg) + RPV (900mg) LA followed by monthly maintenance dosing of 400mg/600mg, respectively.

RESULTS: The first participant enrolled in February 2016. Data are available from 24 current participants through November 2019. Median age was 35.5 years (range 20-67), gender: 11 males/13 females, 7 perinatally infected. Fourteen participants had an AIDS diagnosis at enrollment. CU requests primarily involved chronic non-compliance due to pill phobia or other psychological conditions (11), malabsorption (7), or dysphagia (4). In total, seven participants proceeded directly to injection without oral lead-in (OLI). Seven entered receiving oral ART with suppressed plasma HIV-1 RNA [median CD4 count 340/mm^3 (145-918)] and remained undetectable at last visit. Of the seventeen starting with detectable viremia [median CD4 count of 53/mm^3 (<20-551)], 13 (76%, 4/13 without OLI) reported viral suppression below LLOQ at a median of 2 months (1-4 months). Injection site reactions (ISR) reported in ≥2 participants were mild pain (11/24) and nodule formation (2/24) with no withdrawals for ISR. Three serious adverse events were reported with one judged by the physician as possibly related to CU medications (loss of consciousness). One pregnancy occurred with continued LA dosing planned. Two additional participants developed virologic failure with emergent NNRTI mutations (Y181C) without INSTI mutations and were withdrawn.

CONCLUSIONS: CAB + RPV LA as part of a CU program was initiated for reasons related to compliance challenges or GI conditions. Many participants had advanced disease and detectable viremia at start of therapy with most patients achieving virologic suppression post entry (observed data). CAB + RPV LA CU access has been a valuable treatment option for participants with co-morbidities preventing enteral administration of antiretrovirals.

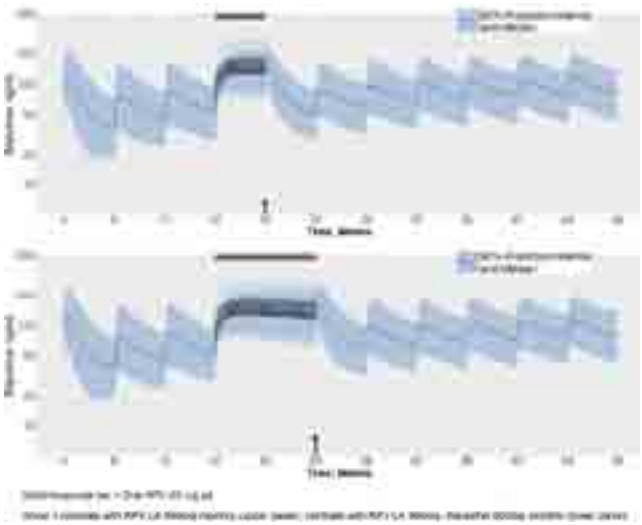
[1]Janssen Pharmaceutica NV, Research and Development, Beerse, Belgium, [2]Janssen Pharmaceutica, Research and Development, Titusville, United States

BACKGROUND: RPV LA is intended for coadministration with cabotegravir long-acting (CAB LA) as a complete 2-drug injectable regimen for HIV-1 treatment. Monthly RPV LA plus CAB LA was noninferior to standard oral therapy in maintaining HIV-1 suppression (ATLAS/FLAIR).

METHODS: Monthly RPV LA consists of 1-month oral RPV 25 mg qd (EDURANT) for tolerability assessment, an initial RPV LA 900mg (3mL) IM dose and subsequent 600mg (2mL) monthly IM doses. PopPK modeling and simulation was used to inform strategies for managing dosing interruptions, aimed at minimizing impact on the overall RPV LA PK profile. Simulations included effects on RPV concentrations of monthly vs 4-weekly dosing, of IM dosing delays, and of bridging with oral RPV to cover planned missed IM injections. Predicted RPV concentrations were compared to the 5th percentile of observed RPV concentrations 4 weeks after the initial RPV LA 900mg dose in ATLAS/FLAIR and to RPV concentrations observed in the oral RPV development program.

RESULTS: Monthly (vs 4-weekly) dosing with a 7-day window has minimal impact on the overall RPV PK profile. IM dosing delays of >7 days may have a larger impact, particularly in the first few months of therapy. If a patient plans to miss a scheduled injection by >7 days, oral RPV can provide coverage of up to 2 missed injections. If time since last injection is ≤2 months, continue with monthly 2mL injections. If time since last injection is >2 months, re-initiate dosing with a 3mL dose and then continue with monthly 2mL injections.



[Figure 1. Simulated RPV plasma concentration-time profiles of bridging with oral RPV 25mg qd during planned RPV LA dosing interruptions for 1 month (resuming with RPV LA 600mg, 2mL; upper panel) and 2 months (resuming with RPV LA 900mg, 3mL; lower panel)]

CONCLUSIONS: Adherence to the monthly RPV LA injection schedule is strongly recommended. Oral therapy to cover planned dosing interruptions of RPV LA injections is predicted to provide exposures within ranges observed in clinical studies. Recommendations for dealing with dosing interruptions are aligned for RPV LA and CAB LA, to facilitate dosing for the complete regimen.

PEB0265

GS-6207 SUSTAINED DELIVERY FORMULATION SUPPORTS 6-MONTH DOSING INTERVAL

R. Begley[1], J. Lutz[1], M. Rhee[1], H. Dvory-Sobol[1], A. Chiu[1], S.K. West[1], J. Corpus[1], J. Ling[1], P. German[1]
[1]*Gilead Sciences Inc, Foster City, United States*

BACKGROUND: GS-6207, a potent, selective, first-in-class, multi-stage inhibitor of HIV-1 capsid is in development for treatment of HIV. Previously, we demonstrated that subcutaneous GS-6207 can be administered quarterly, or less frequently, and has potent antiviral activity (2.2 log decline) in people with HIV. In this study, the safety and single ascending dose (SAD) pharmacokinetics (PK) of a new sustained-delivery SC GS-6207 formulation were evaluated in HIV negative participants, to guide formulation and regimen selection in subsequent clinical trials.

METHODS: In this ongoing, randomized, blinded, placebo-controlled SAD Phase 1 study, participants were randomized (4:1) to receive 300 mg/mL SC GS-6207 (n=8/cohort) or placebo (N=2/cohort), at 300 (1x1.0 mL) or 900 mg (3x1.0 mL or 2x1.5 mL). PK and safety data were collected through ~64 weeks post dose. Single dose (SD) PK parameters were estimated with noncompartmental methods using available data; dose proportionality was assessed.

RESULTS: 30 of 30 participants completed dosing. Interim safety and PK data are available through 40 (300 mg), 28 (900 mg; 3x1.0 mL) and 20 weeks (900 mg; 2x1.5 mL) post-dose. SC GS-6207 was generally well tolerated. No serious or Grade 3 or 4 AEs related to study drug, or AEs leading to discontinuation occurred. The most common AEs were injection site induration (87%), erythema (70%), or pain (63%); all were mild. There were no clinically relevant ≥Grade 3 laboratory abnormalities.

GS-6207 exposures increased in a generally dose-proportional manner from 300 to 900 mg. Maximal concentrations of GS-6207 were achieved 11 to 14 weeks post-dose (T_{max}), and GS-6207 apparent $t_{1/2}$ was ~15 weeks. A slow initial release of GS-6207 was observed, and therapeutic plasma concentrations were sustained for at least 6 months following 900 mg SD. Similar PK was observed following a 900 mg dose administered as either 3 x 1.0 mL or 2 x 1.5 mL SC injections.

CONCLUSIONS: Preliminary PK and safety data suggest SC GS-6207 300 mg/mL (300 and 900 mg SD) is well-tolerated. 900 mg SD provides therapeutic concentrations for 6 months post-dose. These data support use of this formulation as an every 6 month agent (q6mon) in subsequent clinical trials.

ADHERENCE

PEB0266

ANTIRETROVIRAL THERAPY ADHERENCE IN INDIA (2012-18): A SYSTEMATIC REVIEW AND META-ANALYSIS

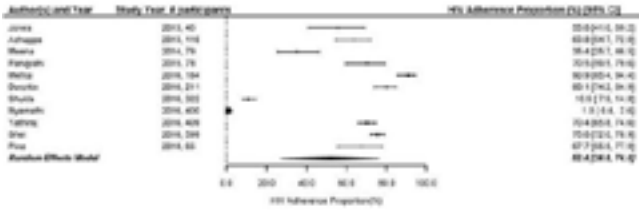
S. Basu[1], Y. Marimuthu[1], S. Garg[1], B. Ganesh[2]
[1]*Maulana Azad Medical College, Community Medicine, New Delhi, India,*
[2]*Indian Council of Medical Research, Microbiology, Chennai, India*

BACKGROUND: India has 2.1 million people living with HIV/AIDS (PLWHA). The objective of this study was to ascertain extent of ART adherence and reasons for non-adherence among PLWHA in India.

METHODS: We conducted a systematic review and meta-analysis using the following criteria: (1) Observational or experimental studies conducted in India (2) English language studies (2). Published during Jan. 2012-Jun. 2018 with data collection during the same period (3). 95% ART Adherence Rate (Primary outcome).

We reviewed bibliographic databases (PubMED, Scopus) and extracted data on study design, period, location, health facility, age-group, adherence rates, factors influencing adherence, etc. Forest plot was used to display the meta-analysis results. Analyses were performed in the R statistical programming language using the 'metafor' package.

RESULTS: A total of 511 records were identified after removing duplicates, 59 full-texts were screened of which 15 studies were included in the meta-analysis. Only one study was conducted in rural India, with <95% adherence reported by all its participants. Forgetfulness (8/15), running out of pills (3/15), distance from health center (2/15), concealment of HIV status from family (2/15, alcohol abuse (3/15), depression (2/15), felt stigma (2/15), side-effects (2/15), and large travel distances (2/15) were significant predictors of non-adherence to ART. The overall pooled estimate of ART adherence was 52.4% (26.8 – 76.8).



[Figure]

CONCLUSIONS: Despite the universal provision of free of cost ART to all PLWHA in government health facilities, suboptimal adherence to treatment persists in a large proportion of PLWHA, especially in rural India. Running out of pills and lack of accessibility of ART centers is a concern for the program suggesting the need for multi-month dispensation of drugs in public health facilities. There also exists paucity of ART adherence studies from high prevalence north eastern states, non-metro cities and most of rural India.

PEB0267

HIGH RATES OF NURSE-LED RAPID ART START AND SUBSEQUENT LINKAGE TO CARE/VIRAL SUPPRESSION AT A LARGE COMMUNITY-BASED HIV TESTING AND PREVENTION SITE IN SAN FRANCISCO, CALIFORNIA, USA

K.A. Christopoulos[1], P.-C. Crouch[1], C. Pilcher[1], N. LeTourneau[1], P. Defechereux[1], C. Schmitto[2], C. Pearson[1], J. Bena[2], S. Scheer[3], L. Hsu[3], E. Mara[3], K. Koester[1], C. Hall[1], R.M. Grant[1], J. Broussard[2]
[1]University of California San Francisco, San Francisco, United States, [2]San Francisco AIDS Foundation, San Francisco, United States, [3]San Francisco Department of Public Health, San Francisco, United States

BACKGROUND: U.S. Department of Health and Human Services guidelines recently endorsed initiation of antiretroviral therapy (ART) immediately at or shortly after HIV diagnosis. Little is known about the outcomes of patients who initiate ART at HIV testing and prevention sites without onsite primary care.

METHODS: The Test and Be Treated (TBT) study is evaluating the outcomes of individuals newly diagnosed with HIV and offered same-day ART at the testing sites of the San Francisco AIDS Foundation (SFAF)/Magnet, a large community-based sexual health and wellness organization in San Francisco. Data on socio-demographics, ART, linkage to care, and viral load (VL) measurements were abstracted from the medical chart and supplemented by data from the San Francisco Department of Public Health HIV surveillance section. We calculated the proportion of individuals who accepted same-day start, as well as overall rates of ART initiation and linkage to care. For those who initiated ART and had at least one follow-up VL with ≥90 days of follow-up time, we calculated the proportion achieving viral load <200 copies/mL. Kaplan-Meier curves summarized time to ART initiation, linkage to care, and viral suppression.

RESULTS: Between April 2018–November 2019, there were 98 new HIV diagnoses. Median age was 31 years and clients were 96% cismen, 78% MSM, 50% Latinx, 11% Black; 37% had residence outside San Francisco county. Same-day ART initiation occurred among 82% of clients, 91% started within one week, and 99% started overall. Of 84 clients with ≥90 days of follow-up, 83% linked to care outside of SFAF, 7% continue to follow at SFAF, 6% are lost to follow-up, and 4% have linkage in process. Median time to charted confirmation of linkage was 20 days (IQR 9-42 days). Viral suppression occurred in 89% and median time to suppression was 34 days (IQR 26-59 days). In those without documented suppression, just over two-thirds were from out of San Francisco, including from outside the U.S.

CONCLUSIONS: An HIV testing and prevention site can successfully initiate same-day ART and rapidly link patients to care. Our study will qualitatively investigate reasons for declining/delaying ART, preferences for follow-up, and the role of out-of-county residence on ART uptake/linkage.

PEB0268

HIGH TREATMENT RETENTION RATES AMONG PATIENTS WITH MULTI-MONTH ANTIRETROVIRAL THERAPY (ART) SUPPLY FROM HIV CLINIC SETTINGS IN NIGERIA

J. Adeola[1], P. Akande[2]
[1]APIN Public Health Initiatives, Strategic Information, ABUJA, Nigeria, [2]APIN Public Health Initiatives, Clinical Services, ABUJA, Nigeria

BACKGROUND: Retention on antiretroviral therapy (ART) is a major challenge among HIV-infected patients even with the availability of free ART in resource limited settings. Frequent dispensing of ART places demand on HIV care providers and the health system. This can lead to suboptimal adherence and retention for patients due to time spent and cost on attending frequent clinic visits. This study was carried out to determine retention on ART among patients with multi-month ART supply from HIV clinics in Nigeria.

METHODS: We conducted a retrospective cohort analysis of 2089 adult HIV-infected patients >=15 years of age, initiated on ART at four HIV clinics in Nigeria from 2016-2017. Retention rate was measured as the proportion of patients alive and on treatment at least 12months after ART initiation. We constructed chi-square statistics and multivariable logistic regression model to measure associations between patient characteristics and retention.

RESULTS: Of the 2089 patients on ART, 1988 (95%) were retained on ART, 1,325 (67%) were female, duration on ART ranged from 12 –24 months; mean age was 38years. In bivariate analysis, factors strongly associated with retention on ART include patients' months of ART supply and Duration on ART. Sex, pregnancy, regimen type and age at ART initiation were not associated with retention on ART after the follow up period. The likelihood of being retained on ART was two times more (OR= 2.47, 95% CI 1.56 – 3.90) among patients with multi-month drug refill visits compared with those with one monthly drug refill visits after adjusting for other factors in the model. Patients on ART for more than 12 months with multi-drug supply were three times more likely to be retained on ART (OR= 3.15, 95% CI 2.04 – 6.04) compared to those with one month drug supply after adjusting for other factors in the model.

CONCLUSIONS: This study further reinforces the benefits of multi-month drug prescription on ART retention. Patients on one month supply with good adherence should be given 2-3 months ARV supply in order to ease the burden of monthly facility visits on the patients, health care workers and the health system in Nigeria.

PEB0269

RATES, PATTERNS AND PREDICTORS OF NON-ADHERENCE TO ART REGIMENS IN KENYA

Z. Kwena[1], B. Irungu[2], M. Muthoni[2], E. Kigondu[2], M. Ngáyo[2]
[1]Kenya Medical Research Institute, Center for Microbiology Research, Kisumu, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya

BACKGROUND: Near perfect adherence to ART is required to achieve viral suppression, prevent developing ART resistance and slower progression to AIDS. We sought to establish rates, patterns and predictors of non-adherence to ART regimens among patients enrolled in HIV care in Kenya.

METHODS: This was part of a case-control cross-sectional study to establish a cost-effective method to measure drug plasma levels and resistant mutations among patients in HIV care. Patients who had been on treatment for the last 12 months and categorized as either

failing treatment (HIV viral load >1000 copies/mL) and responding (HIV viral load <1000 copies/mL) were enrolled from three HIV clinics in Kisumu (western), Nairobi (central) and Malindi (coastal) caring for adult, youth and drug user populations, respectively. We collected data on socio-behavioral, clinic attendance and medication adherence. Data was analyzed using descriptive (count/percent, median/interquartile range(IQR)) as well as inferential (logistic regression) statistics.

RESULTS: One quarter (25%) of the participants reported missing their schedule HIV clinic visit within the preceding three months and 54% reported having missed taking their ARVs for a whole day or more in the preceding six months. Half reported missing ARVs at least once (IQR, 0-5) in the preceding three months. One third (34%) reported missing taking their ARVs continuously for more than three days. When asked the amount of ARVs they had taken for the preceding 30 days, 58% reported taking at least 95% of their ARVs. Overall, 34% of the participants reported that they had had a serious infection thought to be related to their HIV status in 8 days preceding the interview. One third of these (35%) were TB cases; followed by herpes zoster (15%) and pneumonia (8%). Factors independently associated with non-adherence to ARVs were: missing a scheduled visits AOR 0.43 (95%CI: 0.22-0.83), attending clinic in Nairobi AOR 5.72 (95%CI: 3.09-10.60) and increasing age AOR 0.97 (95%CI: 0.95-0.99).

CONCLUSIONS: More than half of patients enrolled in HIV clinics in Kenya miss taking their ARVs which may lead to ARV resistance and poor health outcomes. There is need for programs to ensure delivery of ARVs to young people missing their scheduled visits.

PEB0270

OUTCOMES OF SUSPECTED TREATMENT FAILURE IN A COHORT OF ART PATIENTS IN KENYATTA NATIONAL HOSPITAL, KENYA

K. Mutai[1], P. Muiruri[1], J. Kangethe[1], S. Eshiwani[1]
[1]Kenyatta National Hospital, Nairobi, Kenya

BACKGROUND: According to 2018 Kenya HIV treatment guidelines, treatment failure is suspected among HIV patients with VL≥1000 copies/mL of blood. Enhanced adherence counselling (EAC) is recommended to address poor adherence before switching patients to the next line of treatment. This was an evaluation of the outcomes of interventions after suspected treatment failure.

METHODS: Patients' chart reviews were done on patients enrolled on ART in Kenyatta National Hospital. Patients who had been on ART for at least 12 months and with viral load >=1000 copies per mL in the period between January 2017 and June 2019 were eligible for the study. Data was generated from the electronic medical records. Viral re-suppression and treatment switch indicators were presented as percentages. Associated factors were tested using chi-square test and odds ratios calculated using binary logistic regression. Statistical significance was interpreted at 5% level.

RESULTS: A total of 955 ART patients had suspected treatment failure in the 3-year period under review. The mean age was 39.3 years (SD 14 years); 114 (11.9%) were adolescents (15-19 years) and 92 (9.6%) were young people (20-24 years). Majority (60.7%) were females. Most patients (93.5%) were on first-line ART regimen with a median duration on ART of 61.9 months (IQR 41.6 – 90.0 months). Viral load test was repeated in 857 (90%) patients. Viral re-suppression rate after EAC intervention was 64.1% (549/857) which was achieved in a median duration of 6.1 months (IQR 4.4 – 8.9 months). Age and gender did not influence re-suppression rates. Treatment was changed in 37.4% (357/955) of the patients and 168 (47.1%) achieved viral suppression after switch of ART regimen. Compared to the 25+ years age group, there was a higher risk of switching treatment among adolescents [OR 2.1 (95% CI 1.5-3.2), p<0.001] and young people [OR 1.7 (95% CI 1.1-2.6), p=0.015].

CONCLUSIONS: Poor adherence is an important contributor to high viral load in ART patients thus a substantial proportion of those with suspected treatment failure re-suppressing after undergoing enhanced adherence counselling sessions.

ETHICAL ISSUES IN CLINICAL TRIALS AND TREATMENT STRATEGIES

PEB0271

PERCEPTION AND WILLINGNESS TO PARTICIPATE IN HIV CURE CLINICAL TRIALS AMONG PEOPLE WHO INITIATED TREATMENT DURING ACUTE HIV INFECTION IN AMSTERDAM

M. Dijkstra[1,2], S. Rennie[3,4], H.L. Peay[5], J.M. Prins[1], G. Henderson[3], P.T. Nieuwkerk[6], G.J. de Bree[1], on behalf of the NOVA study team
[1]Amsterdam UMC, Academic Medical Center, Department of Infectious Diseases, Amsterdam, Netherlands, [2]Public Health Service Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [3]University of North Carolina-Chapel Hill, Department of Social Medicine, North Carolina, United States, [4]University of North Carolina-Chapel Hill, UNC Bioethics Center, North Carolina, United States, [5]RTI International, Research Triangle Park, North Carolina, United States, [6]Amsterdam UMC, Academic Medical Center, Department of Medical Psychology, Amsterdam, Netherlands

BACKGROUND: People who initiate antiretroviral therapy (ART) during acute HIV infection (AHI) are potential candidates for HIV cure clinical trials, due to the early reduction in HIV reservoir size. However, these cure trials, which may include ART interruption (ATI), involve potential risks. Assessing views of potential participants is crucial and will provide indispensable information for trial design. Therefore, we explored knowledge and perception of HIV cure and willingness to participate in cure trials among potential trial participants.

METHODS: Between October-December 2018, we conducted 20 in-depth interviews with men who are participating in the Netherlands Cohort Study on Acute HIV infection (NOVA) and who had immediately initiated ART during AHI between 2014-2018. Topics discussed included knowledge and perceptions of cure and two brief standardised scenarios of potential cure trials: one involving brief ATI (re-initiation of ART immediately after viral rebound) and one involving extended ATI (re-initiation of ART one month after viral rebound). Interviews were audio recorded, transcribed, and analysed thematically.

RESULTS: Median age was 39 (interquartile range [IQR] 28-47) years. 18/20 participants were mostly or exclusively attracted to other men. Median years since AHI diagnosis was 1.7 (IQR 1.0-2.4). Most were not familiar with HIV cure, though when asked, described it as complete eradication. Most participants thought being cured would be positive to a greater or lesser extent, but some thought the positive aspects would be undermined by fear of re-infection. 11/20 participants considered participating in the brief ATI scenario versus 4/20 the extended ATI scenario. The predominant motivation for participation was to help others. Six participants mentioned hope of being cured themselves during the study. Main barriers to participation were dif-

ficulties combining study visits with work, fear of onward HIV transmission, possible health impact, and anxiety of interrupting a stable situation (e.g. because of satisfaction with the current ART regimen).
CONCLUSIONS: People with AHI were more willing to participate in brief ATI than extended ATI. Limited knowledge and understanding of cure as HIV eradication underscore the importance of educating potential cure trial participants. Researchers should offer realistic conceptions of HIV cure (i.e. long-term remission rather than eradication) during recruitment and consent processes.

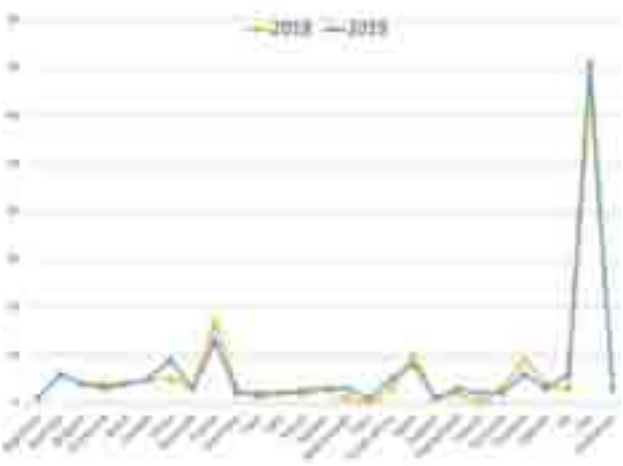
CURE INTERVENTIONS

PEB0272

A LANDSCAPE ANALYSIS OF HIV CURE-RELATED CLINICAL RESEARCH IN 2019

L. Barr[1], R. Jefferys[2]
[1]University of Maryland, Department of Women's Studies, College Park, United States, [2]Treatment Action Group, Basic Science, Vaccines & Cure Project, New York, United States

BACKGROUND: In 2018, we surveyed investigators conducting HIV cure-related clinical research, drawing on information from the online listing established by Treatment Action Group (TAG). The purpose was to perform a landscape analysis of the field. In 2019, we fielded a second survey in order to provide updated information and assess any shifts in the landscape.
METHODS: Trials and observational studies listed as of August 16, 2019 formed the sample set. Survey questions addressed funding, trial development, recruitment, enrollment, participant demographics, antiretroviral therapy status, HIV reservoir assays, invasive procedures, study completion, data sharing and dissemination plans. A survey was sent to the contact(s) for each study. Supplemental information was collected from clinicaltrials.gov and available presentations/publications of study results.
RESULTS: A total of 97 interventional trials and 36 observational studies were identified, with 30 including analytical treatment interruptions. Total projected enrollment is 13,732 participants, with observational studies contributing the majority (8,325). Most interventional trials are in early phases. The majority of current research is located in the USA, with a paucity of locations in settings with the highest burdens of HIV (see Figure 1).



[Figure 1. Study locations, TAG listing 2018 - 2019]

Completed surveys were received for 65 studies, 37 of which had also submitted information in 2018. Analysis of survey responses combined with data from 42 additional studies that presented results over the prior year shows that the research involves predominately (>80%) male participants and is limited in racial and ethnic diversity. Prespecified demographic enrollment targets are rare. Two-thirds of respondents to our previous survey reported that enrollment is progressing more slowly than anticipated.
CONCLUSIONS: A diverse range of interventions are being evaluated in HIV cure research, but participant diversity is far from optimal with a continuing underrepresentation of women. Broadening inclusion and geographic reach will be necessary to achieve the goal of developing widely effective, safe and accessible curative interventions.

NUTRITION

PEB0273

INFLUENCE OF A SUPPLEMENTED MEDITERRANEAN DIET ON THE GUT MICROBIOME PROFILE IN HIV-1 INFECTED INDIVIDUALS

R. Pastor-Ibáñez[1], J. Blanco-Heredia[2], F. Etcheverry[1], F. Díez[1], C. Lucero[1], L. Leal[1], S. Sánchez-Palomino[1], R. Casas[3], M.Á. Navarrete-Muñoz[3], N. Rallón[4], J.M. Benito[4], M. Noguera-Julian[5], R. Paredes[5], R. Estruch[3], D. Torrents[6], F. García[1]
[1]Hospital Clinic de Barcelona, Group of Genomics and Pharmacogenomics in HIV, Barcelona, Spain, [2]Computational Genomics Groups, Barcelona Supercomputing Center (BSC) & IrsiCaixa, Badalona, Barcelona, Spain, [3]Hospital Clinic / Institut d'Investigació Biomèdica August Pi I Sunyer (IDIBAPS), University of Barcelona, Department of Internal Medicine, Barcelona, Spain, [4]Instituto de Investigación Sanitaria-Fundación Jiménez Diaz / Hospital Universitario Rey Juan Carlos, Madrid, Spain, [5]Hospital Universitari Germans Trias i Pujol / IrsiCaixa, Badalona, Spain, [6]Computational Genomics Groups, Barcelona Supercomputing Center (BSC), Barcelona, Spain

BACKGROUND: Supplemented Mediterranean Diet (SMD) with Extra Virgin Olive Oil (EVOO) and walnuts has been associated with a decrease in mortality in healthy population. We assessed whether a SMD can modify the gut microbiome profile and immune activation in ART treated, virologically suppressed HIV infected individuals.
METHODS: HIV-1 infected MSM (n=62) on ART were randomized to either a SMD with 50 g/day of EVOO and 30g/day of walnuts or continue their usual diet (UD) for 3 months. Individual's adherence to diet was monitored using the PREDIMED guidelines (Score: Low<7 points; Normal from 7 to 10; High>10 points). Clinical, metabolic, microbial translocation, inflammatory, immune system and microbiome parameters were assessed at baseline and 3 months after the initiation of SMD. Bioinformatic analysis: QIIME2, LefSe, R 3.5.2. (Selbal, Adonis, Permanova, Pearson's-correlation, Wilcoxon and Dunn's test).
RESULTS: IFNɣ-producing T cells significantly decreased at month 3 respect to baseline in SMD group (CD3+CD4+IFNɣ+: p=0.056; CD3+CD8+IFNɣ+: p=0.018; Tc17 IFNɣ+: p=0.036), but not in UD group. Regarding the microbiome composition, after SMD, less phylum diversity was observed in individuals with Low-adherence (p=0.06). The model distribution distances accepted that genus abundances were affected by the Adherence Score (PERMANOVA: Low-Normal, q=0.03, Low-High, q=0.015; Adonis: p=0.032, R2=0.021). Analyzing the relative abundances according to the SMD adherence Score, we found a substantial increase in High-adherence vs Low-adherence group in Bacteroides (p=0.013), Parabacteroides (p=0.002) and Butyricimonas

(p=0.020). Those differences were reflected in a dismissed Prevotella/Bacteroides ratio in Low-adherence group (P<0.05). LefSe analysis comparing the extreme groups showed substantial differences in the gut microbes at genus level. Particurlarly, Bacteroides in Low-adherence, and Succinivibrio in High-adherence group were the most relevant genus (Selbal: AUC=0.842). Interestingly, individuals who improved their Score more than 3 points presented an enrichment in Bifidobacterium genus after SMD. In these individuals, Bifidobacterium genus was correlated with tolerogenic CD4 T-cell populations: TregCD25+ (P < 0.05; R2 = -0.55).

CONCLUSIONS: The described results show that the intervention with a SMD improves and immune-activation parameters. It is likely that this could be mediated by the change in the composition of microbiome to a more beneficial profile.

SEX-SPECIFIC ISSUES OF ART EFFICACY, ADVERSE REACTIONS AND COMPLICATIONS

PEB0274

MAIN RESULTS OF THE ACTIVE PHARMACOVIGILANCE STRATEGY IN WOMEN LIVING WITH HIV ON DTG-CONTAINING REGIMENS IN BRAZIL

L. Neves da Silveira[1], A..R.P. Pascom[1], M. Freitas[1], C.J.B. Batista[1], G.F.M. Pereira[1], A.A.C.M. Ferreira[1], T.D. Barros[1], A.M.B. Beber[1], V.C.d.S. Lima[1], A.S.D. Guarabyra[1], F.F. Fonseca[1]
[1]Brazilian Ministry of Health, Chronic conditions and Sexually Transmitted Infections department, Brasília, Brazil

BACKGROUND: In 2017, the Ministry of Health of Brazil incorporated dolutegravir (DTG) both for preferred first-line regimen and for switch/rescue regimens. At the same time, an active pharmacovigilance (PV) strategy was implemented for all people living with HIV (PL-HIV) using DTG-containing regimens (DTG-CR). Women has been underrepresented in clinical trials and there is a lack of information of adverse events related to antiretroviral (ARV) among them. In this study, we presented the main results of the PV strategy for women living with HIV (WL-HIV) using DTG-CR in Brazil.

METHODS: WLHIV aged more than 18yo who were using DTG-CR and filled the PV form from April 2017 and October 2019 were included in this analysis. We estimated the incidence of adverse event (AE) by per person year (PY), the prevalence of an AE stratified by some demographic and clinical variables and described the most common AE.

RESULTS: Out of 86,000 WLHIV on DTG-CR, 90% filled the PV form. Data on 77,792 WLHIV, 86,009 PY and 1,062 AE were included; overall incidence rate of AE was 1.23/100PY. Prevalence of AE was 1.4%(IC95%:1.28%-1.45%). The median age was 44yo(IQR:35-53), 47% were white/yellow, 35% were 25-39yo, 28% had 8-11 years of education, the most common region of residence were south and southeast (37% each), 58% were treatment naïve and 42% had a LT-CD4+> 350count/mm3. Most common AE were nausea (0.43%;333), headache (0.27%;212), diarrhea (0.18%;141), skin disorders (0.18%;140), balance disorders (0.15%;120) and insomnia (0.13%; 103). Twenty-one women reported weight gain and seven weight loss. Psychological disorders were reported by 48 women, and out of those 20 reported depression. Severe AE were reported by 72 women, a prevalence of 0.09%;IC95%:0.07%-0.11%.

CONCLUSIONS: This real-life cohort study in Brazil of WLHIV was consistent with randomized controlled trials worldwide, demonstrating low prevalence of self-reported AE associated with the use of DTG-CR and no unexpected symptoms were reported. Considering the difference in pharmacokinetics, use of contraceptive medications and concerns about conception, this study emphasizes the importance of a specific look to WLHIV, especially pregnant women living with HIV, regarding the safety data on the use of DTG.

PEB0275

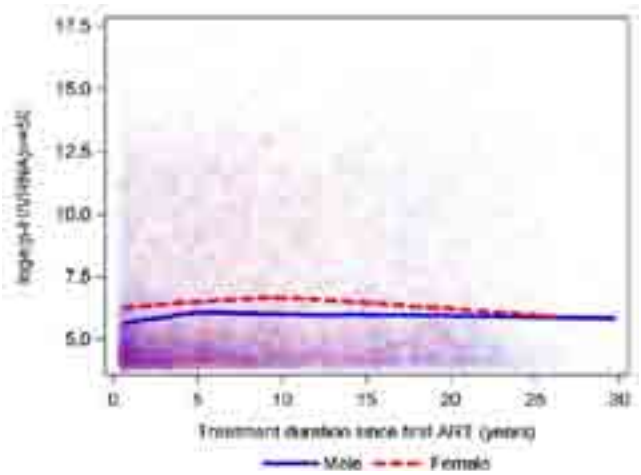
WOMEN ON ART ARE LESS LIKELY TO ACHIEVE HIV RNA <50 COP/ML COMPARED TO MEN: REAL WORLD DATA FROM THE NATIONAL SWEDISH INFCARE COHORT

Å. Mellgren[1,2], M. Lindh[3], J. Brännström[4,5], A. Reepalu[6], V. Svedhem[4,7]
[1]University of Gothenburg, Department of Infectious Diseases, Göteborg, Sweden, [2]Institute of Biomedicine University of Gothenburg, Department of Infectious Diseases, Gothenburg, Sweden, [3]South Älvsborg Hospital, Department of Infectious Diseases, Borås, Sweden, [4]Karolinska Institute, Department of medicine Huddinge, Stockholm, Sweden, [5]South Hospital, Department of Infectious Diseases/Venhälsan, Stockholm, Sweden, [6]Lund University, Clinical infection medicine Department of Translational Medicine, Lund, Sweden, [7]Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden

BACKGROUND: Women are underrepresented in clinical trials and Real World Data are needed to assess ART outcomes in different populations. The Swedish national quality registry InfCareHIV is following all people living with HIV (PLWH) in Sweden since 1999 including sociodemographic data, CD4-cell count, ART and HIV RNA levels. In 2011, a validated health questionnaire was added. The aim was to investigate gender differences in HIV RNA viral load (VL) in PLWH on ART ≥6 months and to assess results in relation to clinical parameters, sociodemographic data and patient-related outcomes.

METHODS: PLWH (≥18 years) on ART for ≥6 months during 2011-2017 were included. All HIV RNA measures were used. The association between VL ≥50 cop/ml and demographic characteristics and clinical data was investigated using binomial regression with log-link function, adjusting for within individual correlation, providing relative risks (RR) with 95% CI as effect size.

RESULTS:



[Figure]

8798 PLWH were followed in the InfCareHIV registry during 2011-2017. The study included 4915 men and 2981 women. Median number of HIV RNA measures were 13 (range 1-66), including 98105 HIV RNA

samples. Median ART duration was 3,2 years (range 0,5-23,6), with no gender difference. Women on ART were more likely to have VL ≥50 cop/ml compared to men with a RR of 1.20 (95%CI 1.10-1.31) p<0.001. Overall, in men 89% (52482/59001) of HIV RNA samples were <50 cop/ml compared to 86,6% (33868/39104) of HIV RNA samples in females. 1871 (38.1%) of men and 1285 (43.1%) of the women had had a HIV RNA ≥ 50 at any time p<0.0001.47,1% had performed health questionnaires (49,7% of men and 42,7% of women). In this subcohort, 89,6% of the men and 80,5% of the women reported optimal adherence.

CONCLUSIONS: National Swedish Real World Data demonstrate a significant difference in ART outcome between women and men. ART adherence may be one explanatory factor.

PREGNANCY (CLINICAL MANAGEMENT ISSUES AND PHARMACOKINETICS)

REVERSE TRANSCRIPTASE AND PROTEASE INHIBITORS MUTATIONAL VIRAL LOAD IN HIV INFECTED PREGNANT WOMEN WITH TRANSMITTED DRUG RESISTANCE IN ARGENTINA

D. Cecchini[1], J. Sfalcin[2], I. Zapiola[3], A. Gomez[2], S. Fernandez Giuliano[3], L. Mammana[3], A. Seravalle[2], M.B. Bouzas[3]
[1]Hospital Cosme Argerich, Infectious Diseases Unit, Buenos Aires, Argentina, [2]CIBIC, Rosario, Argentina, [3]Hospital Francisco J. Muñiz, Virology Unit, Buenos Aires, Argentina

BACKGROUND: Argentina has reported moderate to high levels of transmitted drug resistance (TDR), mostly to NNRTIs, in HIV-infected patients including pregnant women by standard sequencing. However, the percentage of quasispecies harboring resistance mutations (RAMs) and mutational load (ML) remain unknown in those patients with TDR and could be of importance in guiding the selection of maternal antiretroviral therapy and neonatal prophylaxis.

METHODS: Retrospective study in a cohort of 40 naïve HIV-infected pregnant women, whose pretreatment samples had been genotyped by TRUGENE (period 2008-2014). Samples were re-sequenced with Ultra Deep Sequencing (UDS) using a Public Health Agency of Canada protocol on Miseq sequencer (Illumina) and bioinformatics analysis were performed by HyDRA software for a 1% sensibility threshold. TDR mutations were identified according to WHO guidelines. The ML was calculated in each patient considering baseline HIV-1 RNA load multiplied by the frequency of quasispecies harboring RAMs.

RESULTS: By UDS, TDR for NNRTIs, NRTIs and PIs was 17.5% (n=7 patients), 10% (n=4), 12.5% (n=5) respectively. Predominant NNRTI RAMs were K103N (n=4; 10%) and G190A/E/S (n=3; 7.5%). For NNRTIs, 78% of RAMs were present in >93.5% of viral population and ML was >1000 c/mL for 89% of them, with a median (IQR) of 8330 c/ml (7738-29796). The NRTI RAMs corresponded mostly to thymidine-analog associated mutations (7.5%) with a low prevalence of mutations in codon 184 (2.5%). The following NRTI RAMs were described (per patient: % of quasispecies, ML): T215I (99.7%, 11014 c/ml); D67G (1.28%, 502 c/mL); M41L (79.8%, 88578 c/mL) and M184I (1.02%, 173 c/mL). Most frequent PI-RAMS were I85V, M46I, I50V and L90M (n=2, 5% each). For PIs, quasispecies with RAMS corresponded to <2.3% of viral population and ML was <350 c/mL for 77.8% of them, with a median (IQR) of 191 c/ml (54-1274).

CONCLUSIONS: In this cohort of HIV-infected pregnant women, NNRTI-RAMs are predominant within the viral population, usually exceeding the threshold of 1000 c/mL, indicating potential higher risk of perinatal transmission. Conversely, PI mutations appear mostly as minority variants, with potential lower risk of transmission. Among NRTI, the percentage of quasispecies harboring RAMs and ML values were variable within the clinical samples.

PEB0277

EXTENT OF *IN UTERO* TRANSFER OF TENOFOVIR FROM MOTHER TO FETUS: A PAIRED ANALYSIS OF HAIR SPECIMENS COLLECTED AT BIRTH FROM A COHORT IN THE UNITED STATES

J. Pintye[1], Y. Huo[2], D. Kacanek[2], K. Zhang[3], K. Kuncze[3], H. Okochi[3], M. Gandhi[3], Pediatric HIV/AIDS Cohort Study (PHACS)
[1]University of Washington, Biobehavioral Nursing and Health Informatics, Seattle, United States, [2]Harvard TH Chan School of Public Health, Boston, United States, [3]University of California San Francisco, San Francisco, United States

BACKGROUND: As efforts intensify to eliminate vertical HIV transmission, and pre-exposure prophylaxis use burgeons among women of reproductive age, the likelihood of women receiving tenofovir (TFV)-based regimens during pregnancy increases. Understanding pharmacokinetics of *in-utero* TFV transfer is critical for interpreting safety. To evaluate *in-utero* TFV transfer, we measured TFV hair levels at delivery among women living with HIV (WLHIV) receiving tenofovir-disoproxil-fumarate (TDF)-based antiretroviral therapy (ART) and their infants in the United States.

METHODS: Hair samples were collected at or shortly after childbirth from WLHIV and infants enrolled in the Surveillance Monitoring for ART Toxicities Study of PHACS between 06/2014-07/2016. TFV hair levels from mother-infant pairs were analyzed using validated liquid chromatography/tandem mass spectrometry methods. The lower limit of quantification (LLOQ) was 0.00200 ng/mg. Weight-normalized TFV hair concentrations were log-transformed. We calculated individual ratios of infant-to-maternal hair TFV concentrations to determine degree of transfer and Spearman correlation coefficients.

RESULTS: We measured TFV hair levels among 76 mother-infant pairs with TDF-based ART exposure during pregnancy; within this group, 66 (87%) mothers had TFV levels >LLOQ and were included in the analysis with their infants. Median maternal age was 31 years (IQR 26-36); 70% self-identified as non-Hispanic black, and median gestational age at birth was 38 weeks (IQR 38-39). Median time from birth to hair collection was 5 days (IQR 1-15). Median concentration of TFV was 0.02 ng/mg (IQR 0.01-0.03) in maternal hair and 0.80 ng/mg (IQR 0.30-0.80) in infant hair. The mean $\log_{10}$ ratio of infant-to-maternal TFV levels was 1.27 (95% CI 1.08-1.45) and the correlation coefficient between maternal and infant TFV levels was 0.204 (p=0.10). TFV transfer was lower among mothers receiving protease inhibitors (PIs, n=33) compared to those who did not (mean log ratio 1.08 vs. 1.45, p=0.06) and mothers who only used TFV during the 1st trimester compared to 2nd/3rd (mean log ratio -0.58 vs. 1.32, p<0.001).

CONCLUSIONS: Similar to prior studies assessing TFV transfer in cord blood and maternal plasma, we found high rates of TFV transfer *in-utero* using hair levels with a modest positive correlation. Transfer was lower among mothers who received PIs and those with only 1st trimester TFV use.

PEB0279

RISK FACTORS ASSOCIATED WITH ADVERSE BIRTH OUTCOMES AMONG HIV POSITIVE WOMEN IN THE VOLTA REGION OF GHANA

W.K. Axame[1], F.Y. Aku[1], M. Kweku[1], F.N. Binka[1]
[1]University of Health and Allied Sciences, Ho, Ghana, School of Public Health, Department of Epidemiology and Biostatistics, Ho, Ghana

BACKGROUND: HIV in pregnancy negatively influences birth outcomes. Understanding the association between maternal HIV infection and adverse birth outcomes such as low birth weight, preterm delivery and stillbirth will help develop strategies to mitigate the challenge. Hence the study sought to determine risk factors associated with adverse birth outcomes among HIV positive women in the Volta Region of Ghana.

The hypothesis of this study was that, maternal HIV infection was not associated with low birth weight, preterm delivery and stillbirth in the Volta Region of Ghana.

METHODS: A facility-based unmatched case-control study design involving 340 cases and controls from four health facilities in the Volta Region was conducted. A pretested questionnaire was used to collect birth outcome information, socio-demographic characteristics, HIV status, obstetric characteristics and ART history information. EpiData manager and STATA were used for data entry and analysis respectively. Categorical variables were presented using proportions. Multivariate logistic regression was used to determine risk factors associated with birth outcomes. Statistical significance of association was determined at p value of less than 0.05.

RESULTS: :Overall, the prevalence of low birth weight was 15%, preterm delivery, 17.1% and stillbirth, 2.9%. Among cases, prevalence of low birth weight, preterm delivery and stillbirth was 16.6%, 20.6% and 3.5% respectively. For controls, it was 13.5%, 13.5% and 2.4% respectively. Risk factors associated with low birth weight included: primigravidity (AOR=3.36; 95% CI: 1.83-6.15), 4 or more doses of SP/IPTp (AOR=0.43; 95% CI: 0.19-0.99) anaemia (AOR=2.08; 95% CI: 1.15-3.75). More than four Antenatal Care (ANC) visits (AOR=0.37; 95% CI: 0.18-0.76) and malaria (AOR=2.08; 95% CI: 1.10-3.95) were significantly associated with preterm delivery. Predictors of stillbirth were hypertension (AOR=3.41; 95% CI: 1.27-9.19), malaria (AOR=3.75; 95% CI: 1.40-10.04) 4 or more ANC visits (AOR=0.25; 95% CI:0.09-0.71).

CONCLUSIONS: Adverse birth outcomes were more predominant among HIV infected women compared to those without HIV. Maternal HIV infection was not associated with any of these birth outcomes. However, gravidity, doses of SP/IPTp, anaemia, ANC visits, Hypertension and malaria infection were identified as risk factors associated with the reported birth outcomes.

PEB0280

INTEGRATION OF HIV AND OBSTETRIC CARE TO OPTIMIZE HIV MANAGEMENT DURING AND AFTER PREGNANCY

C. Gowda[1,2], B. Wolfe[1], K. Lamberjack[1], L. Crim[1], J. Hunkler[1], M. Brundrett[1,3], M.A. Rosen[4], J.R. Honegger[1,2]
[1]Nationwide Childrens' Hospital, Columbus, United States, [2]The Ohio University College of Medicine, Pediatrics, Columbus, United States, [3]The Ohio University College of Medicine, Pediatrics and Internal Medicine, Columbus, United States, [4]The Ohio University College of Medicine, Obstetrics & Gynecology, Columbus, United States

BACKGROUND: Pregnancy is a pivotal opportunity to engage women in medical care and improve management of HIV. We evaluated if integrated HIV and obstetric care could improve HIV viral suppression during and after pregnancy.

METHODS: All pregnancies from 2005 to 2018 among HIV-infected women at a U.S. site offering obstetric and long-term family-centered HIV care were included. Antiretroviral treatment was available to all women. HIV viral suppression (i.e. HIV RNA ≤200 copies/mL) for each pregnancy was determined at 3 time points (using nearest available testing):

1) conception;
2) delivery; and
3) 9-12 months postpartum.

Factors associated with viral suppression at delivery and postpartum were evaluated using multivariable mixed effects logistic regression models.

RESULTS: There were 270 pregnancies among 179 HIV-infected women, resulting in 244 live births and 0 cases of HIV transmission to infant. Most women were African-American, publicly insured and in their late 20s. Median time from HIV diagnosis to conception was 2.9 years (interquartile range: 0–5.8). Among women with data at all timepoints, the proportion virally suppressed at conception, delivery, and postpartum, respectively, was 4%, 88%, and 61% for 46 newly diagnosed women and 52%, 93%, and 71% for 83 women with established HIV diagnosis prior to their first pregnancy. Trends in viral suppression over time are shown in the Table. Virally suppressed women at conception were 18-fold (adjusted Odds Ratio [aOR]: 18.4; 95% confidence interval: 3.34–101.5) more likely to have suppression at delivery. Postpartum suppression was associated with viral suppression at conception (aOR: 2.56; 95% CI: 1.07–6.11), suppression at delivery (aOR: 4.94, 95% CI: 1.53–16.0), and age (aOR: 1.13 per year increment; 95% CI: 1.04–1.22).

Viral Load Suppression At			Overall* (N=270)	New HIV Diagnosis	Established HIV Diagnosis (n=200)	
Pregnancy Conception	Delivery	9-12 Months Postpartum		First Pregnancy with HIV (n=69)	First Pregnancy with HIV, (n=109)	Subsequent Pregnancy (n=91)
Suppressed	Suppressed	Suppressed	83 (30.7%)	1 (1.4%)	38 (34.9%)	44 (48.4%)
Suppressed	Suppressed	Not Suppressed	10 (3.7%)	1 (1.4%)	4 (3.7%)	5 (5.5%)
Suppressed	Not Suppressed	Suppressed	0 (0%)	0 (0%)	0 (0%)	0 (0%)
Suppressed	Not Suppressed	Not Suppressed	3 (1.1%)	0 (0%)	1 (0.9%)	2 (2.2%)
Not Suppressed	Suppressed	Suppressed	53 (19.6%)	24 (34.8%)	20 (18.3%)	9 (9.9%)
Not Suppressed	Suppressed	Not Suppressed	34 (12.6%)	12 (17.4%)	15 (13.8%)	7 (7.7%)
Not Suppressed	Not Suppressed	Suppressed	5 (1.9%)	3 (4.3%)	1 (0.9%)	1 (1.1%)
Not Suppressed	Not Suppressed	Not Suppressed	18 (6.7%)	5 (7.2%)	4 (3.7%)	9 (9.9%)
Missing ≥ 1 data point			64 (23.7%)	23 (33.3%)	26 (23.9%)	14 (15.4%)

[Table]

CONCLUSIONS: Viral suppression at conception or achieved during pregnancy both strongly predict sustained control nearly 1 year postpartum. Integration of HIV and obstetric care can help optimize management of both conditions.

PEB0281

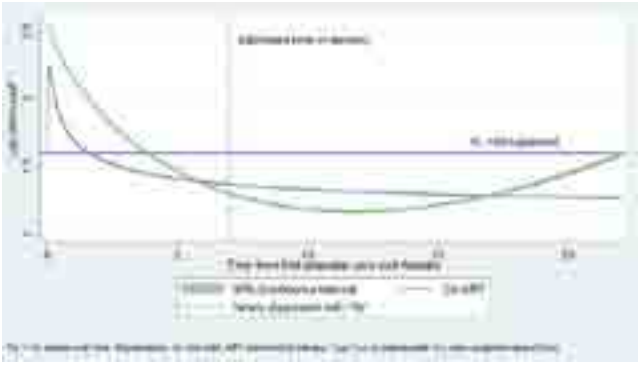
LONGITUDINAL EVOLUTION OF MATERNAL VIRAL LOAD DURING PREGNANCY AND WITHIN 12 MONTHS POSTPARTUM AMONG PREGNANT WOMEN LIVING WITH HIV IN SOUTH AFRICA

F. Moyo[1], A. Haeri Mazanderani[1], G.G. Sherman[1], T. Kufa[1]
[1]National Institute for Communicable Diseases, Centre for HIV & STIs, Johannesburg, South Africa

BACKGROUND: Maternal viraemia is associated with HIV-transmission to infants. Using a national laboratory dataset, we describe maternal viral load (VL) evolution during pregnancy, around delivery and 12-15 months postpartum among pregnant women living with HIV (WLHIV) within the public sector, South Africa.

METHODS: HIV-VLs and pregnancy-related tests performed January 2016-December 2017 from the National Health Laboratory Service's Corporate Data Warehouse were used to create a synthetic cohort of pregnant WLHIV aged 15-49 years. Syphilis screening was assumed to occur at first antenatal care visit (fANC). A syphilis-screening test without prior/ concurrent HIV-VL test identified newly diagnosed, pregnant WLHIV initiating antiretroviral therapy (ART). Cohort entry was at fANC and follow-up was 15months from estimated date-of-delivery. VL changes during follow-up were described using fractional polynomial models. Proportions of viraemic women at different time-points were calculated. Multivariable fractional polynomial models determined factors associated with VL decline during follow-up.

RESULTS: Of 178 319 pregnant WLHIV in the cohort, 85 545 (48.0%) were on-ART, 88 877 (49.8%) were newly diagnosed with HIV. The cohort contributed 345 174 VL measurements [median=2, interquartile range (2-3) VLs per woman] during follow-up. VLs were a median log10 VL 1.9 (0-3.5) at fANC, 1.3 (0-2.2) around delivery and < detectable limit 12-15months postpartum. Median log10 VLs were 3.0 (1.3-4.3) vs. 1.3 (0-2.7) at fANC and 1.3(0-2.3) vs. < detectable limit, 12-15months postpartum for WLHIV diagnosed during pregnancy and WLHIV conceiving on-ART respectively (Figure 1).



[Figure]

At delivery, 36.9% and 14.3% of pregnant WLHIV were viraemic at VL ≥50 and ≥1000 respectively. Being older (≥19 years), conceiving on-ART and having CD4 ≥200 at fANC was associated with sustained VL decline.

CONCLUSIONS: Despite decline in maternal VLs during pregnancy, only 63% reached VL <50 copies/mL by time-of-delivery. Women with VL ≥50 copies/mL in pregnancy and postpartum periods require prioritization for interventions to ensure VL suppression.

PEB0282

THE CHALLENGE OF PERINATALLY HIV-INFECTED WOMEN DURING PREGNANCY

J. Nogueira[1], L. Prieto[2], I. Carrasco[3], M.L. Navarro[3], S. Guillén[4], J.T. Ramos[5], C. Epalza[2], J.I. Bernardino[1], M.d.C. Vinuelas[3], E. Muñoz[2], P. Ryan[6], I. Olabarrieta[7], M.J. Mellado[1], T. Sainz[1], CoRISpe, FARO and Madrid Cohort
[1]Hospital La Paz and IdiPAZ, Pediatrics, Madrid, Spain, [2]Hospital 12 de Octubre, Madrid, Spain, [3]Hospital Gregorio Marañón, Madrid, Spain, [4]Hospital de Getafe, Madrid, Spain, [5]Hospital Clinico San Carlos, Madrid, Spain, [6]Hospital Infanta Leonor, Madrid, Spain, [7]Hospital Severo Ochoa, Madrid, Spain

BACKGROUND: In countries with access to ART, an increasing number of perinatally HIV-infected adolescents and young women are reaching adulthood and becoming pregnant. In this unique population, with a complex social and psychological background and frequently exposed to a high number of antiretroviral regimens, achieving viral suppression might be challenging. The aim of this study was to describe a cohort of vertically HIV-infected mothers, analyzing strategies for PMTCT and describing pregnancy outcomes.

METHODS: A descriptive, retrospective study including perinatally HIV-infected women registered in the Madrid Cohort of HIV-infected children, which gave birth over a 20 years period (January 2000 and December 2019). Medical records were reviewed and clinical and immunovirological regarding infant-mother pairs were collected.

RESULTS: Fifty-nine pregnancies in 34 perinatally HIV-infected women were registered during the study period. Median age at first pregnancy was 21.6 (± 4.4) years, 78% Caucasian. 72,7% of women were on treatment; half of the study cohort had received six or more ART regimens [range 0-14]. Median CD4 T cell count was 561 (413-772) and 66,7% had an undetectable viral load. Reported smoking 38% and 6.8% other substance abuse. Mental disorders (borderline personality disorder, depression, anxiety) were present in 20.4% of women. All but one (who refused ART) were treated during pregnancy, and 88% were suppressed at delivery. Treatment regimen was changed due to pregnancy in 55% of women and included PI in 60%, NNRTI in 17.5% and INI 15.7%. In 16%, intensification of treatment with raltegravir was initiated in order to achieve viral suppression before delivery. 40% of babies were born by cesarean, and four were preterm (2.4%). AZT intrapartum was administered in 93% of cases, and all babies received prophylaxis (77% AZT, triple therapy 17%) and none were breastfed. There was one case of mother-to-child transmission, in a non-adherent mother with mental disorders in which PMTCT measures could not be implemented.

CONCLUSIONS: The unique population of vertically HIV-infected youths poses particular challenges for health care providers. Specific resources and a multidisciplinary approach are needed in order to secure adherence and minimize perinatal transmission risks in this population.

CONTRACEPTION

PEB0283

CONTRACEPTION UPTAKE AMONG HIV POSITIVE WOMEN ON DOLUTEGRAVIR BASED ANTIRETROVIRAL TREATMENT IN URBAN UGANDA: A CROSS SECTIONAL SURVEY

L. Mbabazi[1], M.S. Nabagala[2], S. Okoboi[1], A. Kiragga[2], B. Castelnuovo[1], E. Laker[1], S. Nakalema[1], A. Kamira[1], M. Lamorde[1], S. Kiwanuka[3], J. Kiguli[3]
[1]Infectious Diseases Institute (IDI), Research, Kampala, Uganda, [2]Infectious Diseases Institute (IDI), Statistics, Kampala, Uganda, [3]Makerere University, School of Public Health, College of Health Sciences, Kampala, Uganda

BACKGROUND: In May 2018, the World Health Organization issued a teratogenicity alert for women using dolutegravir (DTG) and emphasized increased integration of sexual and reproductive services into HIV care to meet contraceptive needs of HIV positive women. However, there are scarce data on the impact of this guidance on contraceptive uptake. We assessed contraceptive uptake and factors associated with contraceptive services among HIV positive women on DTG-based regimen in Uganda.

METHODS: A cross-sectional survey was conducted between May 2019 to July 2019 in five government clinics in Kampala where DTG was offered as the preferred first-line ART regimen. We randomly selected non-pregnant participants (aged 15-49 years) using DTG-based regimens. We used interviewer administered questionnaires to collect data on demographics, contraceptive use, social and health system factors. We defined contraceptive uptake as the proportion of women using any method of contraception divided by the total number of women on DTG during the review period. We described patients' characteristics using descriptive statistics. Factors associated with contraceptive uptake were investigated using linear regression (STATA 13).

RESULTS: We enrolled 359 women; median (interquartile range, IQR) age was 38 (32-43) years. One half had attained up to primary education 182/359 (50.7%). The proportion of contraceptive uptake was 138/359 (38.4%). Majority 82/138 (58.6%) used injectable medroxyprogesterone but 15/138 (10.7%) used intrauterine device, 15/138 (10.7%) used condoms alone and 8/138 (5.7%) used contraceptive implants in the study period. Women who reported high affordability of contraceptives were more likely to use contraceptive services compared to women that reported low affordability (adjusted risk ratio (aRR) 1.54; 95% Confidence Interval (CI): 1.09-2.18). In contrast, women aged 40-49 years (aRR 0.59; 95% CI: 0.39-0.90) and those that did not discuss family planning with their partners (aRR 0.44; 95% CI: 0.33-0.59) were less likely to use contraceptive services.

CONCLUSIONS: Despite teratogenicity concerns during the study period, contraceptive uptake was low among women using DTG. Since partner involvement had an impact on contraceptive uptake, couple counseling on family planning could be explored to increase use of contraceptives. Also, integration of family planning services into HIV care should be strengthened.

PEB0284

CHANGUO LANGU: IS IT REALLY HER CHOICE? EXAMINING HEALTHCARE PROVIDER PERSPECTIVES ON DOLUTEGRAVIR AND CONTRACEPTIVE COUNSELLING FOR WOMEN OF REPRODUCTIVE AGE AT A TERTIARY REFERRAL CENTRE IN WESTERN KENYA

J. Thorne[1], C. Bernard[2], J. Humphrey[3], M. Maina[4], B. Jakait[4], R. Patel[5]
[1]University of Toronto/Women's College Hospital, Obstetrics & Gynaecology, Toronto, Canada, [2]Indiana University School of Medicine, Obstetrics & Gynaecology, Indianapolis, United States, [3]Indiana University School of Medicine, Medicine, Indianapolis, United States, [4]Moi Teaching & Referral Hospital, Pharmacy, Eldoret, Kenya, [5]Washington University, Medicine, Seattle, United States

BACKGROUND: In May 2018, the WHO announced a potential increased risk of neural tube defects in women using dolutegravir (DTG) peri-conception, halting roll-out of DTG and leading to confusion among HIV care providers (HCPs) about requirements for its use. Data around best practices to facilitate HCP and patient decision-making for antiretroviral therapy (ART) and contraceptive use are lacking. As part of the ongoing mixed methods Chaguo Langu-My choice study, we qualitatively explored factors facilitating HCP counseling around ART and contraceptive use among women living with HIV (WLHIV) already using DTG in Kenya.

METHODS: We conducted semi-structured, in-depth interviews in English with nine HCPs (eight clinical officers and one peer mentor) at one of Kenya's largest HIV treatment programs. The interviews covered four domains: (1) understanding about DTG and birth defects, (2) knowledge of effective contraception, (3) counselling practices around DTG use in WLHIV of reproductive potential, and (4) views on integrated HIV and family planning care. We used inductive coding and content analysis to identify dominant themes.

RESULTS: We highlight the following four dominant themes:
(1) HCPs reported better knowledge of the benefits of DTG than of its potential risks;
(2) variable knowledge of and comfort discussing contraceptive efficacy for WLHIV on ART prevented many HCPs from counselling effectively on ART and contraceptive options;
(3) HCPs wished to use the concept of informed choice to counsel, but interpreted that as offering either DTG with effective contraception or an alternative ART regimen, reflecting the then national guidelines; and
(4) HCPs want additional clinical decision support tools aligned with national guidelines to optimize contraceptive care for WLHIV on ART, and timely access to expert consultation for complex cases.

CONCLUSIONS: While especially knowledgeable about DTG benefits, HCPs felt uncomfortable with family planning counselling, including around the risks of neural tube defects and contraceptive efficacy with various ART regimens. HCPs desire more clinical decision support and guidance tools to facilitate their counseling on informed choice for ART and contraception among WLHIV; future work needs to explore the contextually appropriate definition of informed choice

PEB0285

CHAGUO LANGU - MY CHOICE: USE OF A NEW PREGNANCY PREFERENCE SCALE AMONG WOMEN OF REPRODUCTIVE POTENTIAL LIVING WITH HIV USING DOLUTEGRAVIR

C. Bernard[1], J. Humphrey[2], J. Thorne[3], W. Fadel[4], V. Omodi[5], M. Maina[5], B. Jakait[5], R. Patel[6]

[1]Indiana University, Obstetrics & Gynecology, Indianapolis, United States, [2]Indiana University, Medicine, Indianapolis, United States, [3]University of Toronto, Obstetrics & Gynaecology, Toronto, Canada, [4]Indiana University, Biostatistics, Indianapolis, United States, [5]AMPATH, Eldoret, Kenya, [6]University of Washington, Medicine, Seattle, United States

BACKGROUND: Women living with HIV (WLHIV) have higher maternal mortality and unintended pregnancy rates than their uninfected counterparts. Incorporating their pregnancy preferences in shared decision-making around reproductive care may improve outcomes, yet such tools are missing. The Desire to Avoid Pregnancy (DAP) scale, the only psychometrically evaluated instrument that captures multifaceted pregnancy preferences, has the potential to fill this gap.

METHODS: As part of the mixed methods study Chaguo Langu -- My Choice, 264 women aged 15-49 years who initiated dolutegravir from October 2017-April 2019 at clinical sites affiliated with the Academic Model Providing Access to Healthcare (AMPATH) program in western Kenya answered the DAP scale via telephone. The scale includes three domains: (1) cognitive self-evaluation of preferences; (2) affective feelings; and (3) anticipated practical consequences of pregnancy/childbearing. Item responses use a Likert scale with a final score of 0-4 (higher score reflects higher desire to avoid pregnancy). We also asked the single "standard" question: "Are you trying to get pregnant now?" and compared the responses via t-test.

RESULTS: The average DAP score in the overall group was 2.29 (range 0-4). Among the 14% of women who answered "yes," they were currently trying to get pregnant, the average score was 0.77 (range 0 to 3.43) compared to 2.53 (range 0.36 to 4) for those who answered "no" (absolute difference 1.76, 95% CI 1.44-2.07, p-value <0.001; Figure 1).

[Figure 1. Comparison of scores on the Desire to Avoid Pregnancy (DAP) scale to responses to the single question "Are you trying to get pregnant now?" among women living with HIV in western Kenya (N=264). This figure depicts a violin plot to show the distribution of data with an embedded box plot to show the minimum, maximum and quartile values.]

CONCLUSIONS: WLHIV who report currently trying to get pregnant have lower average scores on the DAP scale compared to those not currently trying to get pregnant. However, among women who report not currently trying to get pregnant, there is wide score range indicating that the DAP is able to better capture nuance and ambivalence about pregnancy preferences than standard one-item questions. These women may benefit from open-ended counseling, including for both contraception and preconceptual care.

CHAGUO LANGU - MY CHOICE: PATIENT PERSPECTIVES ON COUNSELING AND SHARED DECISION-MAKING AROUND ANTIRETROVIRAL THERAPY AND CONTRACEPTIVE CHOICES

C. Bernard[1], J. Humphrey[2], J. Thorne[3], V. Omodi[4], M. Maina[4], B. Jakait[4], R. Patel[5]

[1]Indiana University, Obstetrics & Gynecology, Indianapolis, United States, [2]Indiana University, Medicine, Indianapolis, United States, [3]University of Toronto, Obstetrics & Gynaecology, Toronto, Canada, [4]AMPATH, Eldoret, Kenya, [5]University of Washington, Medicine, Seattle, United States

BACKGROUND: Efavirenz- or dolutegravir-containing antiretroviral therapy (ART) are commonly used among women living with HIV (WLHIV). Interactions between efavirenz and contraceptive implants may reduce implant effectiveness, and recent evidence suggests potential increased risk of neural tube defects when using dolutegravir peri-conception. These issues create challenges for WLHIV and providers when determining optimal ART, given individual pregnancy and contraceptive preferences. Little is known about the perceptions of WLHIV about their counseling and shared decision-making around ART and contraceptive choices.

METHODS: As part of the ongoing mixed methods study Chaguo Langu - My Choice, we conducted telephone surveys with 385 WLHIV aged 15-49 years who initiated dolutegravir from October 2017-April 2019 at clinical sites affiliated with the Academic Model Providing Access to Healthcare (AMPATH) program in western Kenya. Survey domains included:

1) counseling received about reproductive risks of dolutegravir and efavirenz; and

2) shared decision-making regarding ART and contraception. We report descriptive statistics of survey responses.

RESULTS: Less than half of women reported receiving counseling that dolutegravir could cause problems in pregnancy (46%) and few received counseling that efavirenz could cause problems with contraception (9%). About half (56%) reported receiving contraceptive counseling when initiating dolutegravir. Participants reported higher levels of shared decision-making around contraception compared with ART (e.g. 64% reported that her provider asked about her preferences for contraceptive initiation/change compared to 25% when her ART was changed; Table 1).

Antiretroviral Therapy (ART, n=100)	Agree n (%)	Disagree n (%)	Neither n (%)
I chose to change ART regimens myself	21 (21)	78 (78)	2 (2)
My provider forced me to change ART regimens	42 (42)	49 (45)	9 (9)
My provider did not ask about my preferences when my ART regimen was changed	75 (75)	25 (25)	0 (0)
My provider took time to explain different ART options and their risks/benefits to me	7 (7)	92 (92)	1 (1.0)
Contraception (n=27)	**Agree n (%)**	**Disagree n (%)**	**Neither n (%)**
I chose to change/start contraception myself	15 (68)	7 (32)	0 (0)
My provider forced me to change/start contraception	2 (9)	20 (91)	0 (0)
My provider did not ask about my preferences when my contraception was changed/started	8 (36)	14 (64)	0 (0)
My provider took time to explain different contraceptive options and their risks/benefits to me	10 (46)	12 (54)	0 (0)

[Table 1. Patient perceptions of shared decision-making around antiretroviral therapy and contraceptive use among women living with HIV in western Kenya.

CONCLUSIONS: WLHIV report low levels of counseling and shared decision-making around ART use, including potential ART-contraceptive interactions and teratogenic risks. However, they do report higher levels of shared decision-making around contraceptive use in the same health system, often with the same providers. Given recent outcries from WLHIV to have more agency in ART decision-making, efforts should build on existing paradigms for contraceptive decision-making to improve shared decision-making around ART.

DIAGNOSIS OF HIV DISEASE IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0287

CLINICAL OUTCOME AMONG HIV DIAGNOSED CHILDREN UNDER EARLY INFANT DIAGNOSIS (EID) PROGRAMME IN INDIA: ADDRESSING THE GAPS FOR FURTHER IMPROVEMENT

S. Kamble[1], N. Gawde[2], S. Bembalkar[1], N. Goel[1], M. Thorwat[1], S. Kamble[1], K. Nikhare[1], V. Verma[3], S. Rajan[3], R. Gangakhedkar[4]
[1]ICMR-National AIDS Research Institute, Epidemiology and Bio Statistics, Pune, India, [2]Tata Institute of Social Sciences, Mumbai, India, [3]National AIDS Control Organisation, New Delhi, India, [4]Indian Council of Medical Research, Epidemiology and Communicable Division, New Delhi, India

BACKGROUND: In India, HIV diagnosis is confirmed among new born babies of HIV positive mothers through HIV DNA PCR test under Early Infant Diagnosis (EID) programme. After diagnosis they are linked to ART treatment for improved survival. Gaps in linking of these HIV diagnosed babies for ART treatment were studied along with clinical outcome among them after ART initiation.

METHODS: ART treatment records (n=474) of these children were assessed at 30 ART centres in India. Recorded clinical parameters during baseline and follow up visits were studied and In Depth Interviews (IDI) were conducted among different service providers.

RESULTS: HIV diagnosis was confirmed among 38.4% children before six months of age and delayed beyond one year among 29.5%. Median time (Q1, Q3) to initiate ART after HIV diagnosis was 43 (14,119) days. ART was initiated within 14 days of HIV confirmation only among 1/4th children while 62% were initiated beyond one month of diagnosis.

Proportion of children with lower CD4 count (CD4 percentage for age) was declined from 75% to 28% after 41 months of ART. Improvement from WHO clinical stage 3/4 was noted among all children after 26 months of median ART duration. Proportion of low Weight for Age reduced from 64% to 23% after 41 months of median ART and only 13 opportunistic infections (3 tuberculosis, 3 Pneumocystis jirovecii) were detected during follow up period. In all 23 (7.4%) deaths were reported after 24 months of ART initiation of which 20 occurred during first 6 months of ART initiation, while 11.6% (36) children were lost to follow up.

Illiteracy, unawareness, poor financial conditions, migration, overcrowding at centre, unavailability of identity documents, deaths of parents, perception about child's death, social stigma, long distance to travel were identified barriers for delayed or non-enrolment into ART treatment. Unavailability of full time paediatricians, unavailability or limited paediatric drugs and its formulation and lack of 2nd line Paediatric ART Guideline were system level gaps for delayed ART treatment.

CONCLUSIONS: There is improved clinical outcome among HIV diagnosed children under EID. Accessibility of paediatric ART services should be improved and medical officers should be adequately trained for paediatric ART.

PEB0288

SHARED RISK PROFILES FOR VERTICALLY HIV-INFECTED INFANTS AND HIV-EXPOSED INFANTS WITHOUT EARLY INFANT DIAGNOSTIC (EID) TEST RESULTS - UNRECOGNIZED HIV TRANSMISSION TO INFANTS IN ETHIOPIAN PREVENTION-OF-MOTHER-TO-CHILD TRANSMISSION (PMTCT) PROGRAMS?

J. Walles[1,2], J. Ekström[1], F. Tesfaye[1], T.T. Balcha[1], P. Björkman[1]
[1]Lund University, Clinical Infection Medicine, Translational Medicine, Malmö, Sweden, [2]Central Hospital Kristianstad, Department of Infectious Diseases, Kristianstad, Sweden

BACKGROUND: Early detection of HIV infection by PCR testing (early infant diagnostic testing; EID) is recommended for HIV-exposed infants within two months of age. We analysed prevalence and associated characteristics of mother-to-child-transmission (MTCT), as well as characteristics of pregnancies with absent EID, to estimate MTCT prevalence among infants lacking EID in prevention-of-MTCT (PMTCT) programs in Ethiopia.

METHODS: HIV-positive pregnant women were identified from PMTCT registers from 2013 to 2017 at five public health facilities in central Ethiopia. Missing data was handled using multiple imputations by chained equations (MICE), imputing missing data points by multiple regression in an iterative process, generating 25 complete datasets.

Factors associated with MTCT detected through EID, and with absent EID, were analysed with logistic regression which was performed on each dataset, and the results were pooled. For pregnancies without EID, MTCT prevalence was estimated using MICE.

RESULTS: EID results were available for 880/1012 (87.0%) pregnancies without record of fetal or neonatal death; 15/880 (1.7%) infants were HIV-positive. MTCT was independently associated with maternal HIV diagnosis at delivery (adjusted odds ratio [AOR] 32.6, p=0.007), WHO clinical stage 2 (AOR 8.10, p=0.010), mixed (AOR 23.3, p=0.011) or replacement (AOR 7.01, p=0.034) infant feeding, and lack of infant nevirapine prophylaxis (AOR 21.5, p=0.0007). Absence of EID was independently associated with maternal HIV diagnosis during the pregnancy (AOR 3.30, p<0.0001), or delivery (AOR 4.81, p=0.034), WHO clinical stage 3 (AOR 4.76, p=0.0022), mixed infant feeding (AOR 12.8, p=0.0009), and delivery at another facility (AOR 2.94, p<0.0001) or at home (AOR 4.16, p=0.014).

Using these predictor variables, 1.8% and 7.5% of data was imputed to allow 56/880 and 180/1012 cases to remain in multivariate analysis of MTCT and absent EID, respectively. The estimated HIV prevalence among infants without EID was 14.4/132 (10.9%, AOR=7.09, p=0.0080).

CONCLUSIONS: The rate of MTCT was low in pregnancies with timely EID results among women receiving PMTCT care in Ethiopia. However, EID results were absent in 13.0% of pregnancies. Cases without EID had similar characteristics as those with confirmed MTCT, suggesting high rates of MTCT among infants lost from PMTCT follow-up. Intensified tracing of such infants should be considered.

PEB0289

ASSESSMENT, FEASIBILITY, AND ACCEPTABILITY OF AN ADAPTED HIV RISK SCREENING TOOL TO IDENTIFY UNDIAGNOSED CHILDREN LIVING WITH HIV IN BURUNDI

A. Vrazo[1], A. Ndayizeye[2], H. Gbais[2], A. Amzel[1], A. Yansaneh[1], D. Castor[1], L. Filiatreau[1], J. Kottut[1], J. Niyonkuru[3], F. Dia[3], D. Nimpagaritse[3], C. Niyonsaba[2], B. Nijirazana[2], G. Etheredge[4]

[1]US Agency for International Development, Washington, United States, [2]FHI 360 Reaching an AIDS-Free Generation (RAFG), Bujumbura, Burundi, [3]USAID Burundi, Bujumbura, Burundi, [4]FHI 360, Durham, United States

BACKGROUND: Identifying children living with HIV (CLHIV) is difficult in very low prevalence settings, such as Burundi. The study purpose was to assess the performance of an HIV risk screening tool to target testing to high-risk children at ambulatory/outpatient consultation in Burundi. The objective was to validate the tool in this setting, and to assess feasibility and acceptability of the tool among health providers.

METHODS: A cross-sectional study of 24,601 children aged 1-14 years seeking ambulatory services was implemented at 23 health facilities in five provinces of Burundi over 6 months. All eligible children and caregivers were administered the nine-question screening tool, and all children were referred for HIV testing. Descriptive and exploratory bivariate analyses were performed on quantitative data. Qualitative data were collected through focus group interviews of 43 providers from nine study sites and summarized to identify themes.

RESULTS: The study was stopped early for futility after interim data analyses found a lower than expected positivity rate. Of 16,786 children enrolled, 8,403 (50%) were female. Eighteen children (0.11%) were HIV-positive including 0.07% (9/12,607) < 5 years old and 0.22% (9/4,179) 5-14 years old. A higher positivity rate was found in females 5-14 years old compared to males 5-14 years old (0.4%, 9/2,178 females vs 0%, 0/2,001 males). Positivity rates varied by province, from 0% to 0.39%. Bivariate analyses revealed associations between a positive HIV test and: 1) one or both parents of the child deceased (p=0.046), and 2) recurring diarrhea or ≥2 episodes of diarrhea in the past three months (p=0.097). Providers found the screening tool to be feasible and acceptable, with major themes including: commodity and human resources constraints, and maintaining efficiency in clinic flow.

CONCLUSIONS: While validation of the screening tool was not possible, this is the largest analysis of HIV positivity rates among children at the ambulatory entry point in Burundi. Our findings suggest that whereas a pediatric screening tool may be feasible and acceptable to providers, routine ambulatory index testing is not an effective case finding strategy. Therefore, we recommend implementation of more targeted case-finding approaches for children <15, especially within the 5-14 age group.

NEGATIVE DIAGNOSTIC PCR RESULTS AMONG VERY EARLY TREATED INFANTS IN JOHANNESBURG, SOUTH AFRICA

M. Burke[1], Y. Shen[2], R. Strehlau[1], S. Shiau[3], E.J. Abrams[4,5,6], C.T. Tiemessen[7], L. Kuhn[2,4]

[1]University of Witwatersrand, Department of Paediatrics and Child Health, Empilweni Services and Research Unit, Johannesburg, South Africa, [2]Columbia University Irving Medical Center, Gertrude H. Sergievsky Center, Vagelos College of Physicians and Surgeons, New York, United States, [3]Rutgers School of Public Health, Department of Biostatistics and Epidemiology, Piscataway, United States, [4]Columbia University Irving Medical Center, Department of Epidemiology, Mailman School of Public Health, New York, United States, [5]Columbia University Irving Medical Center, ICAP at Columbia University, Mailman School of Public Health, New York, United States, [6]Columbia University Irving Medical Center, Department of Pediatrics, Vagelos College of Physicians & Surgeons, New York, United States, [7]University of the Witwatersrand, Centre for HIV and STIs, National Institute for Communicable Diseases, National Health Laboratory Services, and Faculty of Health Sciences, Johannesburg, South Africa

BACKGROUND: Early antiretroviral treatment (ART) in neonates may lead to smaller HIV reservoirs. We investigated frequency of and risk factors for testing negative on diagnostic PCR tests in early-treated neonates. Diagnostic PCR tests, which detect total HIV nucleic acids, have been shown to be excellent biomarkers of the quantity of HIV DNA in peripheral blood when the viral load (VL) is undetectable.

METHODS: At Rahima Moosa Mother and Child Hospital, Johannesburg, South Africa, we recruited 73 neonates with confirmed HIV intrauterine infection within <48 hours of life who started ART ≤14 days of birth. Treatment was nevirapine with lamivudine and zidovudine until lopinavir-ritonavir could be used. Infants were followed on ART with repeat VL testing at 1, 2 and 4 weeks of age, every 4 weeks to 24 weeks and then every 8 weeks to 104 weeks. Diagnostic HIV PCR tests were repeated at 24, 48, 72 and 104 weeks. CD4+ T-cell count and percentage was measured at baseline, 24, 48, 72 and 104 weeks.

RESULTS: Of 61 infants surviving on study, 46 (75.4%) attained VL <50 copies/mL and 14/46 (30.4%) who suppressed to <50 copies/mL ever tested diagnostic PCR negative after ART start. Among infants who suppressed, those who ever tested PCR negative on ART had higher CD4 T-cell percentages and higher cycle threshold (CT) values on their birth PCR pre-ART. Sex, age at ART start, birthweight, and pre-ART VL were not significantly different by PCR status (Table). In 10/14 infants, the last available PCR test on ART was still negative.

Infant Characteristics	Total (N=46)	Ever PCR negative (N=14)	Never PCR negative (N=32)	p-value
Sex, N (%) Male Female	 23 (50.0) 23 (50.0)	 6 (42.9) 8 (57.1)	 17 (53.1) 15 (46.9)	0.75
Age at ART start, N (%) 0 to <= 48 hours >48 hours to 14 days	 29 (63.0) 17 (37.0)	 10 (71.4) 4 (28.6)	 19 (59.4) 13 (40.6)	0.52
Birth Weight (grams), Median (IQR)	2,750 (2,425 – 3,180)	2,673 (2,120 – 3,160)	2,750 (2,530 – 3,265)	0.45
Pre-ART HIV RNA (copies/ml), Median (IQR)	11,908 (901 – 116,138)	11,910 (901 – 31,445)	10,725 (910 – 317,660)	0.75
Pre-ART CD4+ T-cell percentage, Median (IQR)	38.30 (28.84 – 49.81)	48.90 (40.62 – 55.86)	32.66 (27.17 – 48.68)	0.01
Diagnostic birth PCR Cycle Threshold (CT), Median (IQR)	26.8 (24.3 – 28.2)	27.8 (27.2 – 30.3)	25.6 (22.9 – 27.9)	<0.01

[Table]

CONCLUSIONS: Almost a third of infants started on ART within 14 days of life and who suppress test negative on diagnostic PCR tests while remaining on ART. This proportion is higher than observed in infants starting ART in the first few months of life. Clinicians should be alert to these false negative results to avoid unnecessary confusion about the infant's HIV status.

PHARMACOKINETICS/PHARMACODYNAMICS/ PHARMACOGENOMICS AND THERAPEUTIC DRUG MONITORING IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0291

MODEL-BASED APPROACH OF DOSE SELECTION AND OPTIMAL PK SAMPLING OF FOSTEMSAVIR FOR PEDIATRIC PATIENTS WITH MULTIDRUG RESISTANT HIV-1 INFECTION

N. Thakkar[1], M. Magee[1], K. Moore[2], P. Ackerman[2], S. Chabria[2], C. Llamoso[2], N. Goyal[1]
[1]GlaxSmithKline, Clinical Pharmacology Modeling and Simulation, Collegeville, United States, [2]ViiV Healthcare, Research Triangle Park, United States

BACKGROUND: Fostemsavir (FTR) is a human immunodeficiency virus type 1 (HIV-1) attachment inhibitor in Phase 3 development for the treatment of adults with multidrug resistant HIV-1 infection. FTR is an extended release prodrug and is hydrolyzed by alkaline phosphatase in the gastrointestinal lumen to its active moiety, temsavir (TMR). TMR is primarily metabolized by esterase-mediated hydrolysis with contributions from cytochrome P450 (CYP) 3A4. The current analysis demonstrates the application of a model-based approach to design an efficient clinical trial of FTR in pediatric patients leveraging the comprehensive data from the adult program.

METHODS: The TMR adult population (POP) PK model with weight-based allometric scaling was used for simulations with parameter uncertainty using the mrgsolve package in R. 500 trials were simulated using different doses by weight bands, and scenarios accounting for both the presence and absence of CYP3A inducer or inhibitor to evaluate the probability of success (PoS) based on Cmax and Ctau-defined criteria to maintain exposures comparable to those observed in adult population. Trial simulations were also conducted to assess optimal PK sampling schemes and subject numbers. The final TMR POP PK model was used for parameter estimation and compared to the true value for each subject to calculate the precision of PK parameter estimates.

RESULTS: Dosing simulations demonstrated the adult dose of FTR 600 mg BID for pediatric subjects ≥ 35 kg and FTR 400 mg BID for subjects ≥ 20 to <35 kg meet defined criteria by providing comparable adult TMR exposure that established FTR safety and efficacy. For intense sampling portion of the study, 6 PK sampling times in a dosing interval (1, 2, 4, 6, 8, 12 hours post-dose) ±30 min in at least 12 of 50 subjects were identified to provide adequate precision in PK parameter estimates.

CONCLUSIONS: The analyses demonstrated that the proposed model-based approach allows implementation of an efficient pediatric study design. It informs critical study aspects such as dosing regimen, PK sampling scheme and number of subjects required for PK sampling while providing targeted drug exposure levels that are safe and efficacious.

DRUG FORMULATIONS FOR INFANTS AND CHILDREN

PEB0292

IMPLEMENTATION OF LOPINAVIR-BOOSTED RITONAVIR AS PREFERRED FIRST-LINE IN CHILDREN LIVING WITH HIV IN SIX REGIONS-TANZANIA

T.J. Masenge[1], G. Antelman[2], R. Van de Van[3], A. Kibona[4], S. Kimambo[3], J. Kalimunda[5], M. Rutahiwa[6]
[1]Elizabeth Glaser Pediatric Aids Foundation, Pediatric and Adolescent Services, Dar es Salaam, Tanzania, United Republic of, [2]Elizabeth Glaser Pediatric Aids Foundation, Research and Evaluation, Dar es Salaam, Tanzania, United Republic of, [3]Elizabeth Glaser Pediatric Aids Foundation, Technical Services, Dar es Salaam, Tanzania, United Republic of, [4]Elizabeth Glaser Pediatric Aids Foundation, Adolescent Health, Dar es Salaam, Tanzania, United Republic of, [5]Unite States Agency for International Development, Health, Dar es Salaam, Tanzania, United Republic of, [6]Ministry of Health Community Development Gender Elderly and Children, National Aids Control Program, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: In 2015, Tanzania adopted the 2013 WHO recommendations to use lopinavir-boosted ritonavir (LPV/r)-based regimen as the preferred first-line antiretroviral threapy (ART) for children aged <3 year, and from 2015 extended to all children age <15 years. We evaluated implementation status and associated viral suppression for different ART regimens as a new drug dolutegravir (DTG), emerged and is now recommended as first-line ART in children ≥ 20 kilograms.

METHODS: A retrospective, cross-sectional review of program data from six regions (Arusha, Dodoma, Kilimanjaro, Manyara, Singida and Tabora) was conducted to describe ART regimens initiated and transitioned to children age 0-14 years, by September 2019. The analysis aimed to show the proportion of children current in care receiving efavirenz (EFV), nevirapine (NVP), LPV/r and DTG-based first-line ART. "optimal regimen" refers to those receiving LPV/r- or DTG-based regimens.

RESULTS: A total of 9,465 children 0-14 years from 363 health facilities were recorded as currently on ART by September 2019; 8,752 (92%) on first-line ART: 1,662 (18%) aged 0-4 years, 3,505 (37%) 5-9 years and 4,298 (45%) 10-14 years. The proportion of children receiving first-line LPV/r-based ART was 10% (n=630) and overall proportion on an optimal regimen was 34% (n=2,122). Most children aged 0-4 years were receiving NVP-based ART (39%, n=251), followed by LPV/r (33%, n=212) and EFV ART (26%, n=166); for children aged 5-14 years, first-line regimens were LPVr in 7% (n=418), NVP 32% (n=1798), EFV 34% (n=1943) and DTG 26% (n=1479). For children 0-4 years, viral suppression (<1,000 copies/mL) on the optimal regimen (LPV/r) was 66% compared to 61% on NVP and 60% on EFV. Viral suppression on optimal regimens (LPV/r or DTG) in children 5-14 years was 65% compared to 67% receiving NVP and 63% on EFV.

CONCLUSIONS: Four years after adoption of LPV/r as preferred first-line for children <15 years, only 10% are receiving LPV/r-based regimen, and one-third are on optimal regimens, indicating very slow adoption of guideline recommendations. Viral suppression for young children receiving NVP or EFV based regimen is low suggesting that this age group needs more vigilant oversight to enhance early uptake of optimized ARV regimens.

CLINICAL TRIALS IN PAEDIATRIC AND ADOLESCENT POPULATIONS

TWENTY-FOUR WEEK SAFETY, TOLERABILITY AND EFFICACY OF DOLUTEGRAVIR DISPERSIBLE TABLETS IN CHILDREN 4 WEEKS TO <6 YEARS OLD WITH HIV: RESULTS FROM IMPAACT P1093

T. Ruel[1], M. Farhad[2], C. Alvaro[2], E. Acosta[3], R. Singh[4], K. George[5], N. Montanez[5], S. Popson[6], M. Bartlett[6], P. Anthony[7], A. Buchanan[8], C. Vavro[8], L. Koech[9], T. Vhembo[10], R. Hazra[11], E. Townley[12], A. Wiznia[13], IMPAACT P1093 STUDY TEAM
[1]University of California, San Francisco, United States, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]University of Alabama at Birmingham, Birmingham, United States, [4]GlaxoSmithKline, Collegeville, United States, [5]FHI 360, Durham, United States, [6]Frontier Science Foundation, Amherst, United States, [7]University of Southern California, Los Angeles, United States, [8]ViiV Healthcare, Research Triangle Park, United States, [9]Kenya Medical Research Institute/ Walter Reed Project, Kericho, Kenya, [10]University of Zimbabwe College of Health Sciences Clinical Trials Research Centre, Harare, Zimbabwe, [11]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Rockville, United States, [12]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [13]Albert Einstein College of Medicine, Bronx, United States

BACKGROUND: Dolutegravir (DTG) is recommended for first-line treatment of adults and children with HIV-1 due to its potency, high barrier to resistance, and tolerability. A 5mg dispersible tablet (DTG-DT) pediatric formulation is being evaluated in IMPAACT P1093, an ongoing phase I/II open-label dose-finding study. Here we present 24-week safety, tolerability and efficacy results among participants 4 weeks to <6 years old.

METHODS: After initial 4-week dose evaluation with an intensive pharmacokinetic cohort, additional participants were enrolled to assess long term outcomes at proposed dosing. DTG-DT was dosed according to age and WHO weight-band (3 to <6 kg: 5 mg; 6 to <10kg: if <6 months 10mg, if ≥6 months 15mg; 10 to <14kg: 20mg, 14 to <20kg: 25mg), and given with a background antiretroviral (ARV) regimen including ≥ one active agent based on genotype. Clinical and laboratory assessments occurred between day 5 and 13, and at weeks 4, 8, 12, 16, 24, 32, 40 and 48 (+/- 3 days). Safety analysis included cumulative data to April 30, 2019.

RESULTS: Among 51 children enrolled from 9 countries (55% female, 75% Black), baseline median (interquartile range) HIV RNA [log10(c/ml)] was 4.3 (3.3;5.8), CD4 count (cells/mm3) was 1866 (1189;2384) and CD4% was 24.2(20.0;31.0); 86% were ARV-experienced. Thirty-four (67%) had HIV RNA data at week 24. While 25 (49%) experienced an adverse event of Grade 3 or higher, none were assessed as related to DTG, and no events led to permanent discontinuation. One death was reported from gastroenteritis and not considered drug-related. DTG-DT palatability was rated average, good, or very good for 98% of respondents..

Age Group	4 wk to <6 mo (n=17)	6 mo to <2 yr (n= 9)	2 to <6 yr (n=8)
HIV RNA <50c/mL*	41% (18, 67)	67% (30, 93)	63% (25, 92)
HIV RNA <400c/mL*	88% (64, 99)	89% (52, 100)	75% (35, 97)
CD4+ cells(cells/mm3)~	351 (-189, 926)	-221 (-962, 150)	76 (-173, 458)
CD4 percent~	5 (3, 9)	3 (-10, 7)	5 (-2, 9)

**Proportion (95% confidence interval); ~Median (interquartile range) change from baseline*

[Table. Virologic and Immunologic Efficacy at Week 24]

CONCLUSIONS: In IMPAACT P1093, once-daily weight-band dosing of DTG-DT was well-tolerated in children 4 weeks to <6 years old, with a robust antiviral effect and improvement in CD4 parameters.

PEB0294

SAFETY OF EARLY INFANT MALE CIRCUMCISION (EIMC) IN A TRIAL OF THE SHANGRING VERSUS THE MOGEN CLAMP IN RAKAI, UGANDA

S. Kiboneka[1], A. Aggrey[1], E. Kankaka[1], R. Nakabuye[1], R. Kusolo[1], F. Nalugoda[1], J. Kasule[1], Q. Awori[2], D. Ouma[3], A. Christensen[4], O.A.H. Alawamlh[5], M. Barone[6], M. Goldstein[5], A. Mushlin[5], J. Reed[7], C. Liu[8], J. Greenwood[8], R.H. Gray[9], M. Wawer[9], P. Li[5], R. Lee[5], G. Kigozi[1]
[1]Rakai Health Sciences Program, Rakai, Uganda, [2]Population Council/ Homa Bay County Teaching and Referral Hospital, Homa Bay, Kenya, [3]Population Council, Nairobi, Kenya, [4]Jhpiego/Iringa Regional Referral Hospital, Iringa, Tanzania, United Republic of, [5]Weill Cornell Medical College, New York, United States, [6]Population Council, New York, United States, [7]Jhpiego, Baltimore, United States, [8]George Washington University, Pullman, United States, [9]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

BACKGROUND: Circumcision reduces male HIV acquisition by up to 60%. Early Infant Male Circumcision (EIMC) has several advantages over adult and adolescent circumcision including lower cost, no risk of an early resumption of sex, and faster wound healing. In this randomized trial, we compared the safety of the ShangRing device with the Mogen Clamp, and maternal satisfaction with the appearance of the infants healed penis.

METHODS: We recruited and randomized a total of 460 infants aged 0-60 days at five health facilities to receive EIMC by Mogen or ShangRing in a 1:1 ratio. Following parental consent, the procedures were conducted by trained clinical officers or registered nurses/ midwives under topical anesthesia using topical (EMLA) cream and rectal paracetamol. Infants were followed-up to day 42 or until complete wound healing. We compared frequency of adverse events, NIPS pain scores, healing time (clean intact circumcision scar), and maternal satisfaction for the two devices using chi-square or Fisher exact tests of proportions and the Mann-Whitney test for medians, as appropriate.

RESULTS: A total of 36 adverse events were observed as definitely or probably related to the procedure. Among these, five were moderate (rate = 1.1%) and did not differ by device (1 bleeding and 2 adhesions for the Mogen clamp versus 1 wound infection and 1 adhesion for the ShangRing, p=0.685). Most mild adverse events were groin rashes (n=15, 3.3%) and adhesions (n=13, 2.8 %), which were more common in the Mogen's arm. Median time (IQR) to wound healing was 15 (14-21) days for both groups, p= 0.182. However, maternal satisfaction was higher for the Mogen clamp compared to the ShangRing (97.8% versus 92.1%, p=0.009). Moderate to severe pain scores were lower in the Mogen compared to the ShangRing arm (14.8% vs 25.2%, p=0.007).

CONCLUSIONS: The ShangRing device has comparable safety and wound healing time to the Mogen clamp but relatively lower maternal satisfaction and slightly higher pain scores.

ARV MANAGEMENT STRATEGIES IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0295

WHERE ARE WE ON THE OPTIMIZATION OF PEDIATRIC ART SERVICES? REVIEW OF CARE PACKAGES IN CHILDREN UNDER 10, TANZANIA

T.J. Masenge[1], A. Kibona[2], R. Van de Ven[3], G. Antelman[4], S. Kimambo[1]
[1]Elizabeth Glaser Pediatric Aids Foundation, Pediatric and Adolescent Services, Dar es Salaam, Tanzania, United Republic of, [2]Elizabeth Glaser Pediatric Aids Foundation, Adolescent Health, Dar es Salaam, Tanzania, United Republic of, [3]Elizabeth Glaser Pediatric Aids Foundation, Technical Services, Dar es Salaam, Tanzania, United Republic of, [4]Elizabeth Glaser Pediatric Aids Foundation, Research and Evaluation, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: After identifying successes and challenges in the provision of optimal care to children, EGPAF-Tanzania implemented a special program to assess antiretroviral (ARV) drug administration to children aged 0-9 years and reviewed results from this program to recommend areas for improvement.

DESCRIPTION: Parents and guardians of children under age 10 years were invited to a special clinic day to meet with pediatric antiretroviral therapy (ART) experts, one-on-one, to explain and demonstrate how ARVs and other drugs are administered. Caregivers were asked to come with all prescribed medications to be assessed on administration and recommendations on areas to improve. To evaluate the adequacy of drug administration, we conducted a retrospective cross-sectional review of children's clinical notes from all children aged <10 years who were receiving ART by June 2019 and attended the expert clinical sessions in 38 high-volume health facilities in two regions (Dodoma and Kilimanjaro) from July–September 2019.

LESSONS LEARNED: 648 children's records were reviewed; 55% were girls. At the time of evaluation, 35% were underweight, 16% had an active opportunistic infection, and 44% had received TB prophylaxis; 61% of children age >6 years had their HIV status fully/partially disclosed to them. A total of 430 (66%) children were receiving an optimal regimen (e.g. LPV/r if weight <10kg, EFV if >=10kg, and DTG if >=20kg). However, only 55% were receiving the correct ARV dosage and 66% the correct dosing frequency. For those receiving LPV/r tablets (which should be swallowed whole), 61% were either crushing or splitting them before administration. Of those eligible for viral load testing, only 59% had results documented.

CONCLUSIONS/NEXT STEPS: Through intensive case management review, we learned more than half of the all-high risk children (aged <10 years) on ART are having sub-optimal drug administration. To improve the quality of care and provide recurring mentorship to providers with little specialized training in pediatric ART/care services, we recommend health facilities to conduct special pediatric clinic days led by expert service providers. This intervention should enable building capacity of guardians on how to properly administer ARVs through observation and on-site teaching.

PEB0296

VIROLOGICAL CHARACTERIZATION IN NEWLY HIV DIAGNOSED ADOLESCENTS IN SPAIN DURING 1980-2017

C. Beltrán-Pavez[1], M. Gutierrez-López[1], C. Epalza[2], M. Rubio-Garrido[1], A. Valadés-Alcaraz A[1], S. Jimenez de Ory[3], E. Cervantes[2], O. Bisbal[2], D. Torres-Fernández[2], C. Diez-Romero[4], J. del Romero[5], I. Castro[6], J.R. Blanco[7], M. Montero[6], J.A. Iribarren[8], M. Navarro[3], S. Guillén[9], J.T. Ramos[10], A. Holguín[1]
[1]Hospital Ramón y Cajal - IRYCIS, Microbiology and Parasitology, Madrid, Spain, [2]Hospital 12 de Octubre, Pediatric Infectious Diseases Unit, Madrid, Spain, [3]Hospital General Universitario Gregorio Marañón, Department of Pediatrics, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, Department of Infectious Diseases, Madrid, Spain, [5]Clínica Sandoval, Madrid, Spain, [6]Hospital Universitario y Politécnico la Fe de València, Unidad de Enfermedades Infecciosas, Valencia, Spain, [7]Hospital San Pedro de Logroño, Enfermedades Infecciosas, Logroño, Spain, [8]Hospital Universitario Donostia, Enfermedades Infecciosas, San Sebastian, Spain, [9]Hospital Getafe, Department of Infectious Diseases, Madrid, Spain, [10]Hospital Clínico Universitario and Universidad Complutense, Department of Infectious Diseases, Madrid, Spain

BACKGROUND: Adolescents account for over 30% of all new HIV infections globally. There are scarce reports focused on virological status in adolescents and no published data from Spain. Virological characterization of newly HIV-1 infected adolescents could help to define and improve their specific needs. The objective is to describe the virological features in adolescents with a new HIV diagnosis in Spain.

METHODS: Retrospective multicenter study performed in adolescents with a new HIV-1diagnosis between 12 and 19 years old, until December 2017 in Spain, and enrolled in the Spanish Paediatric HIV Cohort (CoRISpe) or the Spanish adult HIV cohort (CoRIS). Patients with available resistance pol (protease and/or retrotranscriptase) genotypes prior to ART were included. We analyzed demographical-clinical features and the prevalence of transmitted drug resistance mutations (TDR) by both Stanford algorithm v8.9-1 and the Calibrated Population Resistance (CPR) tool v8.0 for nucleoside analogs retrotranscriptase analogs (NRTI), non-NRTI (NNRTI) and protease inhibitors (PI).

RESULTS: Among the 357 HIV-1-diagnosed adolescents, 108 (30.2%) had available ART-naïve genotypes, being 18.5% diagnosed at 12-17 years old and 81.4% at 18-19 years old. They were mostly male (83.3%), Spanish (65.4%) and a quarter late presenters (<350 CD4 cells/µl or AIDS at diagnosis). The most common HIV transmission route was behavioral (94.4%) and mainly by men who have sex with men (62.9%). The global major TDR rate assessed by Stanford was 15.7% (10.2 % for NNRTIs, 3.7% for NRTIs and 2.7% for PI), being lower (8.3%) using the WHO TDR list (2.8% for NNRTIs, 3.7% for NRTIs and 2.7% for PI). Among these, the most prevalent TDR was E138A (5.5%) at retrotranscriptase, which may reduce the antiviral activity of NNRTI-rilpivirine. Finally, the prevalence of HIV-1 non-B variants was 17.5% (36.8% pure non-B subtypes, 57.9% CRF, 5.3% URF variant at pol), similar rates compared to Spanish adult HIV cohort CoRIS.

CONCLUSIONS: Our data suggest a relative high TDR prevalence in newly HIV-diagnosed adolescents and the need of WHO TDR list update. These findings could have implications for first-line regimen election in ART-naïve adolescents, especially those NNRTI-based.

PEB0297

THE "D.T.G.S" OF DTG FOR CHILDREN AND ADOLESCENTS LIVING WITH HIV (CALHIV): DESCRIPTIONS, TRENDS, AND GAPS OF ROLLING OUT DOLUTEGRAVIR IN CALHIV IN MBEYA, TANZANIA

J. Bacha[1,2,3], B. Mayalla[3], N. Jiwa[3], L. Mwita[3], L. Campbell[1,2,3]
[1]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Pediatrics, Mbeya, Tanzania, United Republic of

BACKGROUND: In 2019, Tanzania procured and rolled out dolutegravir (DTG) for use in new antiretroviral therapy (ART) initiations and shifting exisiting patients to DTG regimens. We describe characteristics and outcomes of this DTG rollout for children and adolescents living with HIV (CALHIV) in Mbeya, Tanzania.

METHODS: Retrospective chart review was done extracting characteristics and outcomes of CALHIV who received DTG at the Baylor College of Medicine Children's Foundation – Tanzania Centre of Excellence (COE) in Mbeya, Tanzania between 1 March 2019 (when DTG became available) and 31 December 2019. HIV viral load (VL) suppression was defined as VL<1000 copies/mL.

RESULTS: In 2019, 681 CALHIV received DTG, representing 46.0% (681/1497) of all CALHIV on ART and 59.6% (681/1142) of CALHIV eligible for DTG by weight (>20kg) at the COE. TLD was used in 66.0% (449/681), followed by 23.9% (163/681) on ABC-3TC-DTG and 10.1% (69/681) on AZT-3TC-DTG. New ART initiations comprised of 12.6% (86/681), while 62.4% (425/681) were shifted from a NNRTI regimen, and 25.0% (170/681) were shifted from a PI regimen.

Among the cohort, 50.0% (341/681) were female, average age was 13.9 years (range 5.0-19.9 years), average time on ART prior to DTG was 5.4 years (range 0-14.4 years), initial WHO stage 3 or 4 was 67.1% (457/681), and 97.8% (624/638) were now WHO T-stage 1. Nutrition status by BMI revealed 22.9% (156/681) with severe malnutrition, 37.9% (258/681) with moderate malnutrition, and 39.1% (266/681) with normal nutrition.

Outcomes revealed no severe drug toxicity and no discontinuations of DTG, and 94.9% (646/681) remained active in care with 5.1% (35/681) transferred out. Multi-month prescriptions were used in 77.2% (526/681) of patients. At the end of the study period, 84.1% (499/593) of patients on DTG with documented VL were suppressed, compared to 76.1% (448/589) of VLs prior to DTG. Among those with pre- and post-DTG VLs (n=117), 63.6% (42/66) of unsuppressed became virally suppressed, and 94.1% (48/51) of suppressed remained suppressed.

CONCLUSIONS: DTG was well tolerated and effective in our clinically diverse cohort of CALHIV, and resulted in viral suppression for many previously unsuppressed CALHIV. These results encourage continued use and scale up of DTG among eligible CALHIV.

PEB0298

EARLY TRENDS IN HIV DRUG RESISTANCE AMONG CHILDREN AND YOUNG PEOPLE (0-24 YEARS) IN ESWATINI

S. Perry[1,2], M. Abadie[1,2], R.A.P. Kuwengwa[3], N. Mthethwa[4], L. Mpango[5], B. Lukhele[1,6], J. Mphaya[7], A.W. Kay[1,2], A. Dinardo[1]
[1]Baylor College of Medicine, Pediatrics, Houston, United States, [2]Baylor College of Medicine Children's Foundation, Swaziland, Pediatrics, Mbabane, Eswatini, [3]Eswatini National AIDS Program, National ART Program Officer, Mbabane, Eswatini, [4]Eswatini National AIDS Program, National Paeds HIV Care & Treatment Coordinator, Mbabane, Eswatini, [5]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Senior Clinical Services Advisor, Mbabane, Eswatini, [6]Baylor College of Medicine Children's Foundation, Swaziland, Executive Director, Mbabane, Eswatini, [7]UNICEF Swaziland, Chief YCSD, Mbabane, Eswatini

BACKGROUND: As treatment-experienced patients continue to fail antiretroviral therapy (ART) throughout Sub-Saharan Africa, there is a growing need for genotyping to not only provide adequate individualized ART, but also to address population level resistance patterns that inform national policy. Long acting and injectable ART is the future for people living with HIV (PLWH) in resource rich countries where Non-nucleoside reverse transcriptase inhibitors (NNRTIs) are no longer being used. This abstract looks at early trends from treatment experienced pediatric and young adult clients in Eswatini.

METHODS: Retrospective review of electronic medical records and genotypes at Baylor Clinic in Mbabane, Eswatini. All genotypes are from treatment-experienced clients, 0-24 years old, failing on a protease inhibitor (PI)-based regimen (at least two detectable viral loads on PI based ART).

RESULTS: 105 genotypes were performed on pediatric patients failing PI based regimens between January 2014 and November 2019 (64.7% males, 35.2% females). Overall, 30% (32/105) show PI resistance needing a change of regimen (9 changed to DRV/r, 15 needed DRV/r plus an integrase inhibitor (INSTI)). Most common PI mutations were M46I/L (25), V82A/T (21) and I54V (23). Most common NNRTI mutations were Y181C/I/V (26), K103N/S (21), E138 A/K/Q (16) and K101E/H/Q/I (15). Rilpivirine is not yet available in Eswatini, yet 37% of genotypes (39/105) had intermediate level or higher resistance to Rilpivirine by Stanford score. Most common nucleoside reverse transcriptase inhibitor (NRTI) mutations were M184V (56), T215F/Y (15), D67N (15) and M41L (15). 36 genotypes were done on children <10 years old. Of those, 81% (29/36) had low level or greater resistance to Abacavir (ABC), mainly due to M184V.

CONCLUSIONS: Early trends from the pediatric HIV drug resistance (DR) program give insight into DR trends in the country and shed light on the future options for our treatment-experienced clients. Due to heavy NNRTI treatment experience, caution will be needed before transitioning toward injectable regimens including long acting Rilpivirine. For clients <10 years, transitioning them to dolutegravir based regimens with ABC may pose a risk of putting them on monotherapy. It is time to advocate for pediatric resistance surveillance testing in Eswatini and other similar settings.

PEB0299

PREVALENCE OF M184V AND K65R IN PROVIRAL DNA FROM PBMCS IN HIV-INFECTED ADOLESCENTS WITH 3TC/FTC EXPOSURE

C. Beltrán-Pavez[1], M. Gutiérrez-López[1], S. Jiménez de Ory[2], M. Santos[2], M. Bustillo[3], L. Prieto[4], T. Sainz[5], S. Guillen[6], A. Piqueras[7], E. Corino[8], J.T. Ramos[9], M.J. Mellado[5], A. Holguín[1], M. Navarro[2], Spanish Paediatric HIV Network (CoRISpe)
[1]Hospital Ramón y Cajal - IRYCIS, Microbiology and Parasitology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Department of Pediatrics, Madrid, Spain, [3]Hospital Infantil Universitario Miguel Servet, Servicio de Pediatría, Unidad Infectología, Zaragoza, Spain, [4]Hospital 12 de Octubre, Infectious Diseases, Madrid, Spain, [5]Hospital Universitario La Paz, Department of Infectious Diseases, Madrid, Spain, [6]Hospital Universitario de Getafe, Servicio de Pediatría, Madrid, Spain, [7]Hospital Universitario y Politécnico la Fe de València, Unidad de Enfermedades Infecciosas, Valencia, Spain, [8]Hospital Universitario Insular de Gran Canaria, Unidad de Enfermedades Infecciosas, Gran Canaria, Spain, [9]Hospital Clínico Universitario, Infectious Diseases, Madrid, Spain

BACKGROUND: HIV treatment simplification improves adherence and quality of life in virologically suppressed patients, being a key aspect in the management of HIV infected adolescents. Simplification strategies with 2-drug combinations based on lamivudine (3TC) or emtricitabine (FTC) are widely used. However, the impact of M184V/I and/or K65R/E/N changes archived in proviral DNA (pDNA) on the risk for virologic failure to 3TC or FTC in a drug simplification context is not well known. We analyzed the prevalence of these resistance changes to 3TC and FTC in pDNA in vertically HIV-infected adolescents who carried M184V/I and/or K65R/E/N in historic plasma samples but reached virological control.

METHODS: The eligible participants were under follow-up in public hospitals in Madrid (Spain). They were aged ≥10 years, 3TC and/or FTC experienced, carried M184V/I and/or K65R/E/N in historic plasma samples, under ART and virologically suppressed (HIV-1 RNA <50 copies/mL) for ≥ 1 years before sampling. Genomic DNA was extracted from PMBCs obtained from The Spanish HIV BioBank. The HIV-1 retrotranscriptase (RT) was amplified and sequenced for resistance testing using Stanford.

RESULTS: Among the 388 patients under follow-up in the Madrid study cohort, 13 (3.3%) met selection criteria. The mean age was 21 years old (range 10-33), all of them were Spaniards, HIV-infected with subtype B, presented good immune status (>500 CD4/mm3) at sampling and had been virologically suppressed an average of 5.7 years (range 1.86-11). The mean time between the 3TC/FTC experience and the first M184V and/or K65E detection in plasma was 6.5 years. RT sequences of the integrated virus were obtained in 12 (92.3%) patients. Among them, only two (16.7%) adolescents harbored M184V in their pDNA after 5.1 and 7 years under viral suppression, respectively, disappearing in the last case after 11 years under suppressed viral load. No pDNA presented the K65R/N/E changes.

CONCLUSIONS: Most (83.3%) adolescents previously infected with resistant viruses carrying M184V/I and/or K65R/E/N in plasma, did not present these changes in pDNA after at least one year of viral suppression. These results suggest that simplification therapies including 3TC and/or FTC could be successful in patients with previous experience and resistance to these drugs.

PEB0300

OPTIMISATION OF FIRST-LINE ANTIRETROVIRAL THERAPY (ART) FOR CHILDREN LIVING WITH HIV IN UGANDA: TRANSLATION FROM POLICY TO ACTION

E. Namusoke Magongo[1], V. Nabitaka[2], G. Kirungi[1], C. Katureebe[1], M. Adler[3], E. Nazziwa[3], P. Nawaggi[2], E. Nyamugisa Ochora[4], H. Tibenderana[5], K. Kasule[6], S. Lubega[7], J. Musinguzi[1]
[1]Ministry of Health, AIDS Control Program, Kampala, Uganda, [2]Clinton Health Access Initiative, Kampala, Uganda, [3]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Entebbe, Uganda, [4]United Nations International Children's Emergency Fund, Kampala, Uganda, [5]United State Agency for International Development, Kampala, Uganda, [6]USAID Strategic Information Technical Support Project Kampala Uganda, Kampala, Uganda, [7]Medical Access Uganda Limited, Kampala, Uganda

BACKGROUND: Uganda has been optimising ART for children: in 2014 the Nucleoside Reverse Transcriptase Inhibitor(NRTI) backbone changed from Zidovudine/Lamivudine(AZT/3TC) to Abacavir/Lamivudine (ABC/3TC); introduction of Lopinavir/ritonavir pellets (LPV/r) in 2016 and Dolutegravir in 2018 for children ≥20kg. Despite these efforts, 52.2% of children aged 3-10 years were still receiving AZT/3TC/NVP(Nevirapine) as first-line ART by June 2018. The aim of the current optimisation strategy (July 2018 to date) is to transition children with viral load < 1000 copies/ml from AZT/3TC to ABC/3TC, and Nevirapine or Efavirenz(high burden of pretreatment drug resistance) to LPV/r pellets/tablets or Dolutegravir-containing first-line ART. Children with viral load > 1000 copies/ml on Nevirapine or Efavirenz are immediately switched to second line ART without a repeat viral load result. We describe below, lessons learned during implementation of the ongoing strategy.

DESCRIPTION: Between June-2018 to September-2019; an optimisation checklist, line-listing tool, standard operating procedures and job aides were developed. The check-list was used to identify eligible children for optimisation at the health facilities. These were transferred to the line listing tool for tracking. Using data from the national reporting system(DHIS-2) and web-based ART ordering system(WAOS), supply chain planning was done. Weekly national planning meetings, cascaded trainings and post-training mentorships were conducted. ART optimisation indicators were incorporated into the weekly PEPFAR surge dashboard to monitor implementation.

LESSONS LEARNED: 71%(6,085/8486) children 3months to <3 years were initiated on LPV/r pellets. Due to global shortage, 1.14%(250/21,898) children 3-<10 years were transitioned to LPV/r tablets from June 2018 to September 2019. 64.7%(6,381/9854) children < 15 years weighing ≥20 Kgs were initiated on Dolutegravir in the same period. Proportions of children on AZT/3TC backbone reduced from 76.8% to 48% by June 2019. At patient level, changing regimens comes with additional challenges of effectively communicating changes in dosing schedules or administration procedures. A real-time reporting platform has been instrumental in monitoring the process.

CONCLUSIONS/NEXT STEPS: The key barrier to ART optimisation for children was inadequate stock of antiretroviral drugs. Dispensing messages for health care workers and a caregiver literacy manual are being developed to address the communication challenges. Continuous mentorship is needed to operationalise changes in guidelines at facility level.

PEB0301

LOW VIRAL SUPPRESSION AMONG CHILDREN RECEIVING ANTIRETROVIRAL THERAPY IN NIGERIA

D. Adegoke[1], O. Ogbanufe[2], A. Yakubu[3], H. Debem[3], A. Alash'le[4], M. Okoye[1], I. Dalhatu[3]
[1]US Centers for Disease Control and Prevention, Laboratory, Abuja, Nigeria, [2]US Centers for Disease Control and Prevention, Care and Treatment, Abuja, Nigeria, [3]US Centers for Disease Control and Prevention, ESI, Abuja, Nigeria, [4]Institute of Human Virology, Laboratory, Abuja, Nigeria

BACKGROUND: The Human Immunodeficiency Virus (HIV) Antiretroviral Therapy (ART) program began in Nigeria in 2002 and scaled-up access to ART among children and adults began in 2016. A key measure of treatment efficacy among people living with HIV receiving ART is viral load suppression (VLS; defined as viral load <1000 copies/ml). Among the few facility-based viral suppression studies in children in Nigeria, none was nationally representative. This study provides national and regional estimates of viral suppression among Children Living with HIV (CLHIV); <15 years) receiving ART.

METHODS: This was a cross-sectional study of CLHIV receiving ART for 12 - 48 months in 67 randomly selected ART facilities across the geopolitical zones in Nigeria. CLHIV were consecutively recruited across facilities. Data was abstracted from patient charts, followed with sample collection and viral load test on ROCHE CAP/CTM instruments. Viral suppression rates were weighted for the study design at 95% confidence limit.

RESULTS: Most of the 280 participating children were on first-line treatment (98.9%), with the remainder on second-line. Overall, viral suppression was 43%. Viral suppression among males and females was 46 and 50% respectively. Viral suppression was highest among the 10-14 age group (51%, CI 95%), and lower among the 1-5 and 6-9 age groups (42%, CI 95%; and 41%, CI 95% respectively). Viral suppression varied significantly by zone (P0.04), with the highest rate in the North Central zone (53%, CI 95%) followed by South East (46%, CI 95%) with the South South zone having the lowest (32%, CI 95%). Viral suppression among those who did not miss appointment was 50% and those who missed appointments was 35%. Viral suppression was indirectly proportional to duration on ART. Pediatrics on TDF+3TC+EFV achieved 71% others 48% and AZT+3TC+NVP 45% viral suppression.

CONCLUSIONS: Viral suppression among children is suboptimal nationwide and differs by age, sex, geographic zone, missed appointments, duration of treatment and Antiretroviral ARV type. Low viral suppression among children is a threat to Nigeria efforts achieving the 3rd 90.

ADHERENCE IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0302

TANZANIA'S SECOND ACT: TO SUPPRESS OR NOT TO SUPPRESS? VIRAL LOAD SUPPRESSION AND ADHERENCE AFTER SWITCHING TO SECOND-LINE ART AT BAYLOR CHILDREN'S CENTER OF EXCELLENCE IN MWANZA, TANZANIA

V. Ip[1], K. Scirto[1], M. Minde[2], L. Mwita[2]
[1]Baylor College of Medicine International Pediatric AIDS Initiative, Mwanza, Tanzania, United Republic of, [2]Baylor College of Medicine Children's Foundation - Tanzania, Mwanza, Tanzania, United Republic of

BACKGROUND: In 2015, nationwide viral load (VL) testing was made available in Tanzania making the monitoring of treatment failure in people living with HIV and switching to second-line antiretroviral therapy (ART) simpler. We reviewed the relationship between adherence and VL when clients are started on second-line ART due to treatment failure at Baylor Center of Excellence (COE) in Mwanza, Tanzania.

METHODS: We retrospectively reviewed charts of 98 clients switched to second-line ART between March 2012 and December 2018 at the Mwanza COE. Data collected from the electronic medical record included: age, sex, time between ART initiation to starting second-line, adherence pre- and post-second-line, reasons for therapy switching, second-line regimen, and follow-up VLs. Poor adherence was defined as pill count </> 95-105% at any visit during the 6 months before or 6 months after switching to second-line. Data was analyzed with Chi-Square and T-tests.

RESULTS: The study included 98 clients (43 female); mean age at starting second-line was 10.6 years. Average time to start second-line after ART initiation was 5 years. The majority of clients were switched to second-line due to virological failure (46/98, 46.9%) and the most common second-line regimen was ABC-3TC-LPV/r (63/98, 64.3%). Most clients had poor adherence 6 months before and after starting second-line (61/98, 62.2% and 55/98, 56.1%, respectively; p=.38). Most clients had VL <1000 copies/ml (79/98, 80.6%) after switching to second-line across 3 age groups (<5 years, 5-12 years, ≥ 12 years), and 67.3% (66/98) had VL < 50. Although there was a statistically significant association between VL suppression and the three age categories (p=.012), in all age groups, there was no significant difference in the mean VLs between those with good versus poor adherence.

CONCLUSIONS: Most clients achieved VLs <1000 after switching to second-line ART, regardless of having good or poor adherence. Interestingly, adherence by pill counts has been an unreliable predictor of viral suppression at our COE. Tanzania would benefit from nationwide resistance testing so only necessary regimen switches are made to preserve future ARV options. Until then, our COE continues to rely on psychosocial counseling and support to address issues of adherence and treatment failure.

PEB0303

ACHIEVING VIRAL SUPPRESSION AMONG NON-SUPPRESSED ADOLESCENTS ON ART IN TANZANIA: EFFECTS OF A TARGETED INTERVENTION

T.J. Masenge[1], G. Antelman[2], A. Kibona[3], L. Pastory[3], R. Van der Ven[4], D. Frank[3], S. Kimambo[4], J. Kalimunda[5]
[1]Elizabeth Glaser Pediatric Aids Foundation, Pediatric and Adolescent Services, Dar es Salaam, Tanzania, United Republic of, [2]Elizabeth Glaser Pediatric Aids Foundation, Research and Evaluation, Dar es Salaam, Tanzania, United Republic of, [3]Elizabeth Glaser Pediatric Aids Foundation, Adolescent Health, Dar es Salaam, Tanzania, United Republic of, [4]Elizabeth Glaser Pediatric Aids Foundation, Technical Services, Dar es Salaam, Tanzania, United Republic of, [5]Unite States Agency for International Development, Health, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Many adolescents on ART are not virally suppressed for multiple reasons, such as adherence challenges or not being on optimal ARV regimens. This review aims to determine the effect of an intervention targeting non- virally suppressed adolescents in Tanzania.

METHODS: An intervention was designed for adolescents 10-19 years who had high viral load (VL, >1000 cp/ml) in 27 adolescent-focused, high-volume facilities. Between May-June 2019, adolescent clients were invited to attend a full one-day workshop with their guardians for intensive group adherence action-planning. Each family unit developed and implemented a personalized three-month plan to address barriers to ART adherence as well as planning for transitioning to Tenofovir/Lamivudine/Dolutegravir (TLD), per national policy. The non-intervention sites continued with the standard of care monthly enhanced adherence counseling. The effects of the intervention on secondary viral suppression are estimated through logistic regression analysis.

RESULTS: Adolescents from the intervention sites (n=293) and non-intervention sites (n=377), who had follow-up VL test results from July-September 2019, were included in the analysis. 55% of the intervention adolescents were on ART for over six years, compared to 42% of non-intervention adolescents (p<.002); 51% were female in both groups. Secondary suppression was 61% (95% CI: 56,67) among adolescents attending interventions sites and 49% (95% CI: 44,54) at non-intervention sites (p=.001). In regression analysis, adolescents attending an intervention site were 60% more likely to achieve secondary viral suppression (OR 1.6, 95% CI: 1.1,2.3) compared to those at non-intervention sites. Transitioning to TLD was independently associated with more than two times the likelihood of viral suppression (OR 2.2; 95% CI: 1.6,3.1).

CONCLUSIONS: ARV regimen optimization, coupled with engaging guardians and peers in directed and individualized action-planning that tackles barriers to adherence in group settings showed significant promise in managing adolescents with unsuppressed viral loads. Although a one-day meeting with guardians, peers, and providers carries some additional costs, it significantly affected secondary viral suppression as compared to the standard of care of three individual adherence sessions.

PEB0304

HIGH HIV VIREMIA AMONG ADOLESCENTS AGED 10-19 YEARS ON ANTIRETROVIRAL THERAPY RECEIVING A SCALED UP DIFFERENTIATED SERVICE DELIVERY IN MALAWI: TEEN CLUB EXPERIENCE

R. Chamanga Kanyenda[1], T. Musukwa[1], J. Sunguti[1], A. Ahimbisidwe[1], I. Phiri[1], H. Nkhoma[1], K. Kudiabor[1], N. Buono[2], A. Auld[2], G. Woelk[3], E. Kim[2], A. Maida[2], T. Maphosa[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Research, Lilongwe, Malawi, [2]Centre for Disease Control, Lilongwe, Malawi, [3]Elizabeth Glaser Pediatric AIDS Foundation, Washington DC, United States

BACKGROUND: Viral suppression is lower in adolescents living with HIV (ALHIV) compared to adults. In Malawi, the Elizabeth Glaser Pediatric AIDS Foundation (EGPAF) established monthly "Ariel teen clubs" to provide a psychosocial and care package to ALHIV to improve clinical outcomes. We evaluated the factors associated with high viral load (VL) in ALHIV enrolled in these clubs.

METHODS: This cross-sectional study used program data from 38 health facilities in four districts in Malawi. The inclusion criteria were all ALHIV aged 10-19 years who attended Ariel teen clubs between September 2018-July 2019, who were on antiretroviral therapy (ART), and had a documented routine VL result. High VL was defined as >1000 copies/mL, and optimal ART adherence was defined as having a pill count of 95%-105%.

Descriptive analysis, chi-square tests and backward elimination multivariable logistic regression modelling was used to identify factors associated with high VL, adjusting for sex, age, district and disclosure of one's HIV status.

RESULTS: Our analysis included 1,345 ALHIV, with a median age of 15 years. More than half of the ALHIV were females (n=712, 53%). High VL was identified in 30% of the ALHIV. ALHIV with poor ART adherence had higher odds of high HIV viremia (adjusted odds ratio [aOR] 1.98, 95% confidence interval [CI] 1.46-2.98) compared to those with optimal ART adherence. ALHIV on second line regimen (Lopinavir-based tail) had increased odds of high viremia (aOR 3.15, 95% CI 1.03-9.6) compared with those on first line (Nevirapine-based tail), while there was no statistically significant difference within the nucleoside backbone of the ART regimen. ALHIV in secondary school were less likely to be virally unsuppressed (aOR 0.5, 95% CI 0.33-0.78) compared to those still in primary school.

CONCLUSIONS: The study noted a substantial proportion of ALHIV with high VL. Factors associated with high VL included a low or high pill count suggestive of adherence problems; being transitioned to second line regimen; and primary school education. A continual focus on adolescents is required to identify interventions that can improve consistent ART treatment adherence. Furthermore, interventions to improve the proportion of youth progressing from primary to secondary school could benefit HIV-related health

PEB0305

RETENTION OF CHILDREN COMPARED TO RETENTION OF WOMEN LIVING WITH HIV IN SUB-SAHARAN AFRICA

H. Miller[1], K. Kelling[1], H.T. Wolf[1]
[1]*Office of the Global AIDS Coordinator, Washington, United States*

BACKGROUND: It is important to understand family structures while ensuring optimal retention in care for all people living with HIV. Children are more likely to be adherent to care if their caregivers are adherent to care for multiple logistical and psychosocial reasons. This study compares retention of children living with HIV (CLHIV) (<15) to women living with HIV (20-49) from October 1, 2018 to September 30, 2019 (FY19) by country.

METHODS: PEPFAR program data from FY19 was analyzed for five countries in sub-Saharan Africa that had the largest number of children on treatment. Within each country, CLHIV <15 and women living with HIV (20-49) were included based on reproductive age range. A limitation was that pediatric data was not linked to their mother's data. Retention was assessed by determining the actual number of clients on treatment compared to the expected number on treatment (sum of 97% retention of clients on treatment at the end of September 30, 2018 and 97% of new patients enrolled on treatment throughout FY19) at the end of FY19. The Chi2 test was used to assess retention by population group.

RESULTS: All countries fell short of reaching the expected number of clients on treatment at the end of FY19. The degree in which countries lost clients ranged from 9%-24% for children and 7%-18% for women. When comparing retention of children to women within a particular country, there were significant differences in retention by age range in all five countries. All countries had significantly lower retention among children compared to women.

Kenya	Population <15 (All sexes)	Actual 73,888	Expected 81,496	P > |t| p<0.0001	% clients lost 9%
	20+ Female	563,327	607,984		7%
Mozambique	<15 (All sexes)	67,555	88,945	p<0.0001	24%
	20+ Female	614,899	747,706		18%
South Africa	<15 (All sexes)	149,763	166,145	p<0.0001	10%
	20+ Female	2,626,459	2,819,245		7%
Tanzania	<15 (All sexes)	59,576	69,693	p<0.0001	15%
	20+ Female	591,394	669,731		12%
Uganda	<15 (All sexes)	62,439	70,288	p<0.004	11%
	20+ Female	594,469	658,179		10%

[Table: Actual versus Expected Treatment Populations and % clients Lost from Care]

CONCLUSIONS: Retention varied by country and, in most countries, children had lower retention compared to women. For mother child pairs, interventions need to prioritize coupling appointments of women and their children.

LEAVING NO TEEN BEHIND: RESULTS FROM TANZANIA'S FIRST CLINICAL HIV CASCADE ANALYSIS FOR ADOLESCENTS

J. George Ng'ariba[1], U. Gilbert[1], H. Khalfani[1], M. Rutaihwa[2], A. Rwebembera[2], J. Kahemele[3]
[1]*UNICEF, Dar es Salaam, Tanzania, United Republic of,* [2]*Ministry of Health Community Development Gender Elderly and Children, NACP, Dodoma, Tanzania, United Republic of,* [3]*Maryland Global Initiatives Tanzania, HIV, Dar es Salaam, Tanzania, United Republic of*

BACKGROUND: Adolescents bear a disproportionate burden of new HIV infections. In Tanzania, about 93,000 adolescents between 10-19 years are living with HIV. Adolescents have limited access to friendly health services to achieve optimal adherence, retention and HIV viral suppression. The cascade analysis aimed at understanding the magnitude and determinants of loss to follow up from the cascade of HIV care among adolescent on ART.

METHODS: The retrospective cohort analysis/study of client's data from the HIV clinical cascade for 3,145 adolescent boys and girls attending 32 health facilities in 4 regions of Mbeya, Iringa, Njombe and Songwe in 2018 for a period of 12 months. These regions have high burden of HIV in Tanzania. Routine client HIV data were analyzed using Stata program, results were presented in chi-square tests.

RESULTS: A total of 3,145 adolescent boys (735) and girls (2,410) on ART were reviewed. Older adolescents (age 15 -19 years) had lower ART initiation rate (61%) compared to younger adolescent 10 – 14 years (85%). Only 39% of adolescent boys aged 15 – 19 years newly identified HIV positive started ART. Viral load testing among adolescents eligible for HIV viral load (HVL) was low ranging between 49% - 58%. Older adolescents had a lower rate of HVL sample collected for HVL testing, and both groups of adolescents had low viral load suppression rates. Older adolescents were 2.24 times more likely of becoming lost to follow-up. Adolescents on ART earlier than 7 days of diagnosis were more likely to be lost to follow up. There is higher risk of becoming lost to follow-up for clients on shorter period on ART compared to beyond 12 months.

CONCLUSIONS: The Government and partners to conduct regular HIV clinical cascade analysis for adolescents to determine if the programme gaps are being closed. Stronger emphasis on client-centered services that differentiate between younger and older adolescents is urgently required. Design focused age specific retention interventions for adolescent's case management. Stronger community-based support to address early patient tracking and tracing practices for all adolescent missing appointments/lost to follow up, scale up of peer support services to improve adherence to medication and viral suppression.

BACKGROUND: Adolescents living with HIV (ALHIV, ages 10-19) experience poor retention in care. Limited detailed qualitative data exist on factors underlying disengagement. We examined reasons for disengagement among ALHIV that were lost to program (LTP).

METHODS: This qualitative study included ALHIV from two large HIV clinics in the AMPATH program in western Kenya who had attended ≥1 visit in the 18 months prior to data collection, but who had not attended clinic ≥60 days past their last scheduled visit. ALHIV and their caregivers were traced in the community and invited to complete semi-structured interviews informed by a socioecological framework.

RESULTS: Interviews were conducted with 32 LTP ALHIV and 25 caregivers. Adolescents averaged age 17.2. Most were female (69%), orphaned (mother/father deceased, 63%), and cared for by someone that was not a biological parent (53%). Twelve (38%) were food-insecure. Reasons for disengagement varied, but centered on family-level factors, particularly when adolescents were orphaned and/or newly living with caregivers who lacked the knowledge or resources to support them in care. Stigma within families resulted in failure to disclose to family members and dropping out of care to avoid disclosure. ("I couldn't come because I never wanted them to know"). Enacted stigma also resulted in situations of neglect of the adolescent's care. ("The family abandoned her"). Transportation time and costs were a frequent challenge, one made more difficult when new caregivers were responsible for orphaned adolescents. Adolescents also anticipated stigma and feared disclosure of their status at clinic or school. ("The school refused me permission to come [to clinic] and I always fear disclosing my status to them"). Mental health issues also led to disengagement. ("I just gave up with life") Poor experiences with clinic staff deterred some from returning to care. ("I feared coming back because I will be quarreled with by the nurses").

CONCLUSIONS: Reasons for LTP centered on family-level factors, stigma, and financial challenges. Adolescents who were orphaned or experience other family-level challenges or financial hardships may require targeted interventions to remain engaged in care. Stigma presents a central barrier to retention.

NON-ADHERENCE AND LOW DRUG LEVELS IMPACT VIRAL OUTCOMES IN HIV-INFECTED KENYAN YOUTH

R. Vreeman[1,2,3], W. Nyandiko[3,4], A.K. DeLong[5], M. Scanlon[1,2], A. Manne[5], M. Coetzer[5], A. Ngeresa[3], J. Aluoch[3], V. Novitsky[5], F. Sang[3], C. Ashimosi[3], S. Ayaya[3,4], E. Jepkemboi[3], M. Orido[3], A. Chory[1,2], J.W. Hogan[3,5], R. Kantor[5], RESPECT (RESistance in a PEdiatric CohorT) Study
[1]Icahn School of Medicine at Mount Sinai, New York, United States, [2]Arnhold Institute for Global Health, New York, United States, [3]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [4]Moi University, Eldoret, Kenya, [5]Brown University, Providence, United States

BACKGROUND: In sub-Saharan Africa (SSA) settings, children living with HIV rarely have comprehensive adherence monitoring or drug resistance genotyping. We longitudinally assessed adherence and its impact on viral outcomes in Kenyan children.

METHODS: We enrolled children ≤15 years on NNRTI-based 1st line ART in AMPATH (Academic Model Providing Access to Healthcare). Adherence was monitored prospectively by caregiver-reported questionnaires, electronic dose monitors (MEMS) and NNRTI levels at 1 month (TP1) and 4 months (TP2) and defined as: (1) any caregiver-reported non-adherence, (2) % MEMS openings, (3) MEMS interruptions ³48 hours, and (4) NNRTI low, therapeutic or high levels. Viral failure (VF) was viral load >1,000 copies/mL, with drug resistance (DR) evaluated in those with VF. VF was modeled with logistic regression (odds ratio (OR) and 95% confidence interval (CI)) for each adherence measure, adjusted for age, CD4%, ART duration and sex. Interaction terms were examined if adherence effect on TP2 VF differed by TP1 VF status. Poisson regression modeled DR mutations.

RESULTS: At enrollment, 227 participants (55% female; median age 8 years; median CD4% 26) were median 2 years on ART (77% NVP-based). VF was 32% (TP1) and 19% (TP2). In 154 TP1 suppressed, 8% had VF at TP2; among 73 VF at TP1, 42% had VF at TP2. There was extensive non-adherence at both TPs by all four adherence measurement strategies. By MEMS, 39% had <90% of doses taken on time at TP1 and 30% had <90% at TP2. MEMS 90-95% were associated with less TP1 VF (OR 0.3; CI 0.1-0.8) compared to MEMS<80%. In TP1-suppressed, therapeutic TP2 drug levels were associated with less VF at TP2 (OR 0.1, CI 0.0-0.7). Genotyping in VFs (n=60 at TP1) showed extensive DR (95% at TP1; 93% at TP2). Low TP1 drug levels were associated with DR accumulation (OR 10.5, CI 1.0-107.2). MEMS adherence <90%, any interruption, and reported non-adherence were empirically associated with DR accumulation but statistical uncertainty was not conclusive [respective OR (CI): 3.4 (0.3-39.3); 5.5 (0.5-65.2); 1.8 (0.1-23.5)].

CONCLUSIONS: Extensive non-adherence, VF and DR were seen in Kenyan children with HIV, outcomes assumed - but seldom documented - in SSA.

SEX-SPECIFIC FACTORS ASSOCIATED WITH SUBOPTIMAL ADHERENCE TO ANTIRETROVIRALS AND DETECTABLE VIRAL LOAD AMONG YOUTH LIVING WITH PERINATAL HIV IN THE UNITED STATES (US)

D. Kacanek[1], Y. Huo[1], K. Malee[2], C. Mellins[3], R. Smith[4], P. Garvie[5], K. Tassiopoulos[6], C. Berman[6], M. Paul[7], A. Puga[5], S. Allison[8], for the Pediatric HIV/AIDS Cohort Study

[1]Harvard TH Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [2]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Science, Chicago, United States, [3]Columbia University Irving Medical Center, Department of Psychiatry, HIV Center for Clinical and Behavioral Studies, New York, United States, [4]University of Illinois at Chicago, Department of Pediatrics, Chicago, United States, [5]Children's Diagnostic and Treatment Center, Research Department, Fort Lauderdale, United States, [6]Harvard TH Chan School of Public Health, Department of Epidemiology, Boston, United States, [7]Baylor College of Medicine, Department of Pediatrics, Retrovirology, Houston, United States, [8]National Institute of Mental Health, Division of AIDS Research, Bethesda, United States

BACKGROUND: Suboptimal adherence and detectable viral load (DVL) are common challenges among youth living with perinatal HIV (YPHIV), yet few studies examine sex differences in associated characteristics. We compared factors associated with suboptimal adherence and DVL by sex among YPHIV in the Pediatric HIV/AIDS Cohort Study Adolescent Master Protocol.

METHODS: At 15 US clinical sites, we obtained data from medical records and in-person assessments. DVL (VL>400 copies/mL) and suboptimal adherence (self- or caregiver report of ≥1 missed antiretroviral dose in the past week) were assessed annually. Associations of individual, social and structural factors with suboptimal adherence and DVL were examined, fitting separate generalized linear mixed effects models stratified by sex, controlling for age.

RESULTS: Girls/young women (GYW) (N=203) completed 625 visits and boys/young men (BYM) (N=178) completed 565 visits between ages 8-21. The proportions of GYW's vs. BYM's visits with suboptimal adherence (37% vs. 34%) and DVL (31% vs. 25%) were similar and increased with age. For GYW and BYM, perceived antiretroviral side effects and stigma/concern about inadvertent disclosure of HIV status were associated with suboptimal adherence. Among GYW only, distressing physical symptoms, recent alcohol use, and exposure to violence and among BYM, having a boyfriend or girlfriend and using a buddy system to support adherence were associated with suboptimal adherence (Table).

	Suboptimal Adherence OR (95% CI)		Detectable Viral Load OR (95%CI)	
	Girls/Young Women	Boys/Young Men	Girls/Young Women	Boys/Young Men
Perceived antiretroviral side effects	4.04 (2.55, 7.84)	3.50 (1.83, 8.74)	4.11 (2.56, 7.82)	2.68 (1.04, 6.34)
Distressing physical symptoms	1.73 (1.01, 2.85)	1.13 (0.66, 1.94)	1.80 (1.09, 3.00)	1.38 (0.74, 2.58)
Alcohol use	2.04 (1.32, 3.03)	0.96 (0.56, 1.67)	1.95 (1.09, 3.50)	1.05 (0.56, 1.95)
Income (ref: >$40,000)				
>$10,000-40,000	2.02 (1.08, 3.78)	1.04 (0.57, 1.88)	2.87 (1.38, 5.94)	2.11 (0.99, 4.50)
≤$10,000	1.55 (0.71, 3.30)	1.13 (0.52, 2.43)	3.09 (1.57, 6.04)	4.29 (1.70, 10.8)
Caregiver Status (ref: Married)				
Separated/divorced/widowed	1.45 (0.81, 2.62)	1.34 (0.62, 2.31)	2.35 (1.30, 4.22)	1.77 (0.87, 3.61)
Never married	1.84 (1.01, 3.35)	1.87 (1.05, 3.30)	2.60 (1.32, 5.10)	1.64 (0.82, 3.26)
Youth has boyfriend/girlfriend	1.57 (0.96, 2.75)	2.12 (1.16, 3.90)	1.78 (0.96, 3.29)	0.87 (0.45, 1.67)
Buddy system	1.43 (0.89, 2.35)	2.35 (1.38, 4.01)	0.53 (0.30, 0.94)	0.69 (0.34, 1.41)
Stigma/Concern about inadvertent disclosure of HIV	2.33 (1.23, 4.43)	2.74 (1.29, 5.81)	1.93 (0.97, 3.86)	2.79 (1.23, 6.34)
Violence exposure	3.34 (2.00, 5.58)	1.44 (0.87, 2.37)	1.93 (1.10, 3.33)	0.98 (0.56, 1.72)

*Separate linear mixed effects models adjusted for age. OR=Odds Ratio, CI=Confidence Interval

[Table: Associations of selected characteristics with suboptimal adherence and detectable viral load]*

Similar to adherence findings, associations with DVL among GYW included perceived antiretroviral side effects, distressing physical symptoms, recent alcohol use, unmarried caregiver, and exposure to violence, while use of a buddy system to support adherence was associated with virologic suppression. For GYW and BYM, lower income, and for BYM, stigma/concern about inadvertent disclosure of HIV were associated with DVL.

CONCLUSIONS: Multi-level factors were associated with suboptimal adherence and DVL and varied by sex, informing adherence interventions. Efforts to reduce antiretroviral side effects and stigma warrant special consideration for YPHIV.

PEB0310

IMPROVING VIRAL LOAD SUPPRESSION RATES AMONG HIV POSITIVE CHILDREN ON ART IN A LARGE VOLUME HIV CLINIC IN WESTERN UGANDA

W. Akobye[1], P. Nahirya Ntege[2], A. Bigirwa[1], R. Ahurra[3], J. Musinguzi[4], P. Nyakaana[5], G. Matsiko[6], G. Ategeka[7], F. Tugumisirize[8], P. Elyanu[2]

[1]Baylor College of Medicine Children's foundation-Uganda., Medical, Fort Portal, Uganda, [2]Baylor College of Medicine Children's Foundation -Uganda, Research, Kampala, Uganda, [3]Fort Portal Regional Referral Hospital, Psychosocial, Fort Portal, Uganda, [4]Fort Portal Regional Referral Hospital, Records, Fort Portal, Uganda, [5]Kabarole People Living with HIV Forum, Community, Fort Portal, Uganda, [6]Hakibaale Kwemanyira Community Based Organization, Community, Fort Portal, Uganda, [7]Fort Portal Regional Referral Hospital, Medical, Fort Portal, Uganda, [8]Fort Portal Regional Referral Hospital, Administration, Fort Portal, Uganda

BACKGROUND: Achieving the UNAIDS global target of 95% viral suppression among HIV clients on ART is critical to ending HIV/AIDS by 2030. In March-2018, viral load suppression rate (VLS) among children living with HIV (CLHV) 0-15yrs at Fort Portal Regional Referral Hospital (FPRRH) was 74%. Unsuppressed viral load delays growth and development, increases the risk of opportunistic infections and death. The objective of the project was to increase VLS among CLHIV (0-15 years) from 74% in March-2018 to 85% in April-2019.

DESCRIPTION: In March-2108, a quality improvement team led by the clinic manager, and comprising of health workers, adolescents and PLHIV held a 2-hour brainstorming session for root causes of low VLS at FPRRH among CLHIV. Interventions were identified in a driver diagram, prioritized using a focusing matrix, and monitored in Plan-Do-Study-Act cycle. Monthly VL tests were extracted from the national VL dashboard and we computed the proportion of children with suppressed VL between Apr-18 and Apr-19.

LESSONS LEARNED: Reasons for low VLS included: caregivers factors (non-disclosure, inadequately informed multiple caregivers, difficulty administering pellets, missing appointments, and representing children during clinic visits); health systems factors (long waiting time, lack of family centered care, partial differentiation of care, loss of records due to disorganized filing system), and unclear policies for differentiated HIV services for families. Prioritized interventions that were implemented included; Filing charts in serial order and by category(child, adolescent, adult), fast tracking lopinavir/ritonavir pellets for the < 3 years, scheduling children for weekly child-friendly clinics, conducting facility-based peer-group meetings for 10-15 year olds, mobilizing school going children for facility-based viral load campaigns during holidays, and conducting home based psychosocial support by social workers to address viral non-suppression. Between Apr-18 and Apr-19, 734 children had valid VL test result, of whom 52% were female. The mean monthly number of VL tests conducted was 62(SD 11). The proportion of CLHIV with suppressed VL test increased from 74% in March-2018 to 85% in April-2019.

CONCLUSIONS/NEXT STEPS: VLS among children improved through stakeholder involvement to provide patient-centered interventions that bridge the gap to reach UNAIDS targets. Low availability and difficulty administering lopinavir/ritonavir require innovative solutions.
