BACKGROUND: WHO and NTLP recommends that all children who are living with HIV need to receive isoniazid preventive therapy (IPT) once screened negative for tuberculosis. When on IPT, pyridoxine (vitamin B6) is recommended as a supplement, however, pyridoxine availability remains a challenge in Tanzania affecting IPT completion rate. This study assesses IPT completion rate in absence of pyridoxine supplementation among children on care and treatment in Mwanza, Tanzania.

METHODS: This is a retrospective cohort study from July, 2014 and May, 2018. Information on date of IPT initiation, completion, discontinuation, nutritional status, weight, and ART regimen, reported or experienced side effects was collected. Cohort characteristics are presented as medians and interquartile ranges, means and standard deviations (SD), or percentages as appropriate. Chi-square tests were used to compare different characteristics between those who completed and did not complete IPT.

RESULTS: A total of 548 children were recruited on IPT, 278 (50.7%) were male, mean age was 10 years (SD 4.2), 11 (2%) had a TB contact, 452 (82.5%) were on NVP/EFV, 96 (17.5%) on LPV/r-based regimen and 13 (2.4%) malnourished. Mortality rate was low (n=1, 0.2%) and 10 (1.8%) were transferred out before IPT completion. IPT completion rate was 88.9% (487/548) at the end of six months as per guidelines. 11.3% (62/548) reported to experience side effects to isoniazid. Reported side effects included skin lesions (54.8%, 34/62) (Figure 1), peripheral neuropathy (21%, 13/62), vomiting and weight loss (14.5%, 9/62), poor energy and depression (9.7%, 6/62), and anemia (6.5%, 4/62). The major reasons for not completing IPT were due to side effects (32.8%, 20/61) and poor adherence (19.7%, 12/61).

Variables	Completed IPT Number (%)	Not Completed IPT Number (%)	P Value
Side effects(all)	22 (35%)	40 (65%)	
Peripheral Neuropathy	1 (0.2%)	8 (13.1%)	<0.01
Rashes	2 (0.4%)	8 (13.1%)	<0.01
Weight loss	11 (2.3%)	22 (78.6%)	<0.01
Average weight change	1.4 SD 1.6	- 0.7 SD 2.3	<0.01

[Table 1. Comparison between those completing vs. not completing IPT.]

CONCLUSIONS: Overall IPT completion rate was good, however, amongst children who experienced side effects it was poor. Major side effects such as peripheral neuropathy, rashes, and weight loss are significant contributors to IPT non-completion. We propose that donor and governmental agencies should increase pyridoxine availability and distribution.

HIV COMPLICATIONS AND CO-MORBIDITIES IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0312

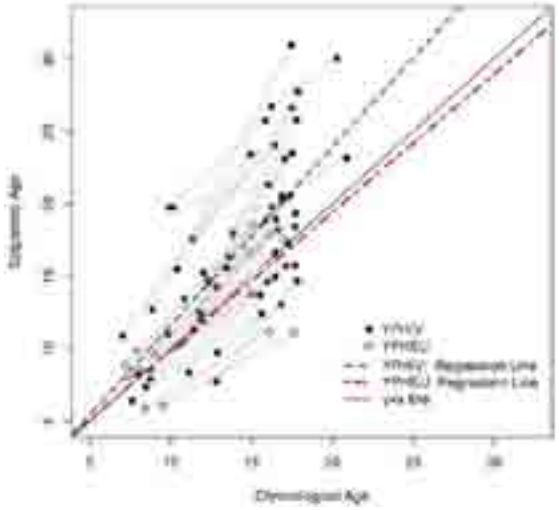
LONGITUDINAL CHANGES IN EPIGENETIC AGE IN YOUTH WITH PERINATALLY-ACQUIRED HIV (YPHIV) AND YOUTH WHO ARE PERINATALLY HIV-EXPOSED UNINFECTED (YPHEU)

S. Shiau[1], S.S. Brummel[2], E.M. Kennedy[3], K. Hermetz[3], R. Hazra[4], S.A. Spector[5], P.L. Williams[2,6], D. Kacanek[2,6], R. Smith[7], S. Drury[8], A. Agwu[9], A. Ellis[10], K. Patel[6,2], G.R. Seage III[6], R. Van Dyke[11], C.J. Marsit[3], Pediatric HIV/AIDS Cohort Study

Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]Emory University Rollins School of Public Health, Department of Environmental Health, Atlanta, United States, [4]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Maternal and Pediatric Infectious Disease Branch, Bethesda, United States, [5]University of California, San Diego, Department of Pediatrics, La Jolla, United States, [6]Harvard T. H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [7]University of Illinois at Chicago, Department of Pediatrics, Chicago, United States, [8]Tulane University School of Medicine, Department of Child and Adolescent Psychiatry, New Orleans, United States, [9]Johns Hopkins University School of Medicine, Departments of Pediatric and Adult Infectious Diseases, Baltimore, United States, [10]Frontier Science & Technology, Amherst, United States, [11]Tulane School of Medicine, Department of Pediatrics, New Orleans, United States

BACKGROUND: Cross-sectional studies have reported epigenetic age acceleration in people living with HIV on antiretroviral therapy (ART), including youth with perinatally-acquired HIV (YPHIV); however, longitudinal evidence is limited. We quantified the rate of change in epigenetic age compared to chronological age over time in YPHIV and youth who are perinatally HIV-exposed uninfected (YPHEU), and among YPHIV, examined associations with cumulative viral load (VL) and CD4 count.

METHODS: 32 YPHIV and 8 YPHEU with peripheral blood mononuclear cell (PBMC) samples collected at two timepoints ≥3 years apart were selected from the US-based PHACS Adolescent Master Protocol. DNA methylation was measured using the Illumina MethylationEPIC (850K) array and epigenetic age was calculated using the Horvath method (353 CpGs). Linear mixed effects models were used to estimate the rate of change in epigenetic age and 95% confidence intervals (95%CI) separately for YPHIV and YPHEU per year increase in chronological age.



[Figure 1. Epigenetic age by chronological age for youth with perinatally-acquired HIV (YPHIV) and HIV-exposed uninfected youth (YPHEU)]

RESULTS: Median age was 11 (range 7-17) and 17 (range 15-21) years at time 1 and 2, respectively. Groups were balanced by sex (51% male) and race/ethnicity (56% non-Hispanic Black). Epigenetic age increased for all YPHIV and YPHEU from time 1 to 2 (Figure 1). Predicted epigenetic age increased by 1.22 years (95%CI: 1.03,1.42) for YPHIV and 0.95 years (95%CI: 0.74,1.17) for YPHEU per year increase in chronological age. In a multivariable model that included chronological age, higher cumulative log10 VL was associated with higher epigenetic age [2.19, (95%CI: 0.65,3.74)], whereas higher cumulative CD4 count/100 cells/mm3 was associated with lower epigenetic age [-0.34, (95%CI: -0.63,-0.056)] in YPHIV.

CONCLUSIONS: We observed an increase in the rate of epigenetic age over time in YPHIV, but not in YPHEU. In YPHIV, higher VL and lower CD4 count were associated with higher epigenetic age, emphasizing the importance of early and sustained suppressive treatment for YPHIV, who will age on lifelong ART.

PEB0313

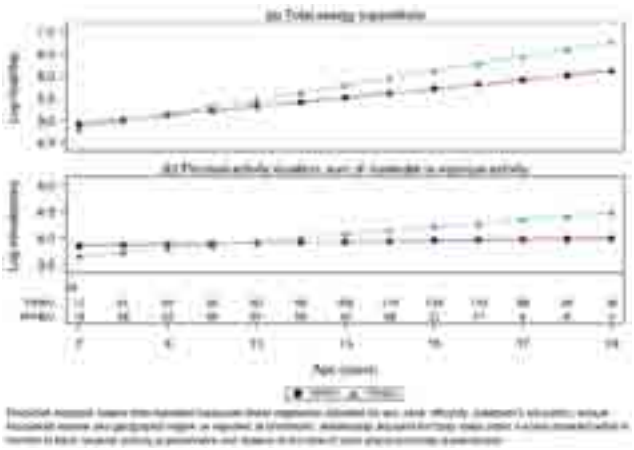
YOUTH LIVING WITH PERINATALLY-ACQUIRED HIV HAVE LOWER PHYSICAL ACTIVITY LEVELS AS THEY AGE COMPARED TO HIV-EXPOSED UNINFECTED YOUTH

S. Dirajlal-Fargo[1], P.L. Williams[2], C. Broadwell[2], E.J. McFarland[3], K.M. Powis[4], J. Jao[5], Pediatric HIV/AIDS Cohort Study (PHACS)
[1]Case Western Reserve University, Pediatrics, Cleveland, United States, [2]Harvard T. H. Chan School of Public Health, Department of Biostatistics, Boston, United States, [3]Children's Hospital of Colorado, Pediatric Infectious Diseases, Denver, United States, [4]Massachusetts General Hospital, Pediatrics, Boston, United States, [5]Northwestern University, Pediatrics, Chicago, United States

BACKGROUND: Low physical activity levels decrease life expectancy. Few studies have evaluated physical activity patterns or their association with vascular inflammation among youth living with perinatally-acquired HIV (YPHIV).

METHODS: We assessed YPHIV and youth perinatally HIV-exposed but uninfected (YPHEU) in the PHACS Adolescent Master Protocol with at least one Block physical activity questionnaire (PAQ) completed between ages 7-19 years. Physical activity metrics were: 1) daily total energy expenditure (TEE); 2) physical activity duration (PAD) defined as the minutes of daily moderate and vigorous activity. Sufficient daily physical activity was defined as having ≥ 60 minutes/day of physical activity, as recommended. In a subgroup, we measured serum biomarkers of coagulation (fibrinogen, P-selectin) and endothelial dysfunction (sICAM, sVCAM, E-selectin) obtained within 3 months of a single PAQ. Repeated measures linear regression models were used to compare the trajectories of log-transformed TEE and PAD by HIV status, adjusting for confounders. Spearman correlations were calculated to assess the relationship of TEE and PAD with vascular biomarkers.

RESULTS: 596 youth (387 YPHIV, 209 YPHEU) completed 1528 PAQs (median PAQs completed=3). Median age at enrollment (Q1, Q3) was 11 (9, 13) years, 51% were female, and 69% were black. TEE and PAD increased with age in both YPHIV and YPHEU. However, even after adjusting for confounders, YPHIV had significantly less increase per year than YPHEU for TEE (6.1% [95% Confidence Interval (CI): 1.9%, 10.2%] less) and PAD (5.5% [95%CI: 1.4%, 9.5%] less) (Figure). At age 14, 44% of YPHIV vs 70% of YPHEU met criteria for sufficient daily physical activity. Among 302 youth with biomarker measures (187 YPHIV, 114 YPHEU), we observed little correlation with TEE or PAD.



[Figure. Predicted adjusted mean physical activity measures by age and cohort]

CONCLUSIONS: YPHIV have lower physical activity levels compared to YPHEU which may negatively impact long-term health. Further research is needed to identify strategies to promote exercise in YPHIV.

PEB0314

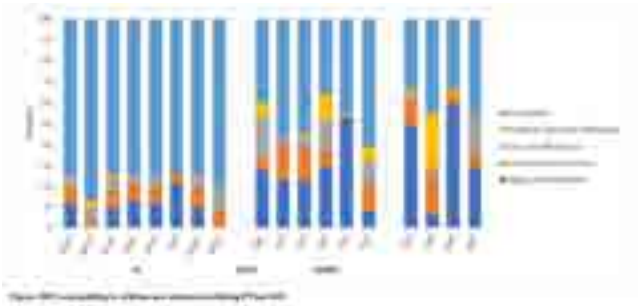
THIRD-LINE COMPROMISE: CHARACTERIZATION OF DRUG RESISTANCE IN UGANDAN CHILDREN AND ADOLESCENTS FAILING SECOND-LINE ANTIRETROVIRAL THERAPY

M. Javier[1], P. Elyanu[2], G.P. Akabwai[2], A. Small[1], A. Kekitiinwa[2]
[1]Baylor College of Medicine, Pediatrics, Houston, United States, [2]Baylor College of Medicine Children's Foundation-Uganda, Kampala, Uganda

BACKGROUND: Development of drug resistant mutations (DRM) is a significant hurdle to epidemic control, particularly for children and adolescents living with HIV, groups with high risk of virologic failure. Here, we characterize resistance patterns of children and adolescents failing second-line ART in an urban Ugandan clinic.

METHODS: In a retrospective cross-sectional study, patients aged ≤ 20 years with drug resistance testing after failing second-line ART between January 2010 and September 2019 were analyzed. Second-line failure was defined as a viral load >1000 copies/mL at least 6 months after initiating PI-based ART with documented failure on a NNRTI-based 1st-line regimen. One patient with major PI mutations after 3 months of second-line ART was included in the analysis. Stanford University HIVdb Program version 8.9-1 was used for mutation reporting and interpretation. For each ART class, a composite genotype susceptibility score (GSS) was calculated. Composite GSS scores ≤1, ≤2.5, and ≤5 indicated significant ART class resistance for NRTI, NNRTI and PI, respectively.

RESULTS: Sixty-two patients were included in the study: 51% female, median age 16 years, median time on 2nd-line therapy 34 months, and median CD4 count 166 cells/mm3. The most common DRM per class was M184V (49%; 31/63), K103N (24%; 15/63) and M46I/L (16%; 10/63). Sixty-nine percent of patients (43/62) had significant resistance to at least one ART class. Of these, 16% (7/43) had significant dual-class resistance and 26% (11/43) had significant resistance to all three classes. Intermediate and high-level resistance was observed in 19% (12/62) of patients to ATV/r and 19% (12/62) to LPV/r. At least low-level resistance was present in 29% (18/62) of patients to ETR and 10% (6/62) to DRV/r.



[Figure. ART susceptibility in children and adolescents failing 2nd line ART.]

CONCLUSIONS: The frequency of significant dual-class ART resistance and compromise of third-line agents in our cohort may have implications for optimal DRM testing in children and adolescents failing second-line ART in Uganda.

PEB0315

A MACHINE LEARNING APPROACH FOR PREDICTING PROBABILITY OF DEATH OR DISEASE PROGRESSION IN AN EARLY-TREATED PEDIATRIC AFRICAN COHORT

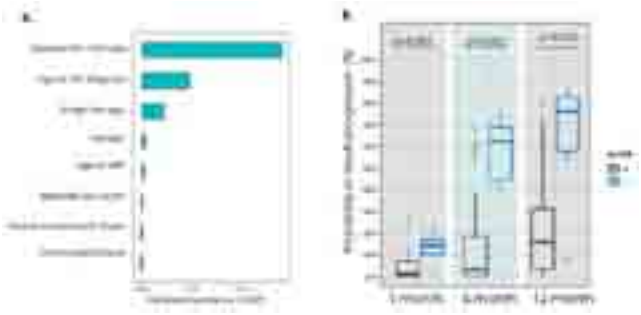
Sergievsky Center, College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, United States, [12]Research Unit in Congenital and Perinatal Infections, Academic Department of Pediatrics (DPUO), Division of Immunology and Infectious Diseases, Bambino Gesù Children's Hospital, Rome, Italy

BACKGROUND: In perinatally HIV infected children, mortality and morbidity are highest in the first months after ART initiation and is linked to advanced disease and late diagnosis. The random forest approach can deal with more predictors than classical models and has no model assumptions such as normality, linearity or hazard proportionality. The aim of this study was to predict the probability of death or clinical progression at a specific time of follow-up.

METHODS: EARTH (EPIICAL consortium) is an African multi-centre cohort enrolling HIV-infected infants treated within 3 months of life (n=151). A total of 134 infants with >1 follow-up visit were included in this analysis. The primary endpoint was the right-censored time to death or progression to AIDS. To predict the outcome, a log-rank random survival forest with imbalance correction was performed in a training subset (n=95, 70%). The algorithm was validated on the remaining 30% (n=39).

RESULTS: A total of 22 infants reached the primary endpoint with 13 (10%) patients dead and 9 (7%) with an AIDS defining condition. A total of 10000 trees were built with an error rate of 20%. The most important predictors of reaching the primary endpoint were baseline HIV viral load, age at diagnosis, weight-for-age, gender, age at ART initiation, and baseline CD4 count. In the validation, the model predicted a higher probability of reaching the primary endpoint among children who did indeed die or progress to AIDS, as compared to the group of children who did well (1-month: 14% vs. 0.01%, p-value=0.045; 6-months: 62% vs. 0.03%, p-value=0.019; 12-months: 76% vs. 16%, p-value=0.012). The AUC for predicting survival or progression was 0.83, 0.84, and 0.72 for 1-month, 6-months, and 1-year respectively.



[Figure]

CONCLUSIONS: This model helps clinicians individualize the probability of death or progression to AIDS at diagnosis and may be useful for the early identification of high-risk patients.

HIV-ASSOCIATED CO-INFECTIONS AND MALIGNANCIES IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0316

PACLITAXEL-ING A PUNCH: SUCCESSFUL TREATMENT OF CHILDREN, ADOLESCENTS, AND YOUNG ADULTS WITH RELAPSED OR REFRACTORY KAPOSI SARCOMA WITH PACLITAXEL IN MBEYA, TANZANIA

L. Campbell[1,2,3], N. El-Mallawany[2,4], J. Slone[2,4], P. Mehta[2,4], A. Kapesa[3], J. Bacha[1,2,3], N.A. Jiwa[3]
[1]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Pediatrics, Mbeya, Tanzania, United Republic of, [4]Texas Children's Hospital Cancer and Hematology Centers, Houston, United States

BACKGROUND: While many young patients with Kaposi sarcoma (KS) can be treated with a combination of bleomycin, vincristine and doxorubicin (ABV) chemotherapy, favorable outcomes can be challenging to attain in resource limited settings. We describe a cohort of pediatric, adolescent and young adult (AYA) patients with KS treated with paclitaxel in Mbeya, Tanzania.

METHODS: Retrospective chart review was conducted of patients with KS who received paclitaxel at the Baylor Tanzania Centre of Excellence in Mbeya, Tanzania between 1 March 2011 and 31 Dec 2019. Paclitaxel was selected for patients with refractory disease after treatment with ABV, KS relapse or contraindication to ABV. Paclitaxel was given at 100-135mg/m2 every 3-4 weeks for 6 cycles; patients who did not achieve complete clinical remission (CCR) were given additional cycles.

RESULTS: 17 patients met criteria and received paclitaxel, or 24% (17/71) of all patients treated for KS during the study period. Among these patients, 88% (15/17) had received prior chemotherapy (ABV), but had refractory disease (9/15), relapsed after ABV (4/15), or had allergic reaction to ABV (2/15). Two patients had pre-existing con-

traindications to ABV and received initial paclitaxel. All HIV+ patients (16/17) received ART and 88% (14/16) achieved VL <1000 cp/mL.

At time of paclitaxel initiation this cohort was 41% (7/17) female, median age 13.5 years (range 5.1-21.3), 94% (16/17) HIV +, all (16/16) on ART for a median of 64.5 months (range 4.4 - 138). 50% (8/16) had WHO severe immunosuppression.

At censure, 82% (14/17) of patients were alive – 71% (10/14) achieved CCR, 29% (4/14) had partial response. None were lost to follow up, median follow up was 37.3 months (range 8-83.5). All deaths (n=3) were due to complications of severe acute malnutrition. No significant differences in presentation or outcomes were seen based on Lilongwe KS stage (Table 1).

Clinical Characteristic	Stage 1: Mild and Moderate Cutaneous/Oral KS (n = 0)	Stage 2: Lymphadenopathic Predominant KS (n = 5)	Stage 3: Woody Edema KS (n = 4)	Stage 4: Visceral or Disseminated KS (n = 8)	p-value
Previously Failed Chemotherapy Regimen	NA	60% (3/5)	100% (4/4)	75% (6/8)	0.6303
Relapsed or Refractory KS	NA	60% (3/5)	100% (4/4)	75% (6/8)	0.6303
Alive	NA	80% (4/5)	75% (3/4)	88% (7/8)	0.3737
Died	NA	20% (1/5)	25% (1/4)	13% (1/8)	0.9999

[Table 1.]

CONCLUSIONS: Favorable outcomes were achievable with paclitaxel despite the severity of KS disease in this cohort and the resource constraints in this setting.

PEB0317

ANTIBODY RESPONSES TO TETANUS TOXOID, REDUCED DIPHTHERIA TOXOID, AND ACELLULAR PERTUSSIS (TDAP) VACCINATION AMONG PERINATALLY HIV-INFECTED THAI ADOLESCENTS STABLE ON COMBINATION ANTIRETROVIRAL TREATMENT

T. Sudjaritruk[1,2], S. Kanjanavanit[3], C. Prasarakee[2], S. Sarachai[2], W. Taweehorm[2], L. Aurpibul[2], K. Sintupat[2], R. Khampan[2], Revaccination-HIV study group

[1]Faculty of Medicine, Chiang Mai University, Department of Pediatrics, Chiang Mai, Thailand, [2]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [3]Nakornping Hospital, Department of Pediatrics, Chiang Mai, Thailand

BACKGROUND: To evaluate the antibody responses to tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis (Tdap) vaccination among perinatally HIV-infected Thai adolescents (PHIVA) stable on combination antiretroviral treatment (cART).

METHODS: A multicenter prospective cohort study was conducted. PHIVA(11-25years) who had:

(1) history of severe immune suppression(CD4<15% or <200cells/mm^3),

(2) currently stable on cART (CD4≥350cells/mm^3, or CD4≥200cells/mm^3 with viral suppression[VS; HIV RNA<50copies/ml]),

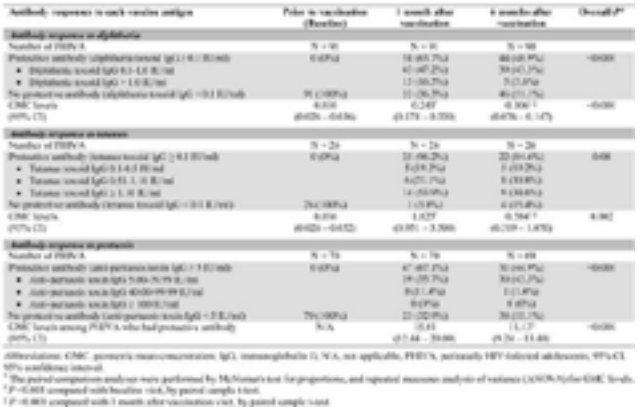
(3) completed a 5-dose series of DTP vaccine during childhood, and

(4) no protective antibodies against either diphtheria, tetanus, or pertussis (as defined below) were enrolled.

PHIVA who had ever received Tdap vaccination were excluded. A single dose of Tdap vaccine (Adacel®, Sanofi Pasteur) was administered intramuscularly. Antibody responses to diphtheria, tetanus, and pertussis were measured at 1 and 6 months after vaccination. Protective antibodies were defined as diphtheria toxoid IgG≥0.1 IU/ml, tetanus toxoid IgG≥0.1 IU/ml, and anti-pertussis toxin IgG≥5 IU/ml, respectively. Paired comparison analysis was conducted to compare antibody responses to each vaccine antigen between visits. Logistic regression analysis was performed to identify associated factors of protective antibodies after vaccination.

RESULTS: Of 115 eligible PHIVA, 59 (51%) were female, a median age was 19 years. At enrollment, 69% were on NNRTI-based cART. A median CD4 was 614cells/mm^3, and 91% had VS. There were 91 (79%), 26(23%), and 70 (61%) PHIVA without protective antibodies against diphtheria, tetanus, and pertussis, respectively. After Tdap vaccination, the proportion of protective antibodies against diphtheria, tetanus and pertussis were 64%, 96% and 67% at 1month, and 49%, 85% and 45% at 6months, respectively (Table 1).

The associated factors of developing protective antibodies at 1month and maintaining protective antibodies at 6months against diphtheria and pertussis were current VS and CD4 ≥200cells/mm^3 before cART initiation (P<0.05), respectively. No serious adverse reactions following Tdap vaccination were reported.



[Table 1. Antibody responses to diphtheria, tetanus and pertussis at 1 and 6 months after tetanus toxoid, reduced diphtheria toxoid and acellular pertussis (Tdap) vaccination among perinatally HIV-infected Thai adolescents stable on combination antiretroviral treatment.]

CONCLUSIONS: The majority of our PHIVA who were stable on cART developed protective antibodies after Tdap vaccination. A follow-up study to determine the rapid waning of antibody levels after vaccination is warranted.

PEB0318

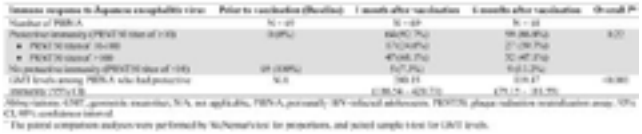
SAFETY AND IMMUNOGENICITY OF LIVE-ATTENUATED JAPANESE ENCEPHALITIS VACCINATION AMONG PERINATALLY HIV-INFECTED THAI ADOLESCENTS STABLE ON COMBINATION ANTIRETROVIRAL TREATMENT

T. Sudjaritruk[1,2], S. Kanjanavanit[3], C. Prasarakee[2], S. Sarachai[2], W. Taweehorm[2], L. Aurpibul[2], J. Saheng[1], K. Sintupat[2], R. Khampan[2], S. Yoksan[4], Revaccination-HIV study group
[1]Faculty of Medicine, Chiang Mai University, Department of Pediatrics, Chiang Mai, Thailand, [2]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [3]Nakornping Hospital, Department of Pediatrics, Chiang Mai, Thailand, [4]Institute of Molecular Biosciences, Mahidol University, Center for Vaccine Development, Bangkok, Thailand

BACKGROUND: To evaluate the safety and immunogenicity of live-attenuated Japanese encephalitis vaccination (LAJEV) among perinatally HIV-infected adolescents (PHIVA) stable on combination antiretroviral treatment (cART).

METHODS: A multicenter prospective cohort study was conducted in Thailand. PHIVA who aged 11-25years, had history of severe immune suppression (CD4<15% or <200 cells/mm^3), were currently stable on cART (CD4≥350 cells/mm^3, or CD 4≥200 cells/mm^3 with viral suppression [VS; HIV RNA<50 copies/ml]), had completed a 3- or 4-dose series of mouse brain-derived inactivated JE vaccine (MBDV) during childhood, and had no protective immunity to Japanese encephalitis virus (JEV) (as defined below) were included. PHIVA who had ever received LAJEV prior to enrollment were excluded. A single dose of LAJEV (IMOJEV®, Sanofi Pasteur) was administered subcutaneously. Adverse reactions following vaccination (30 minutes, and days 1,2,3,7,14) were assessed. Plaque reduction neutralization assa y (PRNT50) was performed at 1 and 6 months after vaccination to assess neutralizing antibodies to JEV, and titers of ≥10 were considered a protective immunity. Paired comparison analysis was conducted to compare immune responses to LAJEV between visits. Logistic regression analysis was performed to identify associated factors of protective immunity after vaccination.

RESULTS: During December 2018 to February 2019, 69 PHIVA were enrolled; 51% were female; a median age was 19 years. At enrollment, 71% were on NNRTI-based cART. A median CD4 was 590 cells/mm^3, and 87% had VS. After LAJEV vaccination, 64 (93%) and 59 (87%) PHIVA developed protective immunity at 1 and 6 months, respectively (Table 1). The associated factors of developing protective immunity at 1 month and maintaining protective immunity at 6 months to JEV were lower HIV RNA levels at baseline and living in rural region (P<0.05), respectively. None of PHIVA reported serious adverse reactions following LAJEV vaccination.



[Table 1. Immune response to Japanese encephalitis virus at 1 and 6 months after live-attenuated Japanese encephalitis vaccination among perinatally HIV-infected Thai adolescents stable on combination antiretroviral treatment.]

CONCLUSIONS: LAJEV is safe and immunogenic among our PHIVA who were stable on cART. Vaccination with LAJEV is an important strategy for disease prevention, and should be considered in PHIVA without protective immunity.

PEB0319

FACTORS ASSOCIATED WITH NECROTIZING ENTEROCOLITIS IN A PUBLIC HOSPITAL IN JOHANNESBURG, SOUTH AFRICA, 2013 – 2018: A CROSS SECTIONAL STUDY

O.M. Ajayi[1], D. Ballot[2], T. Chirwa[3]
[1]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [2]University of the Witwatersrand, Paediatrics, Johannesburg, South Africa, [3]University of the Witwatersrand, Epidemiology and Biostatistics, Johannesburg, South Africa

BACKGROUND: Necrotizing Enterocolitis (NEC) is a devastating gastrointestinal disease that affects newborns. Hence, the aim of the study is to determine the factors associated with NEC among the very low birth weight (VLBW; weight<1,500g) infants in Charlotte Maxeke Johannesburg Academic hospital.

METHODS: This is a retrospective cross-sectional study based on weekly routine collection of hospital records of VLBW babies admitted to CMJAH in South Africa between 2013 and 2018 (n = 2,333). Data was extracted from a standardized VLBW database administered by the unit which is used for registering all VLBW neonates who are born and/or admitted within the first 28 days (neonatal period) of life. Data analysis was done using statistical software for data management and analysis (STATA 15.0). A diagnosis of NEC was made based on clinical and radiological evidence of stage II or III, according to Bell's criteria. Logistic regression analysis was performed to determine the significant risk factor associated with NEC.

RESULTS: Majority of the sample population were males 53% and females 47%.Two hundred and forty-eight (10.63%) infants developed NEC. Multivariable logistic regression: the significant risk factors associated with NEC were, Oxygen given on day 28 (OR 1.27, 95% CI 1.052 – 1.531; p = 0.01), patent ductus arteriosus (PDA) (OR 1.61, 95% CI 1.153 – 2.244; p = 0.005), blood transfusion (OR 1.61, 95% CI 1.153 – 2.244; p = 0.005), surfactant therapy at initial admission (OR 1.49, 95% CI 1.146 – 1.945; p = 0.003) and delivery room nasal CPAP (OR 1.29, 95% CI 0.984 – 1.677; p = 0.06 (marginally significant). The Univariate logistic regression: maternal HIV (OR 1.54, 95% CI 1.214 – 1.959; p = <0.001).

CONCLUSIONS: Patent ductus arteriosus, oxygen given on day 28, blood transfusion, surfactant therapy and delivery room nasal CPAP were associated with increased risk of NEC in CMJAH VLBW infants. Mothers who were HIV positive were 54% more likely to have babies that will develop NEC.

[1]University of California, San Diego, School of Medicine, Neurosciences, La Jolla, California, United States, [2]Harvard T.H. Chan School of Public Health, Harvard University, Boston, Massachusetts, United States, [3]Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States, [4]HIV Center for Clinical and Behavioral Studies, Columbia University, New York, New York, United States, [5]David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, California, United States, [6]University of Illinois at Chicago, Chicago, Illinois, United States, [7]University of Miami Miller School of Medicine, Miami, Florida, United States, [8]National Institutes of Health, Bethesda, Maryland, United States

BACKGROUND: This study examined self-regulatory and other cognitive predictors of substance use (SU) among United States (U.S.) youth with perinatally acquired HIV (YPHIV) and youth exposed perinatally to HIV but uninfected (YPHEU) to inform SU preventive interventions. SU prevention is significant for YPHIV due to SU-related increased health (e.g., worse treatment adherence, poor viral control) and sexual risks.

METHODS: Youth included in these analyses were enrolled in the U.S.-based Pediatric HIV/AIDS Cohort Study Adolescent Master Protocol and aged 7-15 years at baseline. Participants (YPHIV, n=390; YPHEU, n=211) were followed longitudinally for up to 7 years with cognitive testing, self- and caregiver-report behavioral questionnaires, and self-report of alcohol, marijuana, tobacco, and other SU assessed via confidential audio computer-assisted self-interview. Cox survival models examined correlates of incident SU. Generalized estimating equations with a logistic link addressed SU prevalence associations at baseline.

RESULTS:

	Alcohol: Prevalence Analysis	Alcohol: Incidence Analysis	Marijuana: Prevalence Analysis	Marijuana: Incidence Analysis
	Odds Ratio (95% CI), p-value	Hazard Ratio (95% CI), p-value	Odds Ratio (95% CI), p-value	Hazard Ratio (95% CI), p-value
BASC-2 Sensation Seeking (per 10 points)	1.85 (1.48, 2.30), <0.001	1.32 (1.11, 1.58), 0.002	1.43 (1.14, 1.80), 0.002	1.29 (1.07, 1.55), 0.007
Child BRIEF GEC Score ≥65	1.97 (1.02, 3.78), 0.043	0.54 (0.24, 1.21), 0.13	2.21 (1.12, 4.37), 0.022	0.94 (0.49, 1.80), 0.85
Caregiver BRIEF GEC Score ≥65	1.59 (0.88, 2.87), 0.123	1.25 (0.74, 2.10), 0.40	1.21 (0.65, 2.26), 0.54	1.02 (0.65, 1.60), 0.93
WISC-IV Full Scale IQ (per 15 points)	1.77 (1.33, 2.35), <0.001	1.14 (0.97, 1.35), 0.12	1.52 (1.13, 2.05), 0.006	1.06 (0.89, 1.26), 0.52

Odds ratios and hazard ratios were adjusted for caregiver type, sex, Hispanic ethnicity, race, and age; hazard ratios also adjusted for other substance use; BASC-2=Behavior Assessment System for Children-2; BRIEF=Behavior Rating Inventory of Executive Function; GEC= Global Executive Composite; WISC-IV=Wechsler Intelligence Scale for Children-Fourth Edition. For BRIEF and BASC-2, higher scores indicate worse reported problems.

[Table]

About half of youth reported ever using alcohol (48.0%) or marijuana (42.8%) between baseline and their final visit; of those, up to 42% reported negative effects or concerning symptoms (e.g., riding in a car driven by someone who was high, family/friends suggesting they cut back). Higher sensation-seeking and worse self-reported self-regulation and everyday executive functioning skills (BRIEF GEC) were associated with both initiation and prevalent use of alcohol and marijuana for both YPHIV and YPHEU (see Table). Cognitive functioning (WISC-IV) showed a different pattern, with better scores associated with increased likelihood of prevalent or incident alcohol or marijuana use. Interaction tests between YPHIV and PHEU revealed small differences.

CONCLUSIONS: Worse self-regulation predicts alcohol and marijuana use regardless of HIV status, suggesting that SU screening tools and self-regulation-based interventions developed for the general adolescent population could be effective with YPHIV and YPHEU. Higher cognitive performance did not prevent SU among adolescent youth affected by HIV. SU among YPHIV needs greater attention in clinical practice and research to prevent HIV and SU comorbidities and consequences.

PEB0321

RETENTION IN CARE AMONG ADOLESCENTS LIVING WITH HIV IN CAPE TOWN, SOUTH AFRICA

M. Atujuna[1], D. Giovenco[1,2], L.-g. Bekker[1]
[1]University of Cape Town, Desmond Tutu HIV Centre, Department of Medicine, Cape Town, South Africa, [2]University of North Carolina, North Carolina, United States

BACKGROUND: Treatment retention and viral suppression among children and adolescents living with HIV remain essential to reaching UNAIDS 90-90-90 targets. We compared the retention outcomes of children (perinatally infected) and adolescents (mostly behaviorally infected) enrolled in a community-based ART program in Cape Town, South Africa.

METHODS: We utilized routine, longitudinal data collected at a public clinic in an informal community between May 2002 and April 2019. We defined our paediatric and adolescent cohorts as participants ≤12 years or between 17-24 years at ART initiation, respectively. Kaplan-Meier estimates were used to describe distributions of time from ART initiation to "lost to care" (LTC). Participants were categorized as LTC if they had no clinic data within the past 6 months; not known to have died or transferred. Censoring occurred at date of death, date of transfer, or date of study end. Multivariate Cox proportional hazard models were used to estimate hazard ratios (HRs) adjusting for potential confounders.

RESULTS: The paediatric cohort (n=696) was 51% female with a median age of 3 years at ART initiation (IQR=0-6). The adolescent cohort (n=2062) was 92% female with a median age of 22 years at ART initiation (IQR=21-24). Median baseline CD4 cell counts were 461 and 251 cells/μL, in children and adolescent cohorts respectively. Among the paediatric cohort, 444 participants (64%) were LTC over 4647.7 person-years(pys) of follow-up (incidence rate of 9.5 per 100pys). The average time from treatment initiation to LTC was 8.6 years (SE=0.19). Among the adolescent cohort, 1184 patients (57%) were LTC over 6497.6 person-years of follow-up (incidence rate of 18.2 per 100pys). The average time from treatment initiation to LTC was 5.2 years (SE=0.12). Adolescents had a significantly higher risk for being LTC compared to children (adjusted-HR=1.74, 95% CI: 1.52-1.99, p<.001).

CONCLUSIONS: Rates of LTC observed among both cohorts were high. However, there were significantly higher rates of LTC over a shorter time interval for adolescents initiating treatment compared to children. Greater investments in tailored interventions are required to ensure adolescents are initiated earlier and retained in care enabling successful viral suppression in this important population.

MENTAL HEALTH AND NEUROCOGNITION IN PAEDIATRIC AND ADOLESCENT POPULATIONS

PEB0322

NEUROCOGNITIVE FUNCTION IN HIV-INFECTED CHILDREN ON PROTEASE INHIBITOR BASED VERSUS NON- PROTEASE INHIBITOR BASED ANTIRETROVIRAL THERAPY

D. Nalwanga[1], V. Musiime[2,3], J. Senkusu[4], T.T. Ssesanga[5], P. Bangirana[6], P. Musoke[2,7], S. Cusick[8]
[1]Makereere University, College of Health Sciences, Paediatrics and Child Health, Kampala, Uganda, [2]Makerere University, Paediatrics and Child Health, Kampala, Uganda, [3]Joint Clinical Research Center, Paediatrics, Kampala, Uganda, [4]Makerere University, Public Health, Kampala, Uganda, [5]Joint Clinical Research Centre, Paediatrics, Kampala, Uganda, [6]Makerere University, Psychiatry, Kampala, Uganda, [7]Makerere University-Johns Hopkins Collaboration, Paediatrics, Kampala, Uganda, [8]University of Minnesota, Pediatrics, Minnesota, United States

BACKGROUND: HIV infection in children has been associated with significant motor and cognitive deficits. Despite the availability of life-saving antiretroviral therapy (ART), maximizing cognitive function remains a public health imperative. Protease inhibitors (PIs) and non-PIs like zidovudine achieve low and high drug levels in the cerebral spinal fluid (CSF), respectively. High drug levels could result in better neurocognitive function by reducing CSF viral load and inflammation. This study compared the neurocognitive function of HIV infected children receiving PI-based ART to those receiving non PI-based ART.

METHODS: A cross-sectional study was conducted among clinically stable HIV-positive children on non PI-based or PI-based ART respectively for at least one year (viral load < 1000 copies per ml) between 5 and 12 years attending Joint Clinical Research Centre (JCRC), Kampala, Uganda. We excluded children with history of central nervous system infection/event, treatment adherence < 80%, acute malnutrition, hearing/visual impairment, non-English or Luganda speaking or had received both ART regimens. Neurocognitive function was assessed using the Kaufman Assessment Battery for Children second edition (KABC II), and Test of Variables of Attention (TOVA). Age-adjusted neurocognitive z scores for the two groups derived from existing local norms were compared using linear logistic regression models on STATA version 13. The Hommel's method was used to adjust for multiple testing.

RESULTS: Mean age of the children in years (+SD) was 8.5±2.0 and 9.5±1.9 (p=0.030) in the PI (n=32) and non-PI group (n=44), with majority male, (58.8% and 57.1% respectively). Average years of school were 5.4±2.5 and 5.7±1.8 in the PI and non-PI groups respectively (p=0.521). Children in the non-PI group had lower socioeconomic scores than those in the PI-based ART group (5.7±3.3 vs 7.4±2.8, p=0.023). Body mass index for age was comparable between groups (p=0.448). There was no difference in neurocognitive function (i.e. sequential and simultaneous processing, learning, planning, mental processing index, and visual D'prime) between children receiving PI based and non-PI based ART (adjusted p > 0.05).

CONCLUSIONS: We detected no difference in neurocognitive function among children on PI and non PI-based ART therapy. We recommend a study with a larger sample size.

PEB0323

LONGITUDINAL NEUROCOGNITIVE STUDY OF ADOLESCENTS LIVING WITH HIV IN THE CAPE TOWN ADOLESCENT ANTIRETROVIRAL COHORT (CTAAC)

J. Hoare[1], N. Phillips[2], L. Myer[2], H. Zar[2], D. Stein[1]
[1]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [2]University of Cape Town, Cape Town, South Africa

BACKGROUND: Neurocognitive impairment (NCI) despite ART is well known in perinatally-infected HIV+ adolescents (PHIV+), but there are few data on detailed longitudinal changes in NCI over time. NCI can have deleterious effects onadolescents' everyday functioning. This is especially important in adolescents where their ability to function in school will directly affect their economic/social trajectory as adults.

METHODS: Within this sub-study of the Cape Town Adolescent Antiretroviral Cohort (CTAAC), PHIV+ on ART >6m completed baseline and 3-year follow-up assessments including a comprehensive neurocognitive battery assessing function in 10 cognitive domains. We applied the youth HIV-associated neurocognitive disorder (NCD) diagnostic criteriato classify each as having either a major NCD, a minor NCD, or no impairment. To examine the longitudinal differences in cognitive domains and NCD a series of one-way ANOVAs was performed.

RESULTS: Overall 204 PHIV+ ages 9-12 years (mean CD4 cell count 953 cells/μL and 85% VL<50 copies/mL) and 44 age-matched HIV-controls enrolled for the CTAAC neuro-sub study. There were significant differences between the PHIV+ and control groups in the following domains at baseline: general intellectual functioning, executive functioning, attention, working memory, verbal memory, visual memory, visual spatial ability, language and processing speed (p=<.05). At baseline 47% had any NCD. At 3 year follow-up there was significant further deterioration within the PHIV+ in the domains of attention (see figure below), motor co-ordination and working memory (p=<.005). However, the PHIV+ improved significantly in the domains of visual memory and language. In addition there was a shift in diagnoses of NCD at 3 year follow-up, with 61% having any NCD, 53% minor and 8% major. NCD diagnosis was stable over the 3 year period in 69% of PHIV+ , deteriorated in 20% and improved in 10%.

CONCLUSIONS: Neurocognitive impairment remains a significant concern, important to identify and probably largely under recognised in a cohort of treated PHIV+ followed longitudinally. However, NCD diagnosis was not static, 20% of PHIV+ had progressive impairment and 10% improvement in neurocognitive function. Further research into the factors driving both deterioration and improvement in NCD, utilising this prospective cohort in South Africa is needed.

PEB0324

PREVALENCE AND FACTORS ASSOCIATED WITH DEPRESSION AND SUICIDALITY AMONG ADOLESCENTS LIVING WITH HIV ATTENDING THE HIV ADOLESCENCE CLINIC AT KCMC HOSPITAL IN TANZANIA

M. Itana[1], L. Msuya[1], A. Shayo[2,3]
[1]Kilimanjaro Christian Medical University College, Paediatrics, Moshi Kilimanjaro, Tanzania, United Republic of, [2]Kilimanjaro Christian Medical Center, Paediatrics, Moshi Kilimanjaro, Tanzania, United Republic of, [3]Kilimanjaro Christian Medical University College, Moshi Kilimanjaro, Tanzania, United Republic of

BACKGROUND: Mal-adherance of antiretroviral treatment causes increase of AIDS-related deaths among adolescents and has shown to be associated with psychosocial and mental health difficulties. However, depression screening and treatment are limited in sub-Saharan Africa, and there are few population-level studies examining the prevalence and factors associated with depression and suicidality. This study highlights the need to integrate mental health evaluation and treatment into the care provided for adolescents with HIV.The aim of this study is to determine the prevalence and factors associated with depression and suicidality among adolescents with HIV attending adolescent clinic at KCMC

METHODS: A cross-sectional study from January to May 2019 in 10–19 year-old adolescents with HIV attending adolescents' clinic in KCMC Moshi Tanzania.The validated standardized Patient Health Questionnaire 2 (PHQ2) was used to assess symptoms of depression for all the participants,the validity for (PHQ-2 ≥3 demonstrated high sensitivity (91.1%) and moderate specificity (76.8%).If the answer is more than 3 in PHQ 2,then validated standardized Hopkins checklist questionnaire was used to diagnose depression.A test score higher than 1.75 on the HSCL denotes diagnosis of depressed mood.If there is any thought of suicide in Hopkins checklist then Suicidal was assessed by a validated tool Suicidal Behavioral Questionnaire.

RESULTS: The participants enrolled in the study were 169, who scored more than 2 for PHQ 2 were 120 participants. Among 120 the participant median age was 16.0 years(14.0-18.0). The prevalence of depression in adolescents 14% and the prevalence of suicidality was 13%. The subdivision of suicidality showed Suicidal risk ideation at 2.5%, Suicide plan at 5.8%, and suicide attempt at 2.5%. The factors associated with depression were History of violence (OR=9.333, 95%CI=1.804-48.297, P=0.008) and History of being bullied (OR=5.300, 95%CI=1.355-20.736, P=0.017). The factors associated with suicidality were history of violence (OR=6.514, 95%CI, 1.067-39.755, P=0.042) and history of being bullied (OR=4.909, 95%CI, 1.075-22.409, P=0.040).

CONCLUSIONS: Depression is prevalent in Tanzania, and its correlates are gender-specific. Our findings suggest multiple targets for screening and prevention of depression and highlight the need to integrate mental health counseling and treatment into primary health care to decrease morbidity and improve HIV management efforts.

PEB0325

LESSONS LEARNED FROM IMPACT OF MENTAL HEALTH CARE INTEGRATION INTO HIV ADOLESCENT SAME DAY ANTIRETROVIRAL SERVICES ON DRUG ADHERENCE AND CARE RETENTION IN BANGKOK, THAILAND

C. Saisaengjan[1], W.N. Songtaweesin[1], P. Thisayakorn[2], P. Deeklum[1], S. Lonhin[1], T. Theerawit[1], P. Wongharn[1], R. Ramautarsing[3], T. Chinbunchorn[3], S. Amatavete[3], N. Phanuphak[3], T. Puthanakit[1,4], CE-PID - TRC Adolescent Study Team
[1]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Bangkok, Thailand, [2]Chulalongkorn University, Department of Psychiatry, Faculty of Medicine, Bangkok, Thailand, [3]Thai Red Cross AIDS Research Center, PREVENTION, Bangkok, Thailand, [4]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand

BACKGROUND: In an era of same day antiretroviral treatment (SDART) initiation, novel service provision strategies are needed to address psychosocial needs of newly diagnosed HIV-infected youth. We look at lessons learned from implementation of mental health care integration to HIV services for adolescents with horizontally acquired HIV initiating SDART in Thailand.

DESCRIPTION: Between February 2018 and December 2019, 42 adolescents aged between 13-24 years newly diagnosed with HIV at the Thai Red Cross Anonymous HIV Testing Center were initiated on SDART then referred to continue care at the Integrated Youth Care Clinic (IYCC) at King Chulalongkorn Memorial Hospital. The IYCC provided personal case managers who performed mental health screening at baseline, coordinated care between IYCC and psychiatry, and home visitations.

LESSONS LEARNED: At baseline, median age was 17 years (IQR 16-19), median CD4 count 311 cells/mm3, 36 (86%) were MSM and 8 (19%) reported substance use (ketamine or amphetamines). At baseline, screening for depression was done using the patient health questionnaire-9 (PHQ-9), and for anxiety using the generalised anxiety disorder 7-item (GAD-7) scale. Abnormal scores were defined as ≥9 for PHQ-9 and ≥11 for GAD-7. Twelve (29%) had abnormal scores and/or suicidal ideation, received counselling from a clinical psychologist and were linked to psychiatric care within 1 month. Eleven (26%) were diagnosed with mental health disorders (8 depression, 1 gender dysphoria, 1 generalized anxiety disorder, 1 adjustment disorder). Psychosocial issues identified included: family issues, gender stigma, HIV stigma and financial problems. Eight received medication with counselling, and 4 received counselling alone. All were offered peer support, disclosure support, self-esteem building group activities, and financial support for psychiatric care and educational fees as needed. At 6 months, retention was 26/30 (87%), 2/30 (7%) had transitioned to adult services, and 2/30 (7%) lost to follow-up. All 26 adolescents retained at 6 months achieved viral suppression.

CONCLUSIONS/NEXT STEPS: Anticipatory screening and active management of mental health problems from the outset at ARV initiation in horizontally infected adolescents appears to be important in supporting future ARV adherence and retention. Preparation of this adolescent population for future successful transition to adult services is needed.

PEB0326

MENTAL HEALTH AND QUALITY OF LIFE IN CHILDREN LIVING WITH HIV ON ANTIRETROVIRAL THERAPY

S. Shiau[1], H. Evans[2], R. Strehlau[3], Y. Shen[4], M. Burke[3], A. Liberty[5], A. Coovadia[3], E.J. Abrams[6,7], M.T. Yin[2], A. Violari[5], L. Kuhn[4,7], S.M. Arpadi[4,6,7], CHANGES Study Team
[1]Rutgers School of Public Health, Department of Biostatistics and Epidemiology, Piscataway, United States, [2]Columbia University Irving Medical Center, Department of Medicine, Division of Infectious Diseases, Vagelos College of Physicians & Surgeons, New York, United States, [3]University of the Witwatersrand, Empilweni Services and Research Unit, Rahima Moosa Mother and Child Hospital, Department of Paediatrics and Child Health, Faculty of Health Sciences, Johannesburg, South Africa, [4]Columbia University Irving Medical Center, G.H. Sergievsky Center, Vagelos College of Physicians & Surgeons, New York, United States, [5]University of the Witwatersrand, Perinatal HIV Research Unit, Chris Hani Baragwanath Hospital, Johannesburg, South Africa, [6]Columbia University Irving Medical Center, ICAP at Columbia University, Mailman School of Public Health, New York, United States, [7]Columbia University Irving Medical Center, Department of Epidemiology, Mailman School of Public Health, New York, United States

BACKGROUND: Despite antiretroviral therapy (ART), children living with perinatally-acquired HIV (CLWH) continue to experience neurocognitive deficits, mental health problems, and decreased quality of life. Prior studies evaluating the mitigating effects of ART on clinical outcomes have utilized pediatric cohorts initiating older ART regimens with advanced disease and at older ages than currently practiced. The objective of this study is to examine mental health and quality of life in CLWH initiated and well-controlled on potent ART regimens early in life.

METHODS: This study included 463 CLWH and 122 uninfected controls enrolled in the Childhood HAART Alterations in Normal Growth, Genes, and aGing Evaluation Study (CHANGES) in Johannesburg, South Africa. Participants and caregivers completed the Strengths and Difficulties Questionnaire (SDQ) to assess mental health and the Pediatric Quality of Life Inventory (PedsQL) to assess quality of life. For the SDQ, five sub-scale scores were calculated for emotional symptoms, conduct problems, hyperactivity/inattention, peer relationship problems, and pro-social behavior. A total difficulties score was calculated based on the first four sub-scales. For the PedsQL, three summary scores were created for total, physical, and psychosocial health.

RESULTS: Mean age (10.9 years) was similar between CLWH and controls. A greater proportion of CLWH were female (54 vs. 40.2%, p<0.01) than controls. 94.8% of CLWH had a viral load <1000 copies/mL. On the SDQ, CLWH had a higher total difficulties score [2.9 (95%CI: 1.8, 3.9)], and emotional symptoms [1.1 (95%CI: 0.7, 1.5)], conduct problems [0.4 (95%CI: 0, 0.8)], and hyperactivity/inattention [1.5 (95%CI: 1.0, 2.0)] sub-scale scores compared to controls, adjusted for age and sex. On the PedsQL, CLWH had lower mean scores on the total quality of life score [-8.6 (95%CI: -10.3, -6.8)], physical health score [-5.3 (95%CI: -7.4, -3.2)], and psychosocial health score [-9.6 (95%CI: -11.6, -7.7)], adjusted for age and sex.

CONCLUSIONS: Even with well-controlled disease from an early age, CLWH are at higher risk for mental health problems and experience lower health-related quality of life compared to controls. Apart from ART, additional resources and support to improve quality of life and address mental health problems are warranted to optimize outcomes throughout childhood for this vulnerable population.

PEB0327

NEURODEVELOPMENT AT 12 MONTHS OF AGE AMONG VERY EARLY TREATED INFANTS IN JOHANNESBURG, SOUTH AFRICA

R. Strehlau[1], T. van Aswegen[1], M. Burke[1], L. Kuhn[2,3], J. Potterton[4,1]
[1]University of the Witwatersrand, Department of Paediatrics and Child Health, Empilweni Services and Research Unit, Johannesburg, South Africa, [2]Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, Gertrude H. Sergievsky Center, New York, United States, [3]Mailman School of Public Health, Columbia University Irving Medical Center, Department of Epidemiology, New York, United States, [4]University of the Witwatersrand, Department of Physiotherapy, Johannesburg, South Africa

BACKGROUND: Early childhood development (ECD) programmes improve developmental outcomes. Developmental consequences of infant intrapartum HIV infection may be attenuated by early antiretroviral treatment (ART) in neonates. We compared developmental outcomes of two groups of early treated infants with the intervention group (IG) participating in an ECD programme through the first 12 months of life.

METHODS: At Rahima Moosa Mother and Child Hospital in Johannesburg, South Africa, we enrolled 36 confirmed HIV positive early-treated neonates into an IG receiving 3-monthly age-appropriate stimulatory toys and parental information on ECD. At 12 months of age, children were assessed by either a physiotherapist or physician using the Bayley Scales of Infant and Toddler Development-III (BSID-III). Results from the IG were compared with a cohort of early treated children in observational follow-up at the site.

RESULTS: The 36 IG children were compared with 24 from the observational group (OG). At birth, groups showed no significant differences in gestational age, delivery method, anthropometry or breastfeeding rates. Age (days) of ART start was 8.4 (SD 12.49) and 5.42 (SD 5.87), p=0.2806, in the IG and OG respectively. At 12 months 77.8% (28/36) of the IG remained in follow-up and showed no significant differences in anthropometry, WHO staging, viral load or CD4 counts compared with the OG. Mean scaled and composite BSID-III scores for both groups equated with the reference mean of 10 (SD 3) and 100 (SD 15) respectively. Mean scaled and composite scores were non-significantly greater for all subscales in the IG apart from the gross motor subscale (Table 1). IG children scored significantly better on the receptive communication subscale 10.96 (SD 2.35) vs. 9 (SD 4) p=0.0331.

Assessment Subscale	Observational Group (N=24)	Intervention Group (N=28)	p
Cognitive subscale			
Scaled Score, mean (SD)	11 (2)	11 (2.57)	1.000
Composite Score, mean (SD)	103 (9)	105 (12.84)	0.5252
Language Subscale			
Receptive Communication, Scaled Score, mean (SD)	9 (4)	10.96 (2.35)	0.0331
Expressive Communication, Scaled Score, mean (SD)	10 (2)	10.75 (2.08)	0.1931
Language Subscale, Composite Score, mean (SD)	100 (17)	105.21 (2.35)	0.1904
Motor Subscale			
Fine Motor, Scaled Score, mean (SD)	10 (2)	10.5 (2.08)	0.3833
Gross Motor, Scaled Score, mean (SD)	10 (2)	9.25 (2.10)	0.1954
Motor Subscale, Composite Score, mean (SD)	99 (11)	99.46 (9.24)	0.8705

[Table 1.]

CONCLUSIONS: At 12 months of age children starting ART early showed BSID-III results comparable to the reference norm. Participation in an ECD programme in the first year of life in addition to early ART further improved developmental outcomes.

PEB0328

ASSOCIATIONS OF NEVIRAPINE-BASED ART REGIMENS WITH NEUROPSYCHOLOGICAL OUTCOMES IN HIV-POSITIVE CHILDREN

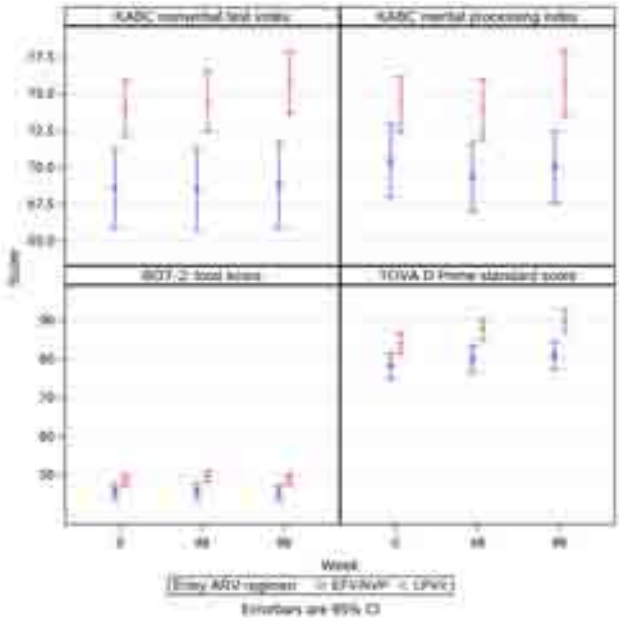
BACKGROUND: IMPAACT P1104s compared neuropsychological outcomes over 96 weeks in HIV-positive (HIV+) children with matched HIV unexposed (HU) and HIV-exposed uninfected (HEU) children, aged 5 to 11 years at 6 sites in Sub-Saharan Africa. Here, we explore HIV-illness related associations with neuropsychological outcomes in the HIV+ cohort.

METHODS: HIV+ children had participated in IMPAACT P1060, which compared efficacy of nevirapine (NVP) versus lopinavir/ritonavir (LPV/r). 96% of eligible P1060 participants enrolled in P1104S. For P1104S, neuropsychological evaluations of KABC cognitive ability, TOVA attention-impulsivity and BOT-2 motor domains were assessed at 0, 48 and 96 weeks. In HIV+ children, clinical, antiretroviral and laboratory (immunological and virological) data from P1060 were combined with clinical and neuropsychological and caregiver data from P1104S to explore associations with neuropsychological outcomes using linear mixed-effects multivariable regression analysis, controlling for personal and caregiver characteristics. Adjusted means with 95% confidence intervals were presented.



[Figure 1.]

RESULTS: The 246 HIV+ children (45% male, mean age at P1104s entry 7.1 yrs (SD 1.2)) had median ART initiation at 15 months (IQR 8.2, 25.2), nadir CD4 count of 632 cells/mm3 (IQR 427, 874); 233 (95%) had a peak viral load >100,000 copies/ml. 164 (67%), 7 (3%) and 71 (29%) were receiving LPV/r, efavirenz (EFV)- and NVP-based ART respectively; 61% had ≥ stage 3 WHO clinical stage.

Use of NVP or EFV at P1104s study start or during follow-up were associated with lower neuropsychological scores compared to LPV/r (Figure), which persisted when controlling for nadir CD4 percent and time-varying HIV viral load. Other predictors of poorer scores in KABC domains included low birth weight, WHO stage 4 disease and serious illness history but not elevated VL on P1060 or P1104.

CONCLUSIONS: Children receiving nevirapine or efavirenz while on P1104s had poorer neuropsychological scores as assessed by the KABC, BOT-2 and TOVA than those on lopinavir/ritonavir.

PEB0329

BEYOND SURVIVAL – STRATEGIES TO PROMOTE THE QUALITY OF LIFE OF HIV INFECTED YOUNG ADULTS AT BOTSWANA-BAYLOR

G. Karugaba[1], K. Katse[1], R. Kgaswane[1], M. Matshaba[1,2]
[1]Botswana-Baylor Children's Clinical Centre of Excellence, Gaborone, Botswana, [2]Baylor College of Medicine, Houston, United States

BACKGROUND: As more HIV infected adolescents survive into young adulthood, there is a push to better understand and promote their quality of life (QOL). Young adults with HIV (YALH) have to contend with challenges related to HIV infection while faced with the developmental tasks of this important phase in life. However, not enough is known about the special strengths, vulnerabilities and QOL of this growing population in Botswana. The aim of this study was to assess the QOL of YALH and identify their perspectives on how to promote their QOL.

METHODS: We used 1) WHOQOL-HIV BREF instrument to assess the QOL of YALH aged 18-29 years. The WHOQOL Group recommends a minimum of 300 participants in sites using the instrument for the first time. 2) in-depth interviews (IDI) with 40 purposefully sampled participants. IDI sample size was determined by data saturation.

RESULTS: 242 females and 257 males were surveyed. The median of overall quality of life and general health perceptions (<70) was used as the upper cut off for poor QOL. The lowest mean QOL scores were recorded in the financial resources facet (33.25); opportunities for recreation/leisure activities (53.56); and satisfaction with sexual life (56.68). IDI results show risk factors of poor QOL to include: poor school performance/achievement; financial stressors due to unemployment/underemployment; orphan hood; stressful romantic relationships; fear of stigma and disclosure; limited social support; poor self-acceptance/image; single parenting by young women; worries and fears about the future; and treatment related challenges. YALH's recommend establishment of policies and programs to increased access to vocational training opportunities; preferential access to youth development schemes; expand employment opportunities for low skilled people; creating and environment of care and concern and protection; and group level interventions to promote self-image, self-confidence and self-esteem in order for YALH to live independently.

CONCLUSIONS: Results of this study demonstrate that being on ART alone does not guarantee good QOL. Many risk factors for low QOL identified by this study are potentially modifiable and can be effectively targeted for policy and interventions to maximize patients' QOL. A multi-sectoral approach is needed to promote the QOL of YALH.

HIV-EXPOSED UNINFECTED CHILDREN

INFANT MORBIDITIES DIFFERENTIALS OF HIV POSITIVE MOTHERS WITH KNOWN VAGINAL DYSBIOSIS STATUS: A STATISTICAL ANALYSIS WITH A SKEWED BINARY OUTCOME USING GENERALISED ESTIMATING EQUATIONS

N. Mwenda[1], R. Nduati[2], G. Kerich[1], M. Kosgey[1]
[1]Moi University, Mathematics, Physics and Computing, Nairobi, Kenya, [2]University of Nairobi, Department of Pediatrics, Nairobi, Kenya

BACKGROUND: Infant morbidity and mortality is an indicator used globally as a measure of a country's health status. This study is about the sexually enhanced diseases which have not been given close attention yet they have the potential of long term morbidity effects. Our objective is to address effects of Vaginal Dysbiosis on long term cause of infants' morbidities.

METHODS: We analyzed infant data from HIV positive mothers whose vaginal dysbiosis status was known from a Randomized Control Trial study conducted in Nairobi, Kenya.

Our aim was to investigate the effect of VD on infant morbidity with time from birth up to six months of age. We derived a score for morbidity incidences depending on the reported illness in the register during scheduled visits only. By adjusting for the mothers VD status, child's HIV status, gender, feeding status and weight for age, we used two approaches for analysis. In our analysis we considered and fitted the traditional Generalized Estimating(GEE) equations and our proposed Skewed Generalized Estimating Equations(SGEE). Our motivation is to account for skewness created in the response during the creation of the morbidity incidence score.

RESULTS: Overall, 327 infants aged 1 to 6 months were included in the study. 1962 repeated measurements were available for analysis

Of the 327 mothers' to the infants, 148(45\%) tested positive for VD while 179(\%) were negative. VD, gender and time were found to be associated with infant morbidities. Women who had VD, at month 1 they had 3.62 odds of morbidity incidences that those who were negative. The effects of VD tend to decrease with time, at five months of age children in the VD group had 1.16 times the odds of having morbidity incidences. In the SGEE model, VD was statistically significant at the 0.05 level with a positive coefficient indicating children in the VD group had a higher probability of having more morbidity incidences.

CONCLUSIONS: Mothers VD status was positively associated with morbidity incidences which highlight the need for early intervention for women who are diagnosed with it. Care to promote better health for infants during growth, is necessary in order to achieve the MDG's.

PEB0331

MAPPING CORTICAL STRUCTURE AND NEUROCOGNITIVE DEVELOPMENT OF HIV-EXPOSED UNINFECTED CHILDREN IN SOUTH AFRICA: NEUROIMAGING OUTCOMES FROM A SOUTH AFRICAN BIRTH COHORT

C.J. Wedderburn[1,2], S. Yeung[1], S. Subramoney[2], J.P. Fouche[2], S.H. Joshi[3], K.L. Narr[3], A.M. Rehman[1], A. Roos[2,4], D.M. Gibb[5], H.J. Zar[2], D.J. Stein[2], K.A. Donald[2]
[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]University of Cape Town, Cape Town, South Africa, [3]University of California Los Angeles, Los Angeles, United States, [4]Stellenbosch University, Stellenbosch, South Africa, [5]MRC Clinical Trials Unit at University College London, London, United Kingdom

BACKGROUND: There are an estimated 14.8 million HIV-exposed uninfected (HEU) children worldwide. HIV-exposure without infection has been associated with developmental delay, however, the neurobiological mechanisms are not yet understood and neuroimaging studies are lacking. We compared the neuroanatomy of HEU and HIV-unexposed (HU) children aged 2-3 years and investigated associations with neurocognitive development.

METHODS: Children from the Drakenstein Child Health population-based birth cohort study underwent magnetic resonance imaging (MRI). Structural T1-weighted images were acquired on a 3-Tesla Siemens Skyra machine at the Cape Universities Brain Imaging Centre, South Africa. All mothers received HIV testing and antiretroviral therapy (ART) per local guidelines; HIV-exposed children were confirmed uninfected. Acquired structural T1-weighted images were processed using FreeSurfer software. Cortical thickness and surface area were extracted for segmented images bilaterally. Regions-of-interest within the frontal lobe were compared between groups using multivariable linear regression adjusting for child age and sex. Neurocognitive development, assessed using the Bayley Scales of Infant and Toddler Development-III, was correlated with cortical structure.

RESULTS: MRI scans from 162 children (70 HEU, 92 HU) (mean age 34.1 months; 94 [58%] male) were included. HEU children had significantly higher cortical thickness measurements in the medial orbitofrontal cortex (mOFC) bilaterally (left side p=0.04, Cohen's d effect size 0.33 [95% CI 0.02 to 0.64]; right side p=0.02, effect size 0.38 [95% CI 0.06 to 0.69]) and the left frontal pole (p=0.01, effect size 0.41 [95% CI 0.10 to 0.72]) compared to HU children. These results held after correcting for household income, maternal education and maternal age. There were no group differences in cortical surface area. Further analyses revealed HEU children had lower language scores than HU children (p=0.02), and cortical thickness in the mOFC was negatively correlated with language development bilaterally (left mOFC r=-0.30, p=0.02; right mOFC r=-0.35, p=0.008).

CONCLUSIONS: At age 2-3 years HEU children had increased cortical thickness in areas of the prefrontal cortex compared to HU children, which correlated with poorer language outcomes. This suggests that *in utero* HIV/ART exposure may impact neurological development with clinical implications of relevance to care of the growing HEU population.

PEB0332

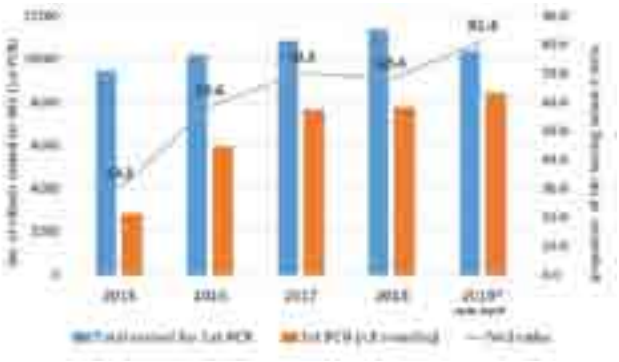
IMPROVEMENT IN TIMELY INFANT HIV TESTING FOLLOWING MONITORING OF ESTIMATED DATE OF DELIVERY (EDD) AND QUALITY REPORTING FOR THE URBAN DISTRICTS OF KAMPALA AND WAKISO, UGANDA

Z. Namukwaya[1], R. Mwondha[1], A. Simwogerere[1], H. Wasswa[1], L. Nakamatte[1], D. Maala[1], C. Ninsiima[1], N. Kalema[1], G.M. Naikazi[2], J. Kigozi[1], A. Muganzi[1], M. Ssuuna[1]
[1]Infectious Diseases Institute (IDI), Makerere University, Outreach, Kampala, Uganda, [2]Mildmay, Medical Services, Kampala, Uganda

BACKGROUND: Timely DNA PCR testing for HIV exposed infants is key to determining the care package for the infants and is associated with better health outcomes. Despite overall improvement in infant HIV testing, early infant diagnosis (EID) within 2 months of birth has remained low at 52% in sub-Saharan Africa, and only 45% in Uganda at the end of 2018. Several interventions were put in place, including monitoring of estimated date of delivery (EDD), and mentoring sites to compile and submit correct and complete reports. We reviewed trends in EID rates from Jan 2015 to September 2019 to assess impact of improved EDD tracking and EID reporting.

METHODS: From March 2017, with support from PEPFAR, the infectious diseases institute (IDI) strengthened EID services at 112 sites in urban Kampala-Wakiso region that included; staff training and mentoring, M&E tools distribution, reporting through the National grid, quarterly performance reviews, and targeted quality improvement projects. From November 2017, IDI strengthened monitoring EDD using the EDD tracker, which is a longitudinal register that enrols pregnant women at ANC1 using their EDD and follows them up through delivery to the time of EID. Clients were followed up with a phone call or home visit as guided by the EDD. EID reports were submitted monthly to the district health information software (DHIS2). We extracted aggregate data for 0-2 month and calculated proportions against total 1st DNA PCR testing and computed trend analysis for proportions using STATA13.

RESULTS: Between Jan 2015 and Sep 2019, there was significant improvement in the proportion of infants testing within 2-months of age, from 30.1% in 2015 to 81.4% by Sept 2019 (pr>chi2 = 0.00).



[Figure. Trends in early infant diagnosis (EID) in the Kampala-Wakiso urban districts of Uganda, Jan 2015-Sep 2019]

CONCLUSIONS: Routine monitoring of EDD, timely program performance reviews and site-specific quality improvement interventions should be scaled up to all sites for improved HEI 0-2 months EID testing and infant outcomes.

PEB0333

HOSPITALIZATION IS ASSOCIATED WITH SEROCONVERSION TO PARAINFLUENZA AND RESPIRATORY SYNCYTIAL VIRUS IN HIV-EXPOSED, UNINFECTED INFANTS BORN IN THE UNITED STATES

C. Smith-Anderson[1], Y. Huo[2], K. Patel[2], K.B. Fetters[3], R. Van Dyke[4], A. Weinberg[1], IMPAACT P1025 and PHACS SMARTT study teams
[1]University of Colorado, Pediatric Infectious Diseases, Aurora, United States, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]University of Colorado, School of Medicine, Aurora, United States, [4]Tulane University, School of Medicine, New Orleans, United States

BACKGROUND: HIV-exposed, uninfected (HEU) infants experience higher rates of morbidity and mortality due to respiratory infections than HIV-unexposed uninfected infants. Very few studies examined the epidemiology of HEU infants' respiratory infections in the United States (US) or other high-income countries. We determined the rate of seroconversion to 6 respiratory viruses and its association with hospitalization in the first year of life among HEU infants born in the US.

METHODS: HEU infants enrolled in International Maternal Pediatric Adolescent AIDS Clinical Trials Group (IMPAACT) P1025 and/or Pediatric HIV/AIDS Cohort Study Surveillance Monitoring for ART Toxicities (PHACS SMARTT) studies with ≥3 blood samples collected at 2, 6, 16, 24 and/or 48 weeks of life were included. Antibodies were measured by quantitative ELISA. Seroconversion was defined as ≥4-fold increase in antibody concentration or a 48-week concentration greater than the upper 95% confidence interval predicted by the maternal antibody decay in serial infant samples, calculated using a mixed effect model. Infants receiving influenza vaccine before seroconversion to influenza A/B were excluded from influenza analyses. A multivariable modified Poisson regression model was fit to evaluate associations of seroconversion to each respiratory virus/family with the risk of hospitalization in the first year of life.

RESULTS: Among 556 HEU, 54% were male, 55% black, 41% Hispanic, 17% preterm, 13% low birth weight, 59% delivered by Cesarean section and 1% breastfed. The incidence of seroconversion per 1000 person-months to respiratory syncytial virus (RSV), influenza A, influenza B, and parainfluenza 1, 2 and/or 3 in the first year of life was 34.2, 38.9, 28.6, and 40.7, respectively. Most seroconversions occurred between 6 and 12 months of age for all viruses. Seroconversion to RSV or parainfluenza increased the risk of hospitalization by >2-fold, while influenza A or B by <1.5-fold (Table).

Respiratory virus	Adjusted relative risk of hospitalization (95% CI)*	p-value
Respiratory Syncytial Virus	2.08 (1.29-3.34)	0.003
Influenza A	1.43 (0.85-2.42)	0.18
Influenza B	1.13 (0.63-2.02)	0.69
Parainfluenza 1, 2 or 3	2.24 (1.40-3.60)	< 0.001
* Model adjusted for sex, race, ethnicity, preterm birth, low birth weight, and mode of delivery		

[Table: Association of respiratory viral infections with hospitalization in the first year of life]

CONCLUSIONS: Among HEU infants born in the US, RSV and parainfluenza infections likely contribute to hospitalization in the first year of life.

PEB0334

DOUBLE TROUBLE: INCREASED RISK OF CONGENITAL CYTOMEGALOVIRUS INFECTION AMONG HIV-EXPOSED NEWBORNS

H. Hyde de Souza[1], I. Boucoiran[2], S. Valois[3], S. Taillefer[3], M. Boucher[2], H. Soudeyns[4], C. Renaud[4], V. Lamarre[5], F. Kakkar[5,3]
[1]University of Montreal, Medicine, Montreal, Canada, [2]University of Montreal, Sainte-Justine Hospital Center, Obstetrics and Gynecology, Montreal, Canada, [3]Centre de Recherche CHU Sainte-Justine, Centre d'Infectiologie Mère-Enfant, Montreal, Canada, [4]University of Montreal, Microbiology, infectious diseeases and immunology, Montreal, Canada, [5]University of Montreal, Sainte-Justine Hospital Center, Pediatrics, Montreal, Canada

BACKGROUND: Congenital cytomegalovirus infection (cCMV) is the leading cause of a treatable congenital infection worldwide. While maternal immunosuppression is a risk factor for transmission, there are currently no recommendations for screening of all infants born to women living with HIV in pregnancy for cCMV. The objective of this study was to examine the association between in utero HIV exposure and the risk of cCMV infection.
METHODS: Between April 1 2014 and March 31st 2018, all HIV exposed infants born at CHU Sainte-Justine Hospital (Montreal, Quebec) were screened for cCMV (birth-3 days of age) by saliva or urine culture, or PCR. All positive screens were confirmed by urine CMV PCR. In parallel, a targeted screening program for cCMV was implemented hospital-wide for all infants who failed their newborn hearing test. The incidence of cCMV infection between the two groups was compared.
RESULTS: During the study period, 156 children were born to women living with HIV. The majority of women (91%) had an undetectable viral load (VL) at the time of delivery, and 81% had a delivery CD4 count >350 cells/mm3. There was only one case of perinatal HIV transmission. 127 (81.4%) of the newborns were successfully screened for cCMV, and 3 (2.36%) were confirmed positive; all 3 were subsequently confirmed HIV uninfected. Only 1 of the 3 had symptomatic cCMV infection and required antiviral treatment for cCMV, in addition to antiretroviral prophylaxis for HIV. All 3 cases of cCMV were born to mothers who were CMV IgG positive and IgM negative at the onset of pregnancy; only one was born to a mother with severe immunosuppression (CD4 count <200 cells/mm3). During the same period, 484 newborns were screened for cCMV due to a failed hearing test, and only 3 (0.62%) were confirmed positive.
CONCLUSIONS: The incidence of cCMV among HEU infants was >3-fold higher than among healthy newborn infants targeted for screening due to failed hearing test, and 4-fold higher than general North American population estimates (0.5%). In the absence of universal screening, these results suggest that that where treatment is available, all HIV exposed infants should be screened for cCMV infection.

PEB0335

RISK FACTORS FOR SMALL FOR GESTATIONAL AGE AND MICROCEPHALY AMONG HIV EXPOSED UNINFECTED INFANTS IN MONTREAL, CANADA

L.-K. Tremblay[1], S. Taillefer[2], S. Valois[2], C. Renaud[3], M. Boucher[4], V. Lamarre[5], H. Soudeyns[3], I. Boucoiran[4,2], F. Kakkar[5,2]
[1]University of Montreal, Medicine, Montreal, Canada, [2]Centre de Recherche CHU Sainte-Justine, Centre d'Infectiologie Mère-Enfant, Montreal, Canada, [3]University of Montreal, Microbiology, Infectious Diseases and Immunology, Montreal, Canada, [4]University of Montreal, Sainte-Justine Hospital Center, Obstetrics and Gynecology, Montreal, Canada, [5]University of Montreal, Sainte-Justine Hospital Center, Pediatrics, Montreal, Canada

BACKGROUND: Children who were HIV exposed but uninfected (HEU) are at increased risk of morbidity and mortality as compared to unexposed controls. Potential risk factors include aberrant *in utero* growth due to maternal HIV infection and/or antiretroviral (ARV) drug exposure. The objective of this study was to determine the incidence and risk factors for small for gestational age (SGA), microcephaly and macrocephaly among a cohort of HEU newborns in Canada.
METHODS: Newborn birth weight (BW), length, and head circumference (HC) were assessed for children born to women living with HIV from the Centre Maternel et Infantil sur le SIDA cohort (CHU Sainte-Justine, Montreal, Quebec) between 1988-2016, for whom linkage to the provincial health administrative database could be done. Data were analyzed using published Intergrowth21 standards, with reported Z scores and percentiles adjusted for gestational age and neonatal sex.
RESULTS: 724 newborns were included in the analysis. Median BW Z score was 0.21 (IQR -0.50-0.90), HC 0.84 (IQR: -0.01-1.56), length 0.22 (IQR -0.50-0.90). Overall, 13% of newborns were preterm (gestational age <37 weeks), 11% were SGA (BW <10th percentile), 2.3% had microcephaly (HC <3rd percentile), and 15.9% macrocephaly (HC>97th percentile). None of the infants with microcepahly or macrocephaly were born to mothers treated with efavirenz or dolutegravir during pregnancy. On univariate analysis, the only significant risk factors for SGA from among maternal age, race, treatment type, delivery CD4 count (dCD4) and viral load (dVL) were maternal dCD4 (*B*:-0.01, p=0.01) and race (*B*:-4.5, p 0.02), both of which remained significant after adjusting for maternal age, treatment type and dVL. Infants born to mothers of African origin had significantly higher birth Z scores than those of Haitian origin (0.274 vs. -0.04, p=0.002). Maternal dCD4 was the only a significant predictor of HC at birth (*B*:-0.01, p=0.016), though it had no impact on infant birth length (*B*=0.003, p=0.14).
CONCLUSIONS: In this cohort, maternal immunosuppression was identified as a potential risk factor for SGA and microcephaly among HEU newborns. Further work needs to be done to assess the long-term health impacts of these extremes of growth.

TRANSITION OF ADOLESCENTS INTO ADULT CARE

PEB0336

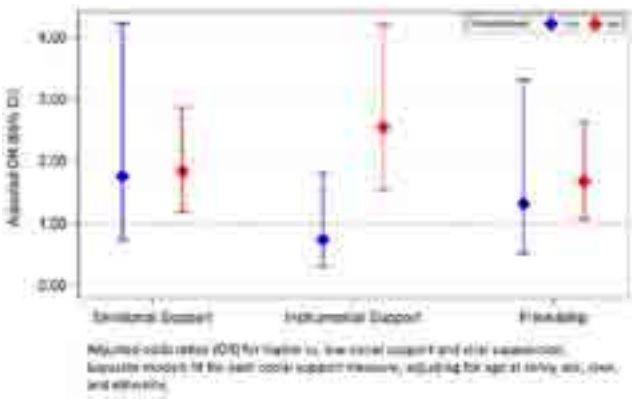
SOCIAL SUPPORT AND VIRAL SUPPRESSION IN YOUNG ADULTS WITH PERINATALLY-ACQUIRED HIV IN THE UNITED STATES

K. Tassiopoulos[1], Y. Huo[2], D. Kacanek[2], K. Malee[3], S. Kohlhoff[4], S. Nichols[5], C. Mellins[6], R. Van Dyke[7], G.R. Seage III[1], Pediatric HIV/AIDS Cohort Study
[1]Harvard T. H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [2]Harvard T. H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Chicago, United States, [4]SUNY Downstate Health Sciences University, Division of Infectious Diseases, Brooklyn, United States, [5]University of California, San Diego, Department of Neurosciences, San Diego, United States, [6]Columbia University Medical Center, HIV Center for Clinical and Behavioral Studies, New York, United States, [7]Tulane University School of Medicine, Department of Pediatrics, New Orleans, United States

BACKGROUND: Few studies have examined the relationship of social support to health outcomes among young adults living with HIV, including perinatally-acquired HIV (YAPHIV). As YAPHIV become less reliant on others, we need to identify modifiable factors such as social support that can enhance sustained viral suppression and health care independence. We examined the relationship of social support to viral suppression among YAPHIV, and the potential modifying role of transition to adult care.

METHODS: Participants included YAPHIV ≥18 years in the Pediatric HIV/AIDS Cohort Study AMP Up cohort. We assessed friendship, emotional and instrumental support using the NIH Toolbox. Viral load (VL) and transition status (pediatric vs adult care) were obtained through chart review. Participants with social support assessed at study entry and ≥1 VL over the next year were included; year 3 social support and subsequent VL were included if available. Low social support was T-score <40 and average/higher ≥40. Viral suppression (VS) was all VL <50 copies/ml. We fit logistic regression models using generalized estimating equations and evaluated transition as an effect modifier with interaction terms.

RESULTS: Among 409 YAPHIV (64% female; 71% Black, 26% Hispanic; median age 21.2 years, 23% transitioned to adult care); 33%, 29% and 31% reported low emotional, instrumental and friendship support, respectively. Forty-three percent were suppressed in the year post-entry; 47% of those with year 3 data were suppressed over the subsequent year.



[Figure. Association of social support with viral suppression, by transition status.]

In multivariable models, higher friendship (odds ratio [OR]=1.62, 95% confidence interval [CI]=1.08,2.42), emotional (OR=1.84, 95% CI=1.24,2.73), and instrumental support (OR=2.03, 95% CI=1.32,3.10) were associated with higher odds of VS. Transition status modified the relationship of instrumental support, with a strong association for those in pediatric but not adult care (interaction p-value=0.02) (Figure.)

CONCLUSIONS: Enhancing social support may promote viral suppression in YAPHIV approaching independence.

PEB0337

VIROLOGICAL OUTCOME AMONG VERTICALLY HIV INFECTED PATIENTS TRANSFERRED FROM PEDIATRIC CARE TO ADULT UNITS IN MADRID

C. Beltrán-Pavez[1], M. Gutiérrez-López[1], M. Rubio-Garrido[1], A. Valadés-Alcaraz[1], L. Prieto[2], J.T. Ramos[3], S. Jimenez De Ory[4], M. Navarro[4], C. Diez-Romero[5], F. Pulido[6], E. Valencia[7], Á. Holguín[1], Madrid Cohort of HIV-Infected Children integrated in the Pediatric Branch of the Spanish National AIDS Network (CoRISpe)
[1]Hospital Ramón y Cajal - IRYCIS, Microbiology and Parasitology, Madrid, Spain, [2]Hospital 12 de Octubre, Infectious Diseases, Madrid, Spain, [3]Hospital Clínico Universitario, Infectious Diseases, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, Pediatrics, Madrid, Spain, [5]Hospital Gregorio Marañón, Infectious Diseases, Madrid, Spain, [6]Hospital 12 de Octubre, HIV Unit, Madrid, Spain, [7]Hospital Universitario La Paz, Internal Medicine Service, Madrid, Spain

BACKGROUND: High numbers of perinatally HIV-infected children are reaching adulthood and are transferred to adult care units. However, little is known about the virological status of this population after transfer. This study aims to describe the virological and immunological features by December 2017 of HIV-infected youths transferred from pediatric to adult units since 1997 vs. the non-transferred patients from the Madrid Cohort of HIV infected children and adolescents in Spain.

METHODS: This retrospective observational study included 290 individuals of the cohort under clinical follow up in 17 hospitals in Madrid by the end of December 2017. Virological and immunological outcomes were compared in transferred vs. non-transferred patients. ART drug resistance mutations and HIV-variants were analyzed in all subjects with available pol sequences and/or genotypic resistance profiles.

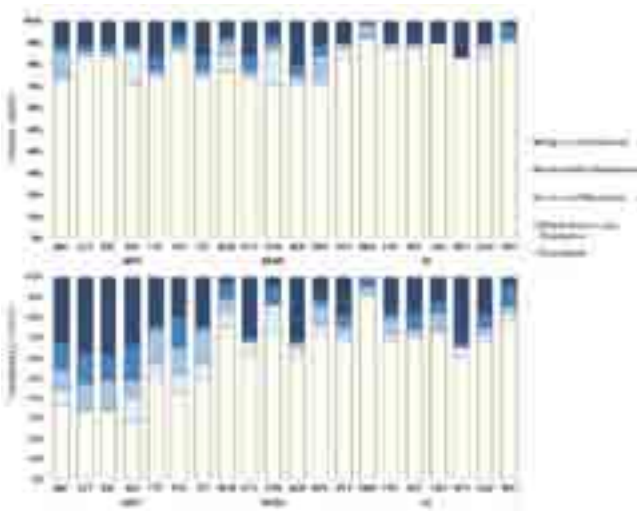


Figure 1. Predicted susceptibility-level to ARV drugs in pretreated patients of the study cohort

RESULTS: Among the study cohort, 133 (72.3%) transferred and 75 (70.7%) children had available resistance genotypes. Most (87.9%) of these 133 transferred had ART experience at sampling, CD4 T

cell >500 cells/mm3 (74%), and undetectable viremia (65%). A third (33.3%) had had a triple-class experience. Although TDR rate was similar among naïve children and transferred (35% vs. 19%; p=0.28), DRM prevalence was significantly higher in pretreated transferred (75.2% vs. 52%; p=0.006), mainly to nucleoside analogs retrotranscriptase inhibitors (66.7% vs. 28%; p<0.0001) and protease inhibitors (31.6% vs. 16%; p=0.0384). HIV-1 non-B variants were less frequent in transferred (6.9% vs. 32%; p<0.0001).

CONCLUSIONS: The most effective current ART regimens allow keeping pediatric patients better controlled than in previous years. Consequently, they will be transferred in the future with a better immune situation and virological control, which will control DRM selection. The frequent historic-resistant genotypes found in transferred youths justifies the reinforcement of HIV resistance monitoring and adherence support after the transition to avoid future therapeutic failures.

PEB0338

THE PATIENT-PROVIDER RELATIONSHIP AND TRANSITION FROM ADOLESCENT TO ADULT FOCUSED HIV CARE: AN INTERNATIONAL QUALITATIVE METASYNTHESIS

E. Barr[1], J. Jones[2], J.L. Raybin[3], L. Abuogi[4], H. Dunlevy[5]
[1]University of Colorado Children's Hospital Colorado, Pediatric Infectious Diseases, Aurora, United States, [2]University of Colorado, College of Nursing, Aurora, United States, [3]University of Colorado Children's Hospital Colorado, Pediatric Palliative Care, Aurora, United States, [4]University of Colorado Children's Hospital Colorado, Center for Global Health, Aurora, United States, [5]University of Colorado, Adult Infectious Diseases, Aurora, United States

BACKGROUND: Approximately 5 million adolescents (ages 15-24) are living with HIV (ALHIV) globally, most of whom will transition to adult HIV care in the next 10 years. Yet, only 40-50% of ALHIV are still engaging in health care 12 months post-transition imperiling long-term individual and public health outcomes. Successful transition may be significantly impacted by the patient-provider relationship. The purpose of this metasynthesis is to explore the effect the patient-provider relationship has on ALHIV transition and to describe strategies extracted from the review to support the development of trusting relationships to promote engagement and retention in care.

METHODS: A review of qualitative studies from PubMed, CINAHL and EBSCO, published between January 2008 and December 2019 was performed using search terms related to HIV, adolescence, and transition to adult care. Inclusion criteria included English-language studies focused on ALHIV and providers. After quality extraction, text data were analyzed using nurse-led, team-based thematic synthesis techniques and international standards.

RESULTS: Fourteen articles with 462 individual participants from 8 countries (including Australia, Brazil, Dominican Republic, India, Jamaica, Puerto Rico, Tanzania, and the United States) met criteria for inclusion. Collectively, four themes around the patient-provider relationship emerged: The familial nature of the patient-provider relationship, stigma as a bond in current provider relationship and a barrier to establishing new ones, the importance of the provider knowing the patient and the patient getting to know the new provider, and capturing the desire for autonomy to support a successful transition. Resulting recommendations to support transition are included in table 1.

Recommendations	Steps to Build a Successful Transition
Develop a Transition Plan	• Establish a stepwise transition model • Develop an individualized plan considering unique developmental and cognitive characteristics • Incorporate family into the transition plan
Prepare the Patient and the Providers	• Educate the adult care provider on adolescent development, building trust, cognitive challenges, the care of children growing up with chronic conditions, caring for patients with trauma histories and providing empathetic care • Establish healthy expectations around transition and provide information to decrease fears and build trust • Create a safe space for transitioning adolescents, including the waiting area and clinic space • Begin the transition process, including education and preparation, earlier • Develop a class focused on creating trusted relationships with health care teams including capacity building: How to share health history, make appointments, and refill prescriptions
Build and Honor Trusting Relationships	• Provide a graduation to mark the culmination of all of the years they have been in care and honor the patient-provider relationship • Transition patients in a group or cohort while providing peer support • Establish excellent reciprocal communication between pediatric and adult care providers throughout the process • Introduce the adult care provider while still in the pediatric clinic • Have a pediatric provider attend the adult care clinic appointment with the ALHIV • Assess engagement in care post transition by evaluating the patient provider relationship and, if necessary, loop the pediatric provider back into care for follow up and support

[Table 1.]

CONCLUSIONS: The patient-provider relationship is an integral part of the transition process, and yet is often neglected in current transition protocols. When planning for transition, it is crucial to look at strategies that develop a strong collaborative connection with new providers to further support patient autonomy and independence, decrease stigma, and facilitate trust and relationship building.

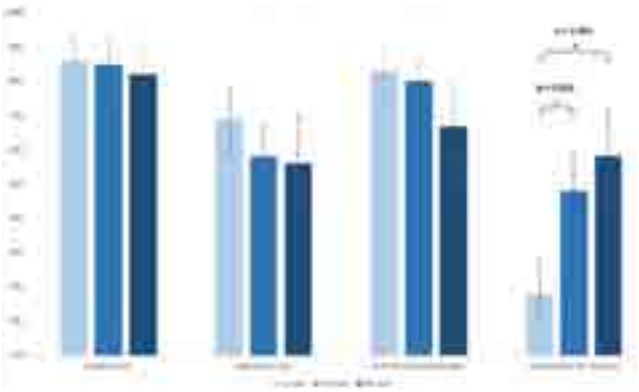
PEB0339

SUSTAINABILITY OF THE HIV CARE CASCADE AMONG ADOLESCENTS AND YOUNG ADULTS TRANSITIONING TO ADULT HIV CARE

A.C. Freitas[1], M.B. Antonio[1], A.N. Lara[1], V.I. Avelino-Silva[1]
[1]Universidade de São Paulo/ Hospital das Clinicas HCFMUSP, Departamento de Doenças Infecciosas e Parasitárias, São Paulo, Brazil

BACKGROUND: Transition to adult care is often associated with laboratory and clinical deterioration among adolescents/young adults living with HIV (AYLH) since early childhood. Few studies present a longitudinal assessment of the HIV care continuum among AYLH after transition to adult care.

METHODS: AYLH referred to the adult outpatient clinic at University of Sao Paulo between January/2001 and December/2019 were included in this retrospective cohort. All participants had ≥1 visit in the adult care facility. Percentages and 95% confidence intervals of AYLH with linkage (having ≥1 viral load [VL] measurement), retention (having ≥2 VL measurements), antiretroviral dispensation (obtained from pharmacy records) and undetectable VL (<40 copies/mL) were retrieved for the 1st, 2nd and 5th years after admission to adult care.
RESULTS: 108 AYLH were included in the study. Median age at transition was 19 years old (range 15-22); 57 (53%) were females, and most (70%) were white/Caucasian. Figure 1 shows the main findings for the HIV care continuum; overall, linkage, retention and antiretroviral use were below desirable levels, while the percentage of AYLH with undetectable VL was very low (18%, 95% CI 11-27%) in the first year after admission to adult care. In the 2nd and 5th years after transition, although the percentages of AYLH with linkage, retention or antiretroviral use did not change substantially, the percentage with undetectable VL increased significantly (p<0.001). Yet, only 69% of AYLH had undetectable HIV VL in the 5th year after admission to adult care.



[Figure 1. Linkage, retention, antiretroviral dispensation and viral suppression among adolescents/young adults living with HIV after admission to adult care]

CONCLUSIONS: Our study shows that indicators of the HIV care continuum are poor among AYLH admitted to adult care and change little in the 2nd and 5th years after transition. While rates of undetectable VL increase after the first year in adult care, promoting linkage, retention and antiretroviral use could further improve optimal viral suppression in this vulnerable population.

PEB0340

WORSE VIROLOGICAL RESPONSE AND DEFICIENT IMMUNOLOGICAL RECOVERY IN YOUNG ADULTS WITH VERTICAL TRANSMISSION OF HIV AFTER TRANSITION TO ADULT CARE

A. Celotti[1], S. Calza[2], A. Di Biagio[3], C. Mussini[4], S. Rusconi[5], S. Bonora[6], S. Di Giambenedetto[7], E. Quiros-Roldan[1], G. Sarteschi[3], M. Menozzi[4], M. Ferrara[6], A. Ciccullo[8], V. Giacomet[9], A. Ferrari[10], R. Badolato[10], I. Izzo[1], F. Castelli[1], E. Focà[1]

Sacco" Hospital, Unit of Infectious Diseases, Milan, Italy, [6]University of Torino and "Amedeo di Savoia" Hospital, Department of Infectious Diseases, Turin, Italy, [7]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Infectious Diseases Unit, Rome, Italy, [8]Catholic University of the Sacred Heart, Department of Safety and Bioethics, Section of Infectious Diseases, Rome, Italy, [9]University of Milano and ASST Fatebenefratelli "L. Sacco" Hospital, Unit of Pediatrics, Milan, Italy, [10]University of Brescia and ASST Spedali Civili Hospital, Unit of Pediatrics, Brescia, Italy

BACKGROUND: Introduction of cART determined an increase of living young adults with vertical transmission (VT) of HIV. This study evaluates long-term efficacy of cART in VT HIV-1 infected adults and factors associated with viro-immunological outcome.
METHODS: Multicenter study including HIV-1 infected subjects with VT ≥18 years old from six large Italian clinics. Subjects were observed from birth to death, lost to follow up or last visit until June 30th 2019. Demographical, clinical, viro-immunological and therapeutical data were collected. Categorical and continuous variables were analyzed; durability and reasons of cART discontinuation were modeled using Cox model for recurrent events. A p-value of <0.05 was considered statistically significant.
RESULTS: 126 subjects were enrolled, 70 females and 56 males, with a median age of 27.8 ± 4.4 years. Most of subjects (84.1%) were born before the introduction of cART in 1996. 15.1% of subjects was lost to follow up, while 2.4% died. Median follow period (since patients were followed in the adult care) was 12.7 ±10.1 years. At 18 years of age, 52/126 (44.4%) subjects had HIV-RNA >50 cp/ml, 47/126 (38.2%) had CD4+ <500/mm3 and 78/126 (67.2%) a CD4+/CD8+ ratio <1. At least one major mutation for NRTI, NNRTI, PI and InSTI was present in 44.3%, 34.3%, 22.9% and 1.4% respectively. At least a single AIDS event was observed in 26.9% of the subjects, while 51.6% had at least one comorbidity. Average number of cART regimen for each patient was 5.6 (1-24) with a median durability of 126.14 ±79.91 weeks. Reasons for cART discontinuation were failure, toxicity, simplification, non-compliance or other causes in 29.6%, 15.4%, 20.3%, 12.6% e 9.7% respectively. HIV-RNA < 50 cp/ml, CD4+ >500/mm3 and CD4+/CD8+ ≥1 were protective factors for cART discontinuation, with HR 0.52 (95% CI 0.39-0.70, p<0.001), 0.66 (0.50-0.86, p=0.003) and 0.61 (0.46-0.81, p=0.003) respectively.
CONCLUSIONS: Our study shows that the subjects with VT of HIV reached the adult age with unsuppressed HIV-RNA, low CD4+ and reduced CD4+/CD8+ ratio in a significant proportion. More efforts are needed in the management of this difficult-to-treat special population displaying at young age a typical profile of heavily cART-experienced and elderly patients.

CLINICAL ISSUES IN MEN WHO HAVE SEX WITH MEN

PEB0341

ENDING THE HIV EPIDEMIC: RAPID ART START AT THE DETROIT STD CLINIC

S. Heisler[1], J. Cohn[2], D. Lukomski[3], K. Tuinier[3]
[1]Wayne State University/Detroit Public Health STD Clinic, Detroit, United States, [2]Wayne State University, Infectious Disease, Detroit, United States, [3]Michigan Department of Health and Human Services, Lansing, United States

BACKGROUND: Wayne County/Detroit in Michigan is a geographic focus area in the national campaign Ending the HIV Epidemic (EtE). Among the EtE pillars are rapid starts of antiretroviral therapy (ARV) for newly diagnosed persons and achieving sustained high levels of virologic suppression on therapy. Our objective was to evaluate the rate of viral suppression and retention in care with a Rapid Start ARV Protocol implemented in a municipal clinic for sexually transmitted diseases (STD) with a high rate of new HIV diagnoses.

METHODS: All patients at the Detroit Public Health STD Clinic seen for new episodes of STD screening, exposure or treatment were offered HIV Ag/Ab testing with approximately 80% acceptance. The Rapid Start ART Protocol was initiated for all patients on the day of HIV diagnosis or the day of initial presentation at the STD clinic. Baseline lab testing was drawn and ARV was provided that day or within a 5 day period. Patients were scheduled for follow-up with the same provider at 1 week and at 1 month to reinforce adherence and perform lab testing. We report retention and viral suppression at ≥1 month.

RESULTS: HIV was newly diagnosed in 56 clinic clients between August 2018- December 2019. Among them, 82% were cis-male, 14% were cis-female and 4% were transwomen; 86% were under the age of 35; 73% were men having sex with men (MSM), and 62% were black MSM under the age of 35. 11 patients younger than 22 years were transferred to our youth HIV clinic; 8 requested follow up at another clinic; 4 had less than one month of participation to date; 1 had HIV VL <200 at baseline. Among the 32 with at least one month of follow up, 28/32 (88%) are virally suppressed (HIV VL < 200) and 23/32 (72%) patients retained in care.

CONCLUSIONS: Rapid ARV start in the STD clinic and close follow-up with same provider leads to high rates of retention in care and viral suppression. This rapid intensive program appears to be an effective approach in an urban setting with a high rate of new HIV diagnosis, predominantly of young black MSM.

PEB0342

OFFER OF A TRIPLE RAPID HIV/HBV/HCV TESTING TO THREE EXPOSED POPULATIONS, INCLUDING MSM, IN DISTINCT COMMUNITY-HEALTHCARE CENTRES IN PARIS AREA (ANRS-SHS-154-CUBE STUDY)

N. Derche[1,2], R. Calin[3,4], V. Massari[5], M. Jauffret-Roustide[6], E. Plenel[1,2], C. Chauvin[2,5], N. Day[7], G. Kreplak[7], A. Maresca[8], P. Chauvin[9], S. Pol[10], S. Louis[11], V. Doré[12], C. Rouzioux[2,1,13], G. Pialoux[3,14]

BACKGROUND: Paris area represents 3,3% of the national population, but 16% of new estimated HIV infections among exposed groups such as men who have sex with men (MSM), people who inject drugs (PWIDs), transgender (TG) and sex workers (SW). The objective of the ANRS-CUBE study was to evaluate the acceptability of a healthcare, community-based strategy offering a triple rapid HIV-HBV-HCV testing, associated to HBV vaccination. The target was three priority groups (MSM, PWIDs and TG/SWs), in three community centers, in Paris area.

METHODS: This longitudinal multicentric non-randomized study included all consenting adults attending one of the centers, between July 2014 and December 2015. Rapid tests for HIV, HBV and HCV were proposed and HBV vaccination, when needed.

RESULTS: A total of 3662 people, (3510 MSM, 80 PWIDs and 72 TG/SW) were recruited in one of the three centers. Acceptability of rapid tests was 98.5% in MSM while only 14.9% in TG/SWs (83.3% had already been tested for HIV), but could not be estimated in PWIDs. Users acceptability of HBV vaccination was weak : only 17.9% of the eligible MSM (neither vaccinated, nor infected) agreed to receive the first dose, 12.2% two doses, 5.9% had a complete vaccination. Users acceptability of HBV vaccination was greater in PWIDs and TG/SWs, but decreased for the last doses (66.7% and 53.3% respectively received a first dose, 24.4% and 26.7% a second dose and 6.7% and 0% a third dose). Fifty-three participants (49 MSM and 4 PWIDs) were discovered HIV positive, more than half with a recent infection. All but two HIV positive participants received appropriate care and antiretroviral therapy within a month.

CONCLUSIONS: Among MSM, rapid HIV-HCV-HBV testing showed a very high level of acceptability, while acceptability for HBV vaccination and triple injections compliance were weak. Our study highlights the deficit of HCV previous screening in MSM (38.4%), suggesting a need for more information on the risk of viral hepatitis. Our results show that frequent HIV testing is not yet in the practices of transgenders. Lastly, we confirm the important role of community centers in reaching key populations including those that combine vulnerabilities.

PEB0343

YOUTH VULNERABLE TO DELAYED ART INITIATION IN A COHORT OF MSM IN HANOI, VIETNAM

R. Bhatia[1], T.T. Truc[2], L.B. Ngoc[3], T.T. Hieu[3], H.T.H. Van[3], B.T.M. Hao[3], L.M. Giang[3]
[1]CDC, Hanoi, Vietnam, [2]University of Medicine and Pharmacy, Ho Chi Minh City, Vietnam, [3]Hanoi Medical University, Hanoi, Vietnam

BACKGROUND: WHO recommends rapid ART initiation. Little is known about ART initiation in MSM in Hanoi. Health in Men (HIM)-Hanoi was an observational cohort of 1893 MSM in Hanoi aged ≥16, conducted from 2017-2019 in an academic sexual health clinic setting. Participants were provided biannual HIV testing, and confirmed positive clients were linked to off-site ART clinics using case management. We report time to ART initiation and associations with rapid ART.

METHODS: We conducted a review of cases newly diagnosed on or after enrollment who had linked to ART and had complete ART clinic records containing date of ART initiation. Chi-squared test or Fisher's exact test were used to determine associations between demographic and behavioral characteristics at enrollment and rapid ART (within seven days of receiving HIV confirmation).

RESULTS: Of 152 newly diagnosed cases, 128 met the study criteria. Median age was 23 (IQR 20-27), and most were employed (118/128, 92%). In the last month, most had two or more sex partners (53/68, 74%) and reported at least two anal sex acts (80/102, 78%); almost half reported inconsistent/condomless sex during the last sex act (56/114, 46%). All accepted case management; median time to ART initiation was 6.5 days (IQR 1-19), with only 11 (8.5%) receiving same-day ART. Overall, 57% (73/128) initiated rapid ART, with 43% (55/128) delaying ART past seven days. Those aged 16-24 years were significantly less likely to initiate rapid ART compared to those aged 25 and above (42/84, 50%, vs 31/44, 70%; p=0.026).

CONCLUSIONS: Nearly half of newly diagnosed MSM in HIM-Hanoi did not initiate rapid ART, a finding which was associated with youth and occurred despite the use of case management, a service which is not routinely offered in other HIV testing centers in Vietnam. Most newly diagnosed MSM reported recent HIV risk behavior associated with sexual HIV transmission, underscoring the need for rapid ART and viral suppression. HIV testing facilities that do not provide ART must develop strategies to improve rapid ART initiation especially for young MSM. Further studies are needed to explore barriers to rapid ART initiation that are not overcome with case management among MSM.

PEB0344

SYPHILIS PREVALENCE AND INCIDENCE AMONG HIV NEGATIVE MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN IN BUENOS AIRES, ARGENTINA

L. Spadaccini[1], C. Frola[1], M.I. Figueroa[1], P. Patterson[1], C. Cesar[1], M. Gismondi[1], C. Perez[1], V. Fink[1], V. Zalazar[1], E. Dell´Isola[1], P. Cahn[1], O. Sued[1]
[1]Fundacion Huesped, Caba, Argentina

BACKGROUND: Syphilis is an important public health problem worldwide; in Argentina the rate of syphilis has increased in recent years, reaching 52.1 people per 100,000 inhabitants in the last year. The objective of this study was to evaluate the prevalence and incidence of syphilis among HIV negative men who have sex with men (MSM) and transgender women (TGW) in order to inform PrEP programs.

METHODS: We conducted a retrospective cohort analysis that included all the syphilis results performed among HIV negative MSMs and TGWs at substantial risk of HIV infection defined as any of the following situations in the last 6 months: >5 sexual partners, anal unprotected sex, use of drugs, sexually transmitted infections (STIs) or transactional sex between March 2018-December 2019. Diagnosis of syphilis was made by the combination of nontreponemal tests (venereal disease research laboratory,VDRL) and treponemal tests (fluorescent treponemal antibody absorption, FTA-ABS or Syphilis rapid tests, Determine or SD-Bioline) using both, the standard and the reverse algorithms. PCR in ulcers were performed if available.

RESULTS: 276 participants (166 MSMs and 110 TGWs) were included. Median age was 32.8 years among MSMs and 28.1 years among TGWs. At baseline 12 MSMs and 28 TGWs had serology compatible with untreated syphilis (prevalence 14.5 (95%CI 10.8-19.1) with 7.2% (95%CI 4.1-12.2) among MSMs and 25.45% (95%CI 18.2-34.3) among TGWs. During follow-up, MSMs provided 135.4 person-years of follow-up (PYFU) and 19 new syphilis cases, while TGWs provided 22.9 PYFU and 10 incidental syphilis, estimating an incidence of 14 and 43 cases/100-PYFU among MSM and TGWs, respectively. Only 1/3 of TGWs had follow-up.

CONCLUSIONS: HIV negative high-risk MSMs and TGWs in Argentina have an extremely high prevalence and incidence of syphilis, highlighting the importance of periodically perform STIs test among this population. Innovative approaches are required to increase retention among TGWs. PrEP programs might an opportunity to prevent, diagnose and treat other STIs.

CLINICAL ISSUES IN TRANSGENDER PEOPLE

PEB0346

PREVALENCE AND INDEPENDENT RISK FACTORS OF HIV AND SYPHILIS INFECTIONS AMONG THAI TRANSGENDER WOMEN WHO HAVE UNDERGONE VAGINOPLASTY PROCEDURES

W. Ratanalert[1], R. Janamnuaysook[1], K. Samitpol[1], P. Getwongsa[1], A. Chancham[1], J. Kongkapan[1], T. Amatsombat[1], J. Rueannak[1], P. Srimanus[1], L. Himma[1], O. Nampaisan[1], J. Peelay[1], R. Sungsongkiat[1], M. Avery[2], S. Mills[2], R. Vannakit[3], P. Suwajo[4], P. Phanuphak[1], R. Ramautarsing[1], N. Phanuphak[1]
[1]PREVENTION, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]FHI 360, LINKAGES Thailand, Bangkok, Thailand, [3]Office of Public Health, USAID Regional Development Mission Asia, Bangkok, Thailand, [4]Plastic and Reconstructive Surgery Unit, Department of Surgery, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

BACKGROUND: Transgender women (TGW) are among the key populations that are most vulnerable to HIV and sexually transmitted infections (STI). Most healthcare services are not tailored to the unique health needs, especially after gender-affirming surgery. Globally, the number of TGW who have undergone vaginoplasty procedures has increased; however, we know very little about the correlation of HIV and STI acquisition and vaginoplasty among TGW.

METHODS: We conducted a retrospective analysis of demographic data, history of vaginoplasty procedures, and sexual risk behaviors from a cohort study of TGW clients from Tangerine Community Health Clinic in Bangkok, Thailand. The prevalence of HIV and syphilis infections were calculated. Logistic regression analysis was performed to characterize the risk of each independent factor as-

sociated with both infections. Outcome measures were compared between TGW who have undergone vaginoplasty and those who have not.

RESULTS: Among 2,926 TGW who attended the clinic from November 2015 to September 2019, 20.3% underwent vaginoplasty. The overall prevalence of HIV-positive status and syphilis were 9 and 8 percent, respectively. History of undergoing vaginoplasty was associated with higher risks of both infections (odds ratio: 5.45 for HIV (P <0.001) and 4.47 for syphilis (P <0.001)). Comparing TGW who have and have not undergone vaginoplasty, 42.6% reported neovaginal sex practice after surgery; and 21.1% still had receptive anal intercourse (versus 50.7% in the latter group). Receptive neovaginal intercourse was shown to be a protective factor of HIV infection (risk reduction ratio (RRR) = 0.08, P <0.001) and syphilis infection (RRR = 0.23, P = 0.004). Multiple logistic regressions showed that receptive anal intercourse, multiple sex partners, engagement in sex work, education below bachelor's degree, and unemployment were all independently associated with either HIV or syphilis infections.

CONCLUSIONS: Receptive neovaginal intercourse is associated with lower odds of HIV and syphilis infections in TGW; on the contrary, undergoing vaginoplasty was associated with higher risks of both infections. Common vulnerable sociodemographic and behavioral risk characteristics also contributed to HIV and STI susceptibility among TGW; therefore, TGW undergoing vaginoplasty need to understand their HIV risks and be offered HIV testing, ART, and PrEP services by providers trained in gender-sensitive care.

CLINICAL ISSUES IN PEOPLE WHO USE DRUGS

PEB0347

ILLICIT OPIOID USE FOLLOWING CHANGES IN OPIOIDS PRESCRIBED FOR CHRONIC NON-CANCER PAIN AMONG PERSONS LIVING WITH AND WITHOUT HIV

P. Coffin[1], C. Rowe[1], N. Oman[1], K. Sinchek[1], G.-M. Santos[1], M. Faul[2], R. Bagnulo[1], D. Mohamed[1], E. Vittinghoff[3]
[1]San Francisco Department of Public Health, Center on Substance Use and Health, San Francisoc, United States, [2]Centers for Disease Control and Prevention, Injury Prevention, Atlanta, United States, [3]University of California San Francisco, Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: After decades of increased opioid pain reliever (OPR) prescribing in the U.S., and utilizing OPRs as quasi-palliative care for persons living with HIV (PLWH), providers are rapidly reducing prescribing. We hypothesized that reduced access to prescribed OPRs would result in increased illicit opioid use among those previously reliant upon OPRs.

METHODS: We conducted a retrospective cohort study among 602 publicly-insured primary care patients who had been prescribed OPRs for chronic non-cancer pain for at least three consecutive months in San Francisco. A historical reconstruction interview and medical chart abstraction focused on illicit substance use and opioid pain reliever prescriptions, respectively, were conducted from 2012 through 2018. We used a nested-cohort design, in which patients were classified, based on OPR dose change, into a series of nested cohorts starting with each follow-up quarter. Using continuation-ratio models, we estimated associations between OPR prescription discontinuation or 30% increase or decrease in dose, relative to no change, and subsequent frequency of heroin and non-prescribed OPR use, separately. Models controlled for demographics, clinical and behavioral characteristics, and past use of heroin or non-prescribed OPRs.

RESULTS: A total of 56,372 and 56,484 participant-quarter observations were included from the 597 and 598 participants available for analyses of heroin and non-prescribed OPR outcomes, respectively. Participants discontinued from prescribed OPRs were more likely to use heroin (Adjusted Odds Ratio (AOR)=1.57, 95% CI: 1.25-1.97) and non-prescribed OPRs (AOR=1.75, 1.45-2.11) more frequently in subsequent quarters compared to participants with unchanged OPR prescriptions. Participants whose OPR dose increased were more likely to use heroin more frequently (AOR=1.67, 1.32-2.12). When restricted to the 31% of participants who were PLWH, OPR dose increase remained associated with increased frequency of heroin use (AOR=3.32, 2.27-4.87). The main limitations were the observational nature of results and limited generalizability beyond safety-net settings.

CONCLUSIONS: Discontinuation of prescribed OPRs was associated with more frequent non-prescribed OPR and heroin use; increased dose was also associated with more frequent heroin use, particularly for PLWH. Clinicians should be aware of these risks in determining pain management approaches.

PEB0348

PURSUING 90-90-90 TARGETS IN RUSSIA: ADDICTION HOSPITAL AS A REACHABLE MOMENT FOR HIV CARE ENGAGEMENT

J. Samet[1], N. Gnatienko[2], S. Bendiks[2], D. Lioznov[3], S. Rosen[4], D. Cheng[5], K. Lunze[1], E. Blokhina[3], E. Quinn[6], V. Truong[2], A. Raj[7], E. Krupitsky[3]
[1]Section of General Internal Medicine, Boston University School of Medicine/ Boston Medical Center, Medicine, Boston, United States, [2]Section of General Internal Medicine, Boston Medical Center, Medicine, Boston, United States, [3]Pavlov University, L'va Tolstogo, Russian Federation, [4]Boston University School of Public Health, Global Health, Boston, United States, [5]Boston University School of Public Health, Biostatistics, Boston, United States, [6]Boston University School of Public Health, Biostatistics and Epidemiology Data Analytics Center, Boston, United States, [7]Center on Gender Equity and Health, University of California San Diego, La Jolla, United States

BACKGROUND: Russia's HIV epidemic is still growing, with highest transmission risks among people who inject drugs (PWID) and their sexual partners. While HIV testing is routinely offered at addiction hospitals, linkage between the addiction and HIV medical systems is poor, impeding achievement of 90-90-90 targets for HIV care. This study describes the percent of HIV-positive PWID who are on ART and characteristics of those who are not, among patients admitted for opioid use disorder (OUD) in an addiction hospital, in order to identify gaps in linkage to HIV care for this population.

METHODS: This is a secondary analysis of screening and baseline data from LINC-II, a randomized controlled trial testing the effectiveness of a three-component intervention (case management, rapid access to ART, naltrexone for OUD) to coordinate addiction and HIV care systems for HIV-positive PWID not on ART. The study screens all HIV-positive persons with OUD admitted to the City Addiction Hospital in St. Petersburg, Russia. We present descriptive statistics on the percent of screened patients on ART and baseline demographics and history of ART receipt for LINC-II participants.

RESULTS: Out of 563 patients screened September 2018 - December 2019, 309/563 (55%) were currently receiving ART. Of the remaining 254 not on ART, 145 met study entry criteria and had the following

characteristics: 65/145 (45%) female, median age 37, median CD4 count 298; 29/123 (24%) had a CD4 count below 200. One quarter (39/145; 27%) of participants never had an outpatient HIV visit, but 98% (142/145) were registered with the AIDS center as an HIV patient. Nearly one-third of participants (45/145; 31%) reported prior (but not current) ART use, among whom 51% (23/45) initiated ART due to low CD4 count and 27% (12/45) due to pregnancy. The main reasons for stopping ART included running out of pills (11/45; 24%), substance use getting in the way (11/45; 24%), side effects (10/45; 22%), and feeling fine without ART (8/45; 18%).

CONCLUSIONS: Significant opportunities exist within Russia's addiction system to engage PWID in HIV care. A focus on improving ART access among this HIV key population could help Russia pursue the 90-90-90 targets.

PEB0349

OPIOID USE IS ASSOCIATED COGNITIVE IMPAIRMENT IN PEOPLE LIVING WITH HIV FROM THE MASH COHORT

J.A. Tamargo[1], C.S. Meade[2], A. Campa[1], S.S. Martinez[1], T. Li[3], K. Sherman[4], M.K. Baum[1], MASH team

[1]Florida International University, Dietetics and Nutrition, Miami, United States, [2]Duke University, Psychology, Durham, United States, [3]Florida International University, Biostatistics, Miami, United States, [4]University of Cincinnati, Cincinnati, United States

BACKGROUND: Despite advances in treatment, neurocognitive impairments (NCI) persist among People Living with HIV (PLWH). In vitro and in vivo studies suggest that opioids may exacerbate NCI associated with HIV infection. However, the effect of opioids on neurocognitive outcomes among PLWH has not been directly studied. This study examined the relationship between opioid use and NCI, as well as other neuropsychiatric symptoms and markers of inflammation among PLWH and HIV-uninfected adults from the Miami Adult Studies on HIV (MASH) cohort.

METHODS: Cross-sectional analysis of 334 PLWH and 357 HIV-uninfected participants from the MASH cohort. The Mini-Mental State Examination (MMSE) was used to assess NCI. PhenX questionnaires and the Center for Epidemiologic Studies Depression Scale (CES-D) evaluated neuropsychiatric symptomatology. Substance use was determined by self-report and urine toxicology. Inflammation was determined with high-sensitivity C-reactive protein (hs-CRP). Cytokines/chemokines were analyzed in a subset of 366 participants. Statistics included logistic and linear regressions (SPSS v23).

RESULTS: Opioids were used by 27.8% PLWH vs. 14.6% HIV-uninfected participants ($\rho<0.001$). NCI (MMSE ≤ 24) was more frequent among virally suppressed (HIV RNA < 50 copies/μL) PLWH than HIV-uninfected (17.1% vs. 11.8%; $\rho=0.049$). Use of opioids, prescribed or illicit, increased the odds for NCI (adjusted OR: 2.26, 95% CI: 1.09–4.69; $\rho=0.029$), and heroin/fentanyl use nearly tripled the odds for NCI (adjusted OR: 2.70; $\rho=0.037$). Depression, lethargy, loss of coordination, mental slowness, forgetfulness, impaired concentration, and apathy were more frequently reported among PLWH who used opioids than those who did not (all $\rho<0.05$); these effects were not seen among HIV-uninfected. Among PLWH, opioid users had higher hs-CRP and lower neuroprotective MIP-1β levels than non-users. Heroin and fentanyl increased log-transformed hs-CRP in regression model ($\beta=0.54$ and $\beta=0.66$, respectively; $\rho<0.01$) for both PLWH and HIV-uninfected participants. Oxycodone increased hs-CRP only among PLWH ($\beta=0.36$; $\rho=0.037$).

CONCLUSIONS: Our findings support a growing body of evidence that suggests a significant contribution of opioid use on NCI in PLWH. Importantly, our results implicate the use of prescription opioids as well as heroin and fentanyl. Elucidation of the mechanisms by which opioids may contribute to cognitive decline in PLWH is needed to identify targeted interventions.

PEB0350

COCAINE, INFLAMMATION AND THE GUT MICROBIOME IN THE MASH COHORT

S. Martinez[1], V. Stebliankin[2], G. Narasimhan[2], A. Campa[1], J. Hernandez[1], G. Zarini[1], J. Tamargo[1], C. Teeman[1], Y. Huang[1], A. Johnson[1], M. Baum[1]

[1]Florida International Unviersity, Department of Dietetics and Nutrition, Miami, United States, [2]Florida International Unviersity, Bioinformatic Research Group, Miami, United States

BACKGROUND: Cocaine use, the most prevalent drug of abuse in Miami, Florida, has also been associated with a pro-inflammatory state and recently with imbalances in the intestinal microbiota as compared to cocaine non-use. However, the mechanisms of how cocaine affects intestinal dysbiosis and inflammation in HIV are not known.

METHODS: A cross-sectional pilot study was conducted on 25 cocaine users (10 females/15 males) and 25 cocaine non-users (14 females/11 males) from the Miami Adult Studies on HIV (MASH) cohort in Miami, FL. Stool samples and blood plasma were collected. Bacterial composition was characterized using 16S rRNA sequencing. Metabolomics in plasma were determined using gas chromatography/mass spectrometry and liquid chromatography/mass spectrometry. IL-6 was determined in plasma using ELISA. LEfSe analysis compared relative abundance of bacterial tax between groups. Pearson's rank was conducted to calculate the correlation (co-occurrence strength) between species and metabolites. Two-way ANOVA identified metabolites exhibiting significant interaction and main effects for experimental parameters of cocaine use and gender.

RESULTS: The relative abundances of the Burkholderiales and Odoribacter orders, *Erysipelotrichaceae* and *Clostridiaceae* families, and *Eubacterium* and *Clostridium* genus were significantly higher in the cocaine use group compared to the cocaine non-use group. A trend of elevated levels of IL-6 was seen in the cocaine use group compared to the cocaine non-use group (4.36, SD=2.01 vs. 3.65, SD=1.63 pg/mL, $P=0.18$). *Eubacterium* ($r=0.36$, $P<0.05$) and *Clostridium* ($r=0.30$, $P<0.05$) genera were also significantly correlated with IL-6. Cocaine use compared to non-use was associated with higher levels of the metabolites: 3-methoxytyrosine and 3-methoxytyramine sulfate ($P<0.05$), products of dopamine catabolism, cortisone ($P<0.05$) and phenylacetate ($P<0.05$), associated with altered microbial metabolism and oxidative stress.

CONCLUSIONS: Cocaine use was associated with higher abundances of taxa and metabolites known to cause proinflammatory states. Understanding key intestinal bacterial functional pathways that may be altered due to cocaine use in HIV infection will provide a better understanding of the relationships between the host intestinal microbiome and inflammation, and potentially provide novel treatments to improve the health of HIV infected substance users.

PEB0351

ASSOCIATIONS BETWEEN METHAMPHETAMINE USE AND LACK OF VIRAL SUPPRESSION AMONG A COHORT OF HIV POSITIVE PERSONS WHO INJECT DRUGS IN HAI PHONG, VIETNAM

J. Feelemyer[1], K. Arasteh[1], D.T. Huong[2], K.T.H. Oanh[3], P.M. Khue[2], H.T. Giang[2], N.T.T. Thang[3], J.P. Moles[4], V.H. Vinh[5], R. Vallo[4], C. Quillet[4], D. Rapoud[4], L. Michel[6], D. Laureillard[7], N. Nagot[4], D. Des Jarlais[1], DRIVE Study Team
[1]New York University, College of Global Public Health, New York, United States, [2]Hai Phong Medical University and Pharmacy, Hai Phong, Vietnam, [3]Center for Supporting Community Development Initiatives, Hanoi, Vietnam, [4]University of Montpellier, Inserm U1058, Etablissement Français du Sang, Montpellier, France, [5]Viet Tiep Hospital, Dept of Infectious and tropical diseases, Hai Phong, Vietnam, [6]Pierre Nicole Center, French Red Cross, CESP/Inserrm 1018, Paris, France, [7]University of Montpellier, Inserm U1058, Etablissement Français du Sang, Infectious Diseases Department, Caremeau University Hospital, Nîmes, France, Montpellier, France

BACKGROUND: Methamphetamine use has been associated with increased HIV viral loads among HIV positive persons, independent of antiretroviral therapy (ART). Given the increase in methamphetamine use in southeast Asia, it is important to understand how increased methamphetamine use may affect particular health outcomes, including viral suppression. In this study, we assess the association between active methamphetamine use and HIV viral suppression among a cohort of persons who inject drugs (PWID) on ART in HaiPhong Vietnam.

METHODS: Participants were recruited from October 2016 to October 2017 using respondent driven sampling (RDS). HIV positive PWID were enrolled in a cohort to assess viral load along with changes in drug use, risk behaviors, and self-report ART use and adherence. PWID were followed for approximately 24 months. Methamphetamine users were divided into three exposure categories: no use, 1-19 days of use, and 20-30 days of use (in the last 30 days). Bivariate and multivariable analysis using random effects ordered logistic regression were used to assess the relationship between self-reported methamphetamine use in the last thirty days and HIV viral load during follow-up. Mediation analysis was conducted using self-report ART adherence.

RESULTS: A total of 645 HIV seropositive PWID were included at baseline; 95% male, average age 40 (SD=6.4). At baseline, methamphetamine use in last 30 days was as follows: 64% no use, 32% intermediate use, and 4% heavy use. Approximately 74% of PWID reported near perfect adherence, and 76% were at viral suppression. In random effects analysis, methamphetamine use in the last 30 days was associated with not being virally suppressed during follow-up (AOR: 1.84, 95% CI: 1.06, 3.12). The relationship was not mediated by self-reported ART adherence (AOR: 1.94, 95% CI: 1.07, 3.52)

CONCLUSIONS: Recent methamphetamine use is associated with lack of viral suppression among PWID in HaiPhong, and remained associated in mediation analysis with self report ART adherence. The results of this study indicate the need for targeted interventions for methamphetamine use with special focus for those with HIV infection. Future studies should attempt to understand the interplay between methamphetamine and HIV pathogenesis, specifically examining how methamphetamine may interact with the effectiveness of ART.

PEB0352

DRUG USE, INFLAMMATION AND CARDIAC MECHANICAL OVERLOAD IN WOMEN LIVING WITH HIV WHO EXPERIENCE HOMELESSNESS AND HOUSING INSTABILITY

E.D. Riley[1], E. Vittinghoff[2], G.B. Beck-Engeser[1], P.O. Coffin[3], P.C. Tien[1], P.Y. Hsue[1], A.H. Wu[4], K.L. Lynch[4], D.S. Kazi[5], P.W. Hunt[1]
[1]University of California, San Francisco, Medicine, San Francisco, United States, [2]University of California, San Francisco, Epidemiology and Biostatistics, San Francisco, United States, [3]Department of Public Health, San Francisco, United States, [4]University of California, San Francisco, Laboratory Medicine, San Francisco, United States, [5]Harvard University, Medicine, Boston, United States

BACKGROUND: Risks of cardiovascular disease (CVD) and heart failure (HF) are high in PLWH and differ by sex. Few CVD-related studies focus on drug use. However, it is common in low-income women living with HIV (WLWH), increases cardiac dysfunction, and influences additional CVD risk factors like inflammation. We sought a better understanding of linkages between drug use, inflammation, and cardiac dysfunction in low-income WLWH.

METHODS: We recruited a probability sample of WLWH from San Francisco shelters, street encampments and a public HIV clinic. Participants completed six monthly study visits. Using linear mixed models and adjusting for CVD risk factors, medications and menopause, we examined the effects of toxicology-confirmed drug use (tobacco, cannabis, alcohol, cocaine, methamphetamine and opioids) and inflammation (C-reactive protein, sCD14, sCD163 and sTNFR2) on log-transformed levels of NT-proBNP, a biomarker of increased mechanical overload and HF.

RESULTS: Among 74 WLWH, the median age was 53 years and 73% were ethnic minority women. At baseline, 72% of participants had hypertension, 8% had a prior MI and 11% had a prior stroke. Tobacco use was confirmed in 65% of participants, cannabis in 53%, alcohol in 28%, cocaine in 49%, methamphetamine in 31% and opioids in 20%. Adjusting for age and race, factors significantly associated with NT-proBNP level included cannabis use (Adjusted Linear Effect [ALE]: 0.60; 95% CI: 0.45-0.80) and sTNFR2 (ALE/SD[3,145ng/mL]: 1.73; 95% CI: 1.42-2.12). Restricting analyses to virally suppressed persons (n=54) did not diminish effects. Also, cannabis use was not significantly associated with sTNFR2, nor did it change the association between cannabis use and NT-proBNP. Factors that were not significantly associated with NT-proBNP levels included HIV viral load, C-reactive protein, hepatitis C infection, and multiple CVD risk factors (e.g., prior MI, BMI, tobacco use and alcohol use).

CONCLUSIONS: Among community-recruited WLWH, NT-proBNP levels signaling cardiac mechanical overload increase as sTNFR2 increases, but are 40% lower among cannabis users. There is no evidence that sTNFR2 mediates the effect of cannabis on NT-proBNP in this population, suggesting independent effects of both. Whether including recent cannabis use to risk stratification tools would improve CVD risk assessment in low-income WLWH merits further investigation.

CLINICAL ISSUES IN OTHER VULNERABLE POPULATIONS, INCLUDING UNSTABLE SETTINGS (MIGRANTS) AND INCARCERATED SETTINGS

[1]Medical Correctional Hospital, Nonthaburi, Thailand, [2]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Tuberculosis Research Unit, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [4]Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Department of biochemistry, Bangkok, Thailand, [5]Preventive Medicine, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, [6]Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [7]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, Bangkok, Thailand

BACKGROUND: Data are lacking or outdated on prevalence of HIV, viral hepatitis infection B, C and sexually transmitted infections such as syphilis among prisoners in the region. We evaluated the prevalence of viral hepatitis and HIV infections among the inmates from Thailand.

METHODS: A cross-sectional study was done among 1028 prisoners from 2 central male prisons in Bangkok, Thailand. Prisoners were screened for HIV, hepatitis B, C and syphilis infections during 2018 to 2019. HBV and HCV infections were defined as positive hepatitis B surface antigen and positive anti-HCV antibody with a detectable HCV RNA (Abbott molecular), respectively. Prevalence (95% confidence interval) were calculated based on the binomial distribution. HBV prevalence was reported with different age groups. Risk factors associated with HCV infections were calculated by logistic regression model.

RESULTS:

	Total (N=1028)	HCV-uninfected (N=967)	HCV infected (N=61)	P-value
Median age (years)	38 (32-50)	38 (31-50)	45 (41-54)	<0.001
Duration in prison (years)	25 (20-31)	25 (20-31)	25 (19-33)	0.52
History of previous incarceration	321 (31.4)	282 (29.4)	39 (63.9)	<0.001
History of substance abuse	645 (62.7)	598 (61.8)	47 (77.1)	0.01
History of injecting drugs use	71 (6.9)	36 (3.7)	35 (57.4)	<0.001
History of syringe sharing for drugs use	40 (3.9)	18 (1.9)	22 (36.7)	<0.001
History of sharing tattoo needles with others	300 (29.3)	272 (28.3)	28 (45.9)	0.003
Have had same sex with men Known HIV status before incarceration Known HBV status before incarceration Known HCV status before incarceration	144 (14.1) 25/641 (3.9) 20/86 (23.3) 5/25 (20)	134 (13.9) 23/592 (2.4) 18/79 (22.8) 1/19 (5.3)	10 (16.4) 6/49 (12.2) 2/7 (28.6) 4/6 (66.7)	0.59 0.002 0.73 0.005

[Table]

A total of 1028 prisoners were screened. The prevalence of HIV, HBV, HCV and syphilis was 2.9% (95%CI, 1.9-4.1), 6.4% (5-8.1), 5.9% (4.6-7.6), and 4.8% (3.5-6.3) respectively. Only 1 (0.1%) and 7 (0.6%) were co-infected with HIV/HBV and HIV/HCV, respectively. HBV prevalence with different age groups was: 3.7% in <30 years, 7% in 31-40 years, 9.7% in 41-50 years and 5.5% in >50 years. Factors associated with HCV infections were age ≥40 years (aOR, 11.51, 95% CI, 4.82-27.51, p<0.001), elementary education level (aOR, 3.09, 95% CI, 1.31-7.26, p=0.01) compared to high school education or higher and previous incarceration (aOR, 2.68, 95% CI, 1.3-5.51, p=0.007) after adjusting previous history of injecting drugs, substance use and needle sharing with others.

CONCLUSIONS: Prevalence of all infections studied among prisoners were higher than general population with similar age groups. Syphilis infections were also common, which suggest the ongoing potential risks of sexual transmission of other infections. HBV vaccination and routine HCV screening and treatment with pan-genotypic direct acting antivirals with minimal specialist requirements should be implemented among the prisoners in the region.

PEB0354

CHARACTERISTICS OF PEOPLE WITH HIV (PWH) AND HIV TREATMENT OUTCOMES IN COMMUNITY PRACTICES IN SOUTHERN VS NON-SOUTHERN US REGIONS

M.K. Rawlings[1], P.E. Sax[2], J. Priest[1], J. Radtchenko[3], J. Mrus[1], J.J. Eron[4], A. Oglesby[1], K.N. Althoff[5], F. Fletcher[6], M. Rampogal[7], S. Santiago[8], R.A. Elion[9]
[1]ViiV Healthcare, Durham, United States, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, United States, [3]Trio Health, La Jolla, United States, [4]University of North Carolina, Division of Infectious Diseases, Chapel Hill, United States, [5]Johns Hopkins University School of Public Health, Baltimore, United States, [6]University of Alabama at Birmingham School of Public Health, Birmingham, United States, [7]Midway Specialty Care Center, Miami, United States, [8]Care Resource, Miami, United States, [9]George Washington University School of Medicine, Washington, United States

BACKGROUND: This study evaluated individual characteristics and antiretroviral therapy (ART) prescribing for people with HIV (PWH) seeking care at practices in southern vs non-southern US regions.

METHODS: PWH (>18yo) starting a new ART between January 2015-September 2019 with viral load at first regimen prescription (baseline), and ≥6 months of prior ART history (if not treatment-naive [TN]), were selected from the Trio Health HIV EMR database. Comparisons of baseline characteristics were conducted via chi-square or T-test statistics. Multivariate logistic regression [LR] with a binary outcome "viremic at last observation" estimated the associations of covariates among those with viral load recorded ≥12 months after baseline (n=12,689). Regions were defined per US Census and sample availability (South included: TX, FL; Non-South: IL, NM, CA, PA).

RESULTS: Of 20,271 PWH, 14,645 (72%) were treatment-experienced ([TE], 7,302, 50% in South) and 5,626 (28%) treatment-naïve ([TN], 3,071, 55% in South). Baseline characteristics of TN and TE groups differed by region [Table].

Among TE, 83% were suppressed at baseline in South vs. 91% in non-South (p<0.001); after ≥12 months, suppression rates were 85% vs. 91%, p<0.001, respectively. Among TE with ≥12 months follow-up, 72% were suppressed in South, 76% in non-South (p=0.008). TE individuals in the South were less likely to be on a single-tablet regimen than non-South (60% vs. 62%, p=0.021), no differences by region among TN (59% vs 58%, p=0.470). Individuals age >50 adjusted odds ratio [aOR]=0.74 (0.65-0.83), white vs. Black aOR=0.62 (0.55-0.69) or other race vs. Black aOR=0.61 (0.49-0.76), treated in non-South aOR=0.66 (0.59-0.74), TE aOR=0.84 (0.71-0.98), or suppressed at baseline aOR=0.29 (0.25-0.34) were less likely to be viremic after ≥12 months.

* significance (p<0.05)	Treatment-experienced non-southern N=7343	Treatment-experienced southern N=7302	Treatment-naive non-southern N=2555	Treatment-naive southern N=3071
Baseline age, mean (SD), p-value	46.6 (12.1)*	47.4 (11.9)*	37.4 (11.9)	39.1 (12)*
Male, N (%), p-value	5877 (87)*	5748 (80)*	2005 (87)	2290 (81)*
Race: White	3946 (63)*	3934 (59)*	1035 (48)*	1461 (50)*

[Table]

CONCLUSIONS: These data suggest population differences and treatment disparities between Southern and other US regions. Policy makers should examine structural and societal reasons for these disparities in an effort to reduce or eliminate them.

PEB0355

THE INFLUENCE OF GENDER, AGE, PLACE OF BIRTH AND WAY OF ACQUISITION ON DISPARITIES IN THE HIV CARE CONTINUUM IN FRANCE

L. Cuzin[1], C. Allavena[2], P. Delobel[3], R. Palich[4], C. Delpierre[5], F. Raffi[2], A. Cabié[1], Dat'AIDS Study Group
[1]Martinique University Hospital, Infectious and Tropical Diseases, Fort de France, Martinique, [2]University Hospital of Nantes, Infectious Diseases, Nantes, France, [3]Toulouse University Hospital, Infectious and Tropical Diseases, Toulouse, France, [4]Pitié Salpêtrière University Hospital, Infectious Diseases, Paris, France, [5]INSERM UMR 1027, Toulouse, France

BACKGROUND: The influence of patients' characteristics on disparities in the HIV care continuum may vary following national organizations. Inspired by the study published by Desir et al. (CID 2019; 68:795-802), we investigated whether these factors have an impact in the HIV care continuum in a universal, national and free healthcare system.

METHODS: The Dat'AIDS French cohort collects longitudinal data on people living with HIV in 18 centers in France. We estimated differences in the 5-year restricted mean percentage of person-time spent (i) in care, (ii) receiving ART and (iii) on ART and virally suppressed among patients diagnosed between 01/01/2013 and 12/31/2017. We compared men vs women, patients born in France vs born abroad, men who have sex with men (MSM) vs men who have sex with women (MSW), MSM vs women, and MSW vs women.

RESULTS: Among 8066 included patients, men (5634, 70%) and women spent 97.7% and 97.5% of person-time in care, 85.6% and 82.8% on ART and 69.9% and 65% suppressed, respectively. Patients born in France (3775, 47%) and patients born abroad spent 97.9% and 97.4% of person-time in care, 87.9% and 81.9% on ART and 74.6% and 62.9% suppressed, respectively. MSM (3925, 49%), MSW (1709, 21%) and women spent 98.2%, 96.5%, and 97.5% of person-time in care, 86.9%, 82.6% and 82.8% on ART, and 72.5%, 63.7%, and 65% suppressed, respectively. Stratified results regarding person-time with suppressed viral load appear in the table (*significant differences).

Born in France	Age	MSM	WOM	MSW	MSM-WOM	95%CI	MSM-MSW	95%CI	WOM-MSW	95%CI
Suppressed	18-32 y	72.4	69.2	69.5	3.2	-4.2 ; 10.6	2.8	-4.5 ; 11.4	-0.3	-10.8 ; 10.7
	32-45 y	74.4	67.1	69.1	7.3*	0.1 ; 15.9	5.3	-0.5 ; 11.6	-2	-11.8 ; 7.3
	+45 y	80.5	70.5	73.3	10*	4.2 ; 15.4	7.2*	3.1 ; 11.9	-2.8	-9.0 ; 3.8
Born abroad										
Suppressed	18-32 y	58.1	60.4	53	-2.4	-7.7 ; 3.0	5.1	-2.8 ; 13.6	7.4	-0.4 ; 16.1
	32-45 y	65.9	66.6	60.1	-0.7	-5.2 ; 3.4	5.8*	0.3 ; 11.1	6.5*	1.6 ; 10.9
	+45 y	75.5	60.7	60	14.8*	8.6 ; 19.9	15.5*	9.6 ; 20.9	0.8	-4.2 ; 6.4

[Table]

CONCLUSIONS: Despite free access to care and universal ART, disparities remain across age, country of birth and way of HIV acquisition. Clinical and public health interventions targeting specific patients' conditions are needed.

PEB0356

NEURAL TUBE DEFECTS AND ADVERSE PREGNANCY OUTCOMES AFTER MATERNAL EXPOSURE TO DOLUTEGRAVIR AND OTHER ANTIRETROVIRAL MEDICATIONS DURING PREGNANCY, UNITED STATES, 2013-2017

K. Hoover[1], W. Zhu[1], Y.-L. Huang[1], E. Clark[2], J. Wiener[1], M. Lampe[1], A. Kourtis[1]
[1]CDC, Atlanta, United States, [2]Emory University, Atlanta, United States

BACKGROUND: A study in Botswana found that exposure to dolutegravir, an integrase strand transfer inhibitor (INSTI), around the time of conception was associated with a slightly increased risk of neural tube defects (NTD). Ongoing monitoring of dolutegravir use and NTDs and adverse pregnancy outcomes among U.S. pregnant women is essential to evaluate the safety of dolutegravir and other antiretroviral (ARV) medications.

METHODS: We analyzed IBM MarketScan commercial and Medicaid databases that included clinical diagnoses, procedures, medications, and variables to link mother and infant pairs. We identified exposures to ARVs (dolutegravir, other INSTIs [raltegravir, elvitegravir], other ARVs), NTDs (anencephaly, spina bifida, encephalocele, inencephaly), and pregnancy outcomes (live birth, stillbirth, spontaneous abortion, induced abortion). We compared the prevalence of NTDs and pregnancy outcomes among HIV-negative women and women with HIV by type of ARV.

RESULTS: Among 7,169 pregnancies in women with HIV, we found 235 exposed to dolutegravir. The prevalence of NTDs was 0 per 1,000 pregnancies among commercially insured women with HIV exposed to dolutegravir and 0.48 (95% CI 0.46-0.51) among HIV-negative women. The prevalence of NTDs was 0 per 1,000 pregnancies among Medicaid insured women with HIV exposed to dolutegravir and 0.58 (0.55-0.61) among HIV-negative women. The prevalence of NTDs were similar among women with HIV exposed to dolutegravir, other INSTIs, or other ARVs, and among HIV-negative women (Table). The prevalence of stillbirth, spontaneous abortion, and induced abortion were higher among women with HIV, including those exposed and unexposed to some classes of ARVs, compared to HIV-negative women (Table).

	Commercial insurance					Medicaid insurance				
Outcome	HIV-negative	Women with HIV				HIV-negative	Women with HIV			
		No ARV	DTG	Other INSTI	Non-INSTI		No ARV	DTG	Other INSTI	Non-INSTI
Pregnancies (N)	3,752,373	1,257	46	256	1,079	2,593,751	1,882	189	743	1,716
NTDs*	0.48 (0.46-0.51)	1.59 (0.19-5.74)	0.00	0.00	0.00	0.58 (0.55-0.61)	0.53 (0.01-2.96)	0.00	0.00	1.75 (0.36-5.10)
Live births *	704.2 (703.7-704.6)	604.6 (577.0-631.8)	478.3 (328.9-630.5)	535.2 (472.0-597.5)	711.8 (683.7-738.7)	746.2 (745.6-746.7)	800.2 (781.4-818.1)	761.9 (694.7-820.7)	732.2 (698.8-763.7)	828.7 (810.0-846.2)
Stillbirths*	3.8 (3.7-3.8)	4.8 (1.8-10.4)	0.0	7.8 (1.0-27.9)	5.6 (2.0-12.1)	4.5 (4.4-4.6)	**8.5 (4.9-13.8)**	5.3 (0.1-29.1)	**13.5 (6.5-24.6)**	**8.7 (4.9-14.4)**

*Prevalence (95% confidence intervals) per 1,000 pregnancies

[PEB0356 Table]

CONCLUSIONS: Although we observed a small number of dolutegravir exposures, the prevalence of NTDs was similar among women exposed to dolutegravir compared to those with no exposure. Administrative databases will be used for ongoing monitoring of NTDs and adverse pregnancy outcomes among women with HIV, including those exposed to ARVs, in the United States.

PEB0357

PERSPECTIVES FROM PATIENTS AND PROVIDERS OF A COMBINED SPECIALTY HIV CLINICAL CARE PROGRAM FOR OLDER PEOPLE LIVING WITH HIV: THE GOLDEN COMPASS PROGRAM AT WARD 86

J. Tan[1], M. Greene[2], B. Cinthia[3], M.L. Hicks[4], J. Oskarsson[4], M. Shields[4], D. Havlir[4], M. Gandhi[4], J. Myers[1]
[1]University of California San Francisco, Medicine, Center for AIDS Prevention Studies (CAPS), San Francisco, United States, [2]University of California San Francisco, Division of Geriatrics, Department of Medicine, San Francisco, United States, [3]University of California San Francisco, San Francisco, United States, [4]University of California San Francisco, Division of HIV, Infectious Diseases, and Global Medicine, San Francisco, United States

BACKGROUND: Few clinical care models exist for people living with HIV (PLWH) over the age of 50 for whom managing long-term HIV-infection intersects with the aging process and its comorbidities. Golden Compass is a multidisciplinary care model within the Ward 86 HIV Clinic at San Francisco General Hospital which offers specialty and primary care provided by HIV clinicians; a designated geriatrician, cardiologist, pulmonologist, and social worker; a pharmacist with expertise in aging; and memory/exercise/narrative classes. The goal of this study was to explore the perspectives of both patients and primary care providers about this care model.

METHODS: We conducted an exploratory, qualitative, in-depth interview study from 09/2018-10/2019 with a convenience sample of 13 patients (Mage=61.4, SD=6.5; 11 were men; 10 were black, Latinx, or Pacific Islander/Hawaiian Native) and 11 primary care providers participating in Golden Compass. A multidisciplinary team read all transcripts independently to identify emergent themes and then met to refine thematic categories. Analytic memoing was done separately for patient and provider transcripts and was cross-checked during regular team meetings. Discrepant interpretations were discussed until agreement was reached.

RESULTS: Patients perceived multiple benefits resulting from specialty assessments in geriatrics, cardiology and pulmonology, medication management, and care coordination within the embedded care model, including self-reported improvements in chronic conditions such as hypertension, diabetes, urinary incontinence, pain, sleep disturbances, and physical stamina. Self-reported benefits from class participation included increased social contact and physical activity, enhanced personal connections, improved self-management skills, and better memory. Providers emphasized the value of comprehensive assessments and expert consultations to their care, including the diagnoses and treatment of aging-related illnesses. Providers cited an enhanced awareness of "geriatric" issues. such as frailty and cognitive impairment, as a result of specialty consultation.

CONCLUSIONS: This exploratory study demonstrated the perceived benefits of comprehensive coordinated care models that include HIV care and designated specialty care for older PLWH and and their providers. Our findings suggest that innovative care models, such as Golden Compass, that embed specialty services into a clinic that provides both HIV and primay care will be of value to the growing, global population of older PLWH.

PEB0358

ISONIAZID TUBERCULOSIS PREVENTIVE THERAPY TOXICITY AMONG HIV-POSITIVE CHILDREN, ADOLESCENTS AND ADULTS IN UGANDA

J. Kanywa[1], M. Mugerwa[2], A. Kekitiinwa[2], M. Adler[3]
[1]Baylor College of Medicine Children's Foundation Uganda, Medical and Psychosocial, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation Uganda, Medical, Kampala, Uganda, [3]Division of Global HIV & TB/ Centers for Disease Control and Prevention (DGHT/ CDC), Global HIV & TB, Kampala, Uganda

BACKGROUND: A 6 months course of Isoniazid tuberculosis preventive therapy (IPT) is being scaled up in Uganda but little is known about its toxicity in antiretroviral therapy experienced children, adolescents and adults. We describe IPT toxicity among these populations at an urban HIV clinic in Uganda during the national scale-up.

METHODS: IPT toxicity reports were retrospectively reviewed (January 1, 2019–July 31, 2019). Patients on antiretroviral therapy and receiving IPT as prophylaxis were included while those on it for tuberculosis disease treatment were excluded.

Patients' ages ranged from 6 to 59 years and the variables studied included age, sex, duration on IPT, toxicity symptoms, time to onset of symptoms, severity, ART duration, regimen and co- morbidities. We

used Division of AIDS (DAIDS) toxicity grading. We abstracted data, performed descriptive analysis and events were reported as proportions.

RESULTS:

Age	0-9 years		10- 19 years		20+ years		Total
Gender	Girls	Boys	Female	Male	Female	Male	All
# Received IPT	394	394	1077	993	1306	565	4729 (59% females)
# With toxicity	1	2	10	0	10	0	23
# Deaths	0	0	0	0	1	0	1
Prevalence	0.3%	0.5%	0.9%	0	0.7%	0	0.5%

[Table]

The most common symptoms were vomiting (14%), yellow eyes (12%), abdominal pain (11%), malaise (11%), and fever (6%) and the median duration on IPT at time of toxicity was 1 month (IQR, 1–3). The median duration of current antiretroviral treatment regimen was 8 months (IQR, 3–46) and most toxicities occurred in patients receiving Tenofovir/Lamivudine/ Efavirenz (39%), Tenofovir/Lamivudine/Dolutegravir (13%) and Zidovudine/Lamivudine/Nevirapine (13%), other regimens (35%). The median age with toxicity events was 19 years (14- 34.5) and three-quarters of IPT-toxicity events were DAIDS grades 3/4 with no co-morbidities.

CONCLUSIONS: Health workers should have a high index of suspicion for IPT toxicity during the first month of initiation especially among symptomatic older adolescent girls.

PEB0359

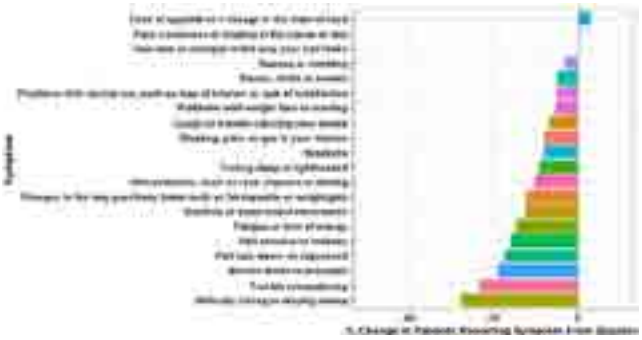
EFFICACY, SAFETY, AND TOLERABILITY OF SWITCHING EFAVIRENZ/EMTRICITABINE/ TENOFOVIR DISOPROXIL FUMARATE (EFV/FTC/ TDF) TO BICTEGRAVIR/EMTRICITABINE/TENOFOVIR ALAFENAMIDE (BIC/FTC/TAF) IN VIROLOGICALLY SUPPRESSED ADULTS WITH HIV-1 INFECTION

E. Lowman[1], N. Lee[1], N. Unger[2], P. Hardigan[3]
[1]Midland Research Group, Oakland Park, United States, [2]Gilead, Medical Affairs, Foster City, United States, [3]Nova Southeastern University, Health Professions Division, Fort Lauderdale, United States

BACKGROUND: With the evolution of potent antiretroviral therapy, virologically suppressed people living with HIV (PLWH) are often switched to regimens considered simpler and safer, with improved tolerability and potentially avoiding long-term toxicities without compromising efficacy. We examined the impact of switching from EFV/FTC/TDF to BIC/FTC/TAF on maintenance of virologic suppression (VS), tolerability, sleep quality and patient reported outcomes.

METHODS: We conducted an open-label, single-center, single-arm, prospective study evaluating the efficacy, safety, and tolerability of switching from EFV/FTC/TDF to BIC/FTC/TAF in PLWH > 18 years of age who were virologically suppressed. Primary outcome was virologic failure (VF; HIV-1 RNA ≥ 50 c/mL) at week 48. Using exact tests we also looked for changes in HIV Symptom Index (HIV-SI) and sleep quality questionnaires results from baseline to week 48.

RESULTS: 100 participants were screened, 90 enrolled and 87 completed 48 weeks. Median age 55 (range 28-71); 94% white, 5% black; 19% identified as Latinx; 98% male. At 48 weeks, VF was seen in 3 participants (3.3%; viral load range 50-54 c/mL). VF due to non-adherence was documented in 1 case. VS was maintained in 92.2%. 4.4% had no virologic data. There were no discontinuations of drug for any reason. Significant improvements were seen in sleep quality by week 4 and were sustained through 48 weeks. There were significant changes from baseline in 18 of the 20 measured HIV-SI symptoms ($p<0.05$). There were significant reductions in mean total cholesterol and LDL (-10.82 and -7.35 mg/dL; $p<0.05$). No significant changes in CD4 cell count, CD4%, weight, serum creatinine, triglycerides or HDL were seen.



[Figure]

CONCLUSIONS: Switching patients from EFV/FTC/TDF to BIC/FTC/TAF is safe, well-tolerated and maintains virologic suppression. Perhaps the greatest benefit is the improvement in sleep quality and a marked reduction in reports of bothersome symptoms.

THE HIV OUTPATIENT STUDY_ IMPROVEMENTS IN HEALTH OUTCOMES IN PEOPLE LIVING WITH HIV, THE UNITED STATES, 1993-2017

K. Buchacz[1], C. Armon[2], F.J. Palella[3], R.M. Novak[4], J. Fuhrer[5], E. Tedaldi[6], D. Ward[7], C. Mayer[8], L. Battalora[9,2], K. Carlson[2], S. Purinton[2], M. Durham[1], J. Li[1], and the HIV Outpatient Study (HOPS) Investigators

[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]Cerner Corporation, Kansas City, United States, [3]Northwestern University Feinberg School of Medicine, Chicago, United States, [4]University of Illinois College of Medicine, Chicago, United States, [5]Renaissance School of Medicine at Stony Brook University, Stony Brook, United States, [6]Lewis Katz School of Medicine at Temple University, Philadelphia, United States, [7]Dupont Circle Physicians Group, Washington D.C., United States, [8]St. Joseph's Hospital Comprehensive Research Institute, Tampa, United States, [9]Colorado School of Mines, Golden, United States

BACKGROUND: Approximately 1.1 million Americans are living with HIV infection and nearly 40,000 are diagnosed with HIV each year. There have been remarkable shifts in the clinical epidemiology of treated HIV infection in the United States (U.S.) during the past 25 years. Few sources of longitudinal data regarding the health of people living with HIV (PLWH) spanning that period of time exist. Long term trend and recent data profiling immunologic and virologic status and mortality among PLWH in routine HIV care can help inform the "baseline" and help gauge progress in reaching goals to Ending the HIV Epidemic in the U.S. by 2030.

METHODS: We analyzed data from the HIV Outpatient Study (HOPS), a well characterized, prospective, socio-demographically diverse U.S.-based cohort of PLWH. Fourteen HOPS clinics (public and private) have participated since 1993 recording over 570,000 patient encounters through mid-2019. We assessed temporal trends in select demographic and health markers (variable timeframes) and mortality (1994-2017) for 10,566 HOPS participants.

RESULTS: From 1993 to 2017, there were substantial increases in the percentage of women (from 11% to 25%), persons aged >55 years (from 4% to 40%), and persons of black race or Hispanic/Latinx race/ethnicity (from 19% to 53%) in the cohort. The median CD4 cell count (CD4) of participants increased from 244 cells/mm^3 in 1993 to 640 cells/mm^3 in 2017. The mortality fell from 121 to 16 per 1,000 person-years from 1994 to 2017 ($p < 0.001$). The median age at death was 39 years (n=159 decedents) in 1994 versus 54 years (n=35 decedents) in 2017. Antiretroviral-naïve PLWH initiated ART progressively sooner after HIV diagnosis: median CD4 at ART start increased from 345 cells/mm^3 (n = 206) to 631 cells/mm^3 (n = 48) from 2000 to 2017. In 2010, 81% of ART-treated HOPS participants had a most recent HIV viral load < 50 copies/mL, compared with 89% in 2017.

CONCLUSIONS: Our findings illustrate dramatic improvements in immunologic recovery, virologic suppression and survival, reflecting advances in earlier diagnosis and more effective treatments for PLWH. Ongoing HOPS data collection describes the health of PWLH in contemporary care and informs progress toward Ending the HIV Epidemic.

EPIDEMIOLOGY OF HIV IN THE GENERAL POPULATION

PEC0359

TESTING PREFERENCES AND CHARACTERISTICS OF THOSE WHO HAVE NEVER TESTED FOR HIV IN THE UNITED STATES

S. Patel[1], P. Chavez[1], B. Emerson[1], M. Pitasi[1], K. Delaney[1]

[1]US Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: The US Centers for Disease Control and Prevention (CDC) recommends persons aged 13-64 years be tested for HIV at least once as part of routine health care; however, these recommendations have not been fully implemented. As the Ending the HIV Epidemic (EHE) initiative in the US gets underway, it is critical to understand the characteristics of those who have never tested for HIV, in order to better leverage and target testing strategies to reach this population.

METHODS: We analyzed data from FallStyles, a web-based survey fielded in October 2019 among a nationally representative online panel. We examined HIV testing history (yes=ever testers vs. no=never testers) by demographic and health-seeking characteristics. We also examined whether never testers lived in areas accounting for the majority of new HIV diagnoses (yes/no), as well as their HIV testing preferences. We calculated weighted proportions and 95% confidence intervals (CI) in SAS 9.4.

RESULTS: Of 3,624 survey respondents, 3,313 answered "yes" or "no" to the HIV testing history question. Of these, 65.7% (CI:63.8-67.6) reported never testing for HIV. Among never-testers: 22.5% (CI:19.8-25.1) were ages 18-29 years and 52.1% (CI:49.6-54.6) were >50 years; 50% were men; 89.6% (CI:87.7-91.5) had completed high school or higher;15.2% (CI:13.1-17.3) were Hispanic and 7.3% (CI: 6.0-8.7) were non-Hispanic black or African American; 41.0% (CI:38.5-43.4) were unemployed. About one-third (32.3%;CI:30.0-34.7) of never testers lived in areas with a high burden of HIV; and 75.8% (CI:73.5-78.1) had seen a primary care provider (PCP) in the last year. In addition, 53.3% of never testers preferred to obtain an HIV test during a routine visit with their health care provider, followed by 12.2% at an urgent care/walk-in clinic, and 18.3% via HIV self-testing (all non-mutually exclusive responses).

CONCLUSIONS: Most respondents had not been tested for HIV, confirming that CDC recommendations are not being fully implemented. Moreover, the majority of never testers reported seeing a PCP in the last year, and would prefer to test in clinical settings, highlighting missed opportunities for HIV testing. Understanding preferred modalities for HIV testing, particularly among never testers, is essential to reach these populations and achieve the goals of the EHE initiative.

PEC0360

HIGH LEVELS OF PRIMARY RESISTANCE AMONG NEWLY DIAGNOSED HIV-1 INFECTED VENEZUELAN PATIENTS

M. Comegna[1], F. Pujol[2], H. Rangel[2], Y. Sulbaran[2]
[1]Hospital Vargas de Caracas, Venezuela, Servicio de Infectologia, Caracas, Venezuela, [2]Laboratorio de Virologia Molecular, CMBC, IVIC, Caracas, Venezuela

BACKGROUND: The Venezuelan health crisis has led to shortage of antiretroviral for people living with HIV-1, with consequent forced suspension of treatment, even in adherent patients. It is estimated that between 2010 and 2016, the number of new cases of HIV infection increased by 24%. By this time there were 120,000 people infected and only 71,210 received antiretroviral therapy. According to Venezuela's Ministry of Health, for that year, the mortality rate increased to 8.3 per 100,000 inhabitants. Since 2012 serious problems began in the supply of antiretrovirals and by 2018, drug unavailability affected 84% of patients. In addition, access to preservatives is very limited in the country for the same reasons. These factors may lead to an increase in primary resistance among HIV-1 patients.
METHODS: The aim of this study was to evaluate the prevalence of primary resistance among newly diagnosed HIV-1 infected adults patients from Hospital Vargas in Caracas, Venezuela in the period from July to November 2019.
The resistance test (PCR amplification, sequencing and resistance analysis through the Stanford University Resistance Database algorithm) was performed as previously reported.
RESULTS: The POL region was amplified from blood of 29 patients (23 M, 6 F). A high prevalence of primary resistance was found:14/28 (48%) HIV-1 isolates harbored at least on mutation to Protease Inhibitor (PRI), or Nucleoside Inhibitor (NRTI) or Non Nucleoside Inhibitor (NNRTI). The most prevalent resistance was to NRTI (24%), and aa K70 of the reverse transcriptase was the most commonly mutated (17%). Ten percent of the isolates share the K103N mutation, conferring resistance to the NNRTI efavirenz and nevirapine.
CONCLUSIONS: These results suggest that, as expected, the health crisis in Venezuela has profoundly impacted the situation of people living with HIV in Venezuela for an increase in primary resistances, compared to previously reported prevalence of 11% in 2004-2007. This make difficult to structure therapeutic regimens and likelihood of therapeutic failures, especially with NRTI and NRTTI.

PEC0361

DEFINING AND MAPPING GEOGRAPHICAL HOTSPOTS TOWARD THE ENDING THE HIV EPIDEMIC IN MEXICO BY 2030

E. Bravo-García[1], H. Ortiz-Pérez[2], J.S. Bravo-García[1], C. Magis-Rodríguez[3]
[1]Spectrum: Educación, Salud y Sociedad, AC, Ciudad de Mexico, Mexico, [2]Universidad Autónoma Metropolitana - Unidad Xochimilco, Departamento de Atención a la Salud, Mexico, Mexico, [3]Instituto Nacional de Salud Pública, Mexico, Mexico

BACKGROUND: Mexico's Health System in local level is coordinated by 246 Jurisdicciones Sanitarias-Sanitary Districts (JS), whom has to operate the health prevention and care actions, among them the HIV program. Each JS is integrated by one or more municipalities. To achieve maximum impact for Ending the HIV Epidemic in Mexico, we should be focus on most affected geographic areas by HIV. The aim is mapping the most important JS to hit the HIV epidemic in next 10 years.
METHODS: We calculate the HIV Incidence and HIV Mortality in Mexico from 2014 to 2018, using epidemiological official data from Ministry of Health, deaths data from the National Institute of Statistics and Geography (INEGI), and population estimates from the National Population Council (CONAPO). INEGI's Digital Map of Mexico was used to generate the mapping, combining the 25 JS with the highest HIV incidence with the 25 JS with the highest HIV mortality.
RESULTS: We identified the 25 JS with highest HIV incidence and mortality rates from 2014 to 2018. By combining both groups, we obtained the 38 JS most affected by HIV epidemic (figure 1). In these geographical areas are living 17.9% of the national population, but are concentrating 38.9% of new HIV infections, and 38.1% of total HIV deaths. The incidence and HIV mortality rates in these 38 JS were twice higher than the national rate. These are areas of great population mobility, areas of the northern and southern border of the country, sites of intense trade and sex tourism, and critical zones of Mexico City.

[Figure. The 38 geographical areas with highest HIV incidence and HIV mortality in Mexico, from 2014-2018]

CONCLUSIONS: The 38 focus areas identified should be prioritized during during the first two years, strengthening the detection, prevention and integral care of PLWHIV. On these way, the efforts will expand nationally for the next 8 years to get the ending of HIV epidemic in Mexico.

PEC0362

TARGETING DIVORCED, SEPARATED, AND WIDOWED PEOPLE TO IDENTIFY UN-DIAGNOSED HIV POSITIVE ADULTS IN ESWATINI, MALAWI, TANZANIA, AND ZAMBIA: ANALYSIS OF FOUR PHIA STUDIES

K. Delele[1], M. Mecha[1], G. Mayanja[1], C. Nkama[2], P. Makelele[2], J. Mandala[3], T. Medrano[4], M. Batagenya[4]
[1]FHI 360, OVC, Addis Ababa, Ethiopia, [2]FHI 360, ZDFPCT Client Experience and PTC, Lusaka, Zambia, [3]FHI 360, PSTS, Washington, United States, [4]FHI 360, IDHS, Washington, United States

BACKGROUND: More than 70% of adults with HIV in Eswatini, Malawi, Tanzania and Zambia have already been diagnosed. Identifying the remaining 30% of undiagnosed adults requires more effective targeting to reach those most likely to be HIV-positive with testing services. Divorced, Separated and Widowed (DSW) adults have shown one of the highest HIV prevalence rates among adult population groups. In this study we analyse HIV positivity rates among different sub-groups of adults, including DSWs, using data from the Eswatini, Malawi, Tanzania, and Zambia Population HIV Impact Assessment (PHIA) household surveys to prove that DSWs should be prioritized for HIV testing.

METHODS: The Eswatini, Malawi, Tanzania, and Zambia Population HIV Impact Assessment (PHIA) household surveys interviewed a total of 86,727 adults between 2015-2016 and conducted HIV rapid testing. Determinants of HIV infection among adults who have never tested for HIV were assessed using multivariable logistic regression. Sampling weights were applied to account for survey design effects.
RESULTS: Across the four countries, 69% of adults have ever tested for HIV. Of the 31% adults who never tested, 11% were DSWs. The overall HIV positivity rate among DSWs in all countries was 5.7% (Eswatini: 10.3%, Malawi: 9%, Tanzania: 4.8%, Zambia: 13.7%). Whereas the positivity rate for married adults was 3.6% and 0.6% among single adults un-diagnosed HIV+ DSWs account for 29% of HIV+ adults who never tested for HIV. During multivariable analysis, urban settings (AOR: 1.76; 95% CI: 1.38-2.23) and DSWs (compared to married adults) were found to have a higher risk (AOR: 1.59; 95% CI: 1.2-2.09). There was no gender difference in HIV positivity.
CONCLUSIONS: Looking at marital status, DSWs have the highest HIV prevalence rate among un-diagnosed adults. Being urban resident and DSW were identified as independent risk factors for high HIV positivity. As DSWs are easily identifiable at community level and they are small in number compared to married and single adults, targeting them may optimize new HIV case finding.

PEC0363

HIV INDEX TESTING IN SOUTH AFRICA: RESULTS FROM THE FIRST YEAR OF SUPPORT IN THE PRESIDENT'S EMERGENCY PLAN FOR AIDS RELIEF (PEPFAR) FOCUS DISTRICTS - FISCAL YEAR (FY) 2019

C. Dietrich[1], G.G. Mona[2], A. Ochieng[2], N. Khanyile[2], G. Kindra[2], V. Da Costa[1], J. Drummond[2], J. Grund[2], R. Lacson[2]
[1]PHI/CDC Global Health Fellows Program, Pretoria, South Africa, [2]US Centers for Disease Control and Prevention, Pretoria, South Africa

BACKGROUND: HIV index testing is a case finding method to diagnose people living with HIV (PLHIV) by testing of biological children and sexual partners of individuals already diagnosed with HIV. PEPFAR, which directly supports 27 districts in South Africa, aims to have 30% of all new HIV cases identified via index testing. The South African National Department of Health (NDOH), with support from PEPFAR, began implementing index testing in October 2017. We describe patterns of case detection with index testing by age and sex after one full year of PEPFAR support.
METHODS: HIV testing services (HTS) data from October 2018–September 2019 for 27 districts were obtained from PEPFAR's routine monitoring database. Numbers of HIV tests performed by either index testing or provider-initiated testing and counseling (PITC), numbers of PLHIV identified, and percentage yield were summarized across reporting quarters (i.e. October–December 2018; January–March, April–June, July–September, 2019) by age (<15 years and ≥15 years) and sex.
RESULTS: PITC accounted for the most positive diagnoses (~523,000) and tests (~8,990,000) compared to other methods. However, index testing was the highest yield approach with an average yield of 29.7% (9.1% all HTS) among males and 33.9% (10.4% all HTS) among females in those aged ≥15 years. Index testing among those <15 years increased from 2.2% to 6.1% of all HTS from the first to the last quarters of FY 2019; the percentage of positives identified from index testing grew from 6.3% to 13.0% during the same time period. Among those ≥15 years, index testing accounted for 1.1% and 0.6% of HTS for males and females, but 5.0% (~13,000) and 3.3% (~15,000) respectively of the more than ~730,000 positive diagnoses.
CONCLUSIONS: After a year of full PEPFAR support for the implementation of index testing, index testing and positives identified through this approach increased markedly for those aged <15 years. While index testing accounted for a small percentage of HTS for those aged ≥15 years in FY 2019, it resulted in a high yield with almost 30,000 positive diagnoses. Additional analyses of index testing in South Africa should be conducted as implementation expands.

PEC0364

PREVALENCE OF SEXUALLY TRANSMITTED INFECTIONS AND USE OF PRE-EXPOSURE PROPHYLAXIS AMONG PATIENTS IN DIFFERENT HIV-TRANSMISSION RISK CATEGORIES FROM TWO URBAN SEXUAL HEALTH CLINICS

L. Platt[1,2], F. Shebl[2], Y. Qian[2], B. Bunda[2], K. Ard[1], I. Bassett[1,2]
[1]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States, [2]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States

BACKGROUND: An increasing proportion of people with HIV in Massachusetts are classified as having no identified risk (NIR) for transmission at the time of diagnosis. It is unclear if this is due to underreporting of behaviors by patients or use of categorization schemes that incompletely account for patient risks. We examined data from two urban sexual health clinics and assessed if sexually transmitted infections (STIs) and use of pre-exposure prophylaxis (PrEP) correlate with current risk categories.
METHODS: During calendar year 2019, all patients at two sexual health clinics in Boston, MA answered questions assessing risk-associated behaviors. We used responses to assign patients to categories currently used by CDC to characterize mode of HIV transmission: men who have sex with men (MSM), injection drug use (IDU), MSM/IDU, high-risk heterosexual sex (sex with someone who is MSM, IDU, or HIV-positive), and NIR. We compared prevalence of empirically treated and/or laboratory-confirmed bacterial STIs considered indications for PrEP (gonorrhea and syphilis for all patients, chlamydia for MSM) and PrEP use across risk categories.
RESULTS: 2372 unique patients were seen, with most categorized as NIR (65.8%) followed by MSM (32.9%). Few patients reported IDU (12, 0.5%), MSM/IDU (10, 0.4%), or high-risk heterosexual sex (9, 0.4%). Although the prevalence of STIs was highest among patients who fit a defined CDC risk category (35.8% of MSM, 16.7% of IDU, 50% of MSM/IDU, and 11.1% of high-risk heterosexual sex) compared to those with NIR (5.3%), a substantial proportion of all STI diagnoses were among people with NIR (22.2%). PrEP use was highest among MSM (50%) and lowest among those with NIR (1.7%). Few patients (<10%) had missing data.
CONCLUSIONS: Two-thirds of patients at two Boston sexual health clinics did not fall into traditional HIV transmission categories, though they comprised >20% of new STI diagnoses. While >5% of these patients were diagnosed with STIs that serve as CDC indications for PrEP, <2% took PrEP in the prior year. To improve identification of those at risk and target HIV prevention measures, we must better understand sources of risk not currently captured by surveillance categories.

PEC0365

MITIGATING MISSED OPPORTUNITIES OF PROVIDER-INITIATED HIV TESTING AMONG ADULTS SEEKING PRIMARY CARE IN COASTAL KENYA

C.A. Agutu[1], T.H. Oduor[1], B.K. Kombo[1], P.M. Mugo[1], S.M. Chira[1], F.W. Ogada[1], T.F. Rinke de Wit[2], W. Chege[3], E.M. van der Elst[1], S.M. Graham[4], E.J. Sanders[1]
[1]KEMRI Wellcome Trust Research Programme, Clinical Trials, Kilifi, Kenya, [2]Amsterdam Institute for Global Health and Development, Global Health, Amsterdam, Netherlands, [3]Division of AIDS (DAIDS), National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), Prevention Sciences Program, Rockville, United States, [4]University of Washington, Global Health, Medicine, and Epidemiology, Seattle, United States

BACKGROUND: Mitigating missed opportunities of provider-initiated testing and counselling (PITC) is essential, as only one in five adults is offered HIV testing when seeking care in sub Saharan Africa. Our aims were to identify predictors of PITC among young adults seeking care for symptoms of acute illness and to understand health care worker (HCW) barriers to PITC implementation.

METHODS: We assessed HIV test coverage among all adult outpatients 18-39 years of age at four public and two private health facilities in coastal Kenya, during a 3- to 6-month surveillance period at each facility. A subset of patients who reported fever, diarrhoea, fatigue, body aches, sore throat or genital ulcers were enrolled to complete a study questionnaire independently of PITC offer. We assessed predictors of PITC in this study population using generalised estimating equations and identified barriers to offering PITC through focus group discussion with HCW at each facility.

RESULTS: Among 10,263 non-research patients, 1,600 (15.6%) were tested for HIV, of whom 30 (1.9%) were newly diagnosed. Among 1,374 study participants, 382 (27.8%) were tested for HIV, of whom 13 (3.4%) were newly diagnosed. Of those offered HIV testing, 94.1% accepted it. Among study participants who were not offered HIV testing, 92.4% would have taken an HIV test if offered. Age 30-39 years (adjusted odds ratio [aOR] 1.5, 95% confidence interval [CI] 1.2-1.9), male sex (aOR 1.4, 95% CI 1.2-1.6), sore throat (aOR 1.2, 95% CI 1.0-1.4), genital ulcers (aOR 2.9, 95% CI 1.9-4.4), HIV testing history more than a year ago (aOR 1.4, 95% CI 1.0-1.9) and never having tested for HIV before (aOR 2.0, 95% CI 1.4-2.8) were associated with an increased odds of PITC offer. Barriers to PITC implementation included shortage of personnel, high workload, perceived slowing down of patient flow, and lack of training.

CONCLUSIONS: PITC coverage was low, but most patients would accept testing if offered. HCW were more likely to test older patients, men, patients with certain symptoms, and patients without a recent HIV test. Missed opportunities of PITC can be mitigated when PITC will be targeted using risk and symptom criteria.

EPIDEMIOLOGY OF HIV IN MEN WHO HAVE SEX WITH MEN

PEC0366

GEOGRAPHIC APPROACH TO HIV PREVENTION-INTERVENTION AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN DC

S. Das[1], A. Allston[1], M. Kharfen[1]
[1]District of Columbia Department of Health, HIV/AIDS, Hepatitis, STD and TB Administration (HAHSTA), District of Columbia, United States

BACKGROUND: In the United States, the HIV epidemic continues to disproportionately affect MSMs, particularly younger MSMs. In DC approximately 46% of the new diagnoses were MSMs in 2018. As DC aims to end the HIV epidemic in the next few years to come, addressing HIV epidemic among MSMs remains the top priorities. This analysis is DC's first attempt to use surveillance data to find MSM hotspots. The analysis also finds association of the MSMs with clinical-demographical characteristics to strategize intervention in DC's ending the HIV Epidemic plan.

METHODS: We used data from the HIV surveillance with DC department of health (DoH) for all people who are HIV positive, currently living in DC and their concurrent care data reported from laboratories and providers. The cases were geocoded and aggregated by census tracts. We implemented Geti-Ord G-statistics to identify MSM hotspots in ArcGIS 10.5.1. Logistic regressions were used to explore clinical and demographical characteristics associated with HIV positive MSMs.

RESULTS: The analysis identified 6001 HIV positive MSMs and 6077 HIV positives non-MSMs (total n=12078) who are currently living in DC. The MSM hotspots identified based on G-statistic were located in central DC covering 35 tracts of wards 1, 2 and 5 ($p<0.001$). At individual level MSMs hotspots showed higher percent of diagnoses among blacks (56.51%), ages 30 – 39 (32.16%) and poor outcomes of viral suppression (13%). The regression showed higher odds of MSM diagnoses were among younger (ages 13 – 19) (OR 3.844; CI 95% 3.3226, 4.4490) population than non-MSMs. The MSMs were at higher odds of late linkage (12 months) (OR 1.2861; CI 95% 1.0834, 1.5268) and poor viral suppression (OR 0.866; CI 95% 0.7775, 0.9656) compared to non-MSMs.

CONCLUSIONS: The identified DC hotspots covering tracts needs immediate attention for prevention-intervention based on the analysis. MSMs were among late linkage to care which may be responsible for poor viral suppression outcomes compared to non-MSMs. It is well known that early linkage to care leads to lower viral suppression. These results will drive space-based interventions such as linkage to care, antiretroviral adherence, viral suppression and increase testing along with culturally appropriate public health messaging.

PEC0367

USE OF HIV PRE-EXPOSURE PROPHYLAXIS AMONG GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN (GBMSM) IN ENGLAND: DATA FROM THE AURAH2 STUDY

N. Hanum[1], V. Cambiano[1], J. Sewell[1], A. Phillips[1], A. Rodger[1], A. Speakman[1], N. Nwokolo[2], D. Asboe[2], R. Gilson[1,3], A. Clarke[4], A. Miltz[1], S. Collins[5], F. Lampe[1]

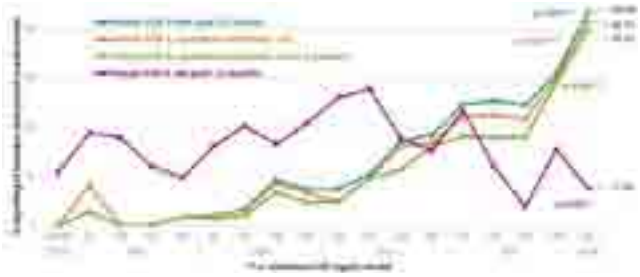
[1]University College London, Institute for Global Health (IGH), London, United Kingdom, [2]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom, [3]Central and North West London NHS Foundation Trust, London, United Kingdom, [4]Brighton and Sussex University Hospital NHS Trust, Brighton, United Kingdom, [5]HIV i-Base, London, United Kingdom

BACKGROUND: Pre-exposure prophylaxis (PrEP) is not yet available through the National Health Service England (NHSE) but has been available through the PrEP Impact Trial (Public Health England) since October 2017, or by online purchasing. We report changes in the use of PrEP and Post-exposure prophylaxis (PEP) among HIV-negative GBMSM in AURAH2, a prospective cohort study, and assess predictors of PrEP initiation.

METHODS: Participants self-completed a baseline paper questionnaire at one of three UK GUM clinics (June 2013-Apr 2016), and subsequent four-monthly and annual online questionnaires, including information on socio-demographics, HIV status, sexual behaviours, to March 2018. Information on PrEP/PEP use in the previous 12 months was obtained from baseline and annual questionnaires. Age-adjusted Poisson models were used to assess factors associated with PrEP initiation among participants who reported never used PrEP at baseline.

RESULTS: 1167 men (mean age 34 years, 84% white, 94% gay, 74% university-educated) completed a baseline questionnaire; 482 completed at least one annual questionnaire. PrEP use in the past year increased from 0% in Jul-Dec2013 to over 40% by Jan-Mar2018; while PEP use declined after 2016 (Figure 1).

Among 460 men who had never used PrEP at baseline, predictors of initiating PrEP included: age ≥40 years (aIRR 4.25, p=0.03); employment (aIRR 2.84, p=0.032); homeowner (aIRR 7.9, p=0.044); recent HIV test (aIRR 5.17, p=0.001); condomless sex in previous 3 months (aIRR 5.01, p<0.001); condomless sex with≥2 partners (aIRR 5.43, p<0.001); group sex (aIRR 1.69, p=0.045); recreational drugs/chemsex use (aIRR 2.05, p=0.007); PEP use (aIRR 4.69, p<0.001); and calendar year (aIRR for 2017-2018 versus 2013-2015 21.19, p<0.001). Online PrEP purchasing still continued even after the PrEP Impact Trial started.



[Figure 1. Prevalence of PrEP and PEP use in the past 12 months over time among GBMSM in the AURAH2 study, 2013 - 2018]

CONCLUSIONS: PrEP use increased significantly over time among a cohort of GBMSM in England reaching over 40%. High-risk HIV-related sexual behaviours, older age and more favourable economic situation were associated with PrEP initiation.

PEC0368

HIV EPIDEMIC TRENDS AND THE IMPACT OF RACE / COLOR ON VULNERABILITY AMONG GAY MEN (MSM) - SAO PAULO STATE, BRAZIL

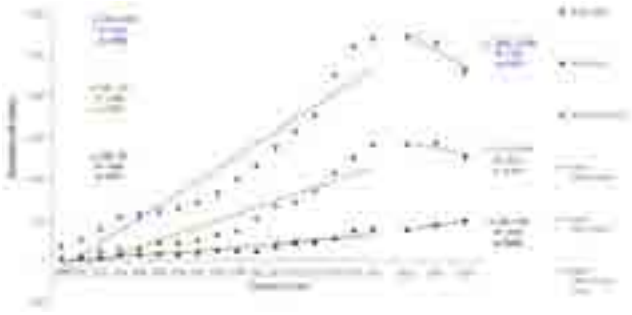
M. Tancredi[1], V. Pinto[2], C. Domingues[1], A. Tayra[1], M. Polon[1], S. Rocha[3], M.C. Gianna[4], R. Alencar[4], A. Gonçalves[5], A. Kalichman[4]

[1]Sao Paulo State AIDS Reference Center, Epidemiology, Sao Paulo, Brazil, [2]Sao Paulo State AIDS Reference Center, IST Outpatient clinics, Sao Paulo, Brazil, [3]Sao Paulo State AIDS Reference Center, AIDS Outpatient Clinics, Sao Paulo, Brazil, [4]Sao Paulo State AIDS Reference Center, Management, Sao Paulo, Brazil, [5]Sao Paulo State AIDS Reference Center, Technical Board, Sao Paulo, Brazil

BACKGROUND: Brazil is a democratic country with high income concentration and great social inequalities. It was also the last Western country to end slavery, and the black population to date has the worst social and health indicators. The objective was to analyze trends of reported HIV infection among MSM in Sao Paulo, according to race between 2000 and 2018.

METHODS: Trend study by polynomial regression models comparing race by HIV diagnosis period. The dependent variable (Y) was the annual number of HIV cases in each category and the independent variable (X) was the time, in calendar years, in the period. The goodness of fit via r^2 and p <0.05 were used to determine which models and data were most appropriate.

RESULTS: In the period there were 75,185 HIV+ male cases, of which 39,793 were MSM. There was an increasing trend between 2000 and 2016 with a speed of 365 cases / year and a first order model [Y = 365X + 3,502; r^2 =0.91; p <0.001], and between 2016 and 2018 the trend was decreasing with a speed of 570 cases / year with linear model [Y = -570X + 6,992; r^2 =0.90; p =0.015]. The figure 1 shows the trends among MSM by race.



[Figure 1. Trends of HIV infection among MSM by race, Sao Paulo, 2000 - 2018.]

CONCLUSIONS: Among MSM the trends were increasing until 2016 for all races. After 2016 there was a fall among whites and mixed-color, more expressive for whites. Among black MSM, the trend continued to grow after 2016 at three times the speed of the previous period. These differences can be explained by difficulties in accessing services, and especially pre-exposure prophylaxis, pointing to structural racism, discrimination and social exclusion suffered by black MSM. These data strongly recommend the formulation of public policies that increase this population's access to health services, information and combined prevention strategies.

PEC0369

THE DECLINE IN NEW HIV DIAGNOSES IN GAY AND BISEXUAL MEN IN THE UK: THE CLINIC IMPACT

A. Brown[1], C. O'Hallaron[2], S. Nash[2], S. Croxford[2], V. Delpech[2]
[1]Public Health England, London, United Kingdom, [2]Public Health England, HIV, London, United Kingdom

BACKGROUND: In the UK, the number of new HIV diagnoses among gay and bisexual men (GBM) fell by 35% from 3,480 in 2014 to 2,250 in 2018. This decrease is confirmed by CD4 back calculation modelling, which indicates a 73% reduction inincident HIV infections in GBM from 2,300 (95% credible interval (CrI) 2,100 to 2,500) in 2014 to 800 (CrI 500 to 1,400) in 2018. This decrease has been linked to the success of combination prevention: HIV testing (including high frequency testing), high ART coverage and increasing PrEP. We examine differential declines in HIV diagnoses at the clinic level.

METHODS: Public Health England undertakes comprehensive surveillance of every UK HIV diagnosis. English HIV clinics were categorised as "large fall clinics" if they had a fall of over 40% (the English average) and a decline of at least 15 HIV diagnoses between 2014 and 2018. Men diagnosed abroad (2,215/11,815) were excluded. Overall, 16 clinics met this criteria, eight in London and eight elsewhere.

RESULTS: Between 2014-2018 new HIV diagnoses declined by 1,409 with 68% of this decline occurring in "large fall clinics". In London large fall clinics, diagnoses fell by 75% (995 to 244) compared to 57% (351 to 151) in large fall clinics outside London. Elswhere, HIV diagnoses decreased by 47% (513 to 270) in London and by 25% outside London (857 to 642).

In large fall clinics, HIV diagnoses declined by 74% in white and 76% in UK-born men compared to 67% and 71% in black, Asian and minority ethnic (BAME) men and men born outside the UK respectively. In other settings, the steepest declines were among white (38%, 1,097 to 677) and UK-born men (32%, 869 to 589). This compares to a 12% decrease in BAME men (238 to 209) and a 26% decrease among men born abroad (435 to 320).

CONCLUSIONS: The reduction in new HIV diagnoses among GBM in England is concentrated in 16 clinics. In other clinics, the decline is less pronounced and mainly observed in white, UK-born men. Further work is needed to ensure prevention initiatives reach everyone, regardless of clinic attended, ethnicity and place of birth.

PEC0370

IDENTIFYING REGIONS OF GREATEST NEED FOR ENDING THE HIV EPIDEMIC: A PLAN FOR AMERICA

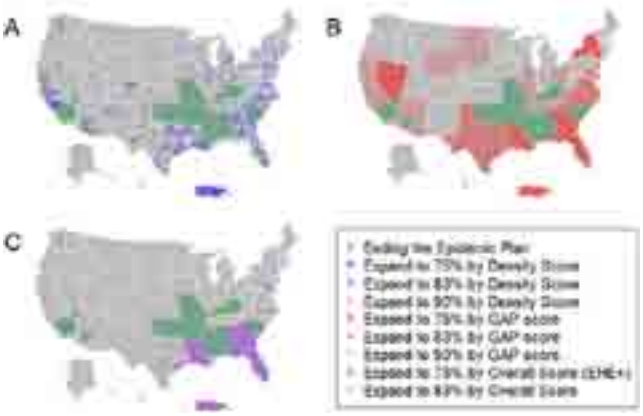
J. Moore[1], M.-C. Boily[2], K.M. Mitchell[2], D. Donnell[3], M.S. Cohen[4,5,6], D. Dimitrov[3,7]
[1]James Moore, Vaccine and Infectious Disease, Seattle, United States, [2]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom, [3]Fred Hutch Cancer Research Institute, Vaccine and Infectious Disease, Seattle, United States, [4]University of North Carolina, Medicine, Chapel Hill, United States, [5]University of North Carolina, Microbiology and Immunology, Chapel Hill, United States, [6]University of North Carolina, AIDSCAP, Chapel Hill, United States, [7]University of Washington, Applied Mathematics, Seattle, United States

BACKGROUND: In the 2019 State of the Union Address, President Trump announced a plan for "Ending the HIV Epidemic (EHE)" in the United States with a goal to reduce new HIV infections by 90% by 2030. Phase one of the plan set an intermediate goal of a 75% reduction within five years, focusing on high incidence counties and states.

METHODS: We assessed the feasibility of the first phase of the plan by estimating the fraction of HIV diagnoses occurring within the targeted region, using a statistical model, which we assessed using ten-fold cross-validation, to predict new HIV diagnoses in each county.

We suggested new areas to add to the current plan, prioritizing by both a "Density score" (blue areas in panel A) quantifying numbers of new diagnoses per square mile and per-capita and a "GAP score" (red areas in panel B) quantifying shortcomings in ART and PrEP uptake, in order to reach areas with 75% of new diagnoses.

RESULTS: We estimated that the current EHE plan targets less than 60% of new diagnoses. Expanding the plan to areas prioritized by both metrics (purple areas in panel C): Puerto Rico, Florida, Georgia, Louisiana, and Maryland as well as parts of New York, North Carolina, Texas, and Virginia increases the potential reach of the plan to 75% of new diagnoses.



[Figure]

CONCLUSIONS: Many of the highest priority areas, both by density of HIV cases and by lack of viral suppression and PrEP use, are not covered by the EHE plan, particularly in the South. The current plan must be expanded to feasibly allow for a 75% reduction in new HIV cases within five years.

PEC0371

TOPS NEED PREP TOO: ALCOHOL AND CONDOMLESS INSERTIVE (TOP) ANAL INTERCOURSE AMONG BLACK/LATINO SEXUAL-MINORITY MALE NON-PREP USERS

T. Washington[1], S. Applewhite[2]
[1]California State University, Social Work, Long Beach, United States, [2]City University of New York, Sociology, New York, United States

BACKGROUND: Since new prevention strategies, such as Pre-Exposure Prophylaxis (PrEP) or having an undetectable viral load have come about, young men who have sex with men (MSM) are using these as characteristics for serosorting and decisions about condomless sex [1].

While these advances are important across the HIV continuum, men who consider themselves a top (the inserter during anal sex) continue to get mixed messages or do not understand the HIV risk of having condomless insertive anal intercourse (CIAI) [2-5]. Given this concern, and recognizing that black and Latino MSM (BLMSM) are disproportionately affected by HIV, we sought to better our understanding of factors associated with CIAI among a high risk sample of BLMSM who are non-PrEP users.

METHODS: Self-report surveys were administered to 188 BLMSM (black=94, Latino=94) at bars/clubs, and public organized events in Los Angeles County; aged 18 to 40 (Mean=24.32, SD=4.45); male; reporting anal intercourse with a man and consumed alcohol within last 30 days. Participants were self-reported HIV negative and non-PrEP users. HIV risk behavioral variables were included, such as substance use before or during sex, and seeking sex online. Binary logistic regression was used to explore unadjusted relative risks between CIAI and HIV risk behaviors, and to further explore adjusted relative risks.

RESULTS: Highlighted findings from the unadjusted odds ratio estimates revealed that BLMSM non-PrEP users who reported drinking alcohol before or during sex were 4.5 times more likely to report CIAI (unadjusted OR=4.55, CI = 1.79-11.56, p= .001). This held true when controlling for drugs before or during sex, poppers use before or during sex, and meeting sex partners online. The adjusted rate indicated that BLMSM who reported drinking alcohol before or during sex were 6 times more likely to report condomless insertive anal intercourse (unadjusted OR=6.00, CI = 2.01-17.85, p= .001).

CONCLUSIONS: The data suggest that BLMSM non-PrEP users practicing CIAI engage in drinking alcohol before and during sex, an additional risky practice. Our data provide evidence that HIV prevention messages/interventions continue to be needed that encourage PrEP use, inform of the risk of CIAI, and alcohol before and during sex risk.

PEC0372

THE PRE-EXPOSURE PROPHYLAXIS (PREP) OBSTACLES SCALE: PRELIMINARY FINDINGS FROM A PILOT STUDY, UNITED STATES

T. Washington[1], H. Klein[2]
[1]California State University, Social Work, Long Beach, United States, [2]Kensington Research Institute, Silver Spring, United States

BACKGROUND: Despite being at the cornerstone of current initiatives to curtail the spread of HIV, Pre-Exposure Prophylaxis (PrEP) medication has been slow to proliferate among many "at risk" sup-groups. This is true for ethnic- minority men who have sex with other men (MSM), who account for the largest number of new HIV diagnoses in the United States. To try to understand why MSM are not adopting PrEP in greater numbers, the present authors have created a 20-item PrEP Obstacles Scale. This paper reports findings for that scale.

METHODS: Purposive sampling was used to derive a sample of 273 diverse MSM, aged 18 and older (M=34.4, SD=13.1). Men completed a brief questionnaire inquiring about their awareness of PrEP, willingness to avail themselves of various sources of information about PrEP, perceptions about PrEP-related stigma, and perceptions about obstacles to PrEP use. By choosing this methodological approach, the researchers' principal goal was to assemble as diverse a sample of MSM as possible. In this manner, the present authors were able to examine differences among different subgroups of MSM–for example, Caucasians versus African Americans versus Latinos, or younger men versus older men–by virtue of each subgroup's representation in the final sample. Cronbach's alpha reliability coefficients were computed for the PrEP Obstacles Scale, for the full sample and for key subgroups. Factor analysis was performed to determine whether or not subscales exist.

RESULTS: The PrEP Obstacles Scale was found to be highly reliable, both in its full version (alpha=0.96) and in its shortened version (alpha=0.95). Reliability estimates were strong for all subgroups based on race, sexual orientation, educational attainment, relationship status, age, and HIV serostatus. Two subscales were created, each with excellent reliability (alpha=0.92 and 0.92), again for the sample as a whole and for all key subgroups.

CONCLUSIONS: The PrEP Obstacles Scale shows great promise for aiding our understanding of why more MSM are not adopting PrEP. It was found to be reliable for all key subgroups under examination, and that is true both for the 20-item and the 8-item version of the scale, and for the two subscales.

PEC0373

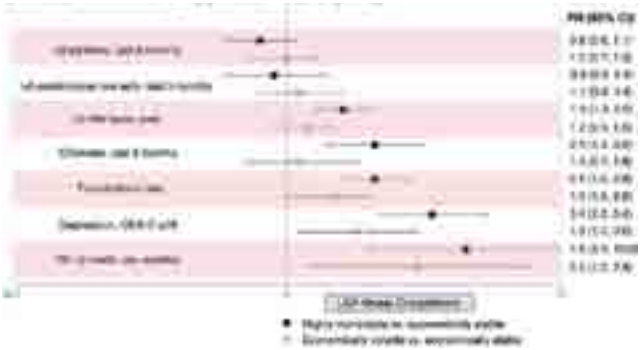
INTERSECTING DETERMINANTS OF HIV-ASSOCIATED VULNERABILITY AMONG BLACK MEN WHO HAVE SEX WITH MEN: A LATENT CLASS ANALYSIS

K. Rucinski[1], L. Eaton[2], J. Maksut[1], V. Earnshaw[3], R. Watson[2]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]University of Connecticut, Department of Human Development and Family Sciences, Storrs, United States, [3]University of Delaware, Department of Human Development & Family Sciences, Newark, United States

BACKGROUND: HIV incidence rates among black men who have sex with men (BMSM) are among the highest in the United States. Implementation of targeted HIV-prevention interventions requires a complete understanding of the multiple and intersecting determinants of HIV-associated vulnerability among BMSM.

METHODS: We used latent class analysis (LCA) to identify underlying constructs of structural vulnerability among 449 BMSM enrolled in a randomized trial in Atlanta. Determinants included in the model were informed by a social-ecological framework, and comprised educational attainment, income level, employment status, and current/former homelessness. The relationship between latent-class membership and individual-level behaviors was characterized using age-adjusted modified-Poisson regression models with robust standard errors to estimate prevalence ratios (PR) and 95% confidence intervals (CI).

RESULTS: We identified three underlying types of HIV-associated vulnerability among BMSM: 1) high educational attainment/employment (representing ~39% of the population), 2) extreme poverty/homelessness (~36%), and 3) poverty/unemployment but high educational attainment (~25%). We labeled these groups as being "economically stable", "highly vulnerable," and "economically volatile," respectively. Compared to BMSM who were economically stable, BMSM who were highly vulnerable were more likely to report recent chemsex (PR: 2.1, 95% CI: 1.4-3.2), transactional sex (PR: 2.1, 95% CI: 1.6-2.8), and regular use of crack/intravenous drugs (PR: 4.5, 95% CI: 2.0-10.0) (Figure).



[Figure. Prevalence ratios (PR) and 95% confidence intervals (CI) for the association of LCA-group type with select sexual-risk behaviours and psychosocial measures (N=449).]

Estimates were generally similar, albeit attenuated, when comparing economically volatile BMSM with those who were economically stable. Importantly, sexual risk behaviors, including condomless sex and sex with multiple partners, were similar across groups. However, highly vulnerable BMSM were the least engaged in HIV-related services.

CONCLUSIONS: Implementation strategies for national HIV-prevention interventions are needed to overcome the multiple structural barriers that impact more proximal HIV risks for BMSM. Reaching diverse groups of BMSM, such as those who remain marginalized from existing HIV services, should be prioritized for HIV prevention and remains central to a comprehensive HIV response.

PEC0374

UNDERSTANDING DIFFERENTIAL RISK AND HEALTH-SEEKING BEHAVIORS BETWEEN HOMOSEXUAL AND BISEXUAL MEN IN PERU: OPPORTUNITIES FOR OPTIMIZING HIV CARE DELIVERY

L. Menacho[1], G. Díaz[1], E. Gonzáles-Lagos[1], J. Zunt[2], P. García[1], J. Clark[3]
[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]University of Washington, Seattle, United States, [3]University of California (UCLA), Los Angeles, United States

BACKGROUND: Bisexual men seem to have different sexual behaviors, needs and preferences for receiving HIV prevention interventions and care. HIV care in Peru is still delivered without considering potential differences among men who have sex with men (MSM). We explored the differences between bisexual and homosexual men in Peru in order to inform future HIV prevention interventions tailored for bisexual men.

METHODS: From February to June 2016, we performed an online survey with Peruvian MSM older than 18 years. By targeted sampling, we hosted the survey on the most visited local gay websites and on Facebook. We conducted bivariate and multivariate analysis to assess differences in self-reported sexual behaviors and other characteristics between self-reported bisexual and homosexual men.

RESULTS: The mean age of the 898 subjects who completed the survey was 30.2 years; over 80% had post–high school education; and 560 (62.4%) self-reported as bisexual (37.6%, homosexual). Overall, the self-reported HIV prevalence was 15.6%. For bisexual men, rates of report of unprotected vaginal sex (UVS) and unprotected anal sex (UAS) with other men varied substantially according to partners; with stable partners: UVS (81.3%) and UAS (70%); with casual partners: UVS (51.6%) and UAS (51.4%); with sex workers: UVS (12.3%) and UAS (31.2%). Compared to homosexual men, bisexual men were significantly more likely to be top or versatile, to have sex under the influence of alcohol with men and women, to prefer health centers not working with gay men, and to have UVS. Bisexual men were significantly less likely to seek care when having symptoms of sexually transmitted infections (38.3% vs. 46.7%; p=0.014), to be tested for HIV, to be HIV positive (12.3% vs. 20.6%; p=0.011), and to have UAS with other men (45.4% vs. 57.1%; p=0.001). In a multivariate analysis, not seeking care at health centers for gay men, and being top or versatile were associated with self-reporting as bisexual.

CONCLUSIONS: Bisexual men report high and differentiated sexual risk behaviors with both men and women. Health seeking behavior and preferences for HIV care are also different. In order to reach bisexual men successfully, HIV prevention interventions need to be tailored specifically for them.

PEC0375

MAPPING AND POPULATION SIZE ESTIMATES OF PEOPLE WHO INJECT DRUGS IN AFGHANISTAN, 2019: SYNTHESIS OF MULTIPLE METHODS

A.A. Atarud[1], S.A. Sayedzai[2], H. Sharifi[3], P. Wesson[4], S.J. Pashtoon[5], F. Tavakoli[3], N. Ghalekhani2[3], M.Z. Harooni[6], S. Maroofi[7], M.B. Hamidi[8], E. Ehsan[9], W. McFarland[4], A. Rasheed[10], N. Hmadard[7], R. Qazizada[8], N.M. Samim[7], T. Aynie[6], A. Mirzazadeh[4]
[1]United National Development Program, Global Fund Program, Kabul, Afghanistan, [2]Ministry of Public Health, Evaluationa and Health Informaiton Directorate, Kabul, Afghanistan, [3]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [4]University of California, San Francisco, United States, [5]Youth Health and Development Organization, Kabul, Afghanistan, Kabul, Afghanistan, [6]United Nations Development Program, Kabul, Afghanistan, [7]Ministry of Public Health, Kabul, Afghanistan, [8]Ministry of Public Health, ANPASH, Kabul, Afghanistan, [9]Ministry of Public Health, ANPASH, AIDS Control Program, Kabul, Afghanistan, [10]Youth Health Development Organizsation, Kabul, Afghanistan

BACKGROUND: Afghanistan experiences a concentrated HIV epidemic among people who inject drugs (PWID). The mapping and population size estimation of PWID provide program staff and policy makers critical information needed for monitoring coverage of programs, and planning appropriate new interventions. We measured locations, typology, and population size of PWID in eight cities, and extrapolate results to other major cities in Afghanistan.

METHODS: PWID (i.e. 18 years or older who inject drugs in the last 12 months) locations, typology and population size was measured by (i) key informant interviews and FGDs, mapping and enumeration with revers tracking method, (ii) the unique object and service multipliers, (iii) capture-recapture, (iv) wisdom of crowds, and (v) a synthesis of the estimates from above methods using the Anchored Multiplier Bayesian approach (point and 95% Credibility Interval [CI]). Then, we used a regression model and several proxy indicators to extrapolate the results to other non-studied major cities.

RESULTS: We found more than 374 hotspots for PWID across the eight cities. Majority of PWID who participated in the study were male (99.3%), reported last injected in last 3 months (82.5%), reported Heroin as the major drug for injection (99.3%), ever tested for HIV (82.0%), and knew their HIV status (70.0%). The self-reported HIV prevalence was 20.7%, ranged from 0% in Zaranj to 63.0% in Kabul. The total number of PWID in 31 major cities was estimated to be 25,736 (95%CI 19,364 to 32,877) persons, which corresponds to 0.69% (95%CI 0.52% to 0.88%) of the adult population (15 – 64y), the highest number 6,061 (95%CI 4,257 to 8,225) living in Kabul.

CONCLUSIONS: Using multiple methods, our study provided estimates for the population of PWID in major cities in Afghanistan. The PWID population size is considerable, and in certain areas, a large number of them are infected with HIV and need to be reached by care and treatment services in Afghanistan.

PEC0376

PERSISTENTLY HIGH HIV RATES AMONG YOUNG MSM DESPITE DECLINES AMONG MID-ADULT AND OLDER MSM CORRESPONDING TO SCALE-UP OF HIV PREVENTION, SILOM COMMUNITY CLINIC IN BANGKOK, THAILAND 2005-2018

S. Pattanasin[1,2], F. van Griensven[3,4], P.A. Mock[1,2], W. Sukwicha[1,2], S. Winaitham[1,2], K. Satumay[1,2], A.C. Hickey[1,2], J. Woodring[1,2], T.H. Holtz[1,2], S. O'Connor[1], T. Siraprapasiri[5], E.F. Dunne[1,2]

[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]Thailand Ministry of Public Health - U.S. Centers for Disease Control and Prevention Collaboration, Nonthaburi, Thailand, [3]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [5]Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand

BACKGROUND: In the last decade, there has been scale up of HIV prevention strategies in Bangkok, Thailand, including HIV treatment, PrEP and HIV testing. Silom Community Clinic (SCC) in central Bangkok provides HIV testing and this open cohort can offer an opportunity to monitor prevention policies and practices. We assessed quarterly trends in HIV-1 frequency and incidence among clinic attendees.

METHODS: Clients attending SCC from 2005–2018 were tested for HIV infection using rapid HIV tests at each visit. We describe the proportion and incidence of HIV and used a restricted cubic spline (RCS) function for time to assessed trends. We compared HIV incidence before and after Quarter 1, 2014 using an indicator variable with Poisson regression with a RCS function for time and age group.

RESULTS: From 2005–2018, 14,034 clients attended SCC for HIV testing; 4,067 tested HIV-positive. The HIV frequency increased from 19·2% in 2005–2006 to 34·0% in 2010, remained stable at about 30% from 2011-2016 and then decreased to 17·2% in 2018 (p < 0·0001). The overall HIV incidence from 2005–2018 was 4·1 per 100 person-years (PY), with an inverted U-shape trend and a peak in 2009 (p < 0·0001). HIV incidence increased from 3·6 per 100 PY in 2005–2006 to 5·4 per 100 PY in 2009 and declined to 4·0 per 100 PY in 2018. From 2005-2018, HIV incidence among young MSM aged 13–21 years remained high at 10·0 per 100 PY compared to those aged 22–29 years and 30 years and older in whom the HIV incidence was 4·9 and 2·4 per 100 PY, respectively.

CONCLUSIONS: We found recent declines in HIV frequency and incidence, corresponding with increased HIV prevention initiatives starting in 2014. However, HIV incidence remained high among young MSM, indicating an ongoing need for targeted testing and prevention activities to further decrease HIV transmission among young MSM in Bangkok.

PEC0377

PREVALENCE AND FACTORS ASSOCIATED WITH HIV INFECTION AMONG MSM WHO HAD A PREVIOUS NEGATIVE HIV RESULT IN BRAZIL

M.D. Guimaraes[1], A.M. Brito[2], M.A. Veras[3], C. Kendall[4], I. Dourado[5], K. Ligia[6], The Brazilian HIV/MSM Surveillance Group

[1]Federal University of Minas Gerais, Preventive Medicine, Belo Horizonte, Brazil, [2]Aggeu Magalhães Institute - FIOCRUZ, Recife, Brazil, [3]Faculdade de Ciências Médicas da Santa Casa de São Paulo, São Paulo, Brazil, [4]Center for Global Health Equity, Tulane School of Public Health and Tropical Medicine, New Orleans, United States, [5]Collective Health Institute, Federal University of Bahia, Salvador, Brazil, [6]Federal University of Ceará, Department of Community Health, Fortaleza, Brazil

BACKGROUND: HIV is still increasing among men who have sex with men (MSM) in several countries, including Brazil, despite recommended test & treat policy. The objective of this analysis was to assess the prevalence of HIV infection among MSM who had a previous negative test in the past 12 months and its associated factors.

METHODS: Respondent Driven Sampling(RDS) cross-sectional study conducted in 2016 in 12 Brazilian cities. HIV serology was performed using standard rapid tests.Risk behavior and sociodemographic data were obtained. RDS weighted prevalence rates with 95% confidence intervals (95%CI) were estimated. Multivariate Poisson regression was used to estimate the prevalence rate ratio (PRR) with 95%CI comparing those who tested HIV positive at the time of the study to those who remained negative.

RESULTS: Among 4176 recruited MSM, 46.6% (1947/4176) reported previous HIV testing in the 12 months prior to the study. Among these, 82.4% (1604/1947) reported an HIV negative result. During the study 113 (7.5%; 95% CI=3.4 - 11.6) tested positive and 92.5% remained negative. Selected factors statistically associated (p<.05) with HIV positivity are shown below.

VARIABLES	PRR (95% CI)
Age(18-24 y.o.)	1.28(1.19-1.39)
No STI counseling past 12 months	2.94(2.73-3.16)
Did not receive free condoms past 12 months	1.36(1.26-1.47)
History of STI past 12 months	2.11(1.92-2.32)
No syphilis testing past 12 months	1.62(1.49-1.75)
Current positive test for syphilis	5.43(5.06-5.83)
Exchanged sex for money past 6 months	1.40(1.30-1.51)
Last receptive anal sex unprotected	1.67(1.55-1.80)
Used social media for sex encounters past 12 months	1.88(1.72-2.06)

[Table]

CONCLUSIONS: It is of extreme concern that 7.5% of MSM who were HIV negative within the past 12 months have seroconverted. Previous testing of these MSM may not have followed proper counseling and/or access to free condom. Unsafe practice persisted, along with paid sex and vitual sex encounters. Not only most of them did not have a previous syphilis testing but also current positivity for syphilis was the strongest factor associated with HIV infection. All these factors may act synergistically as important drives for the persistence of the HIV epidemic among MSM in Brazil. Urgent public actions are needed, including proper counseling, expansion of PrEP, condom availability and also access to HIV self-testing.

PEC0378

PRE- AND POST-EXPOSURE PROPHYLAXIS AWARENESS AND SERVICE USAGE AMONG MEN WHO HAVE SEX WITH MEN IN CHINA: AN INTERVENTIONAL STUDY

X. Wang[1], X. Hu[2], Z. Liu[1], M. Han[1]
[1]National Center for AIDS/STD Control and Prevention, China CDC, Beijing, China, [2]Zhejiang Provincial Center for Disease Control and Prevention, Hangzhou, China

BACKGROUND: With implementation of integrated intervention, HIV transmission is still increasing alarmingly among men who have sex with men (MSM) in China. It is urgent to promote pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP). The aim of this study was to assess the awareness and service usage promotion of PrEP and PEP among MSM.

METHODS: This two-stage interventional study of PrEP/PEP awareness and service usage at baseline and follow-up took place in Harbin, the capital city of Heilongjiang province in China. The study population is MSM in the previous year, 18 years or older, currently living in Harbin. The two main recruitment methods were peer-referral and disseminating survey information through internet. We collected data by asking participants to scan a two-dimensional code with a cellphone and fill out an online questionnaire, which covers demographic and behavior characteristics, and PrEP/PEP awareness, service usage, and future taking willingness. We also sampled blood for HIV tests. Follow-up was in the 3-12 months range after baseline study. HIV-negative MSM at the baseline were imparted PrEP and PEP knowledge. All participants provided written informed consent for blood testing and participation in questionnaire interview. The study protocol and informed consent form was approved by the institutional review board of National Center for AIDS/STD Control and Prevention.

RESULTS: Between January 2018 and March 2019, we enrolled 773 MSM for baseline analysis, 430 of whom were available for follow-up. At baseline, MSM being aware of, and having taken PrEP and PEP accounted for 13.5% (104/773), 1.3% (10/773), 41.8% (323/773), and 5.2% (40/773) respectively. At follow-up, the percentages were 89.3% (384/430), 3.3% (14/430), 94.9% (408/430), and 6.3% (27/430) respectively. Ever took PrEP and ever took PEP were the only associated factor for each other. Being aware of PrEP, being aware of PEP, being willing to take PEP were associated with being willing to take PrEP in future. Being aware of PEP and ever took PEP were associated with being willing to take PEP in future.

CONCLUSIONS: PrEP/PEP awareness and service usage was generally low among MSM in Harbin. To promote PrEP/PEP, PrEP/PEP knowledge dissemination should be expanded and strengthened together among MSM.

PEC0379

SEXUAL PARTNERS AND BEHAVIORS OF MEN WHO HAVE SEX WITH MEN IN RURAL PARAGUAY

G. Aguilar[1], L. Mereles[2], T. Samudio[1], G. Lopez[1], L. Gimenez[1], G. Estigarribia[2]
[1]National HIV Program, Asuncion, Paraguay, [2]Instituto de Investigacion Regional en Salud, Universidad Nacional de Caaguazu, Asuncion, Paraguay

BACKGROUND: Data on rural men who have sex with men (MSM) are rare due to stigma and challenges in recruiting rural MSM for research. Studies worldwide, usually from large cities, find MSM at high risk for STIs. In Paraguay, past studies measured HIV prevalence among MSM at 13%, second only to transwomen at 26%. However, the sexual identities, partnerships, and risks for STIs among rural MSM are unknown and may differ from those of their urban counterparts who may have supportive LGBT communities. It is essential to understand the behavior of rural MSM to prevent STI transmission among themselves and to other populations.

METHODS: We conducted a cross-sectional survey of MSM in a rural area of Paraguay using respondent-driven sampling (RDS). RDS uses long chains of peer referrals to the study to obtain samples of hard-to-reach populations. Men were eligible if they were 18 years or older and had anal sex with a man in the last year. An interview collected demographics and sexual behaviors.

RESULTS: The survey enrolled 400 MSM from the rural area of Paraguay. Most were under 25 years (78.8%); 56% self-reported as homosexual, 36% as bisexuals, and 8% as heterosexual. In the last 6 months, 70% had penetrative sex with men, 40% with cis-women, and 38% with transwomen. Of MSM with a female partner, 56% did not use a condom. A majority (58%) did not know the HIV serostatus of their partners; 7% had sex with an HIV-positive partner.

CONCLUSIONS: RDS was able to recruit a large sample of MSM in rural Paraguay. Sexual identities and gender of partners of rural MSM were varied and included cis- and trans-gender women. The sexual networks and low condom use speak to high potential for STI transmission and the need to reach rural MSM with prevention and care programs.

PEC0380

HIV RELATED BEHAVIOURS, PERCEPTION AND BARRIERS AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN A CONSERVATIVE STATE IN MALAYSIA

W.M. Zahiruddin[1], M.S. Mohd Nawi[1], T.A. Tengku Ismail[1], H. Yusoff[2]
[1]Universiti Sains Malaysia, School of Medical Sciences, Department of Community Medicine, Kubang Kerian, Malaysia, [2]Ministry of Health, Kelantan State Health Department, Kota Bharu, Malaysia

BACKGROUND: HIV epidemic in Malaysia from the 1990s and early 2000 which was largely driven by transmission among injecting drug users has essentially declined and being replaced with an ascent in sexual transmission especially among men who have sex with men (MSM). This breakthrough research is aimed to assess HIV related behaviour and explore perception and barriers among the MSM population in a conservative state in Malaysia.

METHODS: A mixed-method study was conducted in 2019 among MSM population in Kelantan, a north-eastern state in Malaysia. Respondent-driven sampling was done to recruit potential samples. Eligible respondents were required to complete a face to face interview based on Integrated Biological and Behavioural Surveillance (IBBS) in Malay language and underwent HIV rapid testing. A qualitative study was followed up among purposive samples to explore related perception and barriers.

RESULTS: A total of 133 men were enrolled with the majority of the respondents were Malay Muslims (92.5%). Mean age was 25 years old ranging between 18 to 44 years. Only seven (5.2%) were screened to be HIV positive. Twenty-nine (21.8%) did not use condoms during their last anal intercourse. About two-thirds of them have a history of being paid to have sex with men while 25% of them have a history of paying men to have sex in the past 12 months. The respondents have an average of four different male partners in the last month. Twenty-two (12%) respondents never had HIV screening. The majority has obtained condom from NGO workers while only 10 (7.5%) and

23 (17%) obtain them from clinics and pharmacies respectively. Although 21% of them ever heard of pre-exposure prophylaxis (PrEP), none were on the medication. Majority of them perceived themselves as susceptible to get HIV from anal sex activity. However, they also fear of public exposure and expressed barriers in utilising sexual health services.

CONCLUSIONS: Even though HIV prevalence was still low among the MSM population, related risk behaviours and challenges were at an alarming stage. Thus, focused prevention efforts and wider universal health care service accessibility are urgently needed for this key population in the country.

EPIDEMIOLOGY OF HIV IN INFANTS AND CHILDREN

PEC0381

THE PAEDIATRIC HIV PROGRAMME IN JOHANNESBURG FROM 2004 TO 2018: A RETROSPECTIVE ANALYSIS OF PROGRAMME TRENDS

J. Dunlop[1,2], R. Lilian[3], C. Tait[4], J. McIntyre[5,6], H. Struthers[7,8], K. Rees[3,9]
[1]Anova Health Institute, Clinical Care and Research, Johannesburg, South Africa, [2]University of the Witwatersrand, Division of Community Paediatrics, Department of Paediatrics and Child Health, Johannesburg, South Africa, [3]Anova Health Institute, Public Health, Johannesburg, South Africa, [4]Anova Health Institute, Paediatric and Adolescent Scale-up Project, Johannesburg, South Africa, [5]University of Cape Town, School of Public Health and Family Medicine, Johannesburg, South Africa, [6]Anova Health Institute, Chief Executive Officer, Johannesburg, South Africa, [7]Anova Health Institute, Chief Operating Officer, Johannesburg, South Africa, [8]University of Cape Town, Division of Infectious Diseases and HIV Medicine, Department of Medicine, Johannesburg, South Africa, [9]University of the Witwatersrand, School of Public Health and Family Medicine, Cape Town, South Africa

BACKGROUND: The paediatric HIV treatment programme in South Africa has grown since its inception in 2004. Despite this, ART coverage in children, an indicator of the number of children started on ART and retained in care, remains unacceptably low, with only 60% of the 337,000 HIV-positive children in South Africa on ART. This analysis aimed to describe the dynamics of the paediatric HIV programme in Johannesburg, South Africa, to direct interventions towards improving paediatric ART coverage.

METHODS: A secondary analysis was conducted on patient-level HIV treatment data using the nationally mandated database. Children under 15 years' old who initiated ART between December 2004 and December 2018 at public health facilities in Johannesburg were included. We calculated the number of children on ART, and retention by age group, and analysed trends in these indicators.

RESULTS: During the study period, the number of children on ART increased from 221 to 7,630, with the growth rate slowing from 2013. By December 2018, 82.5% of children on ART were aged 5-<15 years, with 65.5% of these being 10-<15 years. The number of children newly initiated on ART ranged from 1,172 to 1,373 between 2013 and 2018, with 34.2% of initiators being less than 1 year, 24.2% 1-5 years and 41.6% 5-<15 years of age in 2018. Despite these initiations, in 2018 the number of children on ART only grew by 97, due to programme losses. In 2018, 924 children (12.1%) aged out, 35 (0.5%) died and 983 (12.9%) were lost to follow-up (LTFU), the latter having increased from 10.7% in 2017. Of those who aged out of the paediatric programme, 4,478 (56.3%) remained in care. Of these, 3,398 (75.9%) were 15-<20 years and 1,080 (24.1%) were 20-<30 years of age. An additional 1,599 (20.1%) who aged out were subsequently lost from the ART programme and 1,883 (23.7%) transferred out.

CONCLUSIONS: The number of children retained on ART has remained unacceptably low despite a stable number of initiations yearly. While aging out of the paediatric programme is a consideration, interrogation of barriers to paediatric retention should be further studied to help realise the UNAIDS 90:90:90 goals in South Africa.

PEC0382

PREDICTORS OF HIV POSITIVE RESULTS AMONG ORPHANS AND VULNERABLE CHILDREN IN TANZANIA

A. Barankena[1], A. Exavery[1], A. Ally[1], J. Charles[1], E. Kuhlik[2], L. Kikoyo[1], E. Jere[1]
[1]Pact, Programs, Dar es Salaam, Tanzania, United Republic of, [2]Pact, Programs, Washington, United States

BACKGROUND: An estimated 92,000 Tanzanian children under the age of 15 years are living with HIV, and about 50% have not been diagnosed. Validated risk assessment tools aid case identification in facility settings Tanzania, incorporating risk assessment by lay social welfare volunteers into an orphans and vulnerable children (OVC) project in Tanzania provides information on risk factors in this population to aid pediatric case finding strategies.

METHODS: The project analyzed data collected between January 2018 to March 2019 in 18 regions of Tanzania. The project developed a HIV screening tool with 18 risk factors which incorporated risks from the four items from Bandason et al and criteria from National HIV services guidelines. Lay social welfare volunteers assessed HIV risk in OVC age 0-17, following caregivers' consent. At-risk OVC with unknown status were referred for HIV testing services (HTS). HIV status was self-reported to volunteers. Eighteen risk factors (independent variables) were analyzed using Pearson's Chi–square test, and inference was made at a significance level of 5%, where HIV self-report status was the outcome variable.

RESULTS: Out of the 47,701 OVC who self-reported their HIV status after their HTS referrals, 1.0% (n = 549) were HIV positive. In the multivariate analysis, OVC with malnutrition were 2.14 times more likely to be HIV positive (aOR=2.14, 95% CI 1.51-3.03). OVC living in households with one or more HIV positive members were 1.71 times more likely to be HIV positive than those without (aOR=1.71, 95% CI 1.41-2.06). OVC who had recurrent skin problem were 2.05 times likely to be HIV positive that those without (aOR=1.54, 95% CI 1.29-3.28). OVC whose one or both biological parents were deceased were 1.23 times likely to be positive (aOR=1.23, 95% CI 1.08-1.54).

CONCLUSIONS: To attain the first 90 in the 90-90-90 global goals among OVC, key risk factors for which are predictive of HIV positive among the OVC are: Malnutrition; one or more household members is HIV positive; recurring skin problems; and having one or both biological parents deceased.

PEC0383

AIDS MORTALITY OF CHILDREN LIVING WITH HIV AND ACCESS TO HIV CARE AND TREATMENT IN BRAZIL, 2018

T. Cherem Morelli[1], R. Vianna Brizolara[1], A.A. Cunha Mendes Ferreira[1], F.K. Alvarenga Pinto[1], R. Castro de Albuquerque[1], L. Neves da Silveira[1], G.F. Mendes Pereira[1], A.F. Kolling[1], M. Araújo de Freitas[1]
[1]Ministry of Health of Brazil, Department of Chronic Disease and Sexually Transmited Infectious, Brasilia, Brazil

BACKGROUND: Brazil has successfully implemented universal access to antiretroviral treatment (ART) and consistently reduced vertical transmission of HIV over the years. However, children still die for AIDS related causes, and there is a lack of information of the status of those children regarding access to care and treatment.
METHODS: We conducted a descriptive cross-sectional study. We have selected all children living with HIV under 13 years-old who died in 2018 and were registered in Brazilian's Mortality Information System with AIDS-related deaths. We assessed the status of access to HIV care and treatment of those children and their mothers using the Notification Disease Information System, the Laboratory Test Control System (data on viral load and CD4 exams) and the Logistic Drug Control System (data on ARV dispensing).
RESULTS: In the year of 2018, Brazil had 46 children under 13 years who died of AIDS-related causes. Median age was 22 months. 52% (24/46) died under 2 years old. Only 43% (20/46) initiated antiretroviral therapy (ART), 10% (2/20) of those abandoned treatment and only 30% (6/20) had the treatment oriented by genotyping exam. The average and median age of the mothers of these children was 26 years old. 59% (27/46) of these women had their HIV status at least six months before the death of their children, 30% (14/46) had their HIV status before pregnancy, 11% (5/46) during the pregnancy and 9% (4/46) during delivery. Only four of these mothers started ART before delivery (9%), but just one was in regular adherence to treatment.
CONCLUSIONS: Despite presenting a limited number of children living with HIV dying of AIDS related causes, most of them are avoidable and are related to health system failure in providing proper care and treatment to all mothers and children, so that vertical transmission may be avoided and deaths from AIDS-related causes among children living with HIV stop happening.

PEC0384

FACTORS ASSOCIATED WITH LATE PRESENTATION OF HIV-INFECTED INFANTS FOR EARLY INFANT HIV DIAGNOSIS (EID) SERVICES IN KENYA

A. Langat[1,2], I. Yonga[3], B. Ochanda[1], T. Callahan[4], B. Onyango[3], A. Waruru[1], B. Singa[5], G. Githuka[6], Y. Liu[4], T. Tylleskar[2], S. Modi[4], MNCH PEPFAR Working group (Lennah Omoto, Stephen Oyule, Jane Muli, Abraham Katana, Lucy Nganga)
[1]Centers for Disease Control, Division of Global HIV/TB (DGHT), Nairobi, Kenya, [2]University of Bergen, Center for International Health, Bergen, Norway, [3]USAID, Health Population & Nutrition Office, Nairobi, Kenya, [4]Centers for Disease Control and Prevention, Division of Global HIV &TB, Atlanta, United States, [5]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [6]Ministry of Health, National AIDS and STI Control Program (NASCOP), Nairobi, Kenya

BACKGROUND: Early infant diagnosis (EID) is defined as infant Polymerase Chain Reaction (PCR) testing at age ≤ 8 weeks. We assessed factors associated with late enrolment into HIV-exposed infants (HEI) services for HIV-infected infants, in sites supported by the US President's Emergency Plan for AIDS Relief (PEPFAR) Kenya.
METHODS: We abstracted routinely collected clinical data on all infants with a positive PCR result from 1347 PEPFAR-supported health facilities for the period October 2016 to September 2018. We aggregated the data from all sites in STATA and examined the association of baseline characteristics to timing of HEI enrollment, using univariate and multivariate logistic regression. Late HEI enrolment was defined as >8 weeks and used maternal start of Anti-retroviral Therapy (ART) as a proxy of time of maternal HIV diagnosis since we did not have actual date of HIV diagnosis.
RESULTS: Of the 4091 HIV-infected infants identified, the median infant age at HIV diagnosis was 13 weeks [interquartile range (IQR), 4-64 weeks] and most [2669 (66.5%)] were enrolled late. The majority of mothers of HIV-infected infants enrolled late, were aged 24-34 years (n=1,291; 51%), did not attend ante-natal clinic (ANC) (n=1247; 50%), and were diagnosed in the postnatal period (n=2012; 50%). Of those diagnosed in the postnatal period, majority were newly-diagnosed as HIV positive (n=1615; 80%).
Factors that were independently associated with late HEI enrollment were lack of maternal ANC attendance (adjusted odds ratio (aOR) 1.54;95% confidence interval (CI) 1.27-1.85), new maternal HIV diagnosis (aOR 1.38; 95% CI 1.17-1.63), lack of maternal ART (aOR 1.96, 95% CI 1.64-2.35), HEI identification in outpatient (aOR 14.2, 95% CI: 7.35-27.6) or inpatient ward (aOR 8.92, 95%CI: 4.16-19.1) and late infant immunization (aOR 1.63, 95% CI: 1.31-2.03).
CONCLUSIONS: Every HIV-infected infant indicates a missed opportunity in Prevention of Mother to Child Transmission (PMTCT) programs. Sustained efforts are needed to ensure mothers attend ANC early to receive HIV testing and be prepared to access EID services for their infants. Finally, routine HIV screening in outpatient and inpatient settings may identify HIV-infected infants earlier.

PEC0385

TREND OF ANTIRETROVIRAL REGIMEN IN HIV-INFECTED PREGNANT WOMEN AND ITS CORRELATION TO MTCT RATE IN A CENTRAL PROVINCE OF CHINA

Y. Dong[1], X. Gui[1], J. Chen[2], X. Zhao[3], H. Li[4], Z. Sang[5], H. Liu[6], Y. Peng[7], W. Guo[1], K. Liang[1]
[1]Wuhan University/Zhongnan Hospital, Wuhan, China, [2]Xiantao CDC, Xiantao, China, [3]Qianjiang CDC, Qianjiang, China, [4]Badong MCH Hospital, Badong, China, [5]Jiayu CDC, Jiayu, China, [6]Shishou MCH Hospital, Shishou, China, [7]Guangshui CDC, Guangshui, China

BACKGROUND: The trends of timing for diagnosing HIV infection, antiretroviral therapy (ART) regimen for pregnant women, and mother-to-child transmission (MTCT) rate in central China from 2004 to 2017 is not well known.
METHODS: From January 2004 to December 2017, HIV-infected pregnant women and their babies in some areas of a central Chinese province were enrolled in this study, and information was collected. Mantel-Haenszel χ2 test and Pearson or Spearman correlation analysis were used to explore trends and correlation of timing of diagnosing HIV infection, ARV regimens, and MTCT rate.
RESULTS: A total of 378 mother-child pairs were included in this study. From 2004 to 2017, the MTCT rate showed a downward trend (P=0.014), and was 4.17% (95%CI: 0.52%-14.21%) from 2016 to 2017; the proportion of diagnoses before delivery showed an upward trend, while diagnoses during or after delivery both showed downward trends (P=0.000), and were accounted as 91.67%, 2.08% and 6.25% from 2016 to 2017, respectively; the proportion of those taking prenatal cART showed an

upward trend, while taking prenatal AZT alone, intrapartum single dosage ART or no ART all showed downward trends (P=0.000), and were accounted as 81.25%, 0%, 0% and 18.75% from 2016 to 2017, respectively. There was a negative correlation between MTCT rate and proportion of those diagnosing before conception and during first trimester (r=-0.811, P=0.027). While a positive correlation between MTCT rate and proportion of those postpartum diagnosis (r=0.869, P=0.011), and a positive correlation between MTCT rate and proportion of no ART in pregnant women (r=0.830, P=0.021) were revealed.

CONCLUSIONS: Although the prevention of MTCT had been gradually improved, there still has a lot of room for improvement. Diagnosing HIV-infected pregnant women as early as possible, and thus providing ART timely, will help to further reduce MTCT rate in the future.

EPIDEMIOLOGY OF HIV IN ADOLESCENTS

PEC0386

A CROSS SECTIONAL STUDY ON HIV-1 MOLECULAR EPIDEMIOLOGY IN NORTHEAST CHINA, 2010-2016

F.-X. Wang[1], Q.-H. Li[2], J.-Y. Wang[3]
[1]South University of Science and Technology, Department of Infectious Diseases, Shenzhen, China, [2]Harbin Medical University, Systemomics Center, College of Pharmacy, and Genomics Research Center, Harbin, China, [3]Harbin Medical University, Department of Microbiology, Harbin, China

BACKGROUND: Human immunodeficiency virus type 1 (HIV-1) was introduced into the Northeast China in the early 1990s, since then reported cases increased yearly. However, to date, none cross sectional study on the molecular epidemiology of HIV-1 infection in this area has been reported. This study aimed to describe the changes of the features of HIV-1 infections in Northeast China during 2010-2016.

METHODS: The blood samples were collected from antiretroviral treatment naïve patients who were first diagnosed as HIV-1 seropositive during 2010-2016 in Northeast China. HIV-1 genotype was identified by sequencing partial gag and env gene fragments and phylogenetic analyses. Patient information including age, sex, CD4 cell count and transmission route were also collected.

RESULTS: A total of 1006 patients were enrolled. Totally, CRF01_AE was the dominant HIV-1 genotype, followed by subtype B, C/BC, unique recombinant forms (URFs) and subtype A. Most infections were identified in patients aged 20-49 among men who have sex with men (MSM) population. Following events occurred during 2010-2016: 1) CRF01_AE and URF infections markedly expanded, while subtype B infections dramatically decreased; 2) the average age of patients decreased, because of the yearly increase of younger patients (aged 20-29) and decrease of older patients (aged = 50) in CRF01_AE group; 3) the average CD4 count increased yearly, due to the increased frequency of patients with CD4 counts more than 500 cell/μL in non-CRF01_AE group, especially in URF infected patients; 4) sexual transmission by MSM population increased, while transmission by heterosexual population decreased, which was mainly determined by CRF01_AE infected patients.

CONCLUSIONS: Rapid spread and expansion of CRF01_AE and URF viruses changed the HIV-1 epidemiologic features in Northeast China during 2010-2016. Timely molecular epidemiology surveillance on HIV-1 infections especially CRF01_AE and newly emerging URF infections was quite required for prevention and control of HIV-1 infection in this area.

PEC0387

ASSESSING THE ADOLESCENT VULNERABILITY INDEX: ASSOCIATIONS WITH HIV AND OTHER STIS AMONG YOUNG WOMEN IN ETHIOPIA

O. Olawore[1], C. Comins[1], A. Mulu[2], S. Ayele[2], M. Biru[2], S. Baral[1], S. Schwartz[1]
[1]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [2]Armauer Hansen Research Institute (AHRI), Addis Ababa, Ethiopia

BACKGROUND: Intersecting economic, structural, and biological factors have resulted in significant HIV risk heterogeneity among adolescent girls and young women (AGYW) across sub-Saharan Africa. To quantify risks and guide the implementation of HIV and sexually transmitted infection (STI) programs, we assess associations between HIV and STI and the Adolescent Vulnerability Index (AVI) among AGYW residing in two cites in Ethiopia.

METHODS: 1501 AGYW aged 15-24 years residing in Addis Ababa (n=800) and Gambella (n=701) between February 2018 and July 2019 were recruited using time-location sampling. Procedures included interviewer-administered behavioral surveys including the AVI as a scale previously used in Eastern Africa and biological testing for HIV, syphilis, and chlamydia. The AVI quantifies vulnerability based on answers given to 15 questions including social vulnerabilities and sexual practices with response scores ranging from 0-3. Risk strata are based on total scores including Low (0-10), Medium (11-21), High (22-31) and Very High (32-43) vulnerability. Logistic regression models were used to estimate the crude and adjusted odds of any STI associated with categories of vulnerability.

RESULTS: The median participant age was 20 years (IQR: 18-22), 947 (64%) were out-of-school, and overall 10% tested positive for chlamydia, syphilis, or HIV. Compared to AGYW scoring low on the vulnerability index, those with medium or higher index scores had greater odds of testing positive for any STI (medium OR: 1.27; 95% CI 0.85-1.91), high/very high OR: 3.42; 95%CI: 2.18-5.37). After adjusting for potential confounders, the association remained significant among AGYW with high/very high index scores (AdjOR: 2.52; 95%CI 1.49-4.29).

Vulnerability Index	N(%)	STI Prevalence	UnadjOR (95% CI)	AdjOR* (95%CI)
Low	582 (38.8)	42/582 (7.2%)	1.00	1.00
Medium	700 (46.6)	63/700 (9.0%)	1.27 (0.85-1.91)	1.13 (0.74-1.74)
High	219 (14.6)	46/219 (21.0%)	**3.42 (2.18-5.37)**	**2.53 (1.49-4.29)**

*Adjusted for age, social support, school attendance, mobility, physical violence, and location

[Table 1: Association between Adolescent vulnerability and any sexually transmitted infection among AGYW in Ethiopia]

CONCLUSIONS: The AVI demonstrates the intersection of social and sexual vulnerabilities among AGYW in Ethiopia and the heterogeneity in risk observed among young women. Our findings suggests the need for holistic and evidence-based responses that address individual and structural risk determinants to reduce the risk of HIV and STIs among AGYW in Ethiopia.

Chan School of Public Health, Immunology & Infectious Diseases, Boston, United States, [4]Chiang Mai University, Faculty of Associated Medical Sciences, Occupational Therapy, Chiang Mai, Thailand, [5]Chiang Mai University, Faculty of Associated Medical Sciences, Chiang Mai, Thailand, [6]Phayao Provincial Hospital, Phayao, Thailand, [7]Prapokklao Hospital, Chantaburi, Thailand, [8]Nong Khai Hospital, Nong Khai, Thailand, [9]Mae Sai Hospital, Mae Sai, Thailand, [10]Rayong Hospital, Rayong, Thailand, [11]Sanpatong Hospital, Chiang Mai, Thailand, [12]Mae Chan Hospital, Chiang Rai, Thailand, [13]Hat Yai Hospital, Songkhla, Thailand, [14]Chiang Kham Hospital, Phayao, Thailand, [15]University College London, MRC Clinical Trials Unit, London, United Kingdom

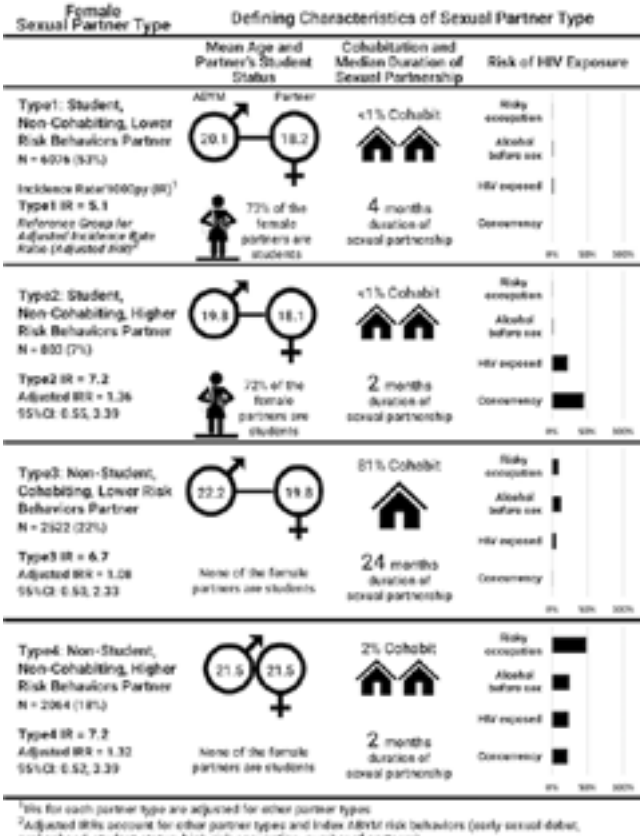
BACKGROUND: There are limited data on the long-term mortality of APHIV receiving ART.
METHODS: TEEWA-1, a cross-sectional study conducted in 2010-2012, enrolled APHIV aged 12-19 years who ever initiated ART in 20 public hospitals across Thailand. Data on sociodemographic, clinical and ART history were collected. In 2018-2019, a repeat cross-sectional study (TEEWA-2) was conducted to ascertain the vital- and follow-up-status of APHIV enrolled in TEEWA-1. Mortality rates were estimated per 1000 person-years (PY), overall and by time-updated age. Patients were considered at risk from entry to the TEEWA-1 until last visit or death. Mortality predictors were explored using the Cox proportional hazard model. The study was approved by Chiang Mai University ethics committee.
RESULTS: Of 884 TEEWA-1 APHIV participants, 873 (99%) completed TEEWA-2. Their characteristics at entry to TEEWA-1 were: 55% females, median [IQR] age 14.6 years [13.2-16.3], 87% living with a family (13% in institutions), 53% double-orphans, 34% single-orphans; median age at ART initiation 9.3 years [7.2-11.5]; all were on ART (72.4% on first-line), 16.5% had viral load (VL) ≥1000 copies/mL; 7.9% had CD4 count <200 cells/mm3.
Overall, 102/873 (11.7%) participants had died, 139 (15.9%) were lost-to-follow-up and 632 (72.4%) were alive and in HIV care. Median time from entry to last visit/death was 6.7 years [5.9-7.7]. Among those who died, median age at death was 19.9 years [18.0-21.2]. Causes of death were available for 73/102 (72%) deaths; 88% were HIV-related (81% had discontinued ART) and 12% were accidents or suicide. Overall, the mortality incidence was 18.6 per 1000PY [95% CI, 15.0-22.2], and by time-updated age:11.6 [4.0-19.2] in 12-14 years, 13.8 [95%CI, 9.8-17.8] in 15-19 years and 33.3 [23.9-42.7] in ≥ 20 years.
Factors associated with mortality at entry to TEEWA-1: older age at ART start (adjusted hazard ratio [95% CI]: 1.08 [1.00;1.15] per year increase, p=0.030) ,VL ≥1000 copies/mL (2.78 [1.67;4.54], p<0.001), on second-line ART (2.44 [1.59;3.73], p<0.001), CD4 count <200 cells/mm3 (4.29 [2.38;7.73], p<0.001), and stunted (<-2 height-for-age-Z-score) (1.52 [1.02;2.29], p=0.042).
CONCLUSIONS: The incidence of mortality among ALHIV was high and increased with age as they entered late adolescence and young adulthood. Support strategies are critically needed to help ALHIV through this transition.

PEC0389

SEXUAL PARTNER TYPES OF ADOLESCENT BOYS AND YOUNG MEN IDENTIFIED THROUGH LATENT CLASS ANALYSIS (LCA) AND INCIDENT HIV-INFECTION IN RAKAI, UGANDA

S. Hoffman[1], A. Zhang[2], N. Nguyen[1], R. Tsong[2], T. Lutalo[3], I. Chen[2], Y. Wei[2], F. Nalugoda[3], C. Kennedy[4], M.K. Grabowski[5,6], J. Li[2], J. Santelli[7]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, Psychiatry, New York, United States, [2]Mailman School of Public Health, Columbia University, Biostatistics, New York, United States, [3]Rakai Health Sciences Program, Kalisizo, Uganda, [4]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [5]Johns Hopkins School of Medicine, Baltimore, United States, [6]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [7]Mailman School of Public Health, Columbia University, Heilbrunn Department of Population and Family Health, New York, United States

BACKGROUND: Sexual partner characteristics are important determinants of HIV risk, but little is known about partner types of sub-Saharan African adolescent boys and young men (ABYM). Using data from the Rakai Community Cohort Study (RCCS) we identified sexual partner types of ABYM and estimated HIV incidence associated with each type.
METHODS: We included sexually active ABYM aged 15-24 from five RCCS data-collection rounds (2005-2013). ABYM reported characteristics for up to four past-year female sexual partners (age, student, cohabiting, relationship duration, high-risk occupation, alcohol before sex, consistent condoms with this partner, and likelihood of partner having concurrent partners and HIV exposure). These characteristics were included in a latent class analysis (LCA) to identify partner types. HIV incidence rate ratios (IRR) for each type (relative to the lowest risk type) were estimated using Poisson regression with GEE to account for multiple observations, adjusting for each ABYM's other partner types and his own risk characteristics.



[Figure]

RESULTS: Among 11,465 partner reports by 4,812 ABYM over five data-collection rounds, men had 1.6 mean partners/round. Four female partner types were identified (see figure on previous page). Two student partner types—with lower risk-behaviors (Type1) and higher risk-behaviors (Type2)—accounted for 52% and 7% of partners, respectively. Two non-student partner types—cohabiting lower risk-behavior partners (Type3) and non-cohabiting higher risk-behavior partners (Type4) accounted for 22% and 18% of partners, respectively. Estimates of partner-specific incidence in the analysis dataset (N=2213 partner-reports, 4066 person-years) was lowest for Type1 and higher for other partner types, but adjusted IRRs relative to Type1 were small and not statistically significant (Figure).

CONCLUSIONS: Among ABYM in Rakai, the most frequent female partner type was a student with lower risk behaviors, but ~30% had partners with higher risk profiles. As ABYM age, it will be important to determine if these higher-risk partner types are associated with elevated incidence.

PEC0390

PROJECTING CHANGES IN AIDS MORTALITY AND HIV INCIDENCE AMONG ADOLESCENTS AND YOUNG PEOPLE IN NIGERIA

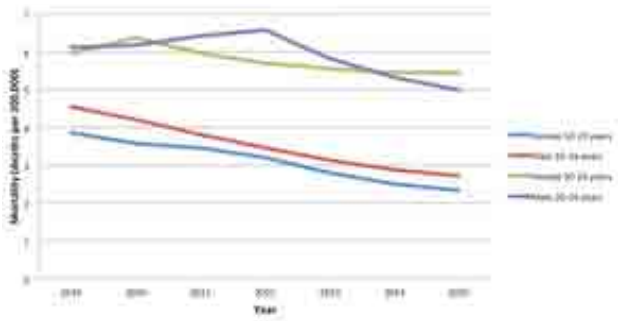
H. Aboki[1]

[1]*National Agency for Control of AIDS (NACA), Community Prevention and Care Services, Abuja, Nigeria*

BACKGROUND: Nigeria is not on track to meet its Fast-Track targets for reduction in new HIV infection and AIDS-related deaths. Females bear more of the burden with higher incidence rates. In 2018, young women aged 20-24 years were estimated to have four times higher HIV prevalence than male peers. This paper examines the projected changes in AIDS mortality and HIV incidence among adolescents and young people aged 10-24 years between 2019 and 2020.

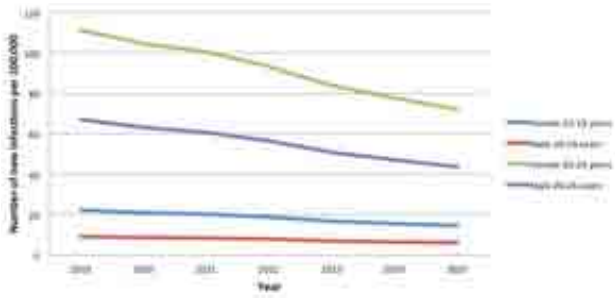
METHODS: Nigeria data on Annual AIDS-related deaths and new HIV infection was extracted from the 2019 EPP/Spectrum files. AIDS mortality rates and HIV incidence rates were compared between male and female adolescents 10-19 years and young people 20 -24 years.

RESULTS: AIDS mortality and HIV incidence are higher among those aged 20-24 years than among adolescents.



[Figure. Projected annual AIDS-related deaths among 10-24 year olds in Nigeria]

Over the six years, AIDS mortality is projected to decrease at a faster annual rate among adolescent girls and boys (females 8.0%; males 8.2%). The rate of decline is much slower among those aged 20-24 years. A marked difference is seen between the sexes; males 3.3% from 6.1 to 5.0 deaths per 100,000 and only 1.4% among females from 6.0 to 5.5 deaths per 100,000.



[Figure. Projected annual new HIV infections among 10-24 year olds in Nigeria]

HIV incidence is projected to be over 2.5 times higher among adolescent girls than boys. HIV incidence declined over the period at similar annual rates; adolescent girls-6.7% and boys-6.6% and young women-7.0% and men-6.9%.

CONCLUSIONS: HIV programming for young people should take into consideration the varying dynamics between age groups and between the sexes and address consequent risks and vulnerabilities.

PEC0391

"HOW COME THEY DON'T TALK ABOUT IT IN SCHOOL?" IDENTIFYING ADOLESCENT BARRIERS TO PREP

L. Gailloud[1], S. Philip[2], T. Gonzalez-Argoti[3], L. Josephs[3], J. Infante[2], J. Mantell[4], L. Bauman[3]

[1]*University of Maryland School of Medicine, Baltimore, United States,* [2]*Montefiore Medical Center, Bronx, United States,* [3]*Albert Einstein College of Medicine, Bronx, United States,* [4]*Columbia University, New York, United States*

BACKGROUND: Pre-exposure prophylaxis (PrEP) was approved for minors in May 2018, however, uptake has been slow. To address the lack of research on adolescents and PrEP, we conducted a qualitative study to explore at-risk adolescents' knowledge about PrEP, barriers to accessing it, and their receptivity to receiving it.

METHODS: 30 in-depth interviews were conducted with Black and Hispanic/Latino HIV-negative, sexually active youth ages 15-17, recruited from four school-based health centers in the Bronx, NY (12 males, 18 females). Inductive and deductive data analysis was conducted with Dedoose.

RESULTS: 28 of 30 youth were unaware of PrEP, and wondered why there was no PrEP education. After a short explanation, almost all (n=28) were enthusiastic about its availability.

However, multiple barriers to PrEP use were identified. *Structural/Access* barriers included failure of providers to educate about PrEP and HIV prevention with youth (n=27), concern that parents will "hinder their sex lives" (n=14), cost/insurance concerns (n=8), and the need to travel to obtain PrEP (n=4). *Patient-level* concerns were an acknowledged inability to adhere to a daily medication (n=14), negative self-perceptions ("I'm not ready to deal with the embarrassment of being on PrEP") (n=8), and concerns about side effects (n=4).

Students were willing to access PrEP at a school clinic (n=22) or from their primary doctor (n=20). Students emphasized the importance of confidential services (n=22), stressing that when something is "leaked towards their parents" they are likely to "never talk to a doctor again." Few valued PrEP for covert use from their partner. Results were consistent for both genders and ethnic groups except for adherence, which more females identified as a barrier (female n=11, male n=3).

CONCLUSIONS: Effective implementation efforts are needed to address adolescent barriers to PrEP. School-based health centers are a strategic site for PrEP provision in the US because they provide confidential and accessible health services at no cost. School-based PrEP education could address the knowledge gap of PrEP, concerns about side effects, and negative self-perceptions.
However, as long as PrEP requires patient adherence to pill-taking, it may be ill suited for many adolescents who are "really not a pill taker".

EPIDEMIOLOGY OF HIV IN WOMEN

PEC0392

PREVALENCE OF STIS, SEXUAL PRACTICES, AND CONTRACEPTION USE AMONG 2083 SEXUALLY ACTIVE WOMEN IN LEBANON

S. Abi Zaki[1], J. Naous[2,1], A. Ghanem[3,1], D. Abou Abbas[1], A. Assi[3,1]
[1]Marsa Sexual Health Center, Beirut, Lebanon, [2]American University of Beirut, Faculty of Medicine, Beirut, Lebanon, [3]University of Saint-Joseph, Faculty of Medicine, Beirut, Lebanon

BACKGROUND: Women residing in Lebanon are reluctant to seek sexual health services for fear of being stigmatized. With no sexual health education, and evidence of stigma in healthcare, women in Lebanon, especially unmarried, are exposed to unwanted pregnancies and sexually transmitted infections (STIs). The aim was to assess rates of STIs, sexual practices, and contraception-use among unmarried sexually active women in Lebanon.
METHODS: An anonymous standardized questionnaire was administered by a healthcare provider to 2083 sexually active women who presented to a sexual-health clinic in Lebanon between 2015 and 2019. Demographics, substance-use, contraception-use, and sexual practices were collected. HIV, HBV, HCV, and syphilis status were evaluated through rapid testing. Presence of genital warts (indicative of HPV) and symptoms of an STI such as gonorrhea, chlamydia, ureaplasma or mycoplasma (dysuria, and/or excessive/foul-smelling discharge) were identified through a clinical exam. Determinants of condom-use, unwanted pregnancies, and symptoms of an STI were assessed using regression models.
RESULTS: The mean age was 27.8(SD: 5), the majority were heterosexual (85%) and unmarried (>85%). There was one case each of HIV, HBV, and syphilis and no cases of HCV. Genital warts were present in 14.7% and symptoms of an STI in 23.5%. Condomless oral, vaginal and anal sex were reported among 95%, 83% and 8% respectively; 41% had ≥2 partners; 38% did not use contraception; 32% had used emergency contraception; 9% had an unwanted pregnancy. Recreational drug use was reported by 44% consisting mainly of cannabis (68%). Inconsistent condom-use was associated with having sexual-health education from unreliable sources such as porn or peers, (p=0.02,adjOR= 1.5), and using natural contraception methods (withdrawal/calendar rhythm) (p=0.008,adjOR= 3.4). Having unwanted pregnancies was associated with older age (p<0.001,adjOR= 1.2), and drug-use (p=0.001,adjOR=1.8). Having symptoms of an STI was associated with condomless vaginal sex (p=0.03,adjOR=2).
CONCLUSIONS: This study is unique in Lebanon and the MENA region. The findings indicate an urgent need to support women in Lebanon, through sexual-health education and nationwide campaigns on prevention and contraception, to become informed and proactive in decisions concerning their sexual health. Additionally, it is essential to subsidize the price of the HPV vaccine to decrease the rate of HPV transmission.

PEC0393

LOGISTICAL CHALLENGES OF DATA COLLECTION IN INVESTIGATION OF MATERNAL DOLUTEGRAVIR USE AND NEURAL TUBE DEFECT RISK: THE BRAZILIAN EXPERIENCE

A.M. Brandão Beber[1], F. Fernandes Fonseca[1], R. Abrahão Ribeiro[1], E. M. Jalil[2], F. Moreira Rick[3], R. Lima[1], V. G. Veloso[2], M.C. Pimenta[1], F. Maruri[4], C. C. McGowan[4], J. L. Castilho[4], A. Kim[5], B. E. Shepherd[5], L. Neves da Silveira[1], R. Girade Corrêa[1], A. S. Benzaken[3], B. Grinsztejn[2], G.F. Mendes Pereira[1], on behalf of the National Cohort Study of Dolutegravir and Pregnancy Outcomes in Brazil
[1]Brazilian Ministry of Health, Department of Chronic Disease and Sexually Transmitted Infections, Brasília, Brazil, [2]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia - Evandro Chagas, Rio de Janeiro, Brazil, [3]AIDS Health Care Foundation, Global Program, São Paulo, Brazil, [4]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases Nashville, Nashville, United States, [5]Vanderbilt University Medical Center, Department of Biostatistics, Nashville, United States

BACKGROUND: On May 2018, the World Health Organization(WHO) issued an alert of a potential neural tube defect(NTD) risk in infants born to women living with HIV(WLHIV) exposed to dolutegravir at conception. We aim to describe challenges of the investigation of NTD among women dolutegravir-exposed at conception in Brazil, initiated immediately after the alert.
DESCRIPTION: We identified 3,344 pregnant WLHIV exposured in the conception period to Dolutegravir, Raltegravir or Efavirenz(within a ratio 3Efavirenz:1Dolutegravir, all on Raltegravir) between January 2015-May 2018, distributed in 429 municipalities, using the national antiretroviral dispensation system. Among those, all WLHIV potentially DTG-exposed(n=490). Standardized data collection was performed using REDCap by 70 local, trained reviewers and overseen by four regional supervisors. Each reviewer was assigned approximately 30 cases(range 4-50) considering distances and transportation challenges. For each case, reviewers visited multiple services(antenatal/HIV care, maternity centers) by air, land or river to complete data collection. Reviewers had weekly goals established by the central team in the Brazilian MoH(BMoH), who monitored study progression by weekly virtual conferences. Considered a public health emergency, the National Ethical Committee provided special authorization for only medical record review.
LESSONS LEARNED: The most difficult challenges were access to medical records, missing information, logistical, and geographical barriers(especially in remote areas). Monitoring reviewer progress in different locations concomitantly throughout the country was also challenging. To overcome these difficulties, reviewers were encouraged to investigate the path WLHIV had taken in health services, even if it meant an individual and logistical effort to overcome geographical and political barriers. The REDCap mobile app with online/offline access and easy synchronization facilitated data collection, since many sites had no internet access, and there was no need to use paper, which made data recording safer. Collaboration between different political layers were necessary to overcome political and local barriers.
CONCLUSIONS/NEXT STEPS A well-designed investigation allowed us to obtain reliable urgent information in a large continental country as a response to a WHO alert. It also highlighted the importance of establishing continuous active pharmacovigilance on the effect

of antiretroviral drugs on WLHIV's life cycle. As a result, BMoH is implementing country wide pharmacovigilance to monitor pregnancy outcomes of WLHIV on antiretroviral.

PEC0394

VIRAL SUPPRESSION AND CONTRACEPTIVE USE AMONG WOMEN INITIATING DOLUTEGRAVIR-CONTAINING ANTIRETROVIRAL THERAPY IN KENYA: THE CHAGUO LANGU STUDY

J. Humphrey[1], V. Omodi[2], C. Bernard[1], J. Thorne[3], M. Maina[2], B. Jakait[2], K. Wools-Kaloustian[1], R. Patel[4]
[1]Indiana University School of Medicine, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [3]University of Toronto, Toronto, Canada, [4]University of Washington, Seattle, United States

BACKGROUND: The WHO currently recommends dolutegravir (DTG) as a preferred first- and second-line antiretroviral therapy (ART) agent for women living with HIV (WLHIV). In 2017, Kenya was among the first countries in sub-Saharan Africa (sSA) to adopt DTG. Following the reported association between DTG and neural tube defects (NTDs) in May 2018, the Kenya National AIDS and STI Control Programme recommended that DTG use be restricted for reproductive-age women to only those using effective contraception. Empiric data examining contraceptive use and viral suppression (VS) among WLHIV following DTG initiation in sSA are lacking.

METHODS: We analyzed medical records of WLHIV 15-49 years of age initiating DTG-containing ART at the Academic Model Providing Access to Healthcare in Kenya from October 2017 to April 2019. We used descriptive statistics to evaluate: (1) use of any contraception or highly effective contraception (i.e. implants, intrauterine devices, injectables, or surgical methods) by 90 days post-DTG initiation; and (2) proportions remaining on or switching off DTG during follow-up. Chi-square analysis was used to compare VS among women who remained on DTG vs. switched to a non-nucleoside reverse transcriptase inhibitor (NNRTI), using the first available viral load within 12 months of DTG initiation or switch.

RESULTS: Among 9053 women who initiated DTG-containing ART, the median (IQR) age at DTG initiation was 44 (40-47) years, 7% initiated DTG as part of their initial regimen and 93% transitioned to DTG from another regimen (95% from an NNRTI). Only 20% of women were documented to be using any form of contraception and 14% were using highly effective contraception after DTG initiation. During follow-up, 89% of women remained on DTG, 10% switched to an NNRTI and 1% to a protease inhibitor. VS was 95% in both the DTG and NNRTI groups (p=0.92), with a median time to viral load tested of 98 (84-128) and 103 (56-182) days, respectively.

CONCLUSIONS: VS was high but effective contraceptive use was low among WLHIV on DTG, and most women remained on DTG despite national and WHO warnings about NTD risk. These findings illustrate the challenge of implementing complex interim guidelines at a large, public-sector HIV treatment program in sSA.

PEC0395

THE IMPACT OF GENDER ON VIROLOGICAL AND IMMUNOLOGICAL OUTCOMES IN PEOPLE LIVING WITH HIV IN GUATEMALA

D. Ortiz[1], H. Marroquin[1], L. Larson[2], K. Franco[1], A. Spec[2], J. Melendez[1], R. Pinzon[1], J. O'Halloran[2], J. Samayoa[1], C. Mejía-Chew[2]
[1]Unidad de la Atención Integral de VIH e Infecciones Crónicas del Hospital Roosevelt "Dr. Carlos Rodolfo Mejía Villatoro", Guatemala, Guatemala, [2]Department of Medicine, Division of Infectious Disease, Washington University in St Louis, Department of Medicine, Saint Louis, United States

BACKGROUND: Guatemala has the second highest gender inequality rate in Central America and one third of persons living with HIV (PLWH) are women. We aimed to analyze how gender influences outcomes in PLWH in Guatemala considering sociodemographic determinants.

METHODS: Data from PLWH enrolled in a prospective cohort between July-Dec 2019 at a large Infectious Diseases Clinic in Guatemala City were analyzed. We included adults (age ≥18 years) with ≥6 months of follow up since antiretroviral therapy (ART) initiation. Demographic, clinical and outcome data were compared based on gender. Significant variables found in the univariate analysis (p<0.2) were included in the multivariate logistic regression model. Outcomes evaluated were viral load (VL) suppression (<50 copies/ml) and CD4 count >500 cells/mm3.

RESULTS: Of 613 patients analyzed, 46% were women and 74.6% were late presenters at diagnosis with a median CD4 count of 190 cells/mm3 (IQR 61-351) and baseline VL of 50,150 copies/ml (IQR 111,79-192,217). Baseline characteristics by gender are summarized in table 1. 473 (77.9%) PLWH were virally suppressed with no significant difference between gender (women 80.8% vs men 75.5%, p=0.11). CD4 counts >500 cells/mm3 were more frequently achieved in women compared to men (54.3% vs 37.2%, p<0.001). In the multivariate analysis adjusted for sexual preference, level of education, language, late presenter, aids defining illness, drug use, sexually transmitted disease and employment status, female gender was significantly associated with higher odds of having normal CD4 count (OR 3.38, 95% CI 2.06-5.4; p<0.001), but not associated with the likelihood of being virally suppressed (OR 1.34, 95% CI 0.81-2.2; p=0.25).

	Men (n=331)	Women (n=282)	P-value
Age at diagnosis (median, IQR)	30 (25-38)	30 (24-39)	0.97
Indigenous ethnicity (N, %)	43 (13)	38 (13.5)	0.86
High school education or higher (N, %)	161 (48.6)	62 (22)	<0.001
Low income* (N, %)	179 (68.3)	136 (92.5)	<0.001
Employed (N, %)	272 (82.2)	144 (51.1)	<0.001
AIDS defining illness (N, %)	120 (36.3)	85 (30.1)	0.11
Baseline CD4 count (median, IQR)	172 (44.0-332.5)	198 (91.50-372.0)	0.005
Baseline viral load (median, IQR)	69,932 (15,428-230,817)	34,985 (7,596-132,592)	0.002
*below Q,3,543.44 quetzales (475 US$)			

[Table 1. Baseline characteristics]

CONCLUSIONS: In our cohort, gender was not a determinant of virologic suppression. After adjusting for late presentation, women achieved higher CD4 counts when on ART. Further follow-up is required to understand the impact of the higher CD4 counts observed in women on other health outcomes in this cohort.

EPIDEMIOLOGY OF HIV IN OTHER KEY VULNERABLE POPULATIONS (E.G., PEOPLE WHO INJECT DRUGS, WOMEN, TRANSGENDER WOMEN, SEX WORKERS, PRISON POPULATIONS, OLDER GROUPS)

PEC0396

LOW UPTAKE OF PREP IN ELIGIBLE YOUNG WOMEN AGED 20-24 YEARS IN MAZOWE, ZIMBABWE

N. Ndlovu[1], E. Chikaka[1]
[1]Africa University, Agriculture and Health Sciences, Mutare, Zimbabwe

BACKGROUND: Young women (YW) have a substantial risk for HIV infection in Zimbabwe as one out of five new HIV infections is found in this age group. Given this high risk of infection, YW are a key group in which PrEP has to be initiated. Asymptomatic screening of YW for sexually transmitted infections (STIs) is not the standard of care in Zimbabwe.The aim of this study was to use an HIV risk assessment tool adapted from iTECH to screen YW for PrEP eligibility and assess the number of women willing to initiate PrEP.

METHODS: We recruited a prospective cohort of YW aged 20-24 years in Mazowe, Zimbabwe. Eligible women were PrEP naïve, sexually active or had reported a one-lifetime sexual partner. Between January to September 2019, the women were followed up every three months. During each visit, the women received an STI test and were screened with the tool. Women were offered PrEP based on their assessment score. We used descriptive analysis to characterise this cohort.

RESULTS: We enrolled 284 YW, median age with a median age of 21.2 years. A number of 128 YW were found to be eligible for PrEP for the following reasons: (14%) had a current STI, (35%) reported inconsistent or no condom use (40%) reported sex partner of unknown HIV status and (11%) reported other reasons. Median years of education for the eligible was 15 years. Only (14%) of the YW who were offered PrEP, accepted it. The acceptance rate appeared higher in those with current STI (27%) and the least in those eligible for other reasons (13%). The main reason for the YW decline of PrEP was because they could not take a daily pill.

CONCLUSIONS: In a cohort of YW with access to targeted PrEP services after testing positive for an STI, PrEP acceptance was low. Specific evidence of their own high HIV risk, coupled with low- barrier access to PrEP, did not translate into PrEP uptake among these YW. Specific and targeted research of PrEP uptake reluctance in YW is needed. Risk awareness and knowledge, does not result in high PrEP uptake in this cohort.

PEC0397

HIV TREATMENT OUTCOMES AMONG PEOPLE WHO INJECT DRUGS IN THE ASIA-PACIFIC: AN OBSERVATIONAL STUDY

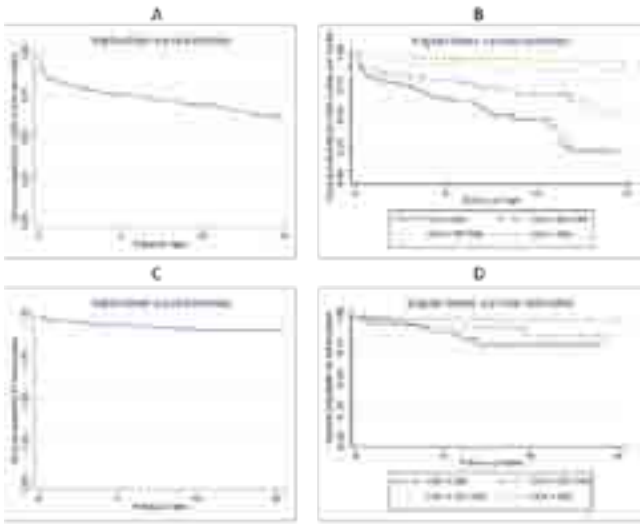
BACKGROUND: We assessed long-term immunologic and virologic responses, incidence of AIDS-defining events, tuberculosis and mortality among people who inject drugs (PWID) receiving combined antiretroviral therapy(cART) in Asian settings.

METHODS: TAHOD is a regional cohort study of adults living with HIV under care at 21 HIV clinical sites in the Asia-Pacific. CD4 count and viral load suppression(VLS) trends among any TAHOD participants reporting injecting drug use as HIV exposure were assessed. VLS was defined as HIV viral load <1,000 copies/mL. Factors associated with mean CD4 changes and combined AIDS-defining events and deaths were analyzed using repeated measures linear regression and survival analysis.

RESULTS: Of 622 PWID included, 93% were male, and median age at ART initiation was 31 years and median pre-cART CD4 count was 71 cells/μL. CD4 counts increased over time, with a median difference of 401(95%CI,372-457) cells/μL at year-10 post ART initiation(n=78). In a multivariable model, current HIV viral load ≤400 copies/mL(vs. >400 copies/mL) and pre-ART CD4 >200 cells/uL(vs. <200 cells/uL) were associated with higher mean CD4 count. Among 361 PWID with >1 viral load measurement after 6 months of treatment, post-cART VLS was 82%(115/140) at 2 years, 88%(82/93) 5 years and 93%(63/68) at 10 years. There were 102 AIDS-defining events(n=52) and deaths(n=50) during 3347 person-years(PYS) of follow-up (incidence 3.05 [95%CI, 2.51 to 3.70] per 100PYS; Figure).

Thirty-five incident TB cases occurred (1.01 [95% CI, 0.73-1.41] per 100PYS). In a multivariable model, previous AIDS diagnosis, lower CD4 counts and cART adherence <95% were independently associated with incidence of new AIDS-defining events and deaths.

CONCLUSIONS: Despite improved immunologic outcomes among PWID over time, findings from this study support the need for further improvements in earlier cART initiation, and improved ART monitoring and adherence support among PWID in HIV care settings in the Asia-Pacific.



A total of 622 PWID included in the study analysis were recruited from 22 sites in Cambodia, China, Hong Kong SAR, India, Indonesia, Japan, Malaysia, the Philippines, Singapore, South Korea, Taiwan, Thailand and Vietnam. Site-stratified survival graphs for A) overall AIDS-defining events/deaths, B) AIDS-defining events/deaths by CD4 group, C) overall tuberculosis, and D) tuberculosis by CD4 group among PWID. Survival estimates of AIDS events/deaths and tuberculosis were stratified by time-updated CD4 covars in graphs B and D.

PEC0398

A NATIONAL SURVEY OF HIV PREVALENCE, CONTINUUM OF CARE AND HIV DRUG RESISTANCE AMONGST FEMALE SEX WORKERS IN SOUTH AFRICA

M. Jaffer[1], G. Hunt[2], M. Milovanovic[1], V. Mbowane[1], K. Hlongwane[1], K. Otwombe[1], F. Abdullah[3], L. Vanleeuw[3], N. Slingers[3], N. Martinson[1], G. Gray[3], R. Jewkes[3], J. Coetzee[1]
[1]Perinatal HIV Research Unit, Johannesburg, South Africa, [2]National Institute for Communicable Diseases, Johannesburg, South Africa, [3]South African Medical Research Council, Pretoria, South Africa

BACKGROUND: HIV prevalence in female sex workers (FSWs) in South Africa (SA) is uncertain, reported between 40-90%. It is therefore crucial to have up-to-date and national information on the HIV cascade of care in FSWs to target interventions. Additionally, rising HIV drug resistance (HIVDR) poses a threat to antiretroviral treatment (ART); recent population level surveillance suggests 27% of virally unsuppressed individuals in SA have evidence of HIVDR. This study aimed to describe HIV prevalence, continuum of care, and drug resistance amongst FSWs in SA.

METHODS: We conducted a cross-sectional, national survey of 3005 FSWs between February – July 2019. Twelve randomly selected sites, across all nine provinces of SA were included. Within sites, sex work hotspots were randomly selected and chain-referral recruitment of FSWs took place at each hotspot. Peer interviewers administered a questionnaire including HIV testing and treatment history, then nurses recorded additional clinical history, conducted HIV rapid testing, and took blood specimens for viral load and HIV drug resistance.

RESULTS: 61.2% (1840/3005) of FSWs tested HIV positive. 89.2% (1641/1840) were known positive, 82.6% (1355/1641) of these reported currently taking ART, and 70.5% (955/1355) on ART were virally suppressed (viral load < 1000 copies/ml). Among participants successfully genotyped (viral load > 400 copies/ml), 64.6% (431/667) had evidence of HIVDR, including 77.8% (330/424) in those ART-exposed and 41.6% (101/243) in those ART-naïve. Mutations selecting resistance to non-nucleoside reverse transcriptase inhibitors (NNRTIs) was the leading finding in 98% of those with HIVDR.

CONCLUSIONS: FSWs remain highly vulnerable to HIV infection. Progress has been made in scaling up diagnosis and treatment amongst FSWs, which bodes well for UNAIDS 90:90:90 targets, but there is no room for complacency. To successfully achieve these targets, virologic failure and thus adherence need to be urgently addressed. Of concern, HIVDR is substantially higher in virally unsuppressed FSWs than in the general population (65% v 27%), and is also present at high levels in ART-naïve FSWs, suggesting both acquired and transmitted resistance. Innovative approaches to improve adherence amongst FSWs, and proactive viral load monitoring are needed. Our data additionally supports the introduction of dolutegravir-containing ART.

PEC0399

BEYOND OVERDOSE: COMPARING DRUG-RELATED DEATHS IN PEOPLE WITH AND WITHOUT HIV IN SAN FRANCISCO

A. Appa[1], C. Rowe[2], P. Coffin[2]
[1]University of California, Zuckerberg San Francisco General Hospital Division of HIV, ID, and Global Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, Zuckerberg San Francisco General Hospital Division of HIV, ID, and Global Medicine, San Francisco, United States

BACKGROUND: Reducing mortality among people living with HIV (PLWHIV) remains a challenge, with the proportion of San Francisco county deaths increasing in PLWHIV who use drugs. However, there are few studies that investigate specific causes of death beyond overdose (ie. infection) that may disproportionately affect PLWHIV. Our objective was to evaluate whether there are certain characteristics of drug-related deaths that differ in those with and without HIV in order to inform targeted drug-related death prevention efforts.

METHODS: We identified 7,056 drug-related deaths in San Francisco county from 2007 – 2018 using a programmatic query of the California Electronic Death Reporting System. Decedents were included if over age 13, and 292 decedents were excluded given death found not to be due to illicit drugs. We performed Chi-squared and Fisher's exact tests to describe characteristics of decedents with and without HIV, followed by multivariable logistic regression to evaluate the relationship between drug-related death involving an infection and HIV status, adjusting for age, sex, and race-ethnicity.

RESULTS: Between 2007 and 2018 in San Francisco county, 223 PLWHIV died related to drugs, and 6,541 people without HIV died related to drugs. Drug-related deaths among those with HIV were more likely to involve methamphetamine (21% vs. 13% in those without HIV, p<0.01); less likely to involve alcohol (26% vs. 46%, p<0.01); and equally likely to involve any opioid (26% in both groups, p=0.98) or cocaine (22% vs. 19%, p=0.26). Both groups had a similar proportion of deaths due to overdose (38% in HIV vs. 37% without HIV, p=0.93) and non-infectious medical cause of death (37% vs. 38%, p=0.76). However, 26% of drug-related deaths in those with HIV involved an acute infection vs. 8% in decedents without known HIV (p=<0.01). In our multivariable model, decedents with HIV had notably increased odds of acute infection involved in drug-related death (OR 5.58, 95% CI 4.02 – 7.74).

CONCLUSIONS: Decedents with HIV had over five-fold increased odds of having a drug-related death involving an infection compared to decedents without HIV. Targeted efforts to combat mortality in PLWHIV should include infection prevention efforts, such as harm reduction practices and vaccination, as well as overdose prevention.

PEC0400

FACTORS ASSOCIATED WITH HIV POSITIVITY AMONG PARTNERS OF HIV-DIAGNOSED PERSONS IN THE UNITED STATES, 2013-2017

W. Song[1], M. Mulatu[1], S. Rao[1], H. Zhang Kudon[1], M. Rorie[1]
[1]Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: Partner services (PS) programs assist HIV-positive persons (index persons) in notifying their sexual and/or needle-sharing partners (partners) of possible exposure to HIV, offering them HIV testing, and linking them to HIV prevention and care services. Data from PS programs that examine the predictors of HIV testing outcomes among partners of HIV-diagnosed persons are limited. This analysis examines associations between demographic and behavioral risk characteristics of index persons and partners and HIV positivity among partners in CDC-funded health departments.

METHODS: We used PS data reported by 60 state and local health departments during 2013-2017. The analytic sample consisted of 86,758 partners who were matched to an index person. We assessed the relationship between partner's HIV positivity with partner and index person demographic characteristics (age, race/ethnicity, and region) and partner–index couple risk characteristics (injection drug use, sex without condom in past 12 months, and male with male partnerships). Adjusted prevalence ratios (aPRs) and 95% confidence intervals (CIs) were used to interpret the results.

RESULTS: A total of 43,420 (50%) partners were tested for HIV, and 7,784 (17.9%) were newly diagnosed with HIV infection. Newly diagnosed HIV positivity was higher among partners aged 13-24 (aPR=0.90, 95% CI=0.84–0.97) than it was among those aged 25-34. Partners named by older index persons (age >=45; aPR=1.20, 95% CI%=1.06-1.36) were more likely to be diagnosed with HIV infection than those named by younger index persons (age 13-24). Partners in the Midwest (aPR=3.27, 95% CI=2.82–3.80) and the South (aPR=2.17, 95% CI=1.96–2.42) were more likely and those in the West (aPR=0.71, 95% CI=0.62–0.80) were less likely to be newly diagnosed with HIV infection compared to those in the Northeast. HIV diagnosis among partners was more likely if both index persons and partners reported unprotected sex (aPR=1.79, 95% CI=1.39–2.30), injection drug use (aPR=1.97, 95% CI=1.78–2.17), or male gender ((aPR=1.15, 95% CI=1.07–1.23).

CONCLUSIONS: HIV positivity among partners was high and associated with demographic and behavioral risk characteristics shared with index persons. Efforts to improve PS programs should include increasing coverage of testing services prioritized to at-risk partners.

PEC0401

SEXUAL PRACTICES, CONTRACEPTION METHODS, AND SELF-REPORTED UROGENITAL SYMPTOMS AMONG 116 REFUGEE WOMEN IN BEIRUT LEBANON

S. Abi Zaki[1], J. Naous[2,1], F. Khalil[1], S. Barakji[3], D. Abou Abbas[1], O. Mahmoud[3], A. Assi[4,1]
[1]Marsa Sexual Health Center, Beirut, Lebanon, [2]American University of Beirut, Faculty of Medicine, Beirut, Lebanon, [3]Palestinian Women's Humanitarian Organization, Burj El-Barajni, Lebanon, [4]University of Saint-Joseph, Faculty of Medicine, Beirut, Lebanon

BACKGROUND: Women refugees in Lebanon face stigma and have limited access to sexual and reproductive health services increasing their risk of sexually transmitted infections (STIs) and unwanted pregnancies. Since abortions are illegal in Lebanon, unwanted pregnancies could prompt women to seek unsafe alternatives,thus compromising their health. The aim of this study was to assess sexual practices, self-reported urogenital symptoms, and prevalence of HIV, HBV, HCV, and syphilis among women visiting a community-led organization in a refugee camp in Beirut, Lebanon.

METHODS: An anonymous questionnaire on methods of contraception, and self-reported symptoms, was administered by a healthcare provider to 116 women who presented to an organization in the Burj El-Barajneh camp between August and December 2019. The presence of HIV, HBV, HCV and syphilis were detected using rapid tests. The presence of candida, bacterial vaginosis, or STIs were detected through clinical diagnosis.

RESULTS: The median age was 33.5 years (range: 15-75). The majority reported unreliable sources of sexual-health education such as peers and/or partners (78%), being married (72.5%), and having low condom-use (83%). The average age of first intercourse was 18 years with 34% being under 18 during first intercourse. Contraception methods were: natural methods (withdrawal/calendar rhythm) (48%), intrauterine device (28.5%), condoms (13%), oral contraceptive pills (7%), and hormonal implants (3.5%). Data on unwanted pregnancies were not collected to avoid reporting bias due to conservative context. Urogenital symptoms (reported by 47%) were: vaginal irritation (14%), pelvic pain (3.5%), excessive/foul-smelling discharge (8%), excessive menstrual bleeding (4%), dysuria (2%), or multiple symptoms (15.5%). The majority never underwent a pap-smear (84%). There were no cases of HIV, HCV, HBV, or syphilis. Yeast infections were diagnosed among 20%, urininary tract infections among 9.5%, bacterial vaginosis among 3.5%, and one suspected case of STI (such as gonorrhea, chlamydia, ureaplasma, or mycoplasma).

CONCLUSIONS: The findings show that refugee women are in need of accessible, and comprehensive sexual-health services.The high rate of yeast infections could also indicate poor quality of water at the camp. Furthermore, there is an imminent need for education on, and access to, effective methods of contraception in order to prevent unwanted pregnancies.

PEC0402

DATA FROM FIRST DISAGGREGATED STUDY SHOWS HIGH HIV PREVALENCE AMONG TRANS WOMEN IN NEPAL

M. Dhakal[1], S. Banik[2], H. Xie[3], S. Sharma[1], R. Lama[1], A. Rai[1], S. Chhetri[1], J. Lin[3], S. Arayasirikul[3], E.C. Wilson[3]
[1]Blue Diamond Society, Kathmandu, Nepal, [2]Baldwin Wallace University, Public Health and Prevention Science, Berea, United States, [3]San Francisco Department of Public Health, Trans Research Unit for Equity, San Francisco, United States

BACKGROUND: In low- and middle-income countries, trans women have 37 times greater odds of having HIV than men and 77.5 times greater odds compared to cisgender women. Nepal is a low-income country with an HIV epidemic concentrated among key populations at risk of HIV. To date, trans women have been aggregated with other populations, like MSM, in HIV sero-prevalance surveys, making it difficult to determine the impact of HIV on trans women and preventing targeted intervention approaches. We conducted the first disaggregated study of HIV among trans women in Nepal.

METHODS: Our study was implemented in in 2019. We used respondent driven sampling to recruit a diverse population-based sample of trans women from Kathmandu Valley, Nepal. We used RDS analyst to determine the HIV point estimate and used the weighted database to determine factors associated with HIV using Stata.

RESULTS: A total of 200 trans women were recruited over a 6-month period. The RDS-weighted HIV prevalence among trans women in Nepal was 10%. Factors associated with having HIV were younger age (OR 4.8 for 18-24 year old participants compared to >24 year olds; 95% CI 1.52-15.39) and having never used hormones (OR 11.4, 95% CI 1.64-79.15) (Table 1). Those who had socially transitioned as trans women had lower odds of having HIV (OR 0.29; 95% CI 0.08-0.98).

CONCLUSIONS: The HIV prevalence among trans women in Kathmandu, Nepal was higher than in any other key population in the country. HIV risk may be most affected by low access to trans medical care and the ability to medically and socially transition. Surprisingly, younger people were more affected by HIV pointing to the need for early interventions with young trans women in Nepal. Prevention efforts in Nepal will also need to address stigma and gender-related social and medical needs in tailored approaches to the HIV response for trans women in country. Future behavioral surveillance efforts are needed to monitor and address the specific needs of trans women that are different from populations with which they are often combined.

PEC0403

EFFECT OF EARLY HIV DIAGNOSIS ON LIFE EXPECTANCY OF PEOPLE WHO INJECT DRUGS (PWID) LIVING WITH HIV IN TAIWAN: A NATIONWIDE POPULATION-BASED COHORT STUDY

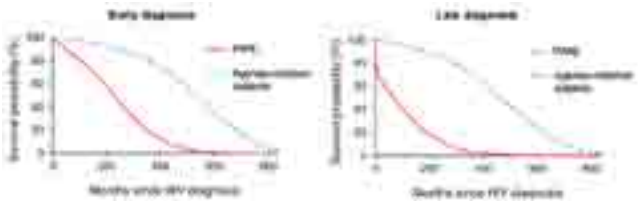
Y.-H. Chen[1], C.-T. Fang[1,2], Y.-L. Huang[1], Y.-C. Cheng[1], F.-Y. Chu[1], J.-D. Wang[3], J.-S. Hwang[4], C.-H. Chen[5]
[1]Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei, Taiwan, Province of China, [2]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan, Province of China, [3]National Cheng Kung University, Department of Public Health, College of Medicine, Tainan, Taiwan, Province of China, [4]Institute of Statistical Science, Academia Sinica, Taipei, Taiwan, Province of China, [5]Centers for Disease Control, Ministry of Health and Welfare, Division of HIV/AIDS and TB, Taipei, Taiwan, Province of China

BACKGROUND: People who inject drugs (PWID) are at high risk of premature death. The benefit of early HIV diagnosis in this key vulnerable population remains controversial due to lack of correcting for lead-time bias in previous studies. We aim to measure the unbiased effect of early HIV diagnosis on life expectancy.

METHODS: This is a nationwide population-based cohort study, involving all PWID living with HIV in Taiwan diagnosed during 2005 to 2014. To correct for lead-time bias, we measure the impact of early (before the onset of AIDS) versus late (at the onset of AIDS) HIV diagnosis on life expectancy loss relative to age/sex-matched subjects from general population. To estimate the life expectancy of PWID living with HIV, we extrapolated 10 years survival curves using a constant excess hazard model. We use multivariable Cox model to evaluate the effect of early HIV diagnosis on cause-specific mortality.

RESULTS: Compared with age/sex-matched reference population, early diagnosed PWIDs (n=5,924) lost 23.4 (±0.6) years while late diagnosed PWIDs (n=108) lost 29.4 (±2.5) years in life expectancy (Figure). Early HIV diagnosis is associated with a reduction of life expectancy loss by 6.0 (±2.6) years. After adjusting for age and other confounders, early HIV diagnosis is associated with significantly lower risk for all-cause mortality (adjusted hazard ratio [aHR]: 0.42, 95%CI: 0.31-0.57) and HIV/AIDS-related mortality (aHR: 0.10, 95%CI: 0.05-0.20). There is also a trend towards lower non-HIV-related mortality (p=0.14) (Table).

CONCLUSIONS: Early HIV diagnosis is associated with improved survival of PWID living with HIV, with a net life expectancy gain of six years after correcting for lead-time bias.



[Figure. Predicted 70 years survival curves]

	All-cause		HIV-related		Non-HIV-related	
Variables	aHR (95%CI)	P	aHR (95%CI)	P	aHR (95%CI)	P
Early vs Late HIV diagnosis	0.42 (0.31-0.57)	<.001	0.10 (0.05-0.20)	<.001	0.69 (0.43-1.14)	0.146
Age at diagnosis	1.05 (1.04-1.06)	<.001	1.07 (1.04-1.09)	<.001	1.05 (1.04-1.06)	<.001
Male vs Female	1.39 (1.14-1.69)	0.001	1.64 (0.75-3.60)	0.213	1.34 (1.06-1.70)	0.015

[Table. Adjusted hazard ratios of mortality among PWID living with HIV (also adjusted for marriage status, diagnosed when stay in criminal justice system, and diagnosed in 2007 or after)]

PEC0404

HIV RISK FACTORS AMONG PRISONERS IN NIGERIA CORRECTIONAL HOMES

G. Ashefor[1], A. Adeyemi[2], G. Aliyu[3], C. Ezeokafor[1]
[1]National Agency for the Control of AIDS, Research, Monitoring and Evaluation, Abuja, Nigeria, [2]Centre for Infectious Diseases Research and Evaluation, Infectious Diseases, Lafia, Nigeria, [3]National Agency for the Control of AIDS, Director General Office, Abuja, Nigeria

BACKGROUND: Prisoners in Nigeria correctional homes or prisons are vulnerable to HIV and other sexually transmitted infections as a result of incarceration, limited prevention programs, poor health care and living conditions. Little is known about the current HIV burden among prisoners in Nigeria and their risk factors. The 2018 Nigeria population-based survey showed HIV prevalence in the general population was 1.3%. The Government of Nigeria in collaboration with UNODC commissioned the national assessment of HIV/AIDS and health services situational study in correctional homes to estimate the burden of HIV infection among prisoners. This study assessed the risk factors associated with HIV among prisoners in Nigeria.

METHODS: Secondary analysis of data collected among 2,511 prisoners in 2019 was done. This was a cross-sectional study undertaken in eleven correctional homes across the six Nigerian geopolitical zones. Structured questionnaire was used to collect sexual, behavioral and reproductive health information. HIV biomarker was collected to ascertain their HIV status. Multiple logistic regression was used to assess their HIV risk.

RESULTS: The mean age was 32.3±10.8years. The highest age group was 25-35years (51.0%). Males were 92.4%, education status: primary, secondary and tertiary were 39.0%, 38.2% and 7.7% respectively. Majority were Christians 70.0%, and Muslim were 29.5%. About 75.0% were employed, 64.7% were single and 30.8% were married. About 24.8% were convicted and 55.0% had used illegal drugs. Mean age of first drug injection was 21±4.6years. Prisoners providing sex to others for money, goods or services regularly and occasionally were 35.7% and 24.4% respectively. Prisoners that had been given infor-

mation on sexual and reproductive health (SRH) were 22.2%. HIV prevalence was 2.8%, male HIV prevalence was 2.7% and female prevalence was 6.9%. Risk factors to HIV infection include being convicted OR=2.5 95%CI 1.7-3.9, drug use OR=1.9 95%CI 1.2-2.7, being female OR=2.7 95%CI 1.3-5.6, poor access to SRH information OR=1.9 95%CI 1.1-3.4 but having tertiary education was protective with OR=0.7 95%CI 0.6-0.9.

CONCLUSIONS: There is a need for targeted HIV prevention programs to be developed and implemented in Nigerian correctional homes to reduce the prevalence of HIV among prisoners which is currently above the national average.

PEC0405

"EVEN IF YOU GET RAPED YOU ARE PROTECTED": RESULTS FROM A MIXED-METHODS, MULTI-SITE STUDY OF PREP ENGAGEMENT AMONG TRANSGENDER WOMEN IN SOUTH AFRICA

T. Poteat[1,2], M. Malik[2], L.L.A. van der Merwe[3], A. Cloete[4], D. Adams[2], B.A. Nonyane[5], A.L. Wirtz[2]
[1]University of North Carolina, Department of Social Medicine, Chapel Hill, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Social Health Empowerment, East London, South Africa, [4]Human Sciences Research Council, Cape Town, South Africa, [5]Johns Hopkins University Bloomberg School of Public Health, International Health, Baltimore, United States

BACKGROUND: South Africa accounts for one-third of all new infections in sub-Saharan Africa (SSA). Transgender women (TW) in SSA face a heavy HIV burden, with prevalence estimates of 25%; TW are twice as likely as men who have sex with men to be living with HIV and less likely to report consistent condom use. The South African HIV National Strategic Plan recommends PrEP for priority populations, but data on TW's PrEP engagement is understudied in SSA. This study aimed to understand South African TW's PrEP awareness and engagement.

METHODS: This parallel mixed-methods study included interviewer-administered surveys with 213 TW and in-depth interviews with 36 TW, in Afrikaans, English, Sesotho, or Xhosa. Data were collected May-November 2018 in Cape Town, Johannesburg, and East London. Stata 14 was used for descriptive statistics and logistic regression modeling. Audio-recorded, transcribed, and translated qualitative transcripts were coded and analyzed using thematic analysis.

RESULTS: The median age of survey participants was 26 years; 63% had a history of sex work, 57% had experienced sexual violence, 38% had been diagnosed with a sexually transmitted infection (STI), and 32% self-reported living with HIV. Among the 129 HIV-negative TW, PrEP awareness and uptake were low: 45% had heard of PrEP, 15% had ever taken PrEP, and 12% were currently taking PrEP. PrEP awareness was higher among TW with a history of sexual violence, sex work, or an STI, suggesting PrEP information has reached some highly vulnerable TW. However, recent condomless receptive anal sex, the highest sexual risk for HIV acquisition, was not associated with PrEP awareness. Qualitative data indicated many PrEP-aware TW knew PrEP prevented HIV, even when raped; however, confusion between PEP and PrEP was common. Additional themes included lack of awareness as a barrier to PrEP uptake, e.g. "Many of our transgender people are getting HIV and … I haven't seen or heard people talking about this PrEP, so I think a lot of people don't know about it."

CONCLUSIONS: TW are a priority population for PrEP in South Africa. Greater attention to raising PrEP awareness and disseminating accurate information to TW is warranted.

PEC0406

HIV EPIDEMIOLOGY AND RISK FACTORS AMONG TRANSGENDER PEOPLE IN MALI

M. Nelson Personna[1], B. David-Gnahoui[2], E. Dioukhane[1], H. Septime[3], F. Sacko[3], A.K. Kanoute[3], M. Dicko[3], B. yameogo[1]
[1]Plan International Canada, Ottawa, Canada, [2]Plan International Canada, Cotonou, Benin, [3]Plan International Mali, Bamako, Mali

BACKGROUND: Globally transgender women are a key population in the HIV epidemic with a higher prevalence than the general population. In Mali the situation of the transgenders was unknown; as a result, the country's HIV strategy has not included trans-specific interventions. To address this gap, Plan International coordinated a size estimation, a study on HIV risk factors and prevalence, the expressed needs as well as a mapping of current interventions potentially benefiting this population.

METHODS: A study was conducted in five key administrative regions and Bamako district. A respondent-driven sampling method was used for the mapping and size estimation. A questionnaire using Kobo Toolbox for real-time data collection about risk factors, expressed needs, and an HIV test was also administered. A field survey combined to the use of geo-referenced coordinates allowed for determination and mapping of the current interventions.

RESULTS: The number of transgender people is estimated at 497 [328 - 1901] in the study area.The majority is relatively young with 75% less than 28 years old and 92% Muslim. Transgender women represent 75.5 %. More than half confirmed commercial or regular casual sex partners. Only 3% have good knowledge of HIV, defined as having knowledge of both transmission and prevention means while 83% have been tested for HIV in the last 12 months. Gender-based violence is frequent (71%) and discrimination within the health system is reported (6.7 %). The primary services accessed by them are condom and lubricant distribution (70%), STI treatment (27%), HIV care (31%) and pre- and post-exposure prophylaxis were at 3% and 6% respectively. HIV prevalence is 11.7% and is higher amongst those who are 25-43 years old (17 %) versus the 18-24 years old (7%). It's also higher among those living with partner (19.4%) versus single (10.5 %).

CONCLUSIONS: This study provides an objective basis for including transgender people in HIV interventions in Mali. While they are not a large group, they lack specific interventions and have a higher HIV incidence than the general population. They remain a marginalized group for which a specific approach is yet to be designed in a predominately Muslim context.

PEC0407

TRANSACTIONAL SEX INCREASES THE INCIDENCE OF HIV AMONG YOUNG WOMEN IN TANZANIA

K. Rucinski[1], G. Mbita[2], K. Curran[3], A. Komba[2], C. Casalini[2], E. Majani[2], M. Drake[2], A. Galishi[2], Y. Mlawa[2], U. Kategile[4], W. Kafura[5], N. Makyao[6], S. Schwartz[1], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [3]Jhpiego, Baltimore, United States, [4]USAID, Dar es Salaam, Tanzania, United Republic of, [5]Tanzania Commission for AIDS (TACAIDS), Dar es Salaam, Tanzania, United Republic of, [6]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program, Dodoma, Tanzania, United Republic of

BACKGROUND: Young women across sub-Saharan Africa experience a high burden of HIV. However, HIV risks are not evenly distributed, and young women in transactional sexual relationships are particularly vulnerable to infection. In Tanzania, empirical estimates

of HIV incidence among young women engaged in transactional sex remain limited. Here, we estimate the association between transactional sex and HIV seroconversion using longitudinal program data from the Sauti Project.

METHODS: The Sauti Project is a PEPFAR/USAID-funded program which has provided combination HIV-prevention services to key and vulnerable populations across Tanzania. Out-of-school adolescent girls and young women (AGYW) aged 15-24 accessing Sauti services completed a behavioral HIV-risk assessment with subsequent HIV testing and treatment referrals. Using program data, we assembled a longitudinal cohort with 12-months of follow-up among AGYW with >1 visit (2016-2017). To estimate the association of transactional sex (sex in exchange for money or services/gifts in the preceding year) and HIV seroconversion, we used marginal structural log-binomial models to calculate risk differences (RD), risk ratios (RR), and 95% confidence intervals (CI).

RESULTS: 3,141 AGYW (median age: 20 years (IQR 18-22)) tested HIV-negative at their first program visit and completed >1 HIV tests over 12-months. 42.6% had engaged in transactional sex in the preceding year; 8.7% had a relationship with a partner ≥10 years older. Early pregnancy, IPV, and food insecurity were common. 107 AGYW seroconverted after their first visit; the overall risk of new HIV infections or annualized HIV incidence was 3.7% (95% CI 3.1-4.4). Transactional sex was associated with HIV incidence at 12-months (RD 1.76 (95% CI:0.26-3.26); RR 1.57 (95% CI:1.07-2.29)).

	No. HIV events	Risk (95% CI)	RD (95% CI)	RR (95% CI)
Unweighted				
Transactional sex	46	4.52 (3.54, 5.77)	1.58 (0.19, 2.97)	1.54 (1.06, 2.24)
No transactional sex	61	2.94 (2.21, 3.91)	REF	REF
Weighted*				
Transactional sex	46	4.86 (3.66, 6.06)	1.76 (0.26, 3.26)	1.57 (1.07, 2.29)
No transactional sex	61	3.10 (2.20, 4.00)	REF	REF

Abbreviations. No.: Number, RD: Risk difference; RR: Risk ratio; CI: Confidence interval

*A minimally sufficient set of confounders was identified using a directed acyclic graph (DAG). Weighted estimates were standardized to the baseline distribution of the following covariates: age, intergenerational sex, early pregnancy, food insecurity, family support, and early sexual debut.

[Table. Unweighted and weighted risk differences (RD), risk ratios (RR), and 95% confidence intervals (CI) for the association of transactional sex with HIV incidence among 3,141 young women in Tanzania accessing HIV-prevention services through the Sauti Project, 2016-2017]

CONCLUSIONS: Implementing differentiated HIV-prevention efforts among AGYW—including a focus on those with specific and heightened risks for HIV such as young women engaged in transactional sex, may be most impactful in realizing population-level declines in HIV incidence and ultimately achieving an AIDS-free generation.

PEC0408

HIV RAPID TESTS AS A DIAGNOSTIC ALTERNATIVE IN COUNTRIES WITH ECONOMIC CRISIS

E. El Hage[1], M. Comegna[2], A. Comegna[1], J. Gonzalez[3], A. Guillen[3], R. Lopez[4], N. Madera[4], M.G. Lopez[5], M. Figuera[5]
[1]Proyecto Once Trece, Caracas, Venezuela, [2]Sociedad Venezolana de Infectologia, Proyecto Once Trece, Caracas, Venezuela, [3]Hospital Vargas, Proyecto Once Trece, Caracas, Venezuela, [4]UNAIDS Venezuela, Caracas, Venezuela, [5]Sociedad Venezolana de Infectologia, Caracas, Venezuela

BACKGROUND: Venezuela, with 28 million inhabitants in 2019, has been facing a socio-political and economic situation that has negatively affected social and health indicators.
It is estimated that between 2010 and 2016, the number of new cases of HIV infection increased by 24%. According to Venezuela's Ministry of Health, for that year, the mortality rate increased to 8.3 per 100,000 inhabitants.
As of 2017, there is no official data.
Since 2012 began the shortage of antiretrovirals and by 2018 affected 84% of patients, this accompanied by total absence of prevention campaigns and failures in supply of condoms.
Currently it is estimated that there are 120,000 people infected and the prevalence of general population is 0.56%
There is great concern about the lack of reagents for diagnosis.
In private labs an HIV test exceeds USD $30.00 and minimum wage in Venezuela is USD $3.00

METHODS: Rapid HIV testing of the brands ALERE DETERMINE™ HIV-1/2, First Response was conducted free, voluntary and confidential between December 1, 2018 and December 1, 2019 in different communities in the country, including key populations such as: deprived of liberty, indigenous people, LGBTQ community, sex workers, young people.

RESULTS: A total of 1737 tests were conducted (1000 M, 737 F) and 67.7% were aged 18 to 35 years old. There were 35 positive tests (23 – 65.71% M, 12 -34.28% F) with a total prevalence of 2.01% where 29 are in ages of 18 to 35 years. The populations most affected were: MSM (16), indigenous (14), women (4), sex workers (1).

CONCLUSIONS: Rapid tests are very useful as an epidemiological tool for HIV diagnosis.
In this study it was observed a high reciptitivity especially in young adult population. It is necessary to insist on campaigns like these in key groups for early diagnosis and treatment.

PREVALENCE OF HIV AND OTHER SEXUALLY TRANSMITTED INFECTIONS AMONG YOUNG THAI MEN AND TRANSGENDER WOMEN SELLING OR TRADING SEX IN THE COPE4YMSM STUDY

A. Hickey[1,2], T. Chemnasiri[1,2], A. Waraporn mongkholkul[2,1], K. Satumay[2,1], K. Pawong[3], C. Ungsedhapand[2,1], S. Sriplienchan[4], W. Sukwicha[1,2], S. Pattanasin[2,1], A. Varangrat[2,1], A. Wirtz[5], B. Weir[5], E. Dunne[2,1], S. Hsu Hnin Mon[5], C. Beyrer[5]
[1]U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]Thailand Ministry of Public Health and U.S. Centers for Disease Control and Prevention Collaboration (TUC), Nonthaburi, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Service Workers in Group (SWING), Bangkok and Pattaya, Thailand, [5]Johns Hopkins University, Baltimore, United States

BACKGROUND: Young men who have sex with men (YMSM) and transgender women (YTGW) who sell and trade sex with other men are a vulnerable population at high risk for HIV and sexually transmitted infection (STI) acquisition and transmission. Understanding the epidemiology of HIV/STI among YMSM and YTGW will assist development of effective prevention interventions.

METHODS: YMSM and YTGW reporting selling or trading sex in the last 12 months and aged 18-26 years enrolled in a combination HIV prevention research study (COPE4YMSM) with optional HIV pre-exposure prophylaxis (PrEP) in Thailand. At enrollment, participants were tested for HIV and syphilis using rapid tests, as well as rectal Neisseria gonorrhoeae (NG) and Chlamydia trachomatis (CT) by nucleic acid amplification tests. We describe baseline HIV and STI prevalence and s using bivariable analysis.

RESULTS: Overall, 901 YMSM (n=818, 91%) and YTGW (n=83, 9%) were enrolled. At the baseline study visit, 43 (4.8%, 95% CI:3.5-6.4) had HIV infection, 126 (14%, 11.8-16.4) had syphilis, 48 (5.3%, 3.9-7.0) had rectal NG and 142 (15.8%, 13.4-18.3) had rectal CT. HIV and STI co-infection

occurred in 28 (65%), most commonly rectal CT in 19 (44%). HIV infection was more common in participants reporting no HIV testing within the preceding 12 months (POR=8.0, 3.9-17.4) and having been previously diagnosed with an STI (POR=5.0; 2.5-10.2). STIs at baseline were higher (POR=1.5; p=1.1-2.0) among participants reporting multiple sexual partners in the last seven days. Although YTGW more commonly reported multiple sexual partners (POR=2.9; 1.5-5.8) and selling or trading sex within the last seven days (POR=2.6; 1.1-6.4), the prevalence of HIV and STIs was not significantly different compared to the YMSM participants.

CONCLUSIONS: Both YMSM and YTGW who sell or trade sex are at substantial risk of HIV and other STI. Although the prevalence of HIV and STIs were similar between YMSM and YTGW, there were distinct differences in types of risk factors, which highlights the need for tailored HIV and STI interventions for this population.

PEC0410

HIGH HIV AND SYPHILIS PREVALENCE AMONG FEMALE SEX WORKERS AT THE BORDER OF SOUTH SUDAN AND UGANDA

A. Okiria[1], V. Achut[2], G.C. Arkangelo[2], A.I. Taban[1], J. Wesson[3]
[1]IntraHealth International, Juba, South Sudan, [2]South Sudan Ministry of Health, Juba, South Sudan, [3]IntraHealth International, Chapel Hill, United States

BACKGROUND: HIV prevalence among the general population in South Sudan, the world's newest nation, is estimated at 2.9%. Limited data exist describing the HIV epidemic among female sex workers (FSW) in the country.

METHODS: With funding from CDC, IntraHealth International conducted a respondent-driven sampling (RDS) biobehavioral survey of FSW aged >15 years in January-February 2017 who sold or exchanged sex in the last 6 months in Nimule, at the Uganda border. Consenting participants were administered a questionnaire and tested for HIV according to the national algorithm. Syphilis was tested using Determine Syphilis+ Rapid Plasmin Reagin. Data were analyzed in SAS and RDS-Analyst. Weighted results are presented.

RESULTS: We enrolled 409 FSW with median age of 23 years (IQR 18-28) and median duration in sex work of four years (IQR 2-6). Over half of FSW were illiterate. Most were from South Sudan (61.4%) and Uganda (36.8%).Only 12.9% of FSW had stayed in Nimule for less than one year. Nearly all (99.2%) FSW lacked comprehensive knowledge of HIV though almost half (48.5%) of FSW had talked to a peer educator or outreach worker about HIV in the last 30 days. More than half (55.3%) had ever tested for HIV. Only 46.4% had used a condom at last sexual act with a client. One in five (19.8%) FSW had a condom break during vaginal or anal sex in last six months. However, only 9.6% used a lubricant during anal or vaginal sex in last six months. HIV prevalence was 24.0% (95% CI: 19.4-28.5) and 9.2% (95% CI: 6.5-11.9) had active syphilis. In bivariate analysis, being non-South Sudanese, <1 year stay in Nimule, and ever testing for HIV, and having active syphilis were associated with HIV infection (P<0.0001). In multivariable analysis, HIV was associated with having active syphilis (aOR: 6.99, 95% CI: 2.23-21.89).

CONCLUSIONS: HIV and syphilis prevalence were high among FSW in Nimule compared to national prevalence. Our findings underscore the importance of providing HIV and syphilis testing for FSW in conjunction with comprehensive combination prevention including comprehensive HIV information, condom use promotion, and availing treatment services for both HIV and syphilis.

PEC0411

SCALE UP OF A MULTI-COUNTRY HIV TEST PROGRAM INDICATES AN UNMET NEED FOR TARGETING POPULATIONS AT HIGHER RISK AND STRATEGIZING IN TEST LOCATION

W. Odoke[1], J. van den Hombergh[2], B. Biwot[1], A. S. Benzaken[3], D. Nazarov[4], P. Reis[5], T. Ford[5]
[1]AIDS Healthcare Foundation Africa Bureau, Nairobi, Kenya, [2]AIDS Healthcare Foundation Netherlands, Amsterdam, Netherlands, [3]AIDS Healthcare Foundation, Manaus, Brazil, [4]AIDS Healthcare Foundation Washington, Washington, United States, [5]AIDS Healthcare Foundation Global, Los Angeles, United States

BACKGROUND: AIDS Healthcare Foundation (AHF) Global Program supports HIV/AIDS prevention in 43 countries in Africa, Asia, Latin America and Europe. The cornerstone of the support is large-scale targeted HIV testing, identifying HIV positives and linking them to HIV care facilities to initiate anti-retroviral therapy (ART).

DESCRIPTION: AHF has gradually stepped up HIV rapid testing in the past 10 years. At country level, rapid test programs are implemented with its local partner organizations, in community settings, through outreach and facility based, adhering to national guidelines. Positive testers are linked to an HIV care facility. Numbers of clients tested went up from 500,000 in 2010 to over 4 million in 2019.

LESSONS LEARNED: The average HIV positivity ratio in 2019 was 3,1% (range by country 0.7% - 6.9%) identifying a total of 128,339 HIV-positive clients, of whom 77% were successfully linked to care facilities. Overall test-positivity in the age group 25-49 years was highest among women (4%), followed by men (3.6%), versus 2.4% and 1.6% respectively among 15-24 years. In the > 45years, male positivity was higher (3.1%) than in females (2.8%). Analyzed by main reason for testing, "Partner positive" scored highest (12.5%) followed by "Injecting drug use" (6.2%) and "Ill health" (3.2%). For 1,625,428 testers a key population (KP) category was reported and positivity peaked among PWID (6.2%) followed by MSM (6.1%) and Sex/Entertainment workers (3.4%). For 3,648,976 testers, positivity was significantly higher at facility (3.9%) as compared to testing in outreach or community settings (1.9%).

CONCLUSIONS/NEXT STEPS Scale-up in people tested for HIV in a large number of sites across 43 countries resulted in sustained HIV-positivity yields against a back-drop of declining estimates of PLHIV unaware of their status. Prevalence was high among young females, older men and KPs such as PWID, MSM and sex workers. Testing at the health facility is more effective in identifying new PLHIV than in community settings. These data point at an unmet need for targeting populations at higher risk and strategizing in location for testing. Further scale up of HIV testing must target difficult to reach populations at elevated risk, using innovative approaches.

PEC0412

HIV MORTALITY AMONG INPATIENTS WITH MENTAL DISORDERS IN BRAZIL, 2000-2015

A.P.S. Melo[1], M.L. Cherchiglia[2], A.L.P. Ribeiro[3], M.D.C. Guimarães[2]
[1]Federal University of São João del Rei, Psychiatry, Divinópolis, Brazil, [2]Federal University of Minas Gerais, Belo Horizonte, Brazil, [3]Federal University of Belo Horizonte, Belo Horizonte, Brazil

BACKGROUND: People with mental disorders (PMD) have a mortality rate 2.22 times higher than the general population, with a decade of Years of Life Lost. PMD are at increased risk mortality due to HIV infection and the majority of these deaths is preventable. Most stud-

ies of HIV among PMD occurred in high-income countries.Objective: To describe the risk of HIV mortality in a nationwide cohort of inpatients with a primary diagnosis of a mental disorder compared to inpatients with diagnoses other than mental disorders from 2000 to 2015 in Brazil

METHODS: This national retrospective cohort included all patients hospitalized through the Brazilian National Health System (SIH-SUS-Brazil) from January 1, 2000 thru May 31, 2015. Time of follow-up was measured from the date of the patients´ first hospitalization until their death, or May 31, 2015. Probabilistic and deterministic record linkages integrated data from SIH and The National Mortality System (SIM). PMD were determined as a primary diagnosis, codes "F00-F99" according to the International Classification of Diseases (ICD-10). HIV mortality was determined when the underlying cause of death was coded "B20 to B24" (ICD-10). Mortality was expressed per 100,000 inpatients and the relative risk (RR) was calculated with 95% confidence interval (CI), comparing HIV mortality among PMD with those with other diagnoses.

RESULTS: A total of 87,561,633 patients were hospitalized in a public system, SIH-Brazil from 2000 to 2015 -1,574,470(1.80%) PMD and 85,987,163 (98.2%) with non-mental disorders. Among 8,453,671 deaths registered in the period, 128,101(1.52%) were due to HIV. Among PMD, we detected 3,398 deaths due to HIV (mortality rate=216/100,000 inpatients). Conversely, we identified 124,703 HIV deaths in non-psychiatric patients (mortality rate 145.2/100,000 inpatients. The relative risk of death due to HIV was 1.49(95% CI=1.44-1.54) (p<.0001), when comparing the two groups.

CONCLUSIONS: Our analysis indicates an excess risk of dying due to HIV among PMD inpatients in Brazil. Prevention of HIV excess mortality should be considered a high public health priority among hospitalized patients in Brazil, with emphasis among PMD. Identification and management of HIV related conditions, including HIV testing and antiretroviral treatment, can reduce premature mortality among.

PEC0413

A SYSTEMATIC REVIEW OF HIV INCIDENCE MEASUREMENT AMONG FEMALE SEX WORKERS IN AFRICA: A STRATEGIC INFORMATION GAP TO BE FILLED IF WE ARE TO ACHIEVE EPIDEMIC CONTROL

H. Jones[1], S. Ali[1], H. Cust[1], B. Rice[1], L. Platt[1], B. Hensen[2], F. Cowan[3,4], J. Hargreaves[1]
[1]London School of Hygiene and Tropical Medicine, Public Health and Policy, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, Infectious and Tropical Diseases, London, United Kingdom, [3]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [4]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom

BACKGROUND: Female sex workers (FSW) in Africa are at high risk of HIV, yet HIV incidence patterns among this group are poorly understood. A Lancet 2012 systematic review included 30 studies of prevalent HIV infection in Africa but no studies measuring HIV incidence. We aimed to identify studies including measures of HIV incidence among FSW in Africa and explore regional and temporal trends in estimates.

METHODS: We conducted a systematic literature review. We screened 8,112 titles and abstracts and reviewed 16 papers, published since 2000, providing measures of HIV incidence from cohort studies among 14 distinct FSW populations in Benin, Burkina Faso, Cote d'Ivoire, Kenya, Rwanda, Tanzania, Uganda and Zimbabwe. Most studies recruited populations accessing clinical services.

RESULTS: The studies included 10,342 women, with sample sizes from 284 to 1640. HIV incidence estimates ranged from 0/100 person-years at risk (pyar) among a population enrolled in an oral PrEP demonstration project in Burkina Faso 2009-2011 to 13.1/100 pyar in a study in Kenya which enrolled women from 1993-1997. Overall, 1131 FSW seroconverted during a total of 25,263.35 person years. Measured HIV incidence was higher in Eastern Africa (3.55/100pyar, 8 studies) than Western Africa (1.4/100pyar, 5 studies), with only 1 study in Southern Africa (Zimbabwe, 9.8/100pyar). Follow up time ranged from nine months to fifteen years. Four studies showed decreased incidence over participation follow-up time, but overall temporal patterns were difficult to detect.

[Figure 1: Estimates of HIV incidence from studies among female sex workers in Africa]

CONCLUSIONS: There is a lack of data on rates, patterns or trends in new HIV infections among FSW in Africa. Available data suggest HIV incidence is high among FSW populations accessing clinical services. There are almost no data from population-based cohorts or to assess whether rates have changed over time. Moving forward this gap must be urgently filled.

PEC0414

THE ROAD TO THE END OF THE EPIDEMIC: A STUDY OF HIV TRANSMISSION ALONG THE TRANSIT CORRIDORS IN TANZANIA IN 2019

C. Said[1], N. Makyao[2], A. Sabasaba[1], R. Mboneko[1], N. Springstubb[3], J. Ndayongeje[1], K. Shimiyu[4], O. Msumi[4], E. Matiko[3], B. Mushubira[3], S. Welty[1], F. Morales[4], A. Ramadhani[2], W. McFarland[1], G. Mgomella[3]
[1]University of California, Institute for Global Health Sciences, San Francisco, United States, [2]National AIDS Control Programme, Dar es Salaam, Tanzania, United Republic of, [3]US Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: The Tanzania HIV Impact Survey (THIS) 2016-2017 reported HIV prevalence of 5.1% among adults 15-64 years in mainland Tanzania; regions with major transit corridors have higher burden of infection. While long-distance truck drivers (LDTDs) and female sex workers (FSWs) have long been characterized as high risk for HIV, less is known about their sexual networks in communities surrounding roadside hotspots.

Our survey sampled populations along transit corridors of Tanzania to characterize sexual networks, HIV risk behaviors, and access to care.

METHODS: A bio-behavioral survey was conducted in roadside hotspots in Kagera, Geita, Mwanza and Pwani regions using time-location sampling methods from February-August 2019. Individuals 15+ years were recruited during peak hours from venues such as bars, guesthouses and truck park areas within each hotspot. HIV- and HIV+ participants were invited to refer sexual partners to the survey,

with an incentive of TZS 6,000 per referral. Face-to-face interviews, HIV counseling, rapid testing and return of results were conducted with all consenting participants.

RESULTS: We enrolled 3,587 participants from 81 venues in 17 hotspots, who recruited 446 sexual partners. HIV prevalence among venue-recruited participants varied by region and sex, ranging from 4.3-5.7% among men and 11.9-18.3% among women — higher than most regional HIV prevalence reported by THIS 2016-2017. Only 14.9% of HIV+ women and 7.5% of HIV+ men reported a known HIV+ status; of whom 90.0% and 87.5%, respectively, self-reported being on ART. Women at venues were petty traders, food vendors, FSWs, barmaids, and guesthouse workers; men at venues were petty traders, food vendors, LDTDs, casual and formal employees. Overlapping sexual networks across mobile, FSW and local populations, concurrent partnerships, transactional sex, and low levels of condom use were reported.

CONCLUSIONS: Our study described high HIV prevalence within sexual networks of mobile populations, their partners, and the communities surrounding hotspots. While prevention interventions often concentrate on LDTDs, these findings underscore high HIV risk among women, indicating a need for interventions focusing on financial independence and improved self-reliance for women. Innovative means of identifying PLHIV including index-testing, HIV self-testing and couples-testing are recommended to reach key and vulnerable populations along transit corridors.

PEC0415

KEY POPULATIONS HIV CARE CASCADES IN ZANZIBAR 2018/2019: MISSING THE MARK ON THE FIRST 90 OF THE UNAIDS 90-90-90 TARGETS

A.U. Khamis[1], S. Mohamed[1], F. Khalid[1], S. Haji[1], A. Othman[1], A. Khatib[1], C. Said[2], N. Springstubb[3], K. Kazaura[3], S. Welty[2], W. McFarland[2], G. Mgomella[3]
[1]Zanzibar Integrated HIV, Hepatitis, Tuberculosis, and Leprosy Programme (ZIHHTLP), Zanzibar Ministry of Health, Stonetown, Tanzania, United Republic of, [2]University of California, Institute for Global Health Sciences, San Francisco, United States, [3]US Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: According to the Tanzania HIV Impact Survey 2016-2017, Zanzibar HIV prevalence among people aged 15-64 years was 0.4%. However, key populations (KP) bear a disproportionate burden of the disease. KP HIV programming is key to epidemic control in Zanzibar. Bio-behavioral surveys (BBS) in 2018/2019 presents the first opportunity to assess progress towards achieving the UNAIDS 90-90-90 targets among KP in Zanzibar.

METHODS: We conducted cross-sectional BBS of MSM, FSW and PWID from September 2018 to April 2019 using respondent-driven sampling (RDS) in Unguja, Zanzibar. Consenting individuals aged 15+ who had lived in Unguja for at least three months, who self-identified as: men who have sex with men (MSM) or female sex workers (FSW) or people who inject drugs (PWIDs) were recruited. HTS was done following the national algorithm. For those HIV+, viral load (VL) was quantified and VL suppression was defined as <1,000 HIV RNA copies/mL. Status of UNAIDS 90-90-90 targets was described using weighted percentages.

RESULTS: Overall, 341 MSM, 580 FSW, and 419 PWID were surveyed, with HIV prevalence at 5.0% (95% CI: 3.1-7.9), 12.1% (95% CI: 5.1-19.0) and 5.1% (95% CI: 2.6-7.5), respectively. Among those living with HIV, 59.7% (95% CI: 35.9-79.6) of MSM, 72.5% (95% CI: 60.7-81.8) of FSW and 47.5% (95% CI: 20.8-75.6) of PWID knew their HIV-positive status. Among those who knew their status, 92.9% (95% CI: 54.3-99.3) of MSM, 94.3% (95% CI: 83.3-98.2) of FSW and 88.1% (95% CI: 31.5-99.2) of PWID were on ART. Of those on ART, 97.9% (95% CI: 80.1-99.8) of MSM, 86.9% (95% CI: 69.1-95.1) of FSW, and 97.6% (95% CI: 68.4-99.9) of PWID were virally suppressed.

CONCLUSIONS: Identification of HIV-positive KP remains the biggest challenge for achieving UNAIDS "90-90-90". There is need for increased testing coverage across all three populations, with a special emphasis on PWID and MSM. Encouragingly, once diagnosed, proportions of ART use and viral suppression among KP are approaching or exceeding the 90% targets. Concerted efforts and intense programmatic focus are needed to diagnose PLHIV among KP in Zanzibar.

PEC0416

FACTORS ASSOCIATED WITH RETENTION OF TRANSGENDER WOMEN LIVING WITH HIV IN A RESEARCH INTERVENTION LEAD BY PEER NAVIGATORS IN SÃO PAULO, BRAZIL

K.C. Bassichetto[1], L. Fasciolo Maschião[1], M. Guimarães[1], P. Galdino Cardin de Carvalho[1], I. Leite Concílio[1], C. Spindola Luciano[1], S. Lippman[2], H. Gilmore[2], J. Sevelius[3], M.A. Veras[4]
[1]Santa Casa de São Paulo Medical School, NUDHES (LGBT Population Health and Human Rights Research Center), Sao Paulo, Brazil, [2]University of California at San Francisco, San Francisco, United States, [3]University of California at San Francisco, Medicine, San Francisco, United States, [4]Santa Casa de São Paulo Medical School, Colective Health/NUDHES (LGBT Population Health and Human Rights Research Center), Sao Paulo, Brazil

BACKGROUND: In general, transgender women (TGW) are more likely to be living with HIV and face greater barriers adhering to treatment (ART). An intervention study, TransAmigas, was developed to evaluate the effect of peer navigation (PN) on retention in care and adherence to ART among TGW living with HIV in São Paulo, Brazil. The purpose of this analysis is to identify factors associated with participant retention in the study.

METHODS: From April 2018-September 2019, TGW living with HIV were recruited from a public health service and were randomly assigned 2:1 to intervention (PN) or control. Chi-square tests, and bivariate and multivariate logistic regression models were used to analyze association of participant retention in the final interview, approximately 9 months following enrollment, with allocation group; telephone contact at 3 months; sociodemographic characteristics (age, education, income, marital status, occupation and ethnicity); reported mental health challenges and violence (presence of severe mental illness – K10 scale), alcohol or substance use, suicide attempt, verbal and sexual violence). Covariate selection maintained those with theoretical relevance and covariates associated with outcome at p <0.05.

RESULTS: Of 113 participants, 75 were allocated to the intervention and 38 to the control group. Overall 79 (69.9%) responded the 9-month interview, with no difference between allocation group (p = 0.50). In bivariate models, having been contacted by telephone at 3 months (p <0.001), higher educational level (> = 12 years) (p = 0.01) were associated with higher retention at 9 months and any use of illicit substances (p = 0.05) with lower retention. In the multivariate model, 3-month telephone contact (aOR: 7.30; 95% CI: 2.70-19.72) and higher education (> = 12 years) (aOR: 3.19; 95% CI: 1.10-9.21) remained associated, adjusted for ethnicity and age.

CONCLUSIONS: Our analyses found that consistent contact was associated with retention in the research, as was higher education level. Future research with this population should include regular contact intervals.

PEC0417

STRATEGIES TO IMPROVE ENROLMENT AND RETENTION OF TRANSWOMEN IN THE TRANS*NATIONAL COHORT STUDY IN SÃO PAULO, BRAZIL

J.L. Gonzalez Junior[1], P. Silveira[2], A. Cezaretto[2], F. Rocha[1], G. Saggese[1], M.A. Veras[1], J. Lin[3], C. Turner[3], E. Wilson[3], W. McFarland[4]
[1]Faculty of Medical Sciences of Santa Casa, Collective Health, Sao Paulo, Brazil, [2]University of São Paulo, Sao Paulo, Brazil, [3]University of California San Francisco (UCSF), San Francisco Department of Public Health, San Francisco, United States, [4]University of California San Francisco (UCSF), San Francisco, United States

BACKGROUND: Transwomen are among the most vulnerable to HIV infection globally. In São Paulo, Brazil, HIV prevalence among transwomen is 29%, compared to 0.4% in the general population. The unmet health and social welfare needs of transgender communities are great while research for the population lags behind. The Trans*National Cohort Study is the world's largest health study of trans femme communities, working in the United States, Brazil, China, and Namibia. The aim of this presentation is to share lessons learned and strategies to improve recruitment, linkage, and retention of transwomen to create a rigorous research platform.

DESCRIPTION: The cohort in São Paulo studies HIV incidence, risk and protective factors among transwomen. Respondent-Driven Sampling (RDS) was applied to recruit diverse participants who were subsequently recruited for the longitudinal cohort. RDS is a chain-referral sampling method in which participants invite other people they know to the study. Enrolled participants (N=606) were expected to complete follow-up visits every six months for 4 visits total. At each visit, participants completed a survey and tested for HIV, syphilis, HBV, and HCV. The field team (2 field supervisors, 2 nurses and 6 interviewers) held regular meetings to identify challenges, strengthen team cohesion, and provide ongoing staff training. Prior to fieldwork, qualitative formative research was conducted to inform study strategies.

LESSONS LEARNED: Recruitment, linkage, and retention strategies were developed and adapted to the specific needs of the population, including: use of preferred name only (no formal ID or civil name); a sensitized team; afternoon and evening working hours as identified in formative research; periodic phone calls; WhatsApp and Facebook appointment reminders at regular intervals prior to study visit dates; a progressively increasing reimbursement protocol; provision of food at study visits; and a gift kit (containing a small bag, lipstick, nail polish, condoms and a disposable enema). Retention and key outcome results will be presented.

CONCLUSIONS/NEXT STEPS Taking into consideration specific needs of transwomen was a key factor when addressing strategies for strengthening the cohort. Promoting a cohesive, well-trained and sensitive team facilitated retention. Regular team meetings focused on continuously reviewing and updating strategies contributed to better results.

EXAMINING THE ASSOCIATION BETWEEN CHILD REMOVAL, HIV AND MATERNAL SURVIVAL PATTERNS IN A CANADIAN COHORT OF MARGINALIZED WOMEN

M. Thumath[1,2,3], J. Barlow[1], D. Humphreys[1], M. Braschel[2], K. Deering[2,4], S. Pierre[5], K. Shannon[2,4]
[1]University of Oxford, Department of Social Policy and Social Intervention, Oxford, United Kingdom, [2]Centre for Gender and Sexual Health Equity, Providence HealthCare, Vancouver, Canada, [3]University of British Columbia, School of Nursing, Vancouver, Canada, [4]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [5]Ktunaxa Nation, ʔAqʔam, St. Mary's Indian Band, Cranbrook, Canada

BACKGROUND: Marginalized women impacted by sex work, drug-use and HIV are dying prematurely. Little is known about the drivers of maternal mortality in this population. This study reported mortality rates among a prospective cohort of marginalized mothers in British Columbia, Canada and investigated predictors of mortality.

METHODS: Data were drawn from seven years (2010-2017) of a merged dataset of two community-based longitudinal open cohorts of over 1000 cis and trans marginalized women in Canada recruited using time-location sampling and community referrals. After restricting to women who had ever had a live birth, we calculated age-standardized mortality ratios using the Canadian female population at the midpoint of the study (2014) as the reference. We identified predictors of mortality using Cox proportional hazards regression.

RESULTS: Among 712 marginalized women aged 19-69 (median 40, IQR 32-46), 39 died between 2010 and 2017, yielding a mortality rate of 10.8 per 1000 person-years. Marginalized women in our cohort were 9.75 (95% CI 6.93-13.33) times more likely to die than Canadian women of the same age. The leading causes of death were injury related (n=19, 48.7%), with overdose (n=17, 89.5%) being the primary cause of death. This was followed by non-communicable diseases (n=9, 23.1%) and communicable diseases (n=2, 5.1%). Baseline predictors of mortality included having HIV (adjusted hazard ratio [HR] 2.55, 95% CI 1.33-4.89), maternal experience of child custody loss (adjusted HR 1.64, 95% CI 0.83-3.23) and intimate partner violence (adjusted HR 2.39, 95% CI 0.82-6.96).

CONCLUSIONS: Marginalized mothers in the cohort are almost 10 times more likely to die than Canadian females of the same age. These deaths likely reflect complex intersections of historical and current inequities, substance use and barriers to care for women living with HIV. In the context of universal, free HIV treatment the increased hazard of mortality among HIV positive women suggests an unmet need for trauma and violence informed care accessible to marginalized mothers, particularly those experiencing child custody loss. The increased hazard of overdose death highlights the need for further gender responsive strategies to prevent overdose among women, including expansion of addiction treatment services accessible to pregnant and parenting women.

PEC0419

FENTANYL AND HIV RISK AMONG URBAN AND SUBURBAN PEOPLE WHO INJECT DRUGS IN MARYLAND

J.N. Park[1], J. Owczarzak[1], M. Morris[1], G. Urquhart[1], N. Weicker[1], S. Rouhani[1], S. Sherman[1]
[1]*Johns Hopkins University, Department of Health, Behavior and Society, Baltimore, United States*

BACKGROUND: Drug overdose is the leading cause of injury death in the US, with escalating rates attributable to illicit fentanyl, a potent synthetic opioid involved in overdose deaths across the country. Receptive syringe sharing (RSS) is a key HIV risk factor, and recent outbreaks among people who inject drugs (PWID) have renewed concerns around the impact of the opioid crisis on HIV rates nationally. This study examines the role of fentanyl on injection-related HIV risk.
METHODS: Recruitment of PWID occurred in 2018-2019 through targeted sampling in a major regional city (Baltimore), and began on November 2019 in a neighboring suburban area (Anne Arundel County). Participants completed a 30-minute ACASI survey assessing their recent (past 3 month) drug use and HIV risk behaviors. Analysis was conducted in Stata/SE 15.1. We also conducted in-depth interviews (n=17/20 in Baltimore; n=2/10 in Anne Arundel) with PWID.
RESULTS: Among 270/350 recruits, mean age was 45, 58% were male, and 56% were Black. 3% initiated opioid use through non-medical fentanyl. However, most (72%) transitioned to non-medical fentanyl injection; 56% recently injected fentanyl/cocaine and 64% recently injected fentanyl. Injection frequency was 1.58 times higher per day among fentanyl injectors. After adjusting for age, gender, race, current homelessness and arrest, fentanyl injection was associated with recent RSS (aOR[Model A]=2.40; 95% CI: 1.02-5.63, p=0.044) and higher recent injection frequency i.e., >90 times (aOR[Model B]=1.83; 95% CI: 1.04-3.25, p=0.036). In-depth interviews indicated that although PWID know that fentanyl is common in the local supply, they are often uncertain about the precise contents of their drugs prior to use. Respondents also discussed structural barriers to sterile syringe access including the absence of syringe exchange in the county, refusal by pharmacists to sell sterile syringes, and fear of arrest by police for carrying syringes, which led them to reuse or share syringes.
CONCLUSIONS: The fentanyl epidemic brings new HIV prevention challenges, including higher injection-related risk of HIV transmission. We need to rapidly expand harm reduction education and services including syringe services programs and engage fentanyl injectors into HIV programs (e.g., test and treat, PrEP) in order to mitigate the risk of future outbreaks.

RISK FACTORS FOR ACQUISITION, INFECTIVITY AND TRANSMISSION OF HIV

PEC0420

IDENTIFYING CONTEXTUAL FACTORS OF THE USE OF HIV TESTING IN THE DEMOCRATIC REPUBLIC OF CONGO: ANALYSIS OF A POPULATION-BASED SURVEY

N.D. Kouevi-Gath[1], S. Samadoulougou[2], F. Kirakoya-Samadoulougou[1]
[1]*Université Libre de Bruxelles, Brussels, Belgium,* [2]*Université Laval, Quebec, Canada*

BACKGROUND: Many studies have underlined a series of individual factors in the use of HIV testing uptake, but very few have assessed the role of contextual factors. This study aims to
(i) determine the prevalence of HIV testing among the sexually active population of the Democratic Republic of Congo (DRC), and
(ii) identify the individual and contextual factors associated to HIV testing uptake.
METHODS: The data used was collected from the second demographic and health survey conducted in the DRC from November 2013 to February 2014. A sample of 14,578 sexually active women aged 15 to 49 and 6,932 sexually active men aged 15 to 59 years were selected. The contextual factors associated with the use of HIV testing were identified using multilevel logistic regression.
RESULTS: Overall, one-quarter of the women (26%, 95% CI (22.6% -29.6%)) and less than one-fifth of the men (18.0%, 95% CI (16%) 6% -20.5%)) reported that they have been tested for HIV. HIV testing uptake was highly associated to some individual factors such as: age, education, religious affiliation (for women), wealth index, marital status, employment, media exposure, the number of sexual partners (among men), knowledge about HIV and the stigma score.
After adjusting for individual variables, women living in communities with the following characteristics higher than the median were more likely to report having tested for HIV: high knowledge of where to test (OR : 2.45 ; 95% CI : 1.92 - 3.1), the low stigma score (OR : 1.28 ; 95% CI : 1.05 - 1.56). They were less likely to report performing the test when the community level of media exposure is low (OR : 0.75 ; 95% CI: 0.60 - 0.94), and the community level of poverty is high (OR : 0.74; 95% CI: 0.58 -0.94). In men, the increased knowledge of testing centers (OR : 1.51 ; 95% CI: 1.21 - 1.90) was significantly associated with HIV testing uptake at the community level.
CONCLUSIONS: Beyond individual characteristics, community characteristics are also important factors that influence HIV testing uptake in the DRC, and these factors should be taken into account in prevention programs around the country.

PEC0421

HIGH LEVELS OF RECEPTIVE SHARING AND HIV AMONG YOUNG PWID WITH HCV FROM 10 U.S. CITIES-IMPLICATIONS FOR HIV ELIMINATION EFFORTS

J. Burnett[1], D. Broz[1], J. Chapin-Bardales[1], C. Blanco[2], E. Teshale[1], C. Wejnert[1], NHBS Study Group
[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]National Institute on Drug Abuse, Bethesda, United States

BACKGROUND: Recent HIV outbreaks in the United States were preceded by dramatic increases in hepatitis C (HCV) infection among young people who inject drugs (YPWID), even in areas where resources for HIV prevention and substance use treatment were available. To inform HIV prevention in this population and prevent future HIV outbreaks, it is critical to understand factors associated with HCV among YPWID.

METHODS: PWID ages >=18 years were recruited using respondent-driven sampling (RDS) for the 2018 National HIV Behavioral Surveillance, interviewed and offered HIV and HCV testing in 10 US cities. HCV testing included antibody and RNA testing for all participants. Behaviors were assessed for the 12 months prior to the interview. Bivariate and multivariable analyses were conducted using log-linked Poisson regression models to test for associations between current HCV infection (RNA-detected) and selected characteristics among YPWID adjusted for network size and region and clustered on RDS recruitment chain.

RESULTS: Of 3,735 PWID, 14% were 18-29 years (YPWID). HIV prevalence was 6% among YPWID and 9% among older PWID; current HCV prevalence was approximately 44% among both age groups. Receptive sharing of syringes or injection equipment was higher among YPWID compared with older PWID (64% vs. 52%, p<0.001). After adjusting for covariates, among YPWID, current HCV infection was associated with the following:

	Adjusted Prevalence Ratio	95% Confidence Intervals
White/other (Reference: black)	2.0	1.0-4.0
Receptively sharing syringes or injection equipment	1.1	1.0-1.2
Injected for two or more years	1.5	1.1-2.3
Accessing a syringe services program (SSP)	1.3	1.2-1.4
HIV positive	1.3	1.1-1.6

[Table]

CONCLUSIONS: Current HCV infection was associated with HIV and high-risk injection behaviors pointing to a vulnerability to further increases in HIV. Similar behaviors put YPWID at risk for both HCV and HIV. YPWID who attend SSPs were more likely to have HCV infection indicating SSPs may be reaching higher-risk populations, as intended. Continuing and improving SSP services will provide opportunities to prevent HIV and HCV infection. Close monitoring of HCV and HIV infection and associated risk behaviors among YPWID will be key to effective tailoring of HIV prevention efforts, prevent HIV outbreaks and respond to the call of the national Ending the HIV Epidemic Initiative.

PEC0422

CHARACTERIZING PROBLEMATIC DRUG USE AMONG TRANSGENDER WOMEN AND CISGENDER MEN DURING THE EMERGING HIV CRISIS IN THE PHILIPPINES

A. Restar[1], A. Ogunbajo[2], R. Chan[3], A. Adia[2], M.I. Quilantang[4], S. Cu-Uvin[2], D. Operario[2]
[1]Brown University School of Public Health, Providence, United States, [2]Brown University School of Public Health, Department of Behavioral and Social Sciences, Providence, United States, [3]The Education University of Hong Kong, Department of Special Education and Counselling, Hong Kong, Hong Kong, SAR of China, [4]University of Philippines, Department of Behavioral Sciences, Manila, Philippines

BACKGROUND: Drug use and HIV are key issues for public health interventions in the Philippines. Yet, little is known about correlates of problematic drug use in the Philippines and specifically, among sexual and gender minorities. We characterized problematic drug use among Filipinx transgender (trans) women and cisgender men who have sex with men (cis-MSM).

METHODS: Using data from an online survey with Filipinx trans women and cis-MSM residing in Manila and Cebu, Philippines (n=320), we conducted multivariate logistic regression procedures to examine associations of problematic drug use (measured by the Drug Use Disorders Identification Test-Consumption; DUDIT-C) with socio-socio-demographic characteristics, social marginalization indicators, and HIV-risk and related factors.

RESULTS: The prevalence of exhibited problematic drug use in this sample was 29.38%. Adjusted for socio-demographic characteristics, significantly (p<0.05) greater odds of problematic drug use were observed among Filipinx participants who recently engaged in sex work (adjusted OR [aOR]=2.79, 95%CI=1.08-7.18), reported having HIV positive and unknown status vs. negative status (aOR=3.61, 95%CI=1.39-9.39, and aOR=13.99, 95%CI=2.04-29.69, respectively), exhibited low HIV knowledge (aOR=4.15, 95%CI=1.82-9.44), and displayed hazardous drinking (aOR=2.77, 95%CI=1.21-6.33).

CONCLUSIONS: Filipinx trans and cis-MSM display a high rate of problematic drug use. Given its correlates of HIV-related indicators, integration of HIV and harm reduction services as a public health intervention could potentially decrease problematic drug use.

PEC0423

MOBILE TECHNOLOGY: AN EVOLVING SOLICITATION PRACTICE AND A HIGH-RISK BEHAVIOUR INDICATOR AMONG FEMALE SEX WORKERS IN INDIA - OPPORTUNITY TO EVOLVE AND STRENGTHEN HIV PREVENTION

S. P. Sakthivel[1], V. Verma[2], B. Rakshasae[3], P. Dixit[3], A. S[4], B. George[5], S. Rajan[6,6]
[1]Independent, New Delhi, India, [2]National AIDS Control Organization, Research, New Delhi, India, [3]Tata Institute of Social Sciences, Mumbai, India, [4]IIPS, Mumbai, India, [5]FHI 360, New Delhi, India, [6]National AIDS Control Organization, Strategic Information and Targeted Intervention, New Delhi, India

BACKGROUND: Background: In India, National AIDS Control Program (NACP) needs to be revamped due to its limitations in accommodating the evolving solicitation approaches among Female Sex workers (FSWs).

The current interventions revolve around the traditional solicitation approaches, including, brothel, street, home, lodge/hotel, highway/ dhaba and bar, while evolving solicitation approaches get unnoticed.

An operational research with the objective understanding the evolving solicitation approaches and its HIV associated risk behaviors was conducted among FSW in 2018-19.

METHODS: Methods: The study was conducted in seven states of India, including, Andhra Pradesh, Delhi, Kerala, Maharashtra, Manipur, Punjab and Tamil Nadu using consecutive mixed method, with qualitative preceding quantitative. 57 key informant interviews (KIIs), 26 Focus Group Discussions (FGDs) and 86 In-depth interviews (IDIs) were conducted for qualitative information and 1750 survey interviews for quantitative data. Inductive analysis was conducted with qualitative data, while descriptive and chi-square analysis was conducted for quantitative data, with 5% statistical significance.

RESULTS: Results: Among 1750 study participants, 41% (724) were soliciting clients through traditional solicitation approaches, while, 59% (1026) practiced evolving solicitation approaches. Within new soliciting approaches, 33% (343) soliciting exclusively through mobile technology (MT), 8% (85) exclusively via mediators and 58% (598) through both MT and new physical spaces (NPS). FSWs soliciting exclusively via MT, have a significant association of sex under the influence of alcohol (65%, 76/117), while inconsistent condom usage and self-reported STI symptoms was found to be significant with MT and MTNPS solicitations. Further, qualitative findings validated that FSW using MT for solicitation were ready to accept the client demands, such as, sex under the influence of alcohol and unsafe sex.

Solicitation Approaches/ Characteristics	Exclusive Mobile based solicitation	Exclusive Mediator based solicitation	Mobile + New form (other than mediator based)
Median age	35	32	34
Median age of first paid sex	27	22	25
Sex under the influence of alcohol	65.0* (76/117)	56.0(14/25)	61.2(137/224)
Unsafe vaginal sex with paid partners	9.3 (30/324)	1.3 (1/77)	7.9(44/556)
Unsafe anal sex with paid partners	50.0 (25/50)	83.9*(26/31)	45.3*(53/117)
Inconsistent Condom usage	40.8*(147/360)	63.5*(54/85)	43.8*(259/592)
Reported of STI symptoms in the last 12 months (the question was asked	40.5*(109/269)	65.4(34/52)	47.0* (194/413)

*significant at p<0.05

[Table]

CONCLUSIONS: Conclusion: In India FSWs using MT for solicitation is a prominent indicator of the FSWs engaging in HIV associated high-risk behaviour. HIV program could consider this tool for identification and educating them on importance of safe-sex and alcohol-free sex.

PEC0424

WHO'S NOT BEING TESTED FOR HIV AND WHY AMONG ADULT PATIENTS IN US EMERGENCY DEPARTMENTS

C. Bennett[1], S. Marks[1], T. Liu[2], M. Clark[3], M. Carey[4], R. Merchant[1]
[1]Brigham and Women's Hospital and Harvard Medical School, Department of Emergency Medicine, Boston, United States, [2]Brown University School of Public Health, Department of Biostatistics, Providence, United States, [3]Brown University School of Public Health, Department of Health Services, Policy, Practice, Providence, United States, [4]The Miriam Hospital, Centers for Behavioral and Preventive Medicine, Providence, United States

BACKGROUND: HIV testing initiatives in United States (US) emergency departments (EDs) have been successful by extending HIV testing to a broader patient population. However, an unknown number of adult ED patients likely remain untested. We sought to:
(1) Estimate the proportion of adult ED patients who have never been tested for HIV,
(2) Determine the common reasons for no previous HIV testing,
(3) Compare recent HIV risk-taking behaviors between those HIV tested vs. not previously tested, and;
(4) Identify factors associated with no previous HIV testing.

METHODS: During 2014 to 2018, English- or Spanish-speaking, 18-64-year-old patients in four EDs in Alabama, California, Ohio, and Rhode Island were surveyed about their demographic characteristics, HIV testing history, and HIV risk-taking behaviors within the past 3 months. Health literacy was assessed using a standardized instrument. Multivariable logistic regression models identified factors associated with no previous testing for HIV.

RESULTS: Of the 1,366 participants, 28% had never been tested for HIV. Of the 337 never tested for HIV, 51% were male, 50% had fewer than 12 years of formal education, and 54% had lower health literacy. Self-reported reasons cited for no previous HIV testing were: "not at risk/not necessary," (51%), "have not considered it" (27%), and "never been asked/offered a test" (14%). HIV risk-taking behaviors in the prior 3 months was similar for those never HIV tested vs tested: injection drug use (9% vs 7%, p<0.23) and condomless intercourse with casual (12% vs 15%, p<0.21) and exchange sexual partners (5% vs 6%, p<0.42). In multivariable models, participants who were white [OR 2.3, 95% CI 1.7-3.2], lacked healthcare insurance [OR 1.5, 95% CI 1.1-2.1], and had lower health literacy [OR 1.5, 95% CI 1.1-1.9] had greater odds of never having been tested for HIV.

CONCLUSIONS: HIV testing remains needed in US EDs, given that a substantial proportion of patients have never been tested for HIV and report recent HIV risk-taking behaviors. Novel interventions are needed to address barriers to HIV testing among those who have never been tested, including perceptions of low risk for HIV and discordance between perceived and actual risk for HIV acquisition.

PEC0425

ELIMINATION OF W. BANCROFTI-INFECTION LEADS TO REDUCED ACQUISITION OF HIV

I. Kroidl[1,2], M. Chachage[3,4], L. Maganga[3], A. Urio[3], T. Marandu[4,3], A. Haule[3], J. Mhidze[3], S. Horn[1], E. Saathoff[1,2], F. Rieß[1], N. Chiwarengo[3], M. Hoelscher[1,2]
[1]University Hospital of the University of Munich (LMU), Infectious Diseases and Tropical Medicine, Munich, Germany, [2]German Center for Infection Research, Partner Site, Munich, Germany, [3]NIMR Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [4]UDSM-Mbeya College of Health and Allied Sciences, Mbeya, Tanzania, United Republic of

BACKGROUND: A previous study in Southwest Tanzania had revealed an increased risk for HIV acquisition in individuals infected with W. bancrofti (published in Lancet, 2016, Oct15). A government treatment program against W. bancrofti commenced in 2009. The impact of this government NTD activity on HIV incidence is studied in an ongoing research project (RHINO-STUDY: "Risk for HIV through NematOdes").

METHODS: The same individuals whose data were collected in 2007-2011 were re-visited in 2019 and screened for W. bancrofti by a filarial rapid test and for HIV using the government test algorithm.

RESULTS: Participants of the previous study activity aged 14-65 years were re-visited in Kyela in 2019. Of those 1141 re-visited, 304 had been previously infected with W. bancrofti, 837 had tested negative for that helminth species. During the previous study time of 2007 to 2011, an overall HIV incidence of 1.0 in 100 person years was seen with a significant difference between the W. bancrofti -infected individuals (1.58 new HIV cases per 100 PY) and the W. bancrofti-uninfected individuals (0.6 cases per 100 PY, p=0.012) in individuals older than 14 years of age.

Re-visiting these individuals in 2019, we found a dramatically reduced W. bancrofti prevalence from 38% (2009) to 0.6% (2019). Regarding HIV, 57 new infections occurred during 8 years (2011-2019) which equates to an incidence of 0.63 per 100 PY. The group of 304 individuals who were previously W. bancrofti- infected (but not anymore after MDA), had 21 new HIV infections (0.86 per 100 PY). While the group of 837 individuals without previous W. bancrofti-infection had acquired 36 new HIV infections (0.54 per 100 PY), the difference was not significant (p=0.422).

CONCLUSIONS: Government treatment against filarial infections almost eliminated W. bancrofti infections in the study area. A group of 304 previously filarial infected individuals is now free of the helminth apart from a few remaining cases. The increased risk for HIV acquisition which was noted among these individuals during a previous study activity, has almost been "normalized" to levels of the surrounding village population. These findings highlight that NTD program activities could help to reduce the spread of HIV.

PEC0426

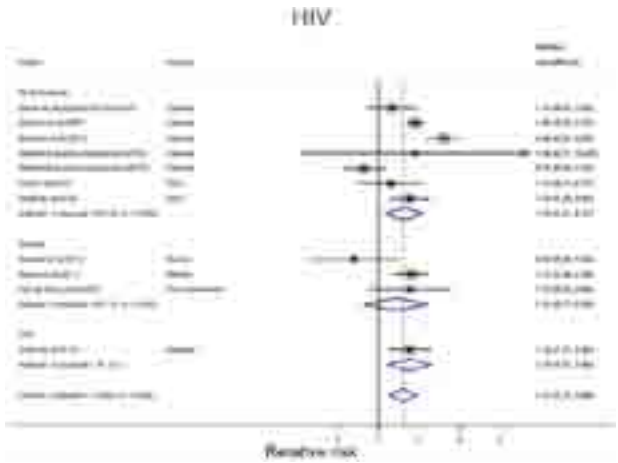
HOMELESSNESS, UNSTABLE HOUSING AND HIV AND HEPATITIS C VIRUS ACQUISITION RISK AMONG PEOPLE WHO INJECT DRUGS: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Arum[1], H. Fraser[1], S. Bivegete[1], A.G. Lim[1], L. Macgregor[1], J.J. Ong[2], A. Trickey[1], J.G. Walker[1], Z. Ward[1], M. Alary[3,4], P. Leclerc[5,6], K. Hayashi[7,8], K. DeBeck[7,8], V. Sypsa[9], L. Platt[2], V. Hope[10], M. Hickman[1], J. Stone[1], P. Vickerman[1]
[1]University of Bristol, Bristol, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Centre de Recherche du CHU de Québec – Université Laval, Montreal, Canada, [4]Institut National de Santé Publique du Québec, Montreal, Canada, [5]Université de Montréal, École de Santé Publique, Montreal, Canada, [6]Direction Régionale de Santé Publique - CIUSSS du Centre-Sud-de-l'Île-de-Montréal, Montreal, Canada, [7]British Columbia Centre on Substance Use, Vancouver, Canada, [8]Simon Fraser University, Vancouver, Canada, [9]National and Kapodistrian University of Athens, Athens, Greece, [10]Liverpool John Moores University, Liverpool, United Kingdom

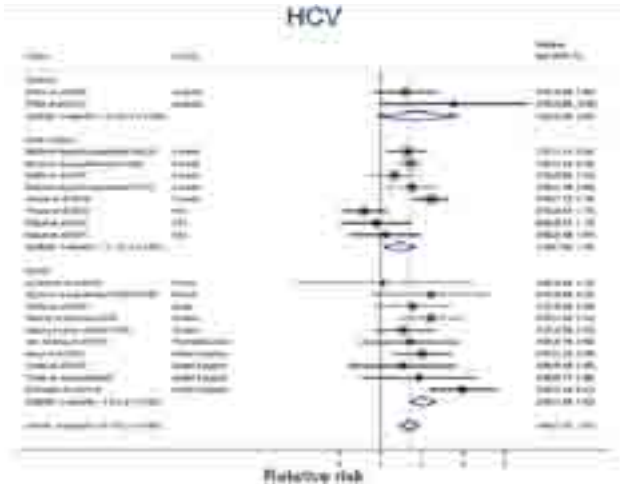
BACKGROUND: People who inject drugs (PWID) experience high rates of homelessness and unstable housing. We assessed whether homelessness or unstable housing elevates HIV or hepatitis C virus (HCV) acquisition risk among PWID.

METHODS: We searched MEDLINE, Embase and PsycINFO databases for studies in any language published from 2000 to June 2019 assessing HIV and/or HCV incidence among community-recruited PWID. Only studies reporting original results were included. We contacted authors of studies that met the inclusion criteria, but that did not report on the outcomes of interest, to request data. We extracted and pooled data from included studies using random-effects meta-analyses to quantify the associations between recent (current or past 3-12 months) homelessness or unstable housing and HIV or HCV acquisition risk among PWID. We assessed the risk of bias using the Newcastle-Ottawa Scale, and between-study heterogeneity using the I2-statistic and p-value for heterogeneity.

RESULTS: Thirty-one estimates (8 unpublished) were included in the final analysis; 11 for HIV and 20 for HCV. Studies originated from North America, Europe, Australia, and Asia. Recent homelessness or unstable housing was associated with a 53% increase in HIV acquisition risk (crude relative risk[cRR] 1.53;95% confidence interval [CI]1.21–1.94;I2=75%;p-value<0.001) and 63% increase in HCV acquisition risk with moderate-high between-study heterogeneity (cRR 1.63;95%CI 1.37-1.93;I2=53.1%;p-value<0.001). This strong association persisted when pooling adjusted estimates.



[Figure]



[Figure]

CONCLUSIONS: Homelessness or unstable housing is associated with substantial increases in HIV and HCV acquisition risk among people who inject drugs and maybe an important target for interventions to reduce blood borne virus transmission.

PEC0427

RISK FACTORS FOR RECENTLY ACQUIRED HIV INFECTION IN SOUTH AFRICAN BLOOD DONORS

K. van den Berg[1,2], M. Vermeulen[3], E.L. Murphy[4,5], R. Swaneverlder[6], J.J. Hemingway-Foday[7], D. Creel[7], U. Jentsch[6], B. Custer[5,4], for the NHLBI Recipient Epidemiology and Donor Evaluation Study-III (REDS-III).
[1]University of Cape Town, Clinical Haematology, Cape Town, South Africa, [2]South African National Blood Service, Translational Research, Johannesburg, South Africa, [3]South African National Blood Service, Operations Testing, Johannesburg, South Africa, [4]UCSF, San Francisco, United States, [5]Vitalant Research Institute, San Francisco, United States, [6]South African National Blood Service, Johannesburg, South Africa, [7]RTI, Bethesda, United States

BACKGROUND: Recruiting safe blood donors amongst the largest HIV-positive population in the world requires current information on risk behaviours in the donor pool. Risk factors among incident rather than prevalent HIV infections are more germane to blood safety as early HIV infections may be sero-silent. We aimed to identify demographic and behavioural risk factors associated with incident HIV infection among blood donors in South Africa.

METHODS: We conducted a case-control study of recently HIV-infected blood donors compared to seronegative controls frequency matched 3:1 on race, age and geography. Incident HIV-infection was defined as HIV antibody negative and RNA positive by individual donation nucleic acid testing (Procleix, Grifols) or normalized optical density < 1.5 on the Limiting Antigen Avidity assay (LAg; Sedia). Risk factors in the past 6 months were ascertained by ACASI interview. We fitted separate multivariable logistic models for males and females and adjusted for multiple comparisons; all results shown were significant at p<0.05.

RESULTS: From November 2014 to January 2018, we enrolled 323 incident HIV cases and 877 controls. Women comprised 71% of cases versus 50% of controls (p<0.0001). Among women, incident HIV infection was associated with current employment (aOR=2.10); sex with an HIV-positive (aOR=27.72) or multiple (>1) male partners (aOR=10.55); no condom use (aOR=3.36); and referral to donation by a healthcare worker (aOR=2.76). The use of THC drugs (aOR=0.41) and private medical insurance (aOR=0.56) were protective. Among men, incident HIV infection was associated with age 31 to 40 years (vs. <31 years; aOR=2.97); high school education (aOR=3.05); married or single partnership (aOR=2.51); >1 sexual partners (aOR=13.55); ≥4 male sexual partners (aOR=10.98); sex partner with unknown HIV status (aOR=22.33); occasional condom use (aOR=3.97); and penetrative injury (aOR=29.96). Private medical insurance was protective (aOR=0.22).

CONCLUSIONS: We identified a set of novel, putative risk factors for incident HIV infection among South African blood donors while confirming previously known sexual risk behaviours. Lack of private health insurance and penetrative injuries may be markers of lower socio-economic status and thereby HIV risk. The detection of risk behaviours by ACASI in previously questioned donors suggests that ACASI has the potential to improve risk identification.

PEC0428

WHAT ARE THE CHARACTERISTICS OF KEY POPULATIONS (KPS) WHOSE HIV STATUS SEROCONVERTED WHILE ENROLLED IN PREVENTION PROGRAMS? RESULTS FROM A KENYAN PROGRAM

O. Musau[1], C. Ochieng[2], P. Mwimali[2], G. Mwayuli[1], C. Ondieki[1], L. Otiso[3]
[1]LVCT Health, Programs, Nairobi, Kenya, [2]LVCT Health, Research and Strategic Information, Nairobi, Kenya, [3]LVCT Health, Executive Director, Nairobi, Kenya

BACKGROUND: Since 2016, LVCT Health implemented HIV prevention program for KPs in line with the National AIDS and STI Control Program guidelines 2014 in 5 Counties in Kenya. This program reached men who have sex with men (MSM), female sex workers (FSW) and people who inject drugs (PWID) in 20 service delivery points. During implementation, the HIV status of some of the KPs turned from negative to positive (seroconverted). This abstract describes key characteristics of those KPs who seroconverted.

DESCRIPTION: Routine individual level client data (client's demographics, risk profile, and services provided during a clinic visit) were collected monthly using MOH-approved tools. When a client seroconverted, a case report detailing the above data points and history of their adherence to prevention services was prepared. Data was manually abstracted from the client's case reports for the period October 2016 – September 2018, entered into MS Excel 2016 and analyzed using descriptive statistics.

LESSONS LEARNED: By September 2018, 31,691 HIV negative KPs (23,079 FSW; 6,188 MSM and 2,424 PWID) had been enrolled. 50(0.16%) clients (27 FSW, 23 MSM, 0 PWID) seroconverted during the period of review. Seroconversion rates were 0.3% MSM and 0.1% FSW. The highest seroconversions were FSW aged (years) 25-29(37%) and 20-24(26%). Among MSM, the highest were aged 20-24(43%). Overall, 37(74%) had no knowledge of HIV status of their regular sexual partners, 17 (34%) had been treated for STIs at least once and 6(12%) had been treated more than once. Majority, 39 (78%) had received condoms regularly, 10 (20%) had ever taken PrEP while 6(12%) reported to be on PrEP at the time of seroconversion.

CONCLUSIONS/NEXT STEPS: Lack of knowledge of the HIV status of regular sexual partners was the most prevalent characteristics. Others included a history of STIs, age (Infection-rate varied with age), and low uptake and possible poor adherence to PrEP. Additionally, some KPs who collected condoms may not have used them. KP programs should look out for individuals with these characteristics and proactively intervene before they acquire HIV. Programs should also extend HIV services to regular sexual partners of KPs and tailor services for young KPS.

PEC0429

RISK FACTORS FOR ACQUISITION OF HIV IN PRE AND POST ART ERAS IN MANICALAND, ZIMBABWE

L. Moorhouse[1], J. Eaton[1], C. Nyamukapa[1], R. Maswera[2], S. Gregson[1]
[1]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe

BACKGROUND: ART was introduced in Zimbabwe in 2005 and widely available from 2008, which has changed people's perception of risk of acquiring HIV infection and sexual behaviour. Increasing focus is being put on risk factor definitions to target prevention interventions and monitor progress of HIV prevention implementation, such as the HIV prevention cascade framework and risk differentiation tools. We used a proximate determinants framework of risk factors for new HIV infection to understand changes in determinants of risk following ART introduction in Manicaland, Zimbabwe.

METHODS: Data from six rounds of the Manicaland cohort study were used (1998-2013), consisting of men and women aged 15-54. Forward stepwise Cox proportional hazards models were fitted using the proximate determinants framework, stratified by sex and ART period, where entry was the first negative HIV test and failure was the first positive HIV test. Risk factors associated with HIV acquisition were compared before and after introduction of ART.

RESULTS: 9563 individuals participated in at least 2 survey rounds. Between 1998-2013, 4013 men contributed 16528 person years (PY) with 213 seroconversions. 5550 women contributed 25,164 PY with 328 seroconversions. Between 2005-2013, 3973 men contributed 14,578 PY with 143 seroconversions. 5831 women contributed 22,218 PY with 298 seroconversions. HIV incidence has declined over time, however differences in sex-specific incidence remain (2009-12 - men: 0.68/100PY (0.49-0.87), women: 0.87/100PY (0.70-1.04)).

Risk factors consistently associated with HIV acquisition included age (men 40-44 years HR 0.31, p=0.007 compared to 20-24 years), multiple sexual partners in the last year (women: HR 3.11, p<0.01), age disparate relationships (women: HR 1.43, p=0.063) and symptoms of STIs (men: HR 2.43, p=0.032).

Risk factors associated with HIV acquisition following ART introduction include being formerly married (women: HR 5.03, p=0.014; men: HR 1.83, p=0.095), self-perception of risk of future infection (women: HR 1.29 (p=0.020), having casual partnerships (women: HR 2.52, p<0.01) and visiting a beer hall (men: HR 1.50, p<0.01).

CONCLUSIONS: Risk factors for new HIV infections have changed since ART introduction. HIV prevention interventions should consider age, sex and sexual behaviour of the target population. Small sample size could prevent associations of risk factors being seen, particularly among men.

PEC0430

FACTORS ASSOCIATED WITH CONDOM USE AMONG GAY MOBILE APP USING MEN WHO HAVE SEX WITH MEN IN TOKYO

A.O. Hill[1], N. Kaneko[2], S. Gilmour[3], B.R. Bavinton[4]
[1]ARCSHS, Melbourne, Australia, [2]Nagoya City University, Nagoya, Japan, [3]St Luke's International University, Tokyo, Japan, [4]Kirby Institute, Sydney, Australia

BACKGROUND: Men who have sex with men (MSM) are disproportionately burdened by the human immunodeficiency virus (HIV), accounting for 78% of all Japanese male HIV cases in 2017. Even though biomedical interventions such as PrEP and PEP are not approved and condoms remain the primary tool for HIV prevention, condom use has been steadily decreasing among gay-venue-attending MSM in Japan. An estimated two-thirds of Japanese MSM are not attached to the gay community, and previous studies have largely sampled gay venues, and have likely failed to achieve diversity in participation.

METHODS: This study examined condom use prevalence and correlates with regular and casual male partners among 1657 MSM in Greater Tokyo. Participants were recruited through advertisements on gay mobile geo-social networking applications (gay mobile apps), which have been found to increase access to MSM not traditionally accessible through venue-based surveys.

RESULTS: Condomless anal intercourse (CLAI) was reported by 68.5% of participants with regular male partners, 54.2% with casual male partners, and 43.7% with female partners. Controlling for eight demographic and structural antecedent factors in multiple regression analysis, inconsistent condom use with casual male partners was more commonly reported among participants living in central Tokyo [adjusted odds ratio (AOR), 1.78 95% CI, 1.06-2.99] and among participants who used gay mobile apps for sex (AOR, 2.01 95% CI, 1.33-3.03). Inconsistent condom use with regular male partners was more commonly reported among participants who identified as a gay community member (AOR, 1.50 95% CI, 1.07-2.10), and who only had male partners (AOR, 1.78 95% CI, 1.13-2.80).

CONCLUSIONS: These results indicate that over half of gay mobile app using Japanese MSM use condoms inconsistently, and may be at risk for HIV. Considering that 1) Tokyo has the highest rate of HIV in Japan, 2) biomedical interventions such as PrEP and PEP are not approved, and 3) inconsistent condom use with casual partners was observed to be higher among MSM residing in central Tokyo and who used gay mobile apps for sex, promoting condom use in central Tokyo through gay apps may be an effective prevention policy to target Japanese MSM, particularly prior to and during the 2020 Olympics.

PEC0431

DISENTANGLING THE CONTRIBUTION OF DIFFERENT OVERLAPPING KEY POPULATIONS TO THE HIV EPIDEMIC IN TIJUANA, MEXICO

H. Fraser[1], A. Borquez[2], J. Stone[1], D. Abramovitz[2], K.C. Brouwer[2], D. Goodman-Meza[2], M. Hickman[1], T.L. Patterson[2], H. Pines[2], J. Silverman[2], L. Smith[2], S.A. Strathdee[2], N.K. Martin[2,1], P. Vickerman[1]
[1]University of Bristol, Bristol, United Kingdom, [2]University of California, San Diego, United States

BACKGROUND: Tijuana has one of the largest populations of people who inject drugs (PWID) in Mexico, and sex-work is quasi-legal for female sex workers (FSW). Tijuana also has a large population of men who have sex with men (MSM), meaning there are overlapping key populations contributing to the HIV epidemic. We model the extent to which HIV transmission is driven by specific key populations and risk behaviours.

METHODS: We developed and calibrated an overlapping dynamic HIV transmission model among PWID, FSW, clients of FSW and MSM using data from several completed and on-going studies. Baseline HIV prevalence was 3.5% (2.3-5.1%) in 2012, 2.7% (1.2-5.2%) in 2013 and 17.3% (12.2-23.4%) in 2012 among PWID, FSW and MSM, respectively. We projected the number of HIV infections over 10 years (2019-2029), and the proportion of these attributable to different key populations and sexual or injecting behaviours (defined as the percentage of new infections prevented when these modes of transmission are removed).

RESULTS: The model projects overall HIV incidence of 0.4 per 100 person-years (95% Credible Interval (95%CrI:0.3-0.6/100pyrs) in 2019 across all key populations modelled. Unprotected sex between men accounted for 56.6% (95%CrI:13.8–82.1%) of all new HIV infections among key populations over 2019-2029, while injecting drug use contributed 31.9% (95%CrI:3.5–82.0%) and unprotected commercial heterosexual sex contributed 15.3% (95%CrI:6.1–22.6%). Non-commercial heterosexual sex contributed <10%. By key population, making all behaviours safe among PWID, FSW, MSM and clients would prevent 52.3% (95%CrI:30.9–87.9%), 17.7% (95%CrI:9.8–24.2%), 57.8% (95%CrI:14.3–82.8%) or 17.7% (95%CrI:8.9–24.0%) of all infections among key populations over 2019-2029, respectively. Among PWID, HIV transmission is due to multiple risk behaviours: 69.9% (15.6–95.2%), 16.6% (2.3–46.7%) and 12.5% (4.7–23.5%) of new infections among PWID over 2019-2029 are due to unsafe injecting, unprotected sex between men and heterosexual transmission between PWID, respectively.

CONCLUSIONS: Most HIV transmission among key populations in Tijuana is due to sexual transmission, although injecting drug use still plays a large role. Removing transmission risks due to unprotected sex between men provides the biggest reduction in new infections, indicating this is a key behaviour to prioritize interventions towards.

PEC0432

SURVEY ON COMMUNITY BREASTFEEDING PRACTICES AND THEIR IMPLICATIONS FOR MOTHER-TO-CHILD TRANSMISSION IN A HIGH HIV PREVALENCE CONTEXT IN SOUTHERN MOZAMBIQUE

S. Fernández-Luis[1,2], L. Fuente-Soro[1,2], T. Nhampossa[1,3], E. Lopez-Varela[1,2], O. Augusto[1], A. Nhacolo[1], H. Guambe[4], K. Tibana[4], M. Urso[5], D. Naniche[2]
[1]Centro de Investigação em Saúde de Manhiça (CISM), Manhiça, Mozambique, [2]Barcelona Institute for Global Health (ISGLOBAL), Barcelona, Spain, [3]Instituto Nacional de Saúde (INS), Maputo, Mozambique, [4]Ministério da Saúde de Moçambique (MISAU), Maputo, Mozambique, [5]Centers for Disease Control and Prevention (CDC), Maputo, Mozambique

BACKGROUND: WHO recommends breastfeeding for 24 months or more for mothers living with HIV while receiving ongoing support for adherence to antiretroviral therapy (ART). We aimed to explore breastfeeding duration among HIV-exposed children in the community and its association with postpartum mother-to-child-transmission (MTCT).

METHODS: From October-2017 to April-2018 a cross-sectional household survey was conducted. Births in the previous 48 months were randomly selected for interview and HIV-testing of mother and child. HIV-infection date in mothers with a first positive test during the survey was calculated as the midpoint between the last negative HIV-test and the survey date, or in women with no previous documentation, between most recent delivery date and survey. Documentation of a previous HIV-positive test was considered to be the infection date. Postpartum-MTCT was assumed for children testing HIV-positive after 6 weeks who had a previous negative result, and for HIV-positive infants born to mothers whose estimated HIV-infection date occurred after birth.

Fine-Gray competing-risk of death regression was used to estimate breastfeeding duration and to assess association with postpartum MTCT.

RESULTS: Among the 5000 mother/caregiver-child pairs selected, 3486 (69.7%) were found and interviewed. Among those, 967 (27.7%) children were HIV-exposed, 2169 (62.2%) were HIV-unexposed and for 350 (10.0%) HIV-exposure was unknown.

After adjusting for censoring, median duration of breastfeeding was 13.0 (95%CI:12.0-14.0) and 20.0(95%CI:19.0-20.0) months, p<0.001 among HIV-exposed and HIV-unexposed children, respectively.

Of the 967 HIV-exposed children, 51 (5.3%) were HIV-positive. Among those, 26 (51.0%) were infected postpartum, 14 (27.4%) peripartum and 11 (21.6%) unknown. In multivariable analysis, breastfeeding duration was not associated with postpartum-MTCT (aSHR:1.0[95%CI:0.9-1.0], p=0.892) whereas children having a hospital admission at any time prior to the survey, or having a mother who initiated ART after birth were more likely to have postpartum-MTCT, (aSHR:71.2[95%CI:13.1-387.4], p<0.001), (aSHR:9.9[95%CI:2.9-33.5], p<0.001), respectively.

CONCLUSIONS: Duration of breastfeeding in HIV-exposed children was lower compared to non-exposed children and no association between breastfeeding duration and post-partum MTCT was found. Child hospitalization and mother's ART initiation after birth were associated with postpartum-MTCT. Identifying and providing early treatment to mothers newly infected during the breastfeeding period should be a priority to reduce postpartum-MTCT.

PEC0433

MODELLING THE FUTURE IMPACT OF UNDERAGE AND COERCED ENTRY INTO SEX WORK ON HIV TRANSMISSION IN TIJUANA, MEXICO

H. Fraser[1], J. Stone[1], A. Zienkiewicz[1], A.G. Lim[1], A. Trickey[1], D. Abramovitz[2], A. Borquez[2], K.C. Brouwer[2], J. Silverman[2], S.A. Strathdee[2], N.K. Martin[2,1], P. Vickerman[1]
[1]University of Bristol, Bristol, United Kingdom, [2]University of California, San Diego, United States

BACKGROUND: Some female sex workers (FSW) are initiated into sex work underage (<18), or are forced/coerced, likely increasing their vulnerability to exploitation, violence and infections, including HIV. We undertake epidemiological analyses and HIV transmission modelling to understand the potential contribution that underage or forced/coerced entry into sex work has on HIV transmission among FSW in Tijuana, Mexico.

METHODS: Data from a 2013/14 bio-behavioural study of FSWs in Tijuana were analysed using regression to determine whether initiating sex work underage or reporting being coerced into sex work (considered separately from underage entry) were related to increased sexual or injecting risk behaviours. A dynamic HIV transmission model amongst FSW and their clients stratified by entry into sex work (coerced/not and minor/adult at initiation) was developed. The model was calibrated to HIV prevalence estimates among adult FSW who initiated as non-coerced adults (1.1%; 95% confidence interval [95%CI]:0–3.8%), coerced adults (4.8%; 95%CI:0.1–16.5%), non-coerced minors (7.8%; 95%CI:2.1–18.9%) and coerced minors (0%; 95%CI:0–16.1%).

RESULTS: Of 300 FSW, 24% reported having initiated sex work underage, which was associated with: higher client volume (incidence rate ratio:1.42; 95%CI:1.12–1.81), higher levels of injecting drug use (IDU) (odds ratio [OR]:2.76; 95%CI:2.24–7.15) and less consistent condom use (OR:0.45; 95%CI:0.25–0.82). Similarly, 20.7% report forced/coerced entry into sex work, which was associated with higher levels of IDU (OR:1.98; 95%CI:1.07–3.65).

The model projects HIV prevalence of 1.8% (95% credible interval [CrI]:1.2–2.4%) among FSW in 2020, with prevalence 1.2 (95%CrI:1.2–1.4) or 1.2 (95%CrI:1.0–1.3) times higher, respectively, if they started sex work underage or were forced/coerced into sex work. Eliminating

additional risks associated with underage or coerced entry into sex work would prevent 38.6% (95%CrI:15.5–49.8%) or 3.4% (95%CrI:-0.2–7.3) of the estimated 305 (95%CrI:203-430) new infections among FSW over 2020-2030, respectively, or 41.8% (95%CrI:18.2–51.0%) in combination.

CONCLUSIONS: Underage and coerced initiation of sex work increase HIV risk among FSW in Tijuana and our modelling suggests underage initiation is an important epidemic driver. For the protection of human rights and the prevention of HIV, addressing underage initiation of sex work should be prioritised.

PEC0434

INCIDENT BACTERIAL SEXUALLY TRANSMITTED INFECTIONS AMONG A PROSPECTIVE BIOBEHAVIOURAL COHORT OF GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN WHO ARE HIV-NEGATIVE OR LIVING WITH HIV IN CANADA

N. Lachowsky[1,2,3], Z. Cui[3], J. Barath[3], A. Lal[3], J. Sang[3,4], T. Grennan[5,4], J. Wong[5,4], E. Roth[1], R.S. Hogg[3,6], D.M. Moore[3,4], and the Momentum Study Team
[1]University of Victoria, Public Health & Social Policy, Victoria, Canada, [2]Community Based Research Centre Society, Vancouver, Canada, [3]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [4]University of British Columbia, Vancouver, Canada, [5]British Columbia Centre for Disease Control, Vancouver, Canada, [6]Simon Fraser University, Burnaby, Canada

BACKGROUND: We examined chlamydia (CT), gonorrhea (GC) and syphilis infection among gay, bisexual and other men who have sex with men (gbMSM) in Vancouver, Canada where HIV Treatment as Prevention (TasP) has been policy since 2010 and pre-exposure prophylaxis (PrEP) has been publicly-funded since January 2018.

METHODS: Sexually-active gbMSM (cisgender and transgender) aged ≥16 years were recruited using respondent-driven sampling (RDS) into a prospective biobehavioural cohort and followed from 02/2012-08/2019 every 6 months. Participants self-completed questionnaires, provided venous blood samples for syphilis serology, and optional urine testing and/or pharyngeal, rectal or urethral swabs for CT/GC. We calculated incidence rates (IR) stratified by HIV status and used generalized estimating equations accounting for clustering by repeated visits to identify predictors of CT/GC infection and syphilis infection. Multivariable models were built using backward selection to minimize QIC.

RESULTS: Of 584 gbMSM (30.1% living with HIV) with a median follow-up of 3.51 years, 217 (37.2%) had any incident STI. Incident CT/GC did not differ between gbMSM living with HIV (IR=14.53/100 person-years) and HIV-negative gbMSM (IR=16.22/100 person-years; RR=1.22, 95%CI:0.94-1.58). The CT/GC IR increased over time for gbMSM living with HIV (aRR=1.11, 95%CI:1.05-0.18) and was stable for HIV-negative gbMSM (RR=1.01, 95%CI:0.94-1.08). Incident syphilis was more likely among gbMSM living with HIV (IR=8.46/100 person-years) than HIV-negative gbMSM (IR=2.68/100 person-years; RR=3.16, 95%CI:1.96-5.10). The syphilis IR was stable among gbMSM living with HIV (RR=1.00, 95%CI:0.94-1.06), but increased over time for HIV-negative gbMSM (aRR=1.19, 95%CI:1.01-1.41).

Predictors varied by HIV status and STI. However, recent condomless anal sex with a serodifferent/unknown status partner predicted incident CT/GC for gbMSM living with HIV (aRR=3.91, 95%CI:1.89-8.06) and HIV-negative gbMSM (aRR=2.98, 95%CI:1.94-4.58). Incident STIs were not associated with PrEP (5.8% ever used) nor HIV optimism-skepticism scale scores.

CONCLUSIONS: STI incidence increased or was stable over time, with syphilis persistently higher among gbMSM living with HIV. STI trends from these cohort data correspond with surveillance data; future multi-jurisdictional research should further evaluate TasP and PrEP policy impact with multiple data sources. In our cohort, incident STIs were generally attributable to condomless seroadaptive HIV prevention practices, indicating the centrality of sexual mixing by HIV status to future primary STI prevention efforts.

PEC0435

FACTORS ASSOCIATED WITH VERTICAL TRANSMISSION OF HIV AMONG EXPOSED INFANTS DURING THE ERA OF PMTCT OPTION B+ IN KYEGEGWA DISTRICT: A CROSS-SECTIONAL STUDY

E. Mugisa[1], M. Mugabekazi[1], P. Nahirya[2], P. Tumbu[3]
[1]Baylor, HIV Prevention, Fort Portal, Uganda, [2]Baylor, Research, Kampala, Uganda, [3]Baylor, Medical and Psychosocial, Kampala, Uganda

BACKGROUND: Despite high anti-retroviral treatment (ART) coverage (93%) for prevention of mother to child HIV transmission (PMTCT), vertical transmission of HIV in Uganda remains high (7.4 %). District PMTCT program data showed a higher level of HIV positivity among exposed infants in Kyegegwa district compared to the regional average (3.1% vs. 2%). We examined factors associated with vertical transmission of HIV in the era of PMTCT option B+ in Kyegegwa district.

METHODS: We conducted a cross-sectional study targeting HIV exposed infants who were alive and receiving clinical care at three health facilities in Kyegegwa district between July and September 2018. Data on infant age, infant gender, infant HIV status and maternal viral load results were abstracted from patient clinic records while data on non-routinely collected data was obtained through interviewing mothers to exposed infants. The study outcome was level of HIV positivity among HIV-exposed infants and the independent variables were attendance of antenatal care, maternal ART status during pregnancy, presence of sexually transmitted infections during pregnancy, place of birth, timing of infant HIV test, status of infant nevirapine prophylaxis at birth and adherence to infant nevirapine syrup. We analyzed descriptive statistics and examined factors associated with vertical transmission of HIV using mixed effects logistic regression.

RESULTS: A total of 208 HIV exposed infants were included in the study; their median age was 17 months [IQR=14-25 months] and majority (57.7%) were male. Eighty six percent (179/208) were tested for HIV within the recommended 6-8 weeks of age. The level of HIV positivity among exposed infants was 3.8% (2.6%-4.2%). At multivariate analysis and application of mixed effects logistic regression, being on ART during pregnancy (aOR 0.02, 95% CI 0.01-0.65; p-value=0.027) was associated with lower odds of vertical transmission of HIV while missed infant nevirapine prophylaxis was associated with higher odds of vertical transmission of HIV (aOR 102, CI 95% 2.60-4087; p-value=0.014).

CONCLUSIONS: Not being on ART during pregnancy and missed infant nevirapine prophylaxis drive vertical transmission of HIV in Kyegegwa district therefore access to and timely initiation of ART during pregnancy and infant nevirapine syrup at birth should be strengthened.

PEC0756

HIV PREVALENCE AMONG CHILDREN OF FEMALE SEX WORKERS IN TWO URBAN COUNCILS OF TANZANIA

C. Kyaruzi[1,1], A. Exavery[2], A. Barankena[1], J. Charles[3], L. Kikoyo[1], E. Jere[1]
[1]Pact Tanzania, Programs, Dar es Salaam, Tanzania, United Republic of, [2]Pact Tanzania, Research and Learning, Dar es Salaam, Tanzania, United Republic of, [3]Pact Tanzania, Monitoring Research and Learning, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: The vulnerabilities of children of female sex workers (CoFSWs) in Tanzania are difficult to observe because sex work is criminalized and highly stigmatized. Field observations from community workers suggest that children of sex workers experience risks in health and safety. Sex workers may engage in risky behaviors including multiple sexual partners, inconsistent condom use, and drug use. This can put their children at increased risk of HIV infection through mother-to-child transmission and may reduce the parents' ability to care for their children. This study explores the prevalence of HIV among CoFSWs enrolled in an orphans and vulnerable children service delivery project in Tanzania.

METHODS: This study examines the PEPFAR/USAID- OVC project data from Kinondoni Municipal and Arusha City Councils in Tanzania. The data was collected by trained lay social welfare volunteers during enrollment of CoFSWs between July and September 2018. Project monitoring tools designed to capture beneficiary information, including risk of HIV infection and access to HIV services were used. Multivariate analysis was conducted using logistic regression to identify characteristics associated with HIV status of the child.

RESULTS: Of the 626 CoFSWs (46% male, 54% female), 13.2% were living with an HIV-positive FSW. HIV prevalence in CoFSWs <15 years was 5%. This was much higher than the national estimate of 0.4% observed in the general population of the same age. In the multivariate analysis, children of HIV-positive FSWs were 8.4 times more likely to be HIV positive than those of HIV-negative FSWs (adjusted odds ratio (OR)=8.41, 95% confidence interval (CI) 3.41–20.76). Children living in Kinondoni council were 3.53 times more likely to be HIV positive than those in Arusha council (OR=3.53, 95% CI 1.37–9.05).

CONCLUSIONS: HIV prevalence among CoFSWs was significantly higher than the general child population in Tanzania. FSWs living with HIV should be targeted with index testing of their biological children. The program's use of FSW trained as lay social welfare volunteers improved identification of CoFSWs and improved their ability to access health, HIV and social services.

EPIDEMIOLOGY OF AIDS EVENTS (E.G., AIDS-RELATED OPPORTUNISTIC INFECTIONS AND CANCERS)

PEC0436

THE TRENDS OF HIV LATE PRESENTERS IN NON-GOVERNMENTAL HOSPITAL, CAMBODIA

P. Srey[1], S. Soeung[2], H. Keath[1], K. Choun[1]
[1]Sihanouk Hospital Center of HOPE, Infectious Disease, Phnom Penh, Cambodia, [2]Sihanouk Hospital Center of HOPE, Infectious Department, Phnom Penh, Cambodia

BACKGROUND: HIV treatment and care have become over burden on the Cambodia's current public health system. Despite the ART availability, HIV patients continued to die and hospitalize, mostly because of their HIV advanced stages to appropriate care services. We aimed to describe the trends of late HIV patients at care entry point over time from 2003-2007, 2008- 2012 to 2013-2017 and to identify risk factors associated with late stage of HIV disease.

METHODS: We conducted a cross sectional study using routinely collected data from a non-government hospital in Phnom Penh, Cambodia. We included all ART naïve adult (age ≥ 18 years old) who enrolled in HIV program from 1st March 2003 to 31st December 2017 into the analysis. HIV late presenters is defined as the presence of CD4 cell count <200 cell/mm3. Data was analyzed by using STATA version 13.

RESULTS: Of the 5369 HIV patients, the mean age at enrollment were between 35 (SD =8.6) and 37 (SD =10.2) years old over these three periods from 2003-2017. Men represented 47% while women represented closely to 53%. HIV late presenters were slightly decreased from 66% (2003- 2007) to 58% (2008- 2012) and remained stable 57% (2013-2017) (P-value <0.001). In these three periods, the first three common clinical presentations for the patients were oral candidiasis (21.6%, 18.5% and 20.5%) followed by chronic diarrhea (13.7%, 6.7% and 5.4%) and extra pulmonary tuberculosis (12.9%, 14.5% and 13.9%). Male sex, age group (>30 years old), marital status (single/divorce), occupation (small business), residence (around great lake region) and WHO advanced clinical stage (stage 3/4) were most significantly associated with HIV late presenter in the three different studies period with P-value <0.05.

CONCLUSIONS: Late presenter was remained high in our study. The most prevalence of opportunistic infections were oral candidiasis, chronic diarrhea and extra pulmonary tuberculosis. Being male, older age, single/divorced, small business, and people from Great lake region were identified as a risk factors for late presentation. More effort need to be done for these special population to improve HIV counseling, testing and linkage system to early ART care to prevent severe opportunistic infections and death.

PEC0437

TUBERCULOSIS TREATMENT CURE AMONG PEOPLE LIVING WITH HIV / AIDS- SAO PAULO- BRAZIL

A. Tayra[1], M.A. Silva[2], S. Fukuzava[3], L. Santos AR[4], J. Leda F[5], S. Sumire[6], M. Tancredi V[1], G. Maria Clara[7]
[1]Center of the STD/AIDS Reference and Training Center (CRT) and the State STD/AIDS Program of São Paulo, Sao Paulo, Brazil, [2]Center of the STD/AIDS Reference and Training Center (CRT), Epidemiological Surveillance, Sao Paulo, Brazil, [3]Epidemiological Surveillance Center Dr Alexandre Vranjac - Secretary of State for Health, Divisao de Tuberculose, Sao Paulo, Brazil, [4]Epidemiological Surveillance Center Dr Alexandre Vranjac - Secretary of State for Health, Tuberculosis Division, Sao Paulo, Brazil, [5]Center of the STD/AIDS Reference and Training Center (CRT) and the State STD/AIDS Program of São Paulo, Research Management, Sao Paulo, Brazil, [6]Center of the STD/AIDS Reference and Training Center (CRT), Doctor of HIV AIDS Patients, Sao Paulo, Brazil, [7]Center of the STD/AIDS Reference and Training Center (CRT) and the State STD/AIDS Program of São Paulo, Technical Board, Sao Paulo, Brazil

BACKGROUND: Tuberculosis (TB) remains the leading cause of death among people living with HIV / AIDS (PVHA). The overall goal for TB is to reduce deaths by 95% and 90% of new cases until 2035. Therefore, it is necessary to monitor and evaluate TB prevention and control activities in PVHA that are well below this target. The aim of this study is to verify the termination of TB treatment among HIV-positive people (TBHIV) in the state of Sao Paulo (ESP) - Brazil.

METHODS: A descriptive analysis of the reported cases of TBHIV from 2011 to 2017 was performed. It were considered to study the termination of treatment: directly observed (DOT) or self-administered (AA) treatment and use of antiretroviral therapy (ART) for HIV and among cases of new TB.

RESULTS: During the period, 142,187 cases of TB were reported in ESP. Among these, 85.5% had HIV serology, 13.1% seropositive. Over these eight years, HIV seropositivity decreased from 14.2% in 2011 to 10.0% in 2017. Of the 2,035 cases of TBHIV in 2017, only 1,144 (56.2%) had a high cure, 402 died (19.8%), 411 (20.2%) abandoned treatment and 78 (3.8%) had no information. Still in 2017, the cure rate among cases on ART was 65.8%.

Among cases with TDO were cured in 65.3%, abandonment was 15.7% and death 15.1%; for those with AA treatment, cure occurred in 49.9%, abandonment was 20.7% and death 25.4%. In the general population, abandonment was 11% and death 7%.

CONCLUSIONS: The cure rate among cases of TBHIV is low; the percentage of abandonment and death among PLHIV was much higher than the general population. TOD when compared to AA contributes to better cure compliance and closure of it, as does the use of TARV. There is a need to investigate the causes of these two unfavorable outcomes in each location, to improve the care process and improve indicators.

PEC0438

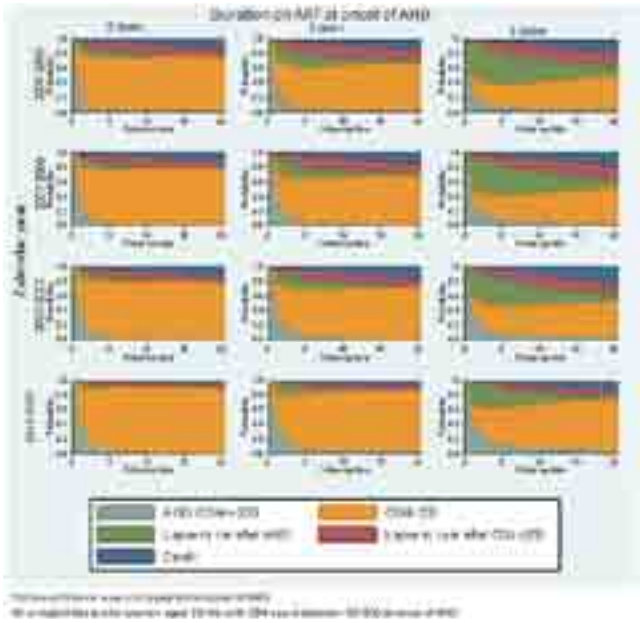
USING A MULTI-STATE MODEL TO EXAMINE ADVANCED HIV DISEASE AND ENGAGEMENT IN CARE AMONG PATIENTS ON ANTIRETROVIRAL THERAPY IN SOUTHERN AFRICA

G. Patten[1], M.-A. Davies[1], N. Ford[2], IeDEA Southern Africa
[1]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Research, Cape Town, South Africa, [2]World Health Organisation, Geneva, Switzerland

BACKGROUND: Patterns of patient engagement in care and clinical stability have changed as ART programmes have expanded and matured in Southern Africa. Increasingly advanced HIV disease (AHD) is found among ART-experienced patients who have interrupted treatment. We explored patterns and predictors of transition from and to AHD.

METHODS: Using data from IeDEA Southern Africa, five states of ART care were defined based on most recent CD4: "AHD" [CD4<200], "CD4≥200", lapse in care [no visit in previous ≥1 year] after AHD, lapse in care after CD4≥200, death. We included data from all patients aged >5 years with CD4 counts at ART start, and ≥1 subsequent CD4 measure. A multistate model was used to estimate transition probabilities between states over time.

RESULTS: Median age at ART start of 462713 patients was 35.5 years (IQR 29.6-42.3), (35.4% male, 68.8% from South Africa). The proportion with AHD at ART start was 50.5% overall and decreased over time [2004-2006: 73.9% vs 2016-2018: 29.3%]. Among patients with CD4≥200 at ART start, the probability of ever having AHD was higher for men and adolescents. By 2 years after starting ART with CD4≥200 in 2010-2012, for those aged 25-40 years, the probability of ever having AHD was 8% for women and 11% for men. For adolescents aged 10-19 years initiating in the same calendar period, the probability was 12% for females and 16% for males.Longer duration on ART prior to AHD onset reduced the probability of transition to CD4≥200 and increased the probability of lapse in care (Figure).



[Figure. Probability of being in each ART care state over time, for different calendar years of ART start and duration on ART at advanced HIV disease (AHD) onset; measured from the date of AHD onset]

CONCLUSIONS: Transition to AHD from a clinically stable state is more likely among men and adolescents. Compared to those initiating ART with AHD, those who experience AHD at longer durations on ART, are less likely to recover to CD4≥200 and more likely to have lapses in care.

PEC0439

EVALUATION OF MENINGEAL CRYPTOCOCCOSIS DIAGNOSIS IN PEOPLE LIVING WITH HIV AND NEUROLOGICAL SYNDROMES IN SANTA CRUZ, BOLIVIA

F. Tinajeros[1], R.N. Davila-Caballero[1], P.P. Carballo-Jimenez[1], R.S. Wills[2], N. Bowman[3], H. Steinberg[4], R.H. Gilman[5]
[1]PRISMA, International Health, Santa Cruz, Bolivia, [2]San Juan de Dios Hospital, Ministry of Health, HIV Program, Santa Cruz, Bolivia, [3]University of North Caroline, Division of Infections Diseases, North Caroline, United States, [4]University of Illinois, School of Public Health, Chicago, United States, [5]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

BACKGROUND: Cryptococcal meningitis (CM) is a common neurological complication in people living with HIV (PLWH). Diagnosis of CM using Cryptococcal antigen (CrAg) detection by Lateral Flow Assay (LFA) may improve the prognosis of this complication by improving detection rates, accelerating diagnosis, and allowing earlier treatment than microscopy- and culture-based methods.
METHODS: From December 2018 to December 2019 we conducted a comparative study to diagnose CM from a prospective cohort of PLWH with neurological syndromes in San Juan de Dios Hospital of Santa Cruz, Bolivia. India Ink (Pelikan) in CSF was compared with CrAg LFA (IMMY kit) in serum and CSF. Patients with other neurological diagnoses were included to assess the specificity of CrAg LFA. Stata SE 15.0 version and Epi Info 7.2 version were used for the statistical analysis.
RESULTS: 29 PLWH with neurological complications were recruited. Mean age was 42 ± 13 years, 25 were men and 4 were woman, and 22 were on retroviral therapy. 12 participants died during the study. The prevalence of CM by CrAg LFA was 38% (11 positives and 18 negatives), but by India ink, only 4 CM cases were detected (14% prevalence). Compared to CrAg LFA, India ink had a sensitivity of 36.3%, specificity of 100%, PPV of 100%, and NPV of 72.0%. The Kappa coefficient showed a moderate concordance to diagnosed CM between India Ink and CrAg LFA (Kappa 42%, 95% CI: 0.11-0.72).
CONCLUSIONS: The CrAg LFA showed substantially greater sensitivity for the diagnosis of CM in people with HIV and neurological syndromes compared to India Ink, detecting almost 3 times as many cases as India ink. The CrAg LFA should be incorporated for the diagnosis of CM in PLWH in hospitals in under developed countries where HIV and its complications are prevalent.

PEC0440

FEMALE VETERANS WITH HIV HAVE AN INCREASED RISK OF HPV-ASSOCIATED GENITAL TRACT CANCERS

E. Clark[1,2], L. Chen[2], Y. Dong[2], S. Raychaudhury[2], J. Kramer[2], E. Chiao[1,2]
[1]Baylor College of Medicine, Medicine - Infectious Diseases, Houston, United States, [2]Michael E DeBakey VA Medical Center, Center for Innovations in Quality, Effectiveness, and Safety, Houston, United States

BACKGROUND: Women living with HIV (WLWH) are thought to be at higher risk for HPV-associated female genital tract cancers (FGTCs) due to their immune status. However, disparities in access to cervical cancer screening often confound the observed difference in cancer incidence between WLWH and their HIV-negative counterparts. We conducted this study to determine if there have been any changes in risk among WLWH who develop FGTCs during the anti-retroviral era in a single-payer health system.
METHODS: Veteran WLWH and age-matched controls receiving care between 1999-2016 were retrospectively identified using Veterans Health Administration (VHA) electronic medical records (EMR). FGTC (cervical, vulvovaginal, anal/rectal, and endometrial/uterine cancer) diagnoses were identified through VHA Cancer Registry review and ICD-9/10 codes.
Demographic, lifestyle, and clinical variables were extracted from EMR for analysis. Incidence Rates (IR), Incidence Rate Ratios (IRR), and 95% confidence intervals (CI) for cancer risk were estimated and Kaplan-Meier survival analysis were conducted.
RESULTS: We identified 1,454 WLWH and compared them to 5,816 age-matched female HIV-negative controls. Twenty-eight WLWH developed HPV-associated FGTCs (2.0% of the cohort), including cervical=22, vulvovaginal=4, and anal/rectal=2. Thirty-two HIV-negative women developed HPV-associated FGTCs (0.6% of the cohort), including cervical = 24, vulvovaginal=5, and anal/rectal=5. The age-adjusted cervical cancer incidence rate (IR) was >6-fold higher in WLWH (203.9 per 100,000 person years [py] [CI 83.6-324.3]) than HIV-negative women (IR = 31.2 per 100,000 py [CI 17.86-44.54]; incidence rate ratio [IRR] = 6.535). The IRs for vulvovaginal and anal cancers were also >3-fold higher in WLWH.
Overall, WLWH were more likely to develop HPV-associated FGTC compared to their HIV-negative counterparts (log rank p values <0.0001). Cervical cancer screening rates were similar between WLWH and HIV-negative women; 601/1,454 (42.2%) of WLWH had cervical cancer screening visits compared to 2,407/5,816 (41.6%, p=0.665) of HIV-negative women.
CONCLUSIONS: Veteran WLWH are more likely to develop FGTCs despite equal access to health care. Even in single-payer health systems, WLWH continue to require special attention to ensure guideline-based high-risk HPV screening for prevention of FGTCs.

EPIDEMIOLOGY OF NON-AIDS INFECTIONS AND COMMUNICABLE DISEASES (E.G., VIRAL HEPATITIS, STIS)

PEC0441

HEPATITIS C INCIDENCE AMONG GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN BEFORE AND AFTER THE AVAILABILITY OF DIRECT ACTING ANTIVIRALS IN AUSTRALIA 2012-2018

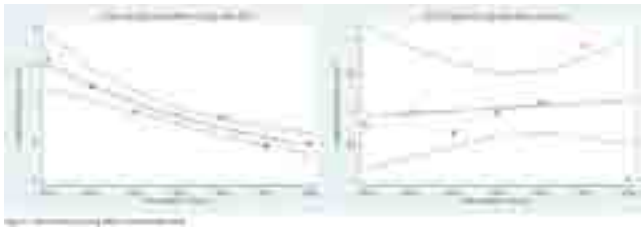
B. Harney[1,2], R. Sacks-Davis[3,2], D. van Santen[1,2], M. Traeger[4,2], A. Wilkinson[4,2], J. Asselin[4], M. Woldegiorgis[4], C. El-Hayek[4,2], C. Fairley[5], M. Bloch[6], G. Matthews[7], B. Donovan[7], R. Guy[7], M. Stoove[4,2], M. Hellard[4,2,8], J. Doyle[4,8], on behalf of ACCESS
[1]Burnet Institute, Disease Elimination Program, Melbourne, Australia, [2]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia, [3]Burnet Institute, School of Public Health and Preventive Medicine, Melbourne, Australia, [4]Burnet Institute, Melbourne, Australia, [5]Melbourne Sexual Health Centre, Melbourne, Australia, [6]Holdsworth House Medical Practice, Sydney, Australia, [7]Kirby Institute, Sydney, Australia, [8]Alfred Health, Melbourne, Australia

BACKGROUND: While hepatitis C virus (HCV) infection among gay and bisexual men (GBM) has been concentrated among GBM living with HIV, there is concern about an increase among HIV negative GBM. With the unrestricted availability of new HCV treatments in Australia since March 2016, modelling suggests HCV elimination is possible among GBM. We examined trends in HCV incidence among GBM from 2012-2018.

METHODS: Data were drawn from 50 sites in seven of eight Australian states and territories participating in the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance. Poisson regression was used to examine trends in incidence by calendar year with date of infection estimated as a random date between the previous negative test and the diagnosis test dates.

RESULTS: Among 7,907 GBM living with HIV there were a total of 35,009 HCV tests with a median of four tests (IQR 3-7) per-person and median test interval of 9.7 months (IQR 5.7-14.8). There were 241 incident HCV cases over 28,204 person-years (PY). Overall incidence was 0.85/100PY, which declined by an average of 18% per year (IRR 0.82, 95%CI 0.76-0.89) from 1.64/100PY in 2012 to 0.47/100PY in 2018 (Figure 1).

Among 18,928 HIV negative GBM there were a total of 61,557 HCV tests with a median of three tests (IQR 2-5) per-person and median test interval of 7.8 months (IQR 3.5-14.8). There were 93 incident cases over 45,476PY. Overall incidence was 0.20/100PY with no significant change over time (IRR 1.02, 95%CI 0.90-1.15).



[Figure 1. HCV incidence among GBM in Australia 2012-2018]

CONCLUSIONS: HCV incidence has declined among GBM living with HIV but not among HIV negative GBM in Australia. A plateau in incidence in 2017 & 2018 among GBM living with HIV underscores the need for a combination of frequent testing, timely treatment uptake, effective behavioural interventions and identifying networks of ongoing transmission to make further progress towards HCV elimination among GBM in Australia.

PEC0442

ESTIMATING THE NUMBER OF PEOPLE WITH HIV WHO WILL SOON HAVE AN INDICATION FOR HEPATITIS A VACCINATION

J. Weiser[1], Q. Vu[1], N. Nelson[2], S. Dasgupta[1], R.L. Shouse[1]
[1]U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]U.S. Centers for Disease Control and Prevention, Division of Viral Hepatitis Prevention, Atlanta, United States

BACKGROUND: People with HIV who contract hepatitis A (HepA) may have prolonged HepA viremia. Many people with HIV have risk factors for which HepA vaccination is recommended, including male-to-male sexual contact, injection and non-injection drug use, homelessness, chronic liver disease, and clotting factor disorders. However, the U.S. Advisory Committee on Immunization Practices (ACIP) recently approved a recommendation that all people with HIV aged ≥1 year be routinely vaccinated for HepA. This recommendation will become official in 2020. The number of adults with HIV who lacked an indication for vaccination prior to the 2020 ACIP update is unknown and could inform public health practice.

METHODS: The Medical Monitoring Project (MMP) is a population-based survey designed to produce nationally representative estimates of the behavioral and clinical characteristics of U.S. adults with diagnosed HIV. We used MMP interview and medical record data collected from 7634 adults during 6/2016-5/2018 to estimate the number and percentage of adults with diagnosed HIV who lacked an indication for HepA vaccination pre-2020 ACIP update.

RESULTS: During the past 12 months, 49% (95% confidence interval [CI], 48%-51%) of U.S. adults with diagnosed HIV reported male-to-male sexual contact, 2% (95% CI, 2-3%) injected drugs, 29% (95% CI, 28%-30%) used non-injection drugs, 8% (95% CI, 8%-9%) experienced homelessness, 14% (95% CI, 13%-14%) had chronic liver disease, and <1% had a clotting factor disorder. An estimated 275048 (95% CI, 264347-285750) had no indication for HepA vaccination pre-2020 ACIP update, representing 31% (95% CI, 30%-32%) of adults with diagnosed HIV. An estimated 145875 (95% CI, 140776-150974) women had no indication, representing 68% (95% CI 66%-70%) of women with diagnosed HIV. An estimated 121796 (95% CI, 113690-129902) of men had no indication, representing 19% (95% CI, 17%-20%) of men with diagnosed HIV.

CONCLUSIONS: More than one-quarter million adults with diagnosed HIV, including two-thirds of women with HIV, had no risk factors for which HepA vaccination was recommended prior to the 2020 ACIP recommendation to vaccinate all people with HIV. Focusing efforts on vaccinating this population may reduce the occurrence of prolonged HepA viremia and the potential to transmit HepA.

PEC0443

MODELLING THE IMPACT OF SCALING-UP HCV SCREENING AND TREATMENT ON THE EPIDEMIOLOGY OF HCV INFECTION IN HIV-POSITIVE MEN WHO HAVE SEX WITH MEN IN HONG KONG

D.P. Chan[1], N.S. Wong[1], B.C. Wong[2], S.S. Lee[1]
[1]Stanley Ho Centre for Emerging Infectious Diseases, Chinese University of Hong Kong, Shatin, Hong Kong, SAR of China, [2]Special Prevention Programme, Department of Health, Centre for Health Protection, Hong Kong, SAR of China

BACKGROUND: The WHO target for the elimination of hepatitis C virus (HCV) by 2030 includes, among other things, a 90% fall of HCV incidence, and an increase in HCV diagnoses to 90%. Scaling-up HCV testing, along with effective treatment would be essential for achieving the goal. This study aimed to examine the impact of scaling-up HCV screening and treatment on HCV incidence and prevalence among HIV-positive men who have sex with men (MSM) in Hong Kong.

METHODS: A deterministic compartmental model was developed to simulate HCV transmission through sexual contacts among HIV-positive MSM in 2005-2030. Four strategies to control HCV were evaluated, each with different treatment coverage, regimens [traditional and direct-acting antiviral (DAA)], and screening strategies. HCV incidence, prevalence and proportion of new infections averted above basecase scenario were projected from 2019 to 2030.

RESULTS: In basecase scenario, simulated HCV incidence among HIV-positive MSM increased from 0.1% per 100 person-years (PY) in 2005 to 8.3% in 2015, and to 6.3% PY in 2030, while its prevalence increased from 0.3%, 20%, and to 42%, respectively. Applying the estimated baseline value of HCV treatment coverage in 2019 (44% coverage, of which 20% on DAA), full baseline screening and 30% annual screening would increase the projected number of new HCV infections (including re-infections) from 544 in 2019 to 739 in 2030. Scaling-up of HCV treatment (90% coverage, of which 20% on DAA) had minimal effect on HCV incidence (0.5% of new infections averted above basecase scenario in 2019-2030). An expansion of DAA therapy (90% HCV treatment coverage, all on DAA) was projected to reduce

new HCV infections by 2.9% in the period. Expansion of DAA treatment for all acute HCV cases (treating all with acute HCV) would further decrease new HCV infections by 7.7%. Scaling-up HCV testing rate (twice annually) without HCV treatment and DAA coverage expansion was projected to give 1.5% more new HCV infections than basecase scenario in 2019-2030.

CONCLUSIONS: This study demonstrated that scaling-up HCV screening alone is not sufficient to reduce HCV incidence. Increasing HCV treatment coverage and access to DAA therapy would effectively reduce HCV incidents among HIV-positive MSM in Hong Kong.

PEC0444

SYPHILIS PREVALENCE AND INCIDENCE AMONG TRANSGENDER WOMEN ATTENDING TANGERINE COMMUNITY HEALTH CLINIC IN BANGKOK, THAILAND

P. Surapuchong[1], R. Janamnuaysook[1], P. Getwongsa[1], A. Chancham[1], J. Kongkapan[1], T. Amatsombat[1], J. Rueannak[1], K. Samitpol[1], P. Srimanus[1], L. Himmad[1], C. Taya[1], S. Mills[2], R. Vannakit[3], P. Phanuphak[1], R. Ramautarsing[1], N. Phanuphak[1]

[1]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]FHI 360, Linkage Thailand, Bangkok, Thailand, [3]USAID Regional Development Mission Asia, Office of Public Health, Bangkok, Thailand

BACKGROUND: Data on the prevalence and incidence of syphilis among transgender women (TGW) in Thailand is limited. As the country is preparing to launch pre-exposure prophylaxis (PrEP) under Universal Health Coverage (UHC) in 2020, baseline syphilis prevalence and incidence data from TGW is needed to monitor potential increase in sexually transmitted infections (STIs) after PrEP scale-up. We studied syphilis prevalence and incidence, as well as factors associated with incident syphilis cases, among TGW clients of the Tangerine Community Health Clinic in Bangkok, Thailand.

METHODS: Tangerine Community Health Clinic has provided integrated hormone and sexual health services to transgender people since 2015. We retrieved treponemal test (CMIA/EIA) screening and RPR confirmatory results, along with demographic characteristics and risk behaviors, from TGW clients between January 2017 and October 2019. Logistic regression was used to evaluate factors associated with incident syphilis infection.

RESULTS: Of 1,462 TGW, 133 (9.1%) had syphilis and 131 (8.9%) had HIV infection at their first visit. At baseline, almost two-thirds (64%) had multiple sex partners and 22.5% reported having had gender-affirming surgery. Around half (54.1%) had educational levels lower than bachelor's degree, 30.1% were unemployed, and 19.7% engaged in sex work. PrEP use at any visits was reported by 4.7%. The incidence of syphilis and HIV infections were 3.4 (95% CI 1.8-6.5) and 0.6 (95% CI 0.2-1.7) per 100 person-years, respectively. No HIV seroconversion was found among those reported PrEP use. Incident syphilis infection was significantly higher in those with HIV (aOR 7.15, 95% CI 4.08-12.51, p<0.0001) and was also associated with being employed (aOR 2.77, 95% CI 1.38-5.59, p=0.004), post-gender-affirming surgery status (aOR 4, 95% CI 1.49-10.72, p=0.006), multiple partners (aOR 3.15, 95% CI 1.56-6.39, p=0.001) and STIs in the past year (aOR 18.48, 95% CI 6.17-55.32, p<0.0001).

CONCLUSIONS: Multiple partners and recent STIs were associated with incident syphilis infection. Effective scale-up of PrEP is expected to attract TGW at high-risk of HIV. Inclusion of screening and treatment of syphilis and other STIs as part of UHC will be crucial for PrEP scale-up. Routine syphilis testing of HIV-positive TGW's should also be ensured.

PEC0445

BURDEN OF AND FACTORS ASSOCIATED WITH SEXUALLY TRANSMITTED INFECTIONS AMONG MEN WHO HAVE SEX WITH MEN IN KIGALI, RWANDA

J.O. Twahirwa Rwema[1], S. Herbst[2], M. Hamill[3], B. Liestman[1], J. Nyombayire[4], S. Ketende[1], A. Mazzei[4], C. Lyons[1], O. Olawore[1], S. Nsanzimana[5], P. Mugwaneza[5], J.D. Makuza[5], A. Kagaba[6], P. Sullivan[7], S. Allen[8], S. Baral[1]

[1]Johns Hopkins University - Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]ICF, Washington DC, United States, [3]Johns Hopkins School of Medicine, Infectious Diseases, Baltimore City, United States, [4]Projet San Francisco, Kigali, Rwanda, [5]Rwanda Biomedical Center, IHDPC, Kigali, Rwanda, [6]Health Development Initiative, Kigali, Rwanda, [7]Emory University - Rollins School of Public Health, Epidemiology, Atlanta, United States, [8]Emory University, Pathology and Laboratory Medicine, Atlanta, United States

BACKGROUND: Globally, sexually transmitted infections (STIs) among men who have sex with men (MSM) continue to increase. In Rwanda, surveillance of STIs relies on syndromic diagnosis with limited empiric data characterizing the burden of specific STIs among MSM. In response, this study evaluated the prevalence of Syphilis, Neisseria gonorrhoeae(NG) and Chlamydia trachomatis(CT) and associated factors among MSM living in Kigali, Rwanda.

METHODS: From March-August 2018, 737 MSM >18 years were enrolled using respondent-driven-sampling (RDS). Structured interviews and HIV/STI screening were conducted. Syphilis was screened with rapid plasma reagin (RPR) confirmed by Treponema Pallidum hemagglutination assay (TPHA). CT/NG were tested by Cepheid GeneXpert. Based on a socioecological conceptual framework, a multivariable robust Poisson regression was used to assess associations of STIs and covariates of interest. Furthermore, multivariable logistic regression analyses were used to evaluate the determinants of urethral and rectal STIs.

RESULTS: Mean age was 27.4 years (range:18-68). The RDS-adjusted HIV prevalence was 9.2% (95%CI:6.4-12.1) and of any STI was 16.7% (95%CI:13.2-20.2%). Syphilis prevalence (RPR+/TPHA+) was 5.7%(42), CT was 9.1%(67) and NG was 8.8% (65). STIs were significantly more common among older MSM and those with HIV (P<0.05). Of 67 CT infections, 67% were urethral, 27% rectal and 6% were dual-site. For the 65 NG infections, 52% were rectal, 29% genital and 19% were dual-site. A quarter 25.8%(23/89) of those with confirmed STI and who returned for their results were symptomatic at time of testing.

Greater age – (25-34) aPR:2.00 (95%CI:1.36-2.94) and (>35 years) aPR:1.87(95%CI:1.12-3.11) compared to 18-24; and STI symptoms in the previous year aPR:1.59(95%CI:1.18-2.17) were positively associated with any STI. Being circumcised was negatively associated with any STI aPR:0.72 (95%CI:0.52-0.98).

HIV was positively associated with rectal- aOR:2.43 (1.00-5.89) but negatively associated with urethral -STIs aOR:0.1 (0.01-0.76). Hazardous alcohol consumption was moderately associated with urethral aOR:2.14 (0.93-4.58) but negatively associated with rectal STIs aOR:0.28 (0.14-0.53).

CONCLUSIONS: MSM, especially those living with HIV, are at high risk of STIs in Rwanda with the vast majority being asymptomatic. Taken together, these data suggest the potential utility of active STIs surveillance strategies using highly sensitive laboratory methods among those at high risk given the anatomic distributions and limited symptomatology of STIs observed among Rwandan MSM.

PEC0446

CHANGES IN STI RATES AT AN UK URBAN SEXUAL HEALTH CLINIC OUTSIDE OF LONDON IN THE ERA OF PREP: MORE FREQUENT TESTING AND CHANGING SEXUAL BEHAVIOURS – UNPICKING THE COMPLEXITY

L. MacGregor[1], N. Speare[2], A. Lorenc[3], J. Kesten[3,1], J. Horwood[3], J. Nicholls[4,1], L. Harryman[2], P. Muir[5], P. Horner[2,1], K. Turner[6]
[1]University of Bristol, Population Health Sciences, Bristol, United Kingdom, [2]Unity Sexual Health, University Bristol NHS Foundation Trust, Bristol, United Kingdom, [3]NIHR CLAHRC West, University Bristol NHS Foundation Trust, Bristol, United Kingdom, [4]North Bristol NHS Trust, Bristol, United Kingdom, [5]PHE South West Regional Laboratory, Bristol, United Kingdom, [6]University of Bristol, Bristol Medical School, Bristol Veterinary School, Bristol, United Kingdom

BACKGROUND: We explore the role of increased STI testing, condom-use and HIV pre-exposure prophylaxis (PrEP) in the increasing number of STI diagnoses among men/trans-persons-who-have-sex-with-men (MSM/TPSM) at a sexual health clinic in Bristol, UK.

METHODS: We examined 13,546 electronic patient clinical records concerning 3,906 MSM/TPSM to identify trends in condom use and STI diagnoses for 3 years from January 2017. We performed linear regression analyses on temporal trends in condomless anal intercourse (CAI) and diagnoses of chlamydia, syphilis and gonorrhoea over this period. All MSM/TPSM clinic attendees (n=2818) were sent an electronic questionnaire (from November 2018 for 12 months), resulting in 617 eligible respondents. Eligibility required completed responses to questions concerning HIV-status and sexual decision-making regarding PrEP use by partners or self; consent to participate; and self-identification as MSM/TPSM.

RESULTS: The total number of visits resulting in diagnoses of chlamydia, syphilis or gonorrhoea in quarter 1 (Q1) 2017 were 112 compared to 177 in Q4 2019, over 1074 and 1202 visits respectively. Hence the proportion of visits resulting in a common STI diagnosis rose from 10.4% to 14.7%, peaking at 17.2% in Q2 2019; regression analysis indicating an average of a 2.3% absolute increase in the proportion of visits resulting in diagnoses per year (p<0.0001). CAI in the 3 months prior to date of clinic visit, increased from 45.9% to 68.5%, regression analysis indicating a 7.1% absolute increase per year (p<0.0001). Questionnaire results also indicated 339/578 (58.7%) of HIV-negative and 29/39 (74.4%) of HIV-positive TPSM/MSM would be more likely to have CAI with someone who was on PrEP than someone who was not on PrEP, whilst 356/578 (61.6%) and 162/578 (28.0%) of HIV-negative individuals said that if they were using PrEP they would be more likely to have CAI with someone who they believed were HIV-negative/positive respectively.

CONCLUSIONS: Rising STI diagnosis rates are not attributable to more frequent testing alone, as the proportion of visits in which STIs are diagnosed wouldn't be expected to increase. However, CAI is being more commonly reported, alongside willingness to forgo condom use among PrEP users and sexual partners of PrEP users (regardless of their HIV-status).

PEC0447

CORRELATES OF ACTIVE SYPHILIS INFECTION AND HIV/SYPHILIS CO-INFECTION AMONG MEN WHO HAVE SEX WITH MEN, TRANSGENDER WOMEN, AND GENDER QUEER INDIVIDUALS IN TWO CITIES IN ZIMBABWE

L. Parmley[1], I. Chingombe[2], M. Mapingure[2], O. Mugurungi[3], J.H. Rogers[4], P. Gozhora[2], Y. Wu[1], A. Hakim[5], S. Miller[1], G. Musuka[2], T.G. Harris[1]
[1]ICAP at Columbia University, New York, United States, [2]ICAP at Columbia University, Harare, Zimbabwe, [3]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe, [4]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Harare, Zimbabwe, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Atlanta, United States

BACKGROUND: Syphilis infection increases HIV acquisition risk for HIV-negative persons and impacts the immunologic and virologic response among people living with HIV (PLHIV). We assessed the prevalence of active syphilis infection and HIV/syphilis co-infection and their determinants among men who have sex with men (MSM), transgender women (TGW), and gender queer (GQ) individuals—populations vulnerable to HIV and syphilis—in Zimbabwe.

METHODS: MSM and TGW/GQ ≥18 years (n=1538) were recruited into cross-sectional surveys using respondent-driven sampling between March-July 2019 in Harare and Bulawayo, Zimbabwe. Participants were tested for HIV, using a three-test algorithm, and syphilis using Chembio DPP Syphilis Screen and Confirm Assay. PLHIV were tested for viral load (VL). Bivariate analyses were used to calculate sample prevalence estimates. A multiple logistic regression model was built to assess correlates of active syphilis infection, adjusting for sociodemographic characteristics which were significant (p<.05) in logistic regression. All analyses were unweighted and did not account for survey design as data did not reach convergence for HIV.

RESULTS: 98.2% of participants consented to biomarker testing (1511/1538). In Harare, 5.5% had active syphilis infection (38/695) and 10.1% of PLHIV were co-infected (15/149). In Bulawayo, 5.6% had active syphilis infection (46/816), and 11.0% of PLHIV were co-infected (21/191). Participants were more likely to have active syphilis infection if they were TGW/GQ (aOR:1.9, CI:1.1-3.2, p=.02), HIV positive (aOR:2.2, CI:1.4-3.6, p=.001), 25-34 years compared to 18-24 years (aOR:2.2, CI:1.3-3.8, p=.003), or had self-reported STI symptoms in the past 12 months (aOR:1.8, CI:1.1-3.0, p=.02). Among PLHIV, co-infection ranged from 13.0% among TGW/GQ (12/92) to 9.7% among MSM (24/248). There were no significant differences in co-infection by gender identity, city, sexual orientation, education, VL suppression (<1000 copies/mL), or awareness of HIV status in logistic regression however the crude odds of co-infection among PLHIV 25-34 years was 3.70 (CI:1.3-11.6, p=.02) compared to <24 years.

CONCLUSIONS: In both cities, active syphilis infection was >6 times higher than estimates for adult males in Harare and Bulawayo (0.8%), and co-infection was nearly fourfold that in the general male PLHIV population (2.8%). Findings highlight that MSM and particularly gender minorities bear a disproportionate burden of syphilis infection in Zimbabwe.

PEC0448

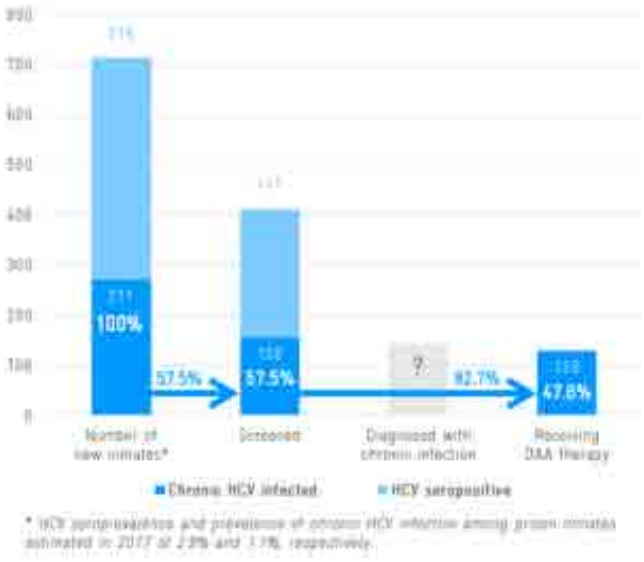
INSUFFICIENT HIV, HBV AND HCV SCREENING IN FRENCH PENAL INSTITUTIONS AND IMPACT ON ACTUAL ACCESS OF INMATES WITH CHRONIC HCV INFECTION TO DIRECT-ACTING ANTIVIRAL (DAA) THERAPY

M. Celse[1], L. Ayachi[1], P. Artières[1], H. Fischer[1], A. Linden[1], S. Musso[1], M. Préau[1], C. Rouzioux[1], C. Silvain[1], M. Suzan-Monti[1], L. Vana[1], P. Yeni[1], C. Goujard[1]
[1]*French National AIDS & Viral Hepatitis Council, Paris, France*

BACKGROUND: Prison inmates represent in France a key population regarding the implementation of a test-and-treat strategy against both HIV and HCV epidemics, with a seroprevalence estimated at 2.0% (2010) and 2.9% (2017), respectively. According to current guidelines, HIV, HBV and HCV screening should be systematically offered at prison admission. Inmates benefit from free access to medical care and treatment during detention, including HCV treatment with Direct-Acting Antivirals (DAAs). However, data on effective implementation of HCV screening and treatment is lacking.

METHODS: Since there is no routine collection of epidemiological data in prison healthcare units, we used activity data from administrative reports to document the number of HIV, HBV and HCV tests performed and to assess the proportion of inmates effectively screened for these infections during their imprisonment in France, in 2017. In three representative regions accounting for 30% of the overall prison population, we conducted an additional survey combining different data sources and collection methods in order to estimate the proportion of inmates with chronic HCV infection having accessed DAA therapy.

RESULTS: The screening rates were similar for HIV, HBV and HCV, suggesting that these tests were offered, accepted and performed as a package. Overall 52% of people entering a penal institution in 2017 were actually screened, with disparities across regions (36% to 67%) and single prison settings. The data used did not allow to distinguish between female and male inmates, while the latter account for 96% of prison population. In our additional survey, overall 47.6% of the inmates estimated to have a replicative chronic HCV infection received an AAD therapy.



[Figure. Engagement in care of HCV-infected inmates detained in three representative French regions in 2017]

CONCLUSIONS: Efficient implementation of test-and-treat strategies against HIV and HCV epidemics in the inmate population requires a drastic improvement of screening in penal institutions. Less than half of chronically HCV infected inmates currently access DAA therapy, mostly due to insufficient screening.

EPIDEMIOLOGY OF NON-AIDS NON-COMMUNICABLE DISEASES (E.G., NON-AIDS CANCERS, CVD)

PEC0449

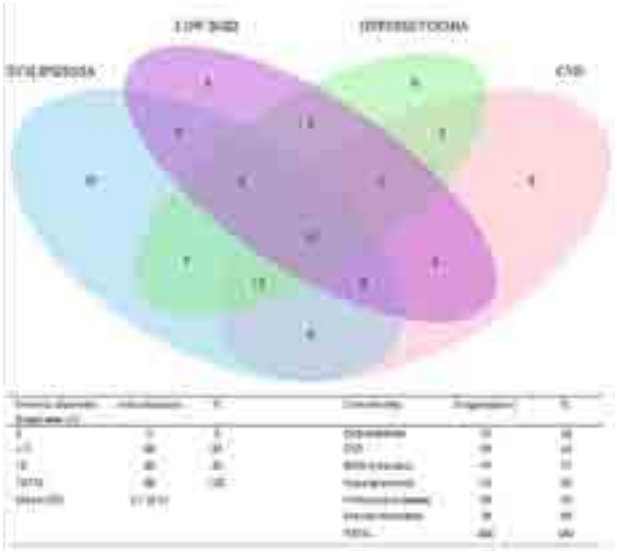
OCCURRENCES AND INTERACTIONS OF CHRONIC COMORBIDITIES AMONG CLINICALLY STABLE HIV PATIENTS ON LONG-TERM ANTIRETROVIRAL THERAPY IN BELO HORIZONTE, BRAZIL: A CROSS-SECTIONAL STUDY

C. Mendicino[1], M.D. Crosland Guimarães[2,1], G.J. da Silva[3], L. Penna Braga[4], C. Menezes de Pádua[1]
[1]*Federal University of Minas Gerais/Pharmacy Faculty, Social Pharmacy Department, Belo Horizonte, Brazil,* [2]*Federal University of Minas Gerais/Medicine Faculty, Public Health Post-Graduate Program, Belo Horizonte, Brazil,* [3]*Federal University of Minas Gerais/Medicine Faculty, Tropical Medicine and Infectology Pos-Graduate Program, Belo Horizonte, Brazil,* [4]*National School of Public Health-Fiocruz, Epidemiology on Public Health Pos-Graduate Program, Rio de Janeiro, Brazil*

BACKGROUND: The frequency of chronic-medical-conditions among people living with HIV (PLHIV) is higher than in general population. These disorders may be associated in a complex/synergic interaction, leading to chronic-diseases, that represent the main mortality causes in PLHIV. In order to provide better quality of life to PLHIV, we aimed to estimate the frequency of chronic-comorbidities and assess their risk-factors among PLHIV on antiretroviral-therapy (ART).

METHODS: Cross-sectional study was carried-out during 2017-2018 in 98 PLHIV (≥18 years) who began ART between 2001-2005 and have been monitored in public health-care (Belo Horizonte-Brazil). The outcome was defined as the count of comorbidities: hyperglycemia, dyslipidemia, cardiovascular-diseases (CVD), low bone-mineral-density (BMD), infectious-diseases and mental-disorders, collected through interviews, laboratory-testing and medical-records. Other variables comprised age/10, gender, immune-recovery (defined as CD4≥500 cells/µl) and physical-activity (Baecke-Questionarie). Descriptive-analyses, absolute/relative frequencies were estimated. The association between the outcome and age and physical-activity was perfomed using Quasipoisson-multilinear-regression model, adjusted by gender and immune-recovery (R-Software version:3.0.1).

RESULTS: Most participants were male (53%), with mean(SD) age=51.8(9.4) years. Approximately 38% presented physical-activity and 76% immune-recovery. We identified 266 comorbidities. 26% of participants had more than 3 comorbidities, resulting on mean(SD)=2.7(1.4) comorbidities/individual. Among the major co-morbidities, dyslipidemia, CVD, BMD and hyperglycemia highlighted with 70 (26%), 59 (22%), 44 (17%) and 42 (16%) respectively. None individual presented hyperglycemia individually, and 14 individuals presented the four major chronic-disorders simultaneously (Figure-1) . Older age presented poor association, however the presence of physical-activity showed considerable protective effect on the number of comorbidities (Table 1).



[Figure 1 - Occurrences and interactions between chronic disorders in people living with HIV under long-term antiretroviral therapy in Belo Horizonte, Brazil.]

Variables			Comorbidites occurences (mean)	Quasipoisson multilinear-regression		
		n (%)		Estimator (β)	CI-95%	p-value
Age/10 (years)	<43	77 (79)	2.0			
	≥43	21 (21)	3.2	0.21	(0.10;0.31)	<0.05
Physical-activities	No	58(62)	3.7			
	Yes	36(38)	3.2	-0.23	(-0.42;-0.04)	<0.05

Table 1: Relationship between the number of chronic-comorbidities and age and habitual physical activities adjusted by gender and immune-recovery in people living with HIV under antiretroviral therapy, Belo Horizonte city, Brazil.

CONCLUSIONS: Currently, due to avaiability of ART, PLHIV live longer, however facing many health challenges on non-communicable diseases. The lifestyle modifications such as physical-activity should be included to improve the health of PLHIV.

PEC0450

EARLY WEIGHT CHANGES ASSOCIATED WITH BICTEGRAVIR-BASED REGIMENS COMPARED TO OTHER INTEGRASE INHIBITORS FOLLOWING ART-INITIATION IN ART-NAÏVE PEOPLE LIVING WITH HIV

S. Ruderman[1], R. Nance[1], B. Whitney[1], B. Harding[1], K. Mayer[2], R. Moore[3], J. Eron[4], W. Mathews[5], B. Rodriguez[6], M. Saag[7], A. Willig[7], S. Lindstrom[1], B. Wood[1], A. Collier[1], G. Burkholder[7], M. Kitahata[1], J. Delaney[8], H. Crane[1]
[1]University of Washington, Seattle, United States, [2]Fenway Institute, Boston, United States, [3]Johns Hopkins, Baltimore, United States, [4]University of North Carolina, Chapel Hill, United States, [5]University of California, San Diego, United States, [6]Case Western University, Cleveland, United States, [7]University of Alabama at Birmingham, Birmingham, United States, [8]University of Manitoba, Winnipeg, Canada

BACKGROUND: Initiation of antiretroviral therapy (ART) has been associated with weight gain among people living with HIV (PLWH), particularly among those starting regimens containing integrase strand transfer inhibitors (INSTIs). Little is known about weight gain associated with bictegravir (BIC), a recently approved INSTI. We evaluated short-term weight gain after ART initiation among ART-naïve PLWH initiating a regimen containing BIC compared to other INSTIs in a US cohort.

METHODS: We included ART-naïve PLWH initiating INSTI-based ART regimens between 2012-2019 across 8 Centers for AIDS Research Network of Integrated Clinical Systems (CNICS) sites. ART regimens included raltegravir (RAL), elvitegravir (EVG), dolutegravir (DTG), and BIC-based regimens with tenofovir disoproxil fumarate (TDF), tenofovir alafenamide fumarate (TAF) or abacavir (ABC) and emtricitabine or lamivudine. We compared weight gain on BIC vs other INSTI-based regimens within six months after ART initiation. Data were modeled using linear mixed models adjusted for age, sex, race, hepatitis B and/or C virus coinfection, nadir CD4, smoking, diabetes, site, anti-psychotic medication use, and regimen, with an interaction between time and regimen.

RESULTS: We included 2,005 PLWH who initiated an INSTI-based regimen. PLWH who began a BIC/TAF-based regimen gained the most weight in the first six months after initiation (5.3 kg; 95%CI: 3.2-7.5). Participants taking BIC/TAF gained significantly more weight than those taking EVG/TDF and EVG/TAF-based regimens, but not significantly more compared to participants taking RAL/TDF, DTG/TDF, and DTG/ABC (Table). PLWH taking BIC/TAF experienced similar weight gain compared to PLWH taking DTG/TAF in the first six months after ART initiation.

	n	Coeff[b] (Δ kg/6 mo)	95% CI		P-value
BIC/TAF (ref)	115	5.31	3.15	7.46	0.00
Regimen type x Time on regimen					
RAL/TDF	96	-2.57	-5.34	0.20	0.07
EVG/TDF	790	-2.82	-5.08	-0.56	0.02
EVG/TAF	252	-2.63	-4.98	-0.27	0.03
DTG/TDF	233	-2.03	-4.41	0.36	0.10
DTG/TAF	116	-0.09	-3.29	3.10	0.95
DTG/ABC	383	-2.30	-4.63	0.04	0.05

[a] Model adjusted for time on regimen, regimen, age, sex, race, Hepatitis C, Hepatitis B, nadir CD4, smoking, diabetes, site, anti-psychotic medication use (time-updated)
[b] Estimated difference in weight change compared to referent group (BIC/TAF)

[Table. Weight change among previously ART-naive individuals over the first 6 months after initiating an INSTI-based regimen in adjusted[a] analyses (linear mixed models). Outcome = weight (kg) - 2005 people, 3.4 observations per person on average]

CONCLUSIONS: In the first six months following ART initiation, PLWH initiating BIC/TAF-based regimens appeared to gain more weight than those initiating some other INSTI-based regimens, with similar gains among those initiating DTG/TAF. Longer-term studies are needed to further investigate these weight gain disparities between INSTI regimens over a longer time period.

PEC0451

THE INCIDENCE OF OROPHARYNGEAL AND ORAL CAVITY CANCERS BY HIV AND MSM STATUS IN BRITISH COLUMBIA, CANADA (1990-2015)

A. Ablona[1], S.M. Beck[2], A.N. Burchell[3], M. Darvishian[4], H. Hamze[2], M. Alvarez[1], A. Yu[1], S. Wong[1], R. Woods[4], P. Bhatti[4], K. Salters[5], M. Krajden[1,2], N. Janjua[1,2], T.J. Grennan[1,2]
[1]BC Centre for Disease Control, Clinical Prevention Services, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada, [3]St. Michael's Hospital, Toronto, Canada, [4]BC Cancer, Vancouver, Canada, [5]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

BACKGROUND: The incidence of HPV-associated oropharyngeal cancers is increasing in Canada. Despite this, little is known about the epidemiology of these cancers as it relates to HIV status, sex, and sexual behaviour.

METHODS: In this retrospective cohort analysis (1990-2015), we created a subset of ~1.2 million individuals from the Integrated Data and Evaluative Analytics (IDEAs) cohort who had tested for or been diag-

nosed with HIV in British Columbia (BC). Squamous cell carcinomas of the oropharynx (tongue–base, soft palate, tonsils, mid-pharynx) and oral cavity (tongue–front 2/3, hard palate, gums, floor of mouth) were assigned using ICD-O-3 codes. Follow-up began at 01/01/1990, date of 16th birthday, or HIV detection (HIV-positive stratum), whichever occurred last, and ended at first cancer diagnosis, HIV diagnosis (HIV-negative stratum), death, or 31/12/2015, whichever occurred first. Individuals aged ≥16 years with ≥6 months of follow-up time were included. Crude incidence rates per 100,000 person-years were calculated over the entire period, stratified by HIV status, sex, and, among males, whether they were men who have sex with men (MSM).

RESULTS: From 1990-2015, there were 663 incident oropharyngeal cancers (n=60 MSM; n=474 male non-MSM; n=129 female) and 511 incident oral cavity cancers, (n=42 MSM; n=295 male non-MSM; n=174 female). Overall, crude incidence rates among HIV-positive individuals, compared with HIV-negative individuals, were higher for both oropharyngeal cancer (13.51 vs. 2.41 per 100,000 person-years, respectively) and oral cavity cancer (8.26 vs. 1.87 per 100,000 person-years, respectively). Oropharyngeal cancer incidence rates were highest among HIV-positive non-MSM males (21.23, 95% confidence interval [95%CI]: 11.05-40.80) and lowest among HIV-negative females (0.82, 95%CI: 0.69-0.98). For oral cavity cancer, incidence rates were highest among HIV-positive MSM (12.46, 95%CI: 6.23-24.92).

CONCLUSIONS: Considering the paucity of oral cancer screening programs in Canada, these results highlight the importance of HPV prevention initiatives, particularly among men living with HIV.

PEC0452

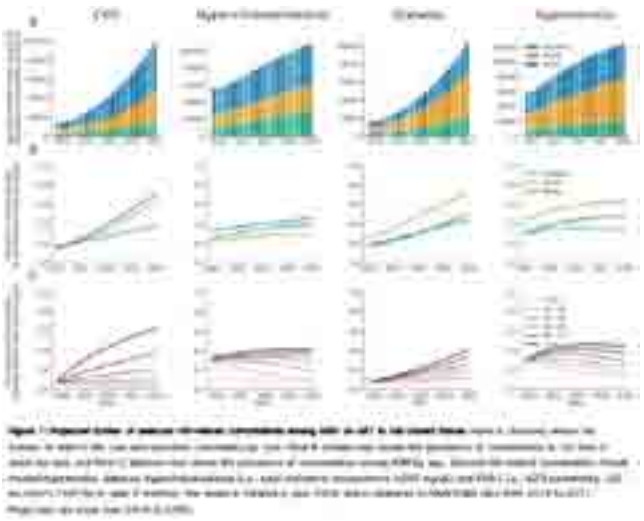
PROJECTING THE BURDEN OF MULTIMORBIDITY AMONG MEN WHO HAVE SEX WITH MEN LIVING WITH HIV IN THE US

P. Kasaie[1], C. Stewart[1], E. Humes[1], J. Zhang[1], A. Justice[2], M.A. Horberg[3], V. Lima[4], C. Boyd[5], M.M. Kitahata[6], M. Klein[7], C. Wong[5], J. Gill[8], H.M. Crane[6], S. Napravnik[9], A. D'Souza[5], M. Silverberg[10], K. Altoff[1]
[1]The Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Yale School of Medicine, New Haven, United States, [3]Kaiser Permanente Mid-Atlantic Permanente Research Institute, Rockville, United States, [4]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [5]The Johns Hopkins University, Baltimore, United States, [6]University of Washington, Seattle, United States, [7]McGill University, Montreal, Canada, [8]Southern Alberta HIV Clinic, Calgary, Canada, [9]University of North Carolina at Chapel Hill, Chapel Hill, United States, [10]Kaiser Permanente Northern California, Oakland, United States

BACKGROUND: As people living with HIV (PLWH) survive to older ages, the overall burden and racial disparities of age-related comorbidities among key populations, including men who have sex with men (MSM), remain uncertain.

METHODS: ProjEcting Age, MultimoRbidity, and PoLypharmacy (PEARL) is an agent-based simulation model of multimorbidity among PLWH in the US (2009-2030), including four HIV-related comorbidities (treated hypertension, diabetes, hypercholesterolemia and chronic kidney disease (CKD)), and presence/absence of four underlying conditions (smoking, Hepatitis C virus (HCV), depression and anxiety). Using data from the North American AIDS Cohort Collaboration on Research and Design (NA-ACCORD), we estimated the prevalence of each comorbidity/condition among MSM receiving ART in 2009 and those starting ART from 2010-17. The incidence of each comorbidity was estimated as a function of age, calendar year, ART initiation year, CD4 at ART initiation, current ART use and prevalence of other comorbidities/conditions. Annual mortality rate was estimated separately for people on and off treatment. All analysis was carried separately by race (for White, Black, and Hispanic MSM).

RESULTS: Along with the underlying increase in number of MSM receiving ART in the US (from 195,000 in 2009 to 444,000 in 2030), the prevalence of HIV-related comorbidities and racial disparities are increasing over time (i.e., Fig.1A: largest concentration of CKD and hypercholesterolemia among White MSM, and diabetes and hypertension among Black MSM). Prevalence of HIV-related comorbidities at the time of death is increasing similarly (Fig.1B). There is a significant increase in prevalence of HIV-related comorbidities with age (e.g., Fig.1C: CKD prevalence increasing from 7.3% in 2009 to 43.9% in 2030 among MSM >60-years-old).



CONCLUSIONS: The projected burden of HIV comorbidities among MSM is increasing over time, with higher prevalence among older MSM, and with sustained racial disparities. Efforts to end the HIV epidemic should be expanded to address the projected comorbidity burden.

PEC0454

INCIDENCE RATES OF ANAL SQUAMOUS CELL CARCINOMA AMONG HIV-POSITIVE AND HIV-NEGATIVE INDIVIDUALS BY MSM STATUS IN BRITISH COLUMBIA, CANADA: A RETROSPECTIVE COHORT STUDY (1990-2015)

S. Beck[1], A. Ablona[2], A. Burchell[3,4], M. Darvishian[5], H. Hamze[1], M. Alvarez[2], A. Yu[2], S. Wong[2], R. Woods[5], P. Bhatti[5], K. Salters[6], M. Krajden[1,2], N. Janjua[1,2], T. Grennan[1,2]
[1]University of British Columbia, Vancouver, Canada, [2]BC Centre for Disease Control, Vancouver, Canada, [3]St. Michael's Hospital, Toronto, Canada, [4]Unity Health Toronto, Toronto, Canada, [5]BC Cancer, Vancouver, Canada, [6]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

BACKGROUND: Anal squamous cell carcinoma (ASCC) is an HPV-associated malignancy that disproportionately impacts people living with HIV and men who have sex with men (MSM). However, population-based incidence rate (IR) estimations that draw on precise laboratory data and MSM statuses are scarce.

METHODS: The Integrated Data and Evaluative Analytics (IDEAs) Cohort includes ~1.7 million individuals who have tested or been case-reported for HIV and other infectious diseases in British Columbia (BC). We created a sub-cohort of HIV-negative and HIV-positive individuals aged ≥16 years with ≥6 months of follow-up time. ASCC diagnoses were ascertained from the BC Cancer Registry (1990-2015).

Follow-up began at first HIV detection (HIV-positive stratum), date of 16th birthday, or 01/01/1990, whichever occurred last. Follow-up ended at first ASCC diagnosis, HIV diagnosis (HIV-negative stratum), death, or 31/12/2015, whichever occurred first. We assessed crude IRs of ASCC stratified by sex, HIV status, and imputed MSM status.

RESULTS: From 1990-2015, there were 425 incident ASCC cases (n=78 MSM, n=119 male non-MSM, n=228 female). Among 1,279,903 HIV-negative individuals (6% MSM, 34% male non-MSM, 59% female), ASCC IRs per 100,000 person-years were 1.81 (95% confidence interval [95%CI]: 1.27-2.59) for MSM, 1.04 (95%CI: 0.85-1.27) for male non-MSM, and 1.45 (95%CI: 1.27-1.65) for females. Among 11,972 HIV-positive individuals (45% MSM, 34% male non-MSM, 21% female), ASCC IRs per 100,000 person-years were 74.94 (56.47-99.44) for MSM, 47.23 (30.47-73.21), for male non-MSM, and 3.79 (0.53-26.91) for females. Among HIV-positive MSM, crude ASCC IRs per 100,000 person-years increased over time: 1990-1999: IR=55.05 (95%CI: 20.66-146.68); 2000-2009: IR=73.74 (95%CI: 48.11-111.99); 2010-2015: IR=82.14 (95%CI: 54.09-124.75).

CONCLUSIONS: ASCC incidence was highest among HIV-positive MSM in BC, with rates in this population increasing over time. These results highlight the need for formalized anal cancer screening programs among people living with HIV in Canada.

DESCRIBING THE SPREAD OF HIV THROUGH MOLECULAR EPIDEMIOLOGY

PEC0455

TEMPORAL ANALYSIS OF HIV SEQUENCE AMONG THE JAPANESE POPULATION REVEALED TRANSMISSION CLUSTERS THAT DO NOT HAVE ACCESS TO THE SUCCESSFUL PREVENTIVE MEASURES WHICH WERE IMPLEMENTED IN JAPAN

T. Shiino[1], A. Hachiya[2], M. Nagashima[3], K. Sadamasu[3], M. Otani[4], M. Koga[5], A. Kamisato[5], K. Yoshimura[3], T. Kikuchi[4], The Japanese Drug Resistance HIV-1 Surveillance Network

[1]National Institute of Infectious Diseases, Infectious Disease Surveillance Center, Tokyo, Japan, [2]Nagoya Medical Center, Clinical Research Center, Nagoya, Japan, [3]Tokyo Metropolitan Institute of Public Health, Tokyo, Japan, [4]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, [5]University of Tokyo, Institute of Medical Science, Tokyo, Japan

BACKGROUND: In Japan, the number of new HIV cases being reported is slowly decreasing after having peaked in 2013. Since the number of reported cases of HIV differs from the incidence of viral transmission, it is unclear whether this infection is suppressed in Japan. Further, the fact that the first set of the 90-90-90 goals is largely unmet in Japan raises concern. Combining information from the Search Program of HIV Nation-wide Cluster database by Sequence (SPHNCS) with time-based phylogenetic analyses within these clusters, we analyzed the transmission dynamics of the recently reported HIV/AIDS cases in Japan.

METHODS: SPHNCS estimates the genetic distance of pol region between a query and the cases collected by Japanese drug resistance surveillance (JDRS) and identifies the domestic transmission cluster (dTC) of the query as the most closely linked neighbor cases (distance of <1.5%). We thus identified dTCs of 2,191 HIV-1 subtype B infected cases collected by JDRS in 2013-2016. We analyzed the phylogeny to estimate the transmission time and fluctuation of the relative population size of the 10 largest dTCs and 8 recently emerging dTCs using Bayesian inferences.

RESULTS: Among 6,797 cases, 5,781(85.1%) belonged to any dTC. Between 2013-2016, 8 of the top 10 dTCs showed a decrease in the transmission events and number of reported cases. Approximately 40% of the top 100 dTCs did not grow much during these 4 years. Conversely, the growing dTCs included sub-clusters with recently reported outbreaks and/or long-term undiagnosed groups. The former and latter groups comprised mostly urban youth and older individuals, respectively. Moreover, dTCs derived from recent cases among singletons could also be classified into two similar backgrounds.

CONCLUSIONS: The results demonstrate the positive and negative consequences of HIV/AIDS prevention strategies implemented in Japan. The positive aspect is that new infection is suppressed in some local populations that are at risk. This may be the consequence of inducement campaigns for HIV testing in several key populations. However, a significant population is still infected and/or hidden away in areas inaccessible to these preventive actions. Detecting such populations using SPHNCS and delivering a matching countermeasure may help in bringing awareness.

PEC0456

TRANSMISSION CHARACTERISTICS OF HIV-1 STRAINS AMONG NEWLY REPORTED HIV INFECTED PEOPLE IN CHINA IN 2018

M. Gan[1], A. Dong[2], Y. Feng[2], Y. Ruan[2], Y. Shao[2], H. Xing[2]

[1]National Center for AIDS/STD Control and Prevention (NCAIDS), Chinese Center for Disease Control and Prevention (China CDC), Division of Virology and Immunology, Beijing, China, [2]National Center for AIDS/STD Control and Prevention (NCAIDS), Chinese Center for Disease Control and Prevention (China CDC), Beijing, China

BACKGROUND: To provide scientific data for the accurate prevention and control of the HIV-1 transmission epidemic in China by studying the transmission characteristics of HIV-1 strains among newly reported HIV infected people in China in 2018.

METHODS: Field survey and sample collection were carried out in 31 provinces of China in 2018 (stratified sampling was carried out in cities where the number of newly reported infections in the same year was the median of the province), and partial sequences of pol region were obtained; sequences with length ≥ 1000bp and mixed base ≤ 5% were selected to carry out phylogenetic tree analysis and construct molecular network with HIV-TRACE, and the threshold of gene distance was set as 0.015; Statistical analysis using logistic regression.

RESULTS: A total of 4276 cases of newly reported HIV infection in 2018 were analyzed. It was found that CRF07_BC (39.7%, 1696/4276) and CRF01_AE (36.9%, 1578/4276) were the main subtypes of HIV-1 in China. We identified that 2241/4276 (52.4%) sequences belonged to molecular transmission clusters, and a total of 375 molecular clusters were identified. Among them, there are 39 cross-regional molecular clusters (clusters with sequences of 3 provinces or more), and the number of people entering the network with cross-regional transmission (1300 cases) is higher than the number of people entering the network with non-inter-regional transmission (941 cases); MSM clusters accounted for the largest proportion (35.9%, 467/1300). Through logistic regression analysis, it was found that MSM transmission was more likely to form cross-regional molecular clusters than heterosexual transmission. In southern China, infected persons were more likely to form cross-regional molecular clusters than those in central, eastern, north, northeast, southwest, and northwestern China.

CONCLUSIONS: A high proportion of HIV-1 cross-regional transmission exists in China; the CRF07_BC subtype is the main driving factor for the formation of cross-regional molecular clusters; South China is the region where HIV-1 transmission is most prevalent. To better control the HIV epidemic in China, there is an urgent need to strengthen information exchange and cooperation among provinces and implement joint prevention and control.

PEC0457

GLOBAL AND REGIONAL EPIDEMIOLOGY OF HIV-1 RECOMBINANTS IN 1990-2015: A SYSTEMATIC REVIEW AND GLOBAL SURVEY

J. Hemelaar[1], R. Elangovan[1], J. Yun[1], L. Dickson-Tetteh[1], S. Kirtley[2], E. Gouws-Williams[3], P. Ghys[4], WHO-UNAIDS Network for HIV Isolation and Characterisation
[1]University of Oxford, Nuffield Department of Women's & Reproductive Health, Oxford, United Kingdom, [2]University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom, [3]UNAIDS, Fast-Track Implementation Department, Geneva, Switzerland, [4]UNAIDS, Strategic Information Department, Geneva, Switzerland

BACKGROUND: Global HIV-1 genetic diversity and evolution form a major challenge to treatment and prevention efforts. An increasing number of distinct HIV-1 recombinants have been identified worldwide, but their contribution to the global epidemic is unknown. We aimed to estimate the global and regional distribution of HIV-1 recombinant forms during 1990-2015.
METHODS: We assembled a global HIV-1 molecular epidemiology database through a systematic literature review and a global survey. We searched PubMed, EMBASE, CINAHL, and Global Health databases for HIV-1 subtyping studies published between Jan 1, 1990 -Dec 31, 2015. Unpublished data was collected through a global survey. We included prevalence studies with HIV-1 subtyping data collected during 1990-2015. Countries were grouped into 14 regions and analyses conducted for four time periods (1990-99, 2000-04, 2005-09 and 2010-15). The distribution of circulating recombinant forms (CRFs), and unique recombinant forms (URFs) in individual countries was weighted according to the number of HIV-infected people in each country to generate regional and global estimates of HIV-1 recombinants in each time period.
RESULTS: Our global data collection yielded an HIV-1 molecular epidemiology database of 383,519 samples from 116 countries over 1990-2015. We found that the proportion of recombinants increased over time, both globally and in most regions. This was due to increases in both the proportion and the number of distinct CRFs detected over time, with 57 CRFs identified globally in 2010-2015. The global and regional distribution of HIV-1 recombinants was highly diverse and evolved over time, and we found extraordinary regional variation in the numbers (0-44 CRFs), types (58 distinct CRFs) and proportions (0-80.5%) of HIV-1 recombinants. Globally, CRF02_AG accounted for 33.9% of recombinants in 2010-2015, followed by URFs(26.7%), CRF01_AE(23.0%), and other CRFs(16.4%). Although other CRFs played smaller roles globally they played increasingly important roles in regional epidemics. East(12.6%), West(15.5%) and Central(21.3%) Africa and Latin America(9.6%) had high proportions of URFs.
CONCLUSIONS: Recombinants play an increasing role in global and regional HIV epidemics, which has important implications for the development of an HIV vaccine, as well as design of diagnostic, resistance and viral load assays. Continued and improved surveillance of the global molecular epidemiology of HIV is crucial.

PEC0458

THE INTERNATIONAL DIMENSION OF HIV-1 CLUSTERS

E. Delgado[1], H. Gil[1], S. Benito[1], J. Cañada[1], M. Sánchez[1], V. Montero[1], E. García Bodas[1], M. Thomson[1], Spanish Group for the Study of New HIV Diagnoses
[1]Instituto de Salud Carlos III, Centro Nacional de Microbiologia, Majadahonda, Spain

BACKGROUND: For more than a decade, numerous studies have reported an increasing frequency of clustering in newly diagnosed (ND) HIV-1 infections in many countries, commonly associated with men who have sex with men. Here we aim at determining the frequency with which HIV-1 infections ND in Spain group in clusters and the countries involved in them, using all protease-reverse transcriptase (PR-RT) sequences obtained by us and available at databases.
METHODS: HIV-1 PR-RT sequences were obtained through RT-PCR amplification from plasma RNA using samples collected from individuals attended at clinical centers from 10 Spanish regions ND of HIV-1 infection in 2017-2019. Phylogenetic analyses were performed with FastTree using all PR-RT sequences obtained by us from samples collected in Spain in 1999-2019 (n=14,886) and those available at the Los Alamos HIV Sequence Database. These were downloaded using the option "one sequence per patient"; sequences < 960 nt long, containing deletions or stretches of ambiguous positions >6 nt long, or without information on country of sample collection were excluded. Two separate analyses were performed, using database subtype B (n=72,345) and non-subtype B (n=80,482) sequences, respectively. Analyses including only viruses collected in Spain were also performed. Transmission clusters (TCs) were defined as those comprising ≥4 individuals supported by local SH-like values ≥0.95.
RESULTS: Of 1,585 PR-RT sequences obtained from ND individuals in Spain, 1,037 (65.4%) grouped in 377 TCs. When only viruses collected in Spain were used in the analyses, 853 (53.8%) grouped in TCs. Of the 377 TCs, only 118 comprised exclusively viruses collected in Spain. 31 clusters observed in the Spanish-only tree were broken up when non-Spanish sequences were included. 18 Spanish TCs were nested within larger predominantly non-Spanish TCs. Countries more frequently participating in TCs comprising viruses from individuals ND in Spain were Germany (participating in 78 TCs), UK (n=74), USA (n=74), Brazil (n=38), Portugal (n=26), Belgium (n=22), and Italy (n=21).
CONCLUSIONS: HIV-1 infections newly diagnosed in Spain frequently group in clusters, which often comprise non-Spanish viruses. When analyzing HIV-1 clustering, inclusion of all available sequences provides a more informative and epidemiologically relevant view of HIV-1 propagation in the global pandemic.

SURVEILLANCE IN KEY POPULATION GROUPS

EARLY SEX WORK INITIATION AND ITS ASSOCIATION WITH CONDOMLESS SEX AND SEXUALLY TRANSMITTED INFECTIONS AMONG FEMALE SEX WORKERS IN IRAN

A. Mirzazadeh[1], M. khezri[2], M. Karamouzian[3], H. Sharifi[2], A. Haghdoost[2], S. D. Baral[4]
[1]University of California, Department of Epidemiology and Biostatistics, Institute for Global Health Sciences, San Francisco, United States, [2]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance Institute for Futures Studies in Health Kerman University of Medical Sciences, kerman, Iran, Islamic Republic of, [3]School of Population and Public Health, Faculty of Medicine, University of British Columbia, Vancouver, Canada, [4]Department of Epidemiology, Key Populations Program, Center for Public Health and Human Rights, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

BACKGROUND: Early sex work initiation among female sex workers (FSW) increases their vulnerabilities to HIV and other sexually transmitted infections (STIs) as well as high-risk sexual practices. This study aimed to examine the prevalence of early sex work initiation, and its association with condomless sexual practices, and HIV/STIs among FSW in Iran.

METHODS: We recruited 1,347 FSW from 13 cities in Iran in 2015. Eligible women were FSW who were ≥18 years and reported selling sex in exchange for livelihood with more than one client within the previous 12 months. We examined the association of early sex work initiation (<18 years old) with HIV and human papillomavirus, chlamydia, trichomoniasis, syphilis, and gonorrhea, and two condomless sex indicators. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were reported using multivariable logistic regression.

RESULTS: A total of 131 (10.1%) FSW reported early sex work initiation. In comparison with those who had started sex work ≥ 18, early initiators were younger (mean (SD): 28.7 vs. 36.0 years), reported never being married (22.1% vs. 4.5%), had lower educations (77.9% vs. 61.6%), and were involved in sex work >10 years (55.0% vs. 30.2%). Early initiators were also more likely to report last-month inconsistent condom use (aOR = 3.31, 95% CI:1.82, 6.02, P-value <0.001), and last-sex condomless intercourse (aOR = 1.72, 95% CI: 1.15, 2.56, P-value = 0.007). There was no statistical association between early sex work and HIV (aOR = 1.40, 95% CI: 0.43, 4.53, P-value = 0.544), and any STIs (aOR = 1.01, 95% CI: 0.69, 1.48, P-value = 0.934), except for chlamydia (aOR = 2.09, 95% CI:1.08, 4.04, P-value = 0.027).

CONCLUSIONS: Our findings highlight the need to develop, implement and evaluate evidence-informed interventions for FSW who initiated sex work early in Iran. While specific interventions such as screening for STIs are helpful, advanced counselling for condom use are required to encourage safe sex practices among FSW who initiated sex work early. Future research in the area of condom use in Iran can focus on identifying and tackling the barriers to condom use among FSW who initiated sex work early.

PEC0460

DISTRIBUTION AND TEMPORAL TREND IN TIME FROM HIV INFECTION TO DIAGNOSIS AMONG MSM: EVIDENCE FROM A SYSTEMATIC REVIEW

S. Gbadamosi[1], D. Sheehan[1], R. Dawit[1], R. Jebai[1], M.J. Trepka[1]
[1]Florida International University, Epidemiology, Miami, United States

BACKGROUND: The HIV epidemic disproportionately affects men who have sex with men (MSM). As such, characterizing the time from infection to HIV diagnosis in this population is crucial to assess transmission risk potential and the effect of HIV testing practices in recent decades. Thus, the objective of the study was to examine the distribution and temporal trend in time from HIV infection to diagnosis for MSM using a systematic review of the literature.

METHODS: Following PRISMA guidelines, two authors independently searched MEDLINE and Embase without geographic or date restrictions, and bibliographies of included citations. Authors utilized a combination of keywords and Medical Subject Heading terms for the search. Eligibility criteria for inclusion were met if the study investigated MSM with HIV, reported any measure on time from HIV infection to diagnosis, and was published in English in a peer-reviewed journal. Data on study setting, modeling techniques, and measures of time from HIV infection to diagnosis were extracted. Subsequently, a narrative synthesis and pooled mean analysis with equal weighting of eligible studies were done.

RESULTS: The search identified 1651 unduplicated citations. After screening titles and abstracts, 146 of 1651 were included for full-text review; nine articles were eligible for inclusion in the study. All eligible studies were conducted in high-income countries: United Kingdom (n=3), United States (n=2), France (n=2), Australia (n=1) and the Netherlands (n=1). While earlier studies utilized the CD4-staged back-calculation modeling technique (n=6), recent studies used the CD4-depletion model (n=3). Overall, the mean time from HIV infection to diagnosis for MSM was 4.2 years. Before the advent of antiretroviral therapy in 1996, mean time from HIV infection to diagnosis was 7.8 years (range: 5.6–11.6 years). The mean times in subsequent cohorts were: 2000–2006 (mean: 4.2 years, range: 2.3–6.2 years); 2007–2011 (mean: 3.3 years, range: 0.9–5.0 years); and 2012–2015 (mean: 3.2 years, range: 2.7–3.7 years).

CONCLUSIONS: In high-income countries, MSM live with undiagnosed HIV for approximately 3 years. Decreases in mean time from HIV infection to diagnosis for MSM over time were observed. Findings highlight need for targeted initiatives to increase routine HIV testing in this population.

PEC0461

DECLINE IN HIV PREVALENCE AMONG MEN WHO HAVE SEX WITH MEN IN DAR ES SALAAM, TANZANIA: EFFORTS TOWARDS THE ATTAINMENT OF THE 2030 GOAL

E.J. Mmbaga[1,2], A. Mwijage[3], K. Moen[1], M. Leshabari[3], N. Makyao[4], A. Ramadhan[4], B. Mutayoba[4], D.W. Meyrowitsch[5], T. Lange[5], B. Tersbøl[5], G.H. Leyna[2,6]
[1]University of Oslo, Community Medicine and Global Health, Oslo, Norway, [2]Muhimbili University of Health and Allied Sciences, Epidemiology and Biostatistics, Dar es Salaam, Tanzania, United Republic of, [3]Muhimbili University of Health and Allied Sciences, Behavioral Sciences, Dar es Salaam, Tanzania, United Republic of, [4]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program, Dodoma, Tanzania, United Republic of, [5]University of Copenhagen, Public Health, Copenhagen, Denmark, [6]Tanzania Food and Nutrition Centre, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Implementation of a comprehensive package of HIV interventions for key populations in Tanzania started in 2014 to accelerate progress towards the 2030 goal of ending the epidemic. No study has so far examined the state of the epidemic among men who have sex with men (MSM) after the launch of this package. We estimated the prevalence of HIV infection and associated sexual behaviors among MSM in Dar es Salaam nearly half a decade after the implementation of the package.

METHODS: A cross-sectional survey using respondent-driven sampling was used to recruit MSM aged 18 and above. We carried out structured interviews followed by blood sample collection for HIV testing. Independent risk factors for HIV infection were examined using weighted logistics regression modelling.

RESULTS: A total of 777 MSM with mean age of 26 were recruited. The weighted HIV prevalence was 8.3% (95%CI: 6.3-10.9) as compared to 22.3% (95%CI: 18.7-26.4) observed in a similar survey in 2013. Half of the participants had had sex with more than 2 partners in the month preceding the survey. Among those who had engaged in transactional sex, 80% had used a condom during last anal sex with a paying partner. Participants aged 25 and above had 4 times higher odds of being infected than those aged 15-19. HIV infection was associated with multiple sexual partnerships (AOR, 3.0; 95%CI: 1.8-12.0), not using a condom during last sex with non-paying partner (AOR, 4.1; 95%CI: 1.4-7.8), and ever engaged in group sex (AOR, 3.4; 95%CI: 1.7-13.6). Having used a condom during transactional sex was associated with 60% reduced odds of infection.

CONCLUSIONS: HIV prevalence among MSM in Dar es Salaam has decreased by more than half over the past 4 years, coinciding with the implementation of a comprehensive package for HIV interventions among key populations. It is nonetheless twice as high as that of men in the general population. Increased protected anal sex and a decline in infection in the general population could have played a role. To achieve the 2030 goal, behavioral change interventions and roll-out of new intervention measures such as pre-exposure prophylaxis are urgently needed.

PEC0462

TRENDS IN PREVALENCE OF HIV AND OTHER STIS AMONG KEY POPULATIONS IN THREE DISTRICTS IN BOTSWANA: RESULTS OF THE 2017 BEHAVIORAL AND BIOLOGICAL SURVEILLANCE SURVEY AMONG KEY POPULATIONS IN BOTSWANA

W. Dikobe[1], L. Okui[1], C. Akolo[2], D.K. Kanyenvu[3], K. Kusi[3], R. Kereng[1], O. Komotere[1], M. Gilbert-Lephodisa[1], B. Nkomo[3], J. Ngidi[4], S. Chishala[4], J. Bolebantswe[3], C. Petlo[3], M. Mine[5], M. Merrigan[2]
[1]FHI 360, Gaborone, Botswana, [2]FHI 360, Washington, United States, [3]Ministry of Health and Wellness, Dept of HIV/AIDS and Prevention, Gaborone, Botswana, [4]Botswana Harvard, HIV Reference Laboratory, Gaborone, Botswana, [5]Ministry of Health and Wellness, National Health Laboratory, Gaborone, Botswana

BACKGROUND: The first Behavioral and Biological Surveillance Survey (BBSS1) in Botswana was conducted in 2012 to generate baseline information on the prevalence and incidence of HIV and other STIs among female sex workers (FSWs) and men who have sex with men (MSM). The study results highlighted critical gaps in the provision of HIV and STI services for key populations (KPs). Five years later, the second BBSS (BBSS2) was conducted to better understand the dynamics of HIV transmission in these populations. We compared trends in the prevalence of HIV and other STIs between BBSS1 and BBSS2.

METHODS: Both studies used a cross-sectional design to establish the prevalence of HIV and other STIs among the selected KP groups. A mapping exercise of all venues where FSWs solicited clients was used to create a time-location sampling frame, while respondent-driven sampling was used for the often hidden MSM population. Comparisons were only made for the three districts represented in BBSS1 (Gaborone, Francistown, Chobe) and only for the STIs previously studied in BBSS1 (syphilis, gonorrhea, and chlamydia).

RESULTS: Overall, HIV prevalence among FSWs decreased from 61.9% (BBSS1) to 51.3% (BBSS2). HIV prevalence among MSM increased significantly from 13.1% (BBSS1) to 19.1% (BBSS2) (p=0.016). The most common STI for both groups in both studies was chlamydia. FSWs experienced an increase in the prevalence of chlamydia (11.9% to 13.7%) and syphilis (3.5% to 6.7%) and decline in gonorrhea (10.5% to 7.2%) from BBSS1 to BBSS2. Among MSM, there was decline in prevalence for all three STIs from 2.9% to 1.7% for gonorrhea, from 11.3% to 9.2% for chlamydia, and from 2.7% to 1.8% for syphilis. Finally, self-reported access to ART treatment improved significantly, from 25% to 88% (p=0.000) for FSWs, and from 13.1% to 82.1% for MSM from BBSS1 to BBSS2.

CONCLUSIONS: Prevalence of HIV and STIs remains high among KPs in Botswana. Given the correlation between STIs and HIV transmission, there is a need to scale up combination prevention strategies that include prevention education, pre-exposure prophylaxis (PrEP), and promotion of condom and lubricant use.

PEC0463

TRANSITIONS BETWEEN PREP ELIGIBILITY STATES AND HIV INFECTION IN A COHORT OF HIV-NEGATIVE MEN WHO HAVE SEX WITH MEN IN LISBON: A MULTI-STATE MODEL ANALYSIS

P. Meireles[1], C. Moreira[1,2], M. Rocha[3,4], M. Plankey[5], H. Barros[1,6]
[1]EPIUnit - Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal, [2]CMAT – Centre of Mathematics –– University of Minho, Braga, Portugal, [3]GAT – Grupo de Ativistas em Tratamentos, Lisbon, Portugal, [4]Coalition PLUS Community-Based Research Laboratory, Patin, France, [5]Georgetown University Medical Center, Washington, DC, United States, [6]Faculdade de Medicina, Universidade do Porto, Alameda Prof. Hernâni Monteiro, Porto, Portugal

BACKGROUND: At any one point in time, eligibility for preexposure prophylaxis (PrEP) is based on self-reported risk behavior together with clinical data. We aimed to describe the transitions between PrEP eligibility states comprising HIV infection, among HIV-negative Men who have Sex with Men (MSM).

METHODS: We used data from 1177 adult MSM enrolled in the open, prospective Lisbon Cohort of MSM who had at least one follow-up visit and two consecutive measurements of PrEP eligibility from March 2014 to March 2018. A time-homogeneous Markov multi-state model was applied, describing transitions between PrEP eligibility states (eligible and ineligible) and from each of these to HIV infection, by estimating its intensities and probabilities. The Portuguese National Health Service guidelines were used to define eligibility.

RESULTS: The estimated transition intensities were similar for ineligible–eligible (I–>E) (1.591 [1.323; 1.913] and eligible–ineligible (E–>I) (1.493 [95% CI 1.241; 1.795]) while the transition eligible–HIV infection (E–>HIV) was 22 times more likely than ineligible–HIV infection (I–>HIV) (0.032 [95% CI 0.020; 0.050] vs. 0.001 [95% CI 0.000; 0.982]). The transition probabilities estimated for 90 days were similar for the transition I–>E and E–>I (0.275 [95% CI 0.233; 0.310] vs. 0.258 [95% CI 0.218; 0.290]) while the transition E–>HIV was 4.4 times more likely than I–>HIV (0.007 [95% CI 0.005; 0.032] vs. 0.002 [95% CI 0.001; 0.143]). The transition probabilities increased with time; they were similar between the two eligibility states, but the ratios between the transition probabilities to HIV infection decreased.

CONCLUSIONS: The transition probability to HIV infection was higher at any time from the eligible state than from the ineligible state, but ratios between these probabilities decreased with time, indicating being ineligible was only a short-time indicator of a lower probability of acquiring HIV. Additionally, once an individual met any of the eligibility criteria for PrEP, the risk of seroconversion increased 22-fold. Therefore, anticipating and avoiding changing to an eligible state is challenging and demands delivering PrEP sooner than later.

PEC0464

CORRELATES OF HIV INFECTION AND VIRAL LOAD SUPPRESSION AMONG MEN WHO HAVE SEX WITH MEN IN GHANA

S. Quaye[1], S. Nguah[2], A. Dompreh[2], N. Wabiri[3], T. Agyarko Poku[2], K. Atuahene[4], Y. Adu-Sarkodie[2]
[1]US Centers for Disease Control and Prevention, Division of Global HIV&TB (DGHT), Accra, Ghana, [2]Kwame Nkrumah University of Science and Technology, College of Health Sciences, Kumasi, Ghana, [3]Human Sciences Research Council, HIV/AIDS, STIs & TB Research Programme, Johannesburg, South Africa, [4]Ghana AIDS Commission, Accra, Ghana

BACKGROUND: Men who have sex with men (MSM) are disproportionately affected by HIV in Ghana with limited data on number on treatment and virally suppressed. In 2017, PEPFAR through CDC funded a Biological Behavioural Survey (BBS) among MSM covering all 10 regions in Ghana. Results indicated low self-reported ART status. HIV Positive Samples were analyzed for viral load levels to validate self-reported ART status results and estimate viral suppression.

METHODS: The study recruited 4,095 MSMs using respondent-driven sampling across 10 regions in Ghana in an average of 14 weeks. HIV antibody and viral load testing were performed on collected samples. HIV testing used First Response rapid test, reactive specimens were confirmed using OraQuick rapid test, and viral load testing was done using COBAS AmpliPrep/TaqMan 96, 23 months after being drawn. Population-based estimates of the cascade indicators were derived using individualized RDS weights. Bivariate descriptive analysis was done using RDS A, Stata v31.1 and MS Excel.

RESULTS: Estimated number of MSM in Ghana is 54,759, (0.72% of adult male population). HIV prevalence is 18.1% (95% CI; 15.8-20.3). Viral load test showed overall viral suppression of 39.6% (95%CI:34.2-45.3). 8.7% (95%CI:6.3-11.9) had undetectable HIV-1 RNA and 6.5% (95%CI:4.1-10.1) showed <20 copies. 3.7% (95%CI:2.4-5.8) HIV positives self-reporting to have taken ARVs in the last 12 months, of which 80.5% (95%CI; 55.6 -93.2) were suppressed. 38.3% (95%CI; 32.8-44.2) who did not self-disclose their last 12 months ART status were found to be suppressed. Viral suppression among 18-24 years (40.0%, 95%CI:32.1%-48.5%) and those greater than 24 years (39.9%, 95%CI:32.6-47.7%) were not significantly different (p=0.991).

Region	N	Suppressed (n)	Crude	Adjusted (95% CI)
Greater Accra	244	118	48.8	47.8 [39.8-56.0]
Ashanti	132	41	31.1	26.7 [18.2-37.4]
Brong-Ahafo	23	4	17.4	19.0 [6.5-44.0]
Central	60	12	20	16.8 [8.4-30.9]
Eastern	55	12	21.8	22.9 [12.9-37.2]
Northern	21	5	23.8	16.5 [6.1-37.6]
Volta	69	23	33.3	31.2 [19.9-45.4]
Western	65	25	38.5	38.5 [25.6-53.2]
Total	669	240	35.9	39.6 [34.2-45.3]

[Table 1 HIV Viral Suppression by Region; Ghana]

CONCLUSIONS: Data shows significantly higher HIV prevalence and lower viral suppression among MSM compared with the general population. BBS self-reported ART status underestimate UNAIDS FastTrack 1st and 2nd 90s targets. Viral load testing should be integral to BBS.

PEC0465

OUTCOMES OF HIV POSITIVE SURGICAL PATIENTS ADMITTED TO A SOUTH AFRICAN REGIONAL HOSPITAL: A RETROSPECTIVE CLINICAL AUDIT

L.M. Rapolai[1], G. Snoyman[1], A. Diayar[1], U.A. Izegbu[1], C. do Vale[1]
[1]*University of Witwatersrand, Department of Clinical Medicine, Johannesburg, South Africa*

BACKGROUND: The outcomes of HIV-positive surgical patients admitted to ICUs in regional hospitals in settings with high HIV prevalence rates are not well described. There is a need for a better understanding of outcomes to inform ICU management strategies for HIV-positive surgical patients. The aim was to determine the testing rates and impact of HIV on patient outcomes based on HIV status and CD4 count.

METHODS: A retrospective clinical audit was conducted of surgical patients, admitted to the open ICU at Thelle Mogoerane Regional Hospital in South Africa, from 2016 through 2017. All surgical patients (pediatric and adult) were treated by the general surgical team. Data was collected from the ICU register and clinical records, then imported into SPSS 25 for analysis using Pearson chi-squared tests to explore associations with mortality in ICU.

RESULTS: Of the 361 surgical patients, the median age was 37 years and 69.81% were male. 52 patients (14,4%) were HIV positive, 29 patients (8%) were negative and 280 (77.6%) were untested. No significant association between HIV and mortality were noted in the overall sample comparing HIV-positive versus HIV-negative versus HIV-unknown [30.0%, 37.1%, 30.4%] but ICU admissions of longer than 5 days were associated with higher mortality among HIV-positive patients [p = 0.027]. There was a significant association between HIV and developing sepsis in the ICU [HIV-positive = 17.1%, HIV-negative = 1.7%, HIV-unknown = 3.5%, p < 0.001]. Of the 52 HIV positive patients, 36 (69.2%) had their CD4 count tested. There was a 50.0% mortality rate among patients with CD4 counts less than 200 cells/μL and a 5.9% mortality rate in those with CD4 counts greater than 200 cells/μL (p = .047). Trauma patients with CD4 counts of less than 200 cells/μL had a 40.0% mortality rate, whereas all trauma patients with CD4 counts greater than 200 cells/μL were discharged (p = .042).

CONCLUSIONS: The HIV testing rate of surgical patients was low. Low levels of HIV testing are a significant barrier to improving outcomes of surgical ICU patients in high HIV prevalence settings. Among HIV-positive patients, longer ICU admissions and low CD4 counts were associated with higher mortality rates.

PEC0466

HOMELESSNESS AT HIV DIAGNOSIS IS ASSOCIATED WITH LOWER VIRAL SUPPRESSION DESPITE HIGH RATES OF LINKAGE IN SAN FRANCISCO

D. Sachdev[1], C. Toomey[1], J. Chin[1], R. Kohn[1], E. Mara[1], E. Antunez[1], A. Hughes[1], S. Cohen[1], L. Hsu[1]
[1]*San Francisco Department of Public Health, San Francisco, United States*

BACKGROUND: The proportion of people newly diagnosed with HIV (PWH) in San Francisco (SF) who are experiencing homelessness is increasing. We compared time to HIV care linkage, retention, and viral suppression (VS) among PWH in SF by housing status at time of HIV diagnosis.

METHODS: Housing status (stable or homeless) was determined through partner services investigations. Homeless included those residing in a vehicle, couch-surfing or staying temporarily in a single room occupancy. We compared housed and homeless PWH by sociodemographic and risk characteristics, proportion linked to care at 1 month, retained at 3-9 months, and VS at 3 and 12 months, and median time from diagnosis to care, ART initiation, and VS.

RESULTS: Of 197 people diagnosed with HIV in 2018, 175 (89%) had housing status data, of which 29% were experiencing homelessness. Homelessness was not associated with sex, race, age or median CD4, but was associated with insurance status and transmission category (p<.0001). Overall 94% were linked to care within one month. There were no differences by housing status in median days from HIV diagnosis to first care visit, first care to ART initiation and diagnosis to first VS, as well as proportions linked to and retained in care (Table). Stably housed persons had higher VS than homeless at 3 months (79% versus 60%; p=.03) and at 12 months (88% versus 74%; p=.03).

	Stably housed (n=125)	Homeless (n=50)	P-value
Median CD4 count at diagnosis	440	511	0.26
Median days from HIV diagnosis to first care	3	2	0.33
Median days from first care to ART initiation	0	1	0.13
Median days from ART to first viral suppression	37	45	0.17
Median days from diagnosis to viral suppression	47	61	0.09
% Linked to care in 1 month	116/123 (94%)	43/47 (91%)	0.50
% Retention at 3-9 months after linkage within 1 month	96/116 (83%)	36/43 (84%)	1.00
% Viral suppression at 3 months	90/114 (79%)	26/43 (60%)	0.03
% Viral suppression at 12 months	104/118 (88%)	34/46 (74%)	0.03

[Table]

CONCLUSIONS: PWH experiencing homelessness were significantly less likely to have VS after diagnosis, despite having high rates of linkage and retention. Stable housing is critical to achieve 90-90-90 in SF.

PEC0467

HIV PREVALENCE AND INCIDENCE TRENDS AMONG KEY POPULATIONS IN UKRAINE, 2013-2017

M. Kornilova[1], Y. Sazonova[2]
[1]*Alliance for Public Health, Monitoring and Evaluation, Kyiv, Ukraine,* [2]*Yale School of Public Health, Albany, United States*

BACKGROUND: Ukraine is experiencing one of the biggest HIV epidemic in the World, the epidemic is concentrated in all three key populations: PWID, MSM and SWs. Efforts that community-based organizations investing in HIV prevention slow down the disease spread among KP. To have a better understanding of where transmission is still ongoing we have conducted this analysis.

METHODS: We performed secondary analysis of data obtained in the 3 subsequent rounds of the integrated bio-behavioral surveys among PWID, MSM and CSW conducted in 2013, 2015 and 2017. We analyzed HIV prevalence and incidence and used the multiple logistic regression to identify the key factors associated with the HIV incidence. To measure HIV incidence we have used LAg rapid recency tests (Asante) followed by the VL count for each positive sample to discard false recent results.

RESULTS: HIV prevalence among all three KPs hasn't changed much in the last 4 years and accounted among PWID 19.7% in 2013; 21.9% in 2015 and 22.6% in 2017. Among MSM 5.9%; 8.5 and 7.5% respectively.

Among SWs 7.3% in 2013; 7% in 2015 and 5.9% in 2017. HIV incidence has shown an increasing trend among PWID and SWs. Among PWID it increased from 0.74% in 2013 to 1.36% in 2015 and 2.44% in 2017. Among SWs it dropped down from 0.44% in 2013 to 0.21% in 2015 and increased to 0.56% in 2017. MSM 0.91% in 2013; 1.39% in 2015 and 0.56% in 2017.

The logistic regression indicated that HIV incidence in all groups is strongly associated with the male gender and the injecting drug use. The HIV incidence among those who inject has been associated with injecting several times a day OR 1.2(95%CI 1.1-1.4) use of non-sterile syringe OR 2.7(95%CI 1.2-6.4) and purchasing drug in a pre-filled syringe OR 1.5(95%CI 1.1-2.4).

CONCLUSIONS: Injecting drugs continues to contribute to HIV transmission in Ukraine. The only group demonstrating a steady growing HIV incidence is PWID; among other KPs incidence is also linked to injecting. More efforts need to be invested in harm reduction and the new prevention methods. PrEP for PWID might be considered as a perspective prevention method.

PEC0468

USE AND WILLINGNESS TO USE PREEXPOSURE PROPHYLAXIS FOR HIV AMONG MEN WHO HAVE SEX WITH MEN

P. Meireles[1], F. Fernandes[1,2], J. Rojas[3,4], M. Rocha[3,4], H. Barros[1,5]
[1]EPIUnit - Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal, [2]Unidade de Saúde Pública – ACES Baixo Mondego, Figueira da Foz, Portugal, [3]GAT – Grupo de Ativistas em Tratamentos, Lisbon, Portugal, [4]Coalition PLUS Community-Based Research Laboratory, Patin, France, [5]Faculdade de Medicina, Universidade do Porto, Alameda Prof. Hernâni Monteiro, Porto, Portugal

BACKGROUND: The Portuguese National Health Service (NHS) provides preexposure prophylaxis (PrEP) for HIV prevention, free of charge, since February 2018. About 1000 individuals are on PrEP, and most are men who have sex with men (MSM). We aimed to describe PrEP use and willingness to use in a large cohort of HIV-negative MSM and to compare PrEP users and non-users.

METHODS: We used data from 6164 participants in the Lisbon Cohort of MSM – an open, prospective cohort of HIV-negative MSM testing at a community-based center in Lisbon, with a baseline visit between April 2011 and July 2019, who answered either in a baseline or follow-up interview to the question: did you use PrEP in the last 12 months/since the last visit? We report the proportion of participants who used PrEP at least once, and the willingness to use PrEP at their most recent visit.

RESULTS: PrEP use was reported by 198 (3.2%) participants, of whom 57 (28.8%) started using after its introduction. Out of the 122 that provided additional information on their PrEP use, 86 (70.5%) were using daily, 31 (25.4%) on-demand, and 5 (4.1%) reported other regimes. The sources of PrEP varied according to the timing of the initial PrEP experience – prescribed by a physician (13.0% before Feb/2018 vs. 71.9% after Feb/2018), and online self-medication (40.7% before Feb/2018 vs. 15.8% after Feb/2018). PrEP users presented more frequently eligibility criteria for PrEP at baseline (83.2% vs. 66.4%). Half non-PrEP users reported wanting to use PrEP, 29.3% said maybe or to not know, and 20.7% were not willing to use. Willingness to use PrEP was positively associated with having an indication for PrEP (OR: 1.52; 95% CI 1.32-1.77). Among non-users, HIV incidence per 100 person-years was 1.31 (95% CI 1.08-1.58), while among PrEP users, it was 0.67 (95% CI 0.25-1.79).

CONCLUSIONS: PrEP use and willingness to use were related to behavioral indication, showing an appropriate self-risk assessment, and were higher than previously reported among MSM in Portugal. The proportion of men obtaining PrEP from a physician increased significantly after PrEP became available at the Portuguese NHS, making proper care more likely.

PEC0469

COUNTING 'HARD-TO-REACH' POPULATION IN A DATA CONSTRAINED SETTING: A BSS OF MSM IN GHANA

J. Lamptey[1], E. Larbi[1], K. Atuahene[1]
[1]Ghana AIDS Commission, Research Monitoring and Evaluation Division, Accra, Ghana

BACKGROUND: Men who have sex with Men (MSM) are a hidden population , who are affected by HIV in Ghana with limited national data on their population size. In view of this, a Biological Behavioural Survey (BSS) among MSM was conducted on a national scale covering all 10 regions.

The primary objectives were to measure the prevalence of HIV and other sexually transmitted infections, their associated risk behaviors and estimate the population size of MSM in Ghana.

METHODS: The study was undertaken in 2017 and used multiple methods to estimate the size of the MSM population in Ghana. Size estimation methods used were service multipliers, unique object multiplier, RDS size estimation, Literature review and consensus on estimates using a modified Delphi Approach. RDS-A tool was employed for data analysis.

Fifty semi-structured interviews with key informants using purposive sampling technique to determine network size and seed selection in the first phase led to recruitment of 100 MSM. Focus group discussion (FGD) of 50 MSM comprising 5 per region was undertaken to map out MSM hot spots in each region using an ethnographic mapping approach. Respondent Driven Sampling was used to recruit participants in the Phase 2 with a target sample size of 500 MSM per region.

RESULTS: The overall size estimate of MSM in Ghana is 54,759 with plausibility bounds of 18 126 - 79 313. This represents 0.72% (0.24% to 1.04%) of adult male population aged 18 years and above in Ghana. Region specific estimates range from a size estimate of 4,018 MSM (0.62% of adult male population) in Volta to 11,435 MSM (0.78% of adult male population) of MSM in the Ashanti region of Ghana.

CONCLUSIONS: Using multiple methods provide a better estimate for MSM population size especially when they are hidden. It has policy change implications to reach the MSM population nationwide with needed prevention, treatment, care and support services.

PEC0470

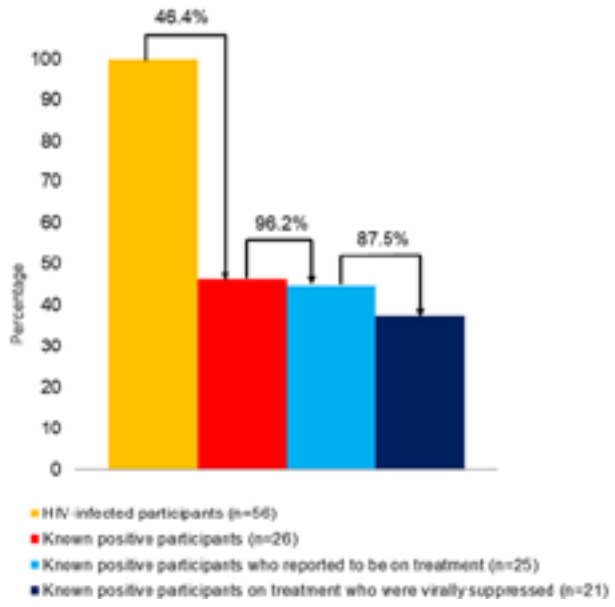
ASSESSING THE HIV CARE CASCADE AMONG BRIDGING POPULATIONS, INCLUDING GAY AND BISEXUAL MEN AND TRANSGENDER WOMEN AND THEIR SEXUAL PARTNERS IN COASTAL KENYA

M. Dijkstra[1,2], J. Mwambi[3], A. Omare[3], K. Ramko[3], C. Karani[3], M. Shally[3], K. Mohamed[3], G. Makau[3,4], J. Esbjörnsson[4,5], M. Schim van der Loef[2,1], T. Oduor[3], E. van der Elst[3], E. Sanders[3,5]
[1]Amsterdam UMC, Academic Medical Center, Department of Infectious Diseases, Amsterdam, Netherlands, [2]Public Health Service Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [3]Kenya Medical Research Institute, Wellcome Trust Research Programme, Kilifi, Kenya, [4]Lund University, Lund, Sweden, [5]The University of Oxford, Oxford, United Kingdom

BACKGROUND: Data on the HIV care cascade among bridging populations, including gay and bisexual men and transgender women (GBT) and their sexual partners in sub-Saharan Africa, are scarce. We assessed care cascade indicators among newly diagnosed and previously known to be HIV positive GBT in coastal Kenya.

METHODS: From April through August 2019, participants were recruited for HIV testing by lay GBT peer mobilisers, clinic staff, and through assisted partner notification services (APNS). We compared characteristics of newly diagnosed and known positive participants using chi-square or Wilcoxon signed-rank tests. Viral load was determined with GeneXpert for 53/56 participants with sufficient blood plasma sample volume.

RESULTS: HIV prevalence was 11.2% (56/500). Out of the 56 HIV-infected participants, 30 (53.6%) were newly diagnosed, and 26 (46.4%) were previously known to be HIV positive (Figure).



[Figure. The HIV testing and care cascade among gay and bisexual men and transgender women and their sexual partners in coastal Kenya]

Of these, 46 (82.1%) were male, 7 (12.5%) female, and 3 (5.4%) transgender women. Compared with known positive participants, a larger proportion of newly diagnosed participants was mobilised (70.0% vs. 26.9%, p=0.001), identified as male (93.3% vs. 69.2%, p=0.045), and reported to be bisexual (50.0% vs. 15.4%, p=0.019). Median viral load was 149,000 copies/ml (IQR: 63,600-391,000) among newly diagnosed bisexual men, and 63,200 copies/ml (IQR: 14,150-482,500; p=0.354) among newly diagnosed gay/homosexual men. Twenty-five (96.2%) known positive participants were on treatment, and 21 (87.5%) were virally suppressed. Median viral load was 35,600 (IQR: 17,350-121,800) copies/ml among the four unsuppressed known positive participants.

CONCLUSIONS: Peer mobilisation and APNS enabled identification of newly diagnosed participants, including mostly bisexual men with high viral loads, potentially a bridging population in coastal Kenya. Among known positive participants, care cascade indicators met the second and third 90 indicators. In order to reduce HIV incidence, HIV prevention programmes should encourage uptake of regular HIV testing, specifically among bisexual men.

PEC0471

HIV AMONG PEOPLE EXPERIENCING HOMELESSNESS IN LOS ANGELES COUNTY

K. Poortinga[1], Y. Hu[1], C. Magana[1], M. Pérez[1], A. Kim[1]
[1]Los Angeles County, Department of Public Health, Los Angeles, United States

BACKGROUND: Homelessness is a major crisis in Los Angeles County (LAC). Approximately 59,000 persons are homeless in LAC and vulnerable to health disparities, including HIV disease. Despite an increased risk, HIV among homeless in LAC has not been measured using surveillance data. We describe HIV diagnoses and care indicators among homeless persons in LAC.

METHODS: Using LAC's Enhanced HIV/AIDS Reporting System, we quantified HIV diagnoses in 2013-2018 by housing status. Housing status was: "homeless" if (1) the person's medical record or address was recorded as homeless or not housed, or (2) the address was a homeless shelter; and "non-homeless" if these criteria were not met. We examined HIV care indicators based on HIV laboratory tests: (1) linked-to-care (any test performed ≤1 month post-diagnosis), (2) retained-in-care (≥2 tests performed within 3 months within 12-months post-diagnosis), and (3) virally suppressed (VS: HIV-1 RNA<200 copies/mL within 12-months post-diagnosis). We tested for differences in demographic and behavioral characteristics in diagnoses and care indicators by housing status using bivariate analyses. Log-binomial generalized regression modeling tested for differences in care indicators by housing status.

RESULTS: Overall, 633 of 11466 (5.5%) persons diagnosed with HIV in a 6-year period were homeless, increasing from 4.6% of diagnoses in 2013 to 7.2% in 2018. Compared with non-homeless persons diagnosed with HIV in 2013-2018, homeless persons were significantly more likely to be transgender persons, African Americans, injection drug users (IDUs), and men who have sex with men who inject drugs (p<0.001). After controlling for gender, age, race/ethnicity, and mode of transmission, newly diagnosed homeless persons vs. non-homeless were as likely to link-to-care but less likely to remain retained-in-care (Adjusted Prevalence Ratio [APR] 0.88, 95% Confidence Interval [CI] 0.80-0.97) and achieve VS (APR 0.74, 95% CI 0.66-0.83). VS was lowest among homeless IDUs.

CONCLUSIONS: Increasing numbers of HIV diagnoses are among homeless in LAC. Homeless persons are as likely to access care but may require additional support to stay in care and achieve VS. Local jurisdictions should include housing status when considering HIV disparities. Further research is needed to understand the resources needed by homeless clients for successful retention in HIV care.

PEC0472

SOCIAL DETERMINANTS OF HEALTH AMONG PERSONS DIAGNOSED WITH HIV, 2017, SAN FRANCISCO, CALIFORNIA, USA

S. Pipkin[1], A. Vu[1], N. Hessol[2], L. Hsu[1]
[1]San Francisco Department of Public Health, Applied Research, Community Health Epidemiology and Surveillance Branch, San Francisco, United States, [2]University of California, Clinical Pharmacy and Medicine, San Francisco, United States

BACKGROUND: Measurements of social determinants of health (SDH) help to quantify health differences between populations or geographic areas and can provide insight for identifying populations or areas that may benefit from HIV prevention, testing, and treatment initiatives. We undertook an exploratory analysis of the SDH among people with HIV in San Francisco (SF) California to help inform program expansion.

METHODS: Using the SF HIV case surveillance registry, we identified persons 18 years and older who resided in SF at time of HIV diagnosis during 2017. Census tract level SDH data was derived from the U.S. Census Bureau American Community Survey (ACS) 2013-2017. The three SDH indicators were: federal poverty level, educational attainment, and median annual household income. Residential addresses at diagnosis were geocoded to the census tract level and assigned SDH indicator values by linking to the ACS. HIV diagnosis rates per 100,000 population were calculated by SDH indicators and demographic characteristics. The proportions of SDH indicators by transmission category were calculated.

RESULTS: Among 247 SF residents diagnosed with HIV in 2017, 207 (84%) had SDH information and were included in the analyses. The overall HIV diagnosis rate was 27.7 per 100,000; diagnosis rates were highest among people living in areas with ≥19% below poverty level (52.6/100,000), ≥18% less than high school diploma (34.7/100,000), and annual household income below $54,000 (54.0/100,000). Among men, the highest HIV diagnosis rates also occurred among people living in areas with highest poverty level (81.9/100,000), lowest education level (54.9/100,000), and lowest median household income level (85.8/100,000). By age, rates increased with increasing percent below poverty for all age groups younger than 65 years old. For racial/ethnic groups, Latinx and whites experienced higher rates with increasing poverty level and decreasing income. A greater proportion of people who injected drugs (PWID) resided in the highest poverty level areas; heterosexuals resided in the lowest education areas; and men who have sex with men (MSM) resided in the highest education and income areas.

CONCLUSIONS: Targeting neighborhoods with lower socio-economic status for HIV prevention, testing, and treatment efforts may improve HIV outcomes, especially among Latinx, whites, PWID and heterosexuals.

PEC0473

DEVELOPMENT OF A UNIQUE IDENTIFIER CODE TO IMPROVE SURVEILLANCE AND ACCESS TO SERVICES FOR KEY POPULATIONS' IN SIERRA LEONE

M. Thumath[1,2], E.J. Nyuma[3], K. Mansary[3]
[1]University of Oxford, Department of Social Policy and Social Intervention, Oxford, United Kingdom, [2]Centre for Gender and Sexual Health Equity, Providence HealthCare, Vancouver, Canada, [3]National HIV/AIDS Secretariat, Office of the President, Freetown, Sierra Leone

BACKGROUND: Sierra Leone's fragile health system was weakened by the Ebola outbreak in 2015 and a series of natural disasters including severe mudslides. Sierra Leone is classified as a mixed HIV epidemic with an estimated adult prevalence of 1.4% and 2,800 AIDS-related deaths (UNAIDS, 2017). Female Sex Workers (FSWs), Men who sex with men (MSM) and People who inject drugs (PWIDs) have higher prevalence rates (estimated 6.7%-14%). Cascade of care data disaggregated by key population is not currently available. Unique Identifier Codes (UICs) are valuable tools in helping to protect the privacy of key populations, while also assisting organizations in ensuring program quality and retention along the HIV care and treatment cascade.

DESCRIPTION: Working in partnership with the National HIV/AIDS Secretariat, we developed a simple and cost effective alpha numeric UIC system to improve coverage of services to key populations (KPs) most affected by HIV in Sierra Leone. In October 2018 we conducted 6 site visits, 40 key informant interviews and 3 focus groups and 3 pilots with 66 beneficiaries to assess the acceptability and feasibility of the UIC.

LESSONS LEARNED: From Nov 1, 2018 to Jan 1, 2020 over 102,397 unique clients have been registered in the new UIC database with participation from 100% (n6) of funded organizations serving key populations in Sierra Leone and no recorded client refusals. The duplication rate is currently estimated at 2.36% (n2,418). A robust pilot phase with ongoing monitoring for feasibility and patient preference is needed to eliminate non-stable characters in the code such as district where client was reached or highly confidential questions like last name. Similarly, extensive training and ongoing clinical supervision is needed to minimize duplication and ensure the code is consistently applied by all organizations.

CONCLUSIONS/NEXT STEPS A functioning UIC system, in conjunction with the countries ongoing efforts to improve prevention, treatment and care for key populations, aims to decrease morbidity and mortality related to HIV in Sierra Leone. There remain important opportunities to integrate the country's monitoring and evaluation system and UIC code with a robust evaluation of the entire cascade of care for key populations in Sierra Leone.

DETERMINING THE INCIDENCE OF HIV

PEC0474

COMPARISON OF POC RTRI RESULTS WITH LABORATORY-BASED LAG AVIDITY AND VIRAL LOAD TEST RESULTS

F. Bangara[1,2], S. Gugsa[2,3], G. O'Malley[3,2], T. Dobbs[4], Y. Babaye[1,2], J. Theu[1,2], I. Namakhoma[1,2], K. Curran[4], J. Kandulu[5], B. Mvula[6], D. Payne[7], G. Bello[8,1,2]
[1]University of Washington, Lilongwe, Malawi, [2]International Training and Education Center on Health, Recency Surveillance Program, Lilongwe, Malawi, [3]University of Washington, Department of Global Health, Seattle, United States, [4]Centers for Disease Control and Prevention, Atlanta, United States, [5]Malawi Ministry of Health, Health Technical and Support Services, Lilongwe, Malawi, [6]Malawi Ministry of Health, National HIV Reference Laboratory, Lilongwe, Malawi, [7]Centers for Disease Control and Prevention, Lilongwe, Malawi, [8]Malawi Ministry of Health, Epidemiology Unit, Lilongwe, Malawi

BACKGROUND: In order to assess the feasibility of identifying newly HIV infected individuals and interrupting transmission, Malawi conducted a field test for HIV surveillance using Point-of-Care (POC) rapid tests for recent infection (RTRI). The aim was to evaluate the performance of the POC RTRI in routine HIV testing services (HTS) settings and compare with laboratory-based Limiting Antigen (LAg) Avidity Enzyme Immunoassay (EIA).

METHODS: POC RTRI tests were conducted by trained HTS providers at 12 health facilities randomly selected among recency surveillance sites in Blantyre district from June to August 2019. POC RTRI was integrated to routine HTS algorithm, using the Asante HIV-1 Rapid Recency Assay (Sedia Biosciences, Portland OR, USA). Eligible participants (≥13 years of age, no prior HIV diagnosis) and who consented to recency testing were tested with the Asante. Dried blood spot samples obtained at POC were later tested for LAg and VL at the National HIV Reference Laboratory. Asante test results were compared with laboratory-based Sedia HIV-1 LAg Avidity EIA results, with LAg optical density number ≤ 1.5 being recent. Both tests were analyzed in combination with viral load (VL) testing using a recent infection test algorithm (RITA). Individuals testing recent on either test and with unsuppressed viral load (≥1000 copies/ml) were classified as RITA recent. POC and laboratory-based results were assessed for kappa (κ) and percent agreements.

RESULTS: A total of 578 samples were tested using Asante RTRI at POC, of which 8.9 % (52/578) were recent. When the same 578 samples were subjected to Sedia LAg EIA in laboratory setting, 9.3% (54/578) were recent, representing a 92.7% agreement with a kappa of 0.56. When comparing of POC Asante RITA results and laboratory-based LAg RITA, recent HIV infection rates were 6.1% (35/578) and 5.5% (32/578), respectively, with a 95% agreement and κ=0.54.

CONCLUSIONS: POC RTRI, conducted by trained HTS providers, had moderate agreement with laboratory-based recent infection determination tests. Including viral load testing helped identify false recents. POC RTRI can be used to conduct population-level surveillance of new HIV infections and observe trends in population subgroups as percent agreement was similar across subgroups.

PEC0475

THREE HIV INCIDENCE ESTIMATION METHODS REVEAL HIGH INCIDENCE AMONG FEMALE SEX WORKERS IN JUBA AND NIMULE, SOUTH SUDAN

A.J. Hakim[1], A. Bolo[2], S. Gutreuter[1], V. Achut[3], J. Katoro[2], G. Caesar[3], R. Lako[3], A.I. Taban[4], E. Yufenyu[1], B. Parekh[1], V. Shanmugam[1], B.N. Lobojo[4], J. Wesson[5], A.G. Okiria[4]
[1]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]US Centers for Disease Control and Prevention, Juba, South Sudan, [3]South Sudan Ministry of Health, Juba, South Sudan, [4]IntraHealth, Juba, South Sudan, [5]IntraHealth, Chapel Hill, United States

BACKGROUND: Novel approaches are needed to estimate HIV incidence among key populations because of their relatively small population size. We utilized three methods to estimate HIV incidence among female sex workers (FSW) in South Sudan's capital, Juba, and Nimule, on the border with Uganda. HIV prevalence among FSW was 38.7% and 24.0% in the two cities, respectively. HIV incidence in the general population is 1.17% (95% CI: 0.65–2.16) in South Sudan and 1.37% (95% CI: 1.15–1.64) in Uganda.

METHODS: We conducted respondent-driven sampling surveys of FSW aged ≥15 years who sold sex in the last 6 months. Data collection in Juba occurred November 2015-March 2016 and in Nimule January-February 2017. HIV testing followed the national testing algorithm. Incidence was estimated using Osmond's method, testing history, and a biomarker-based method. Osmond's method considers date of first risk behavior and HIV diagnosis. The biomarker-based method used Sedia™ HIV-1 Limiting Antigen-Avidity (LAg) confirmed by an algorithm of LAg≤1.5 normalized optical density units plus viral load ≥1000 copies/mL. The mean duration of recent infection was 161 (95% CI: 148–174) and proportion false recent 0.0%.

RESULTS: We enrolled 838 FSW in Juba and 409 in Nimule. HIV incidence in Juba was estimated at 3.84% (95% CI: 3.32–4.40) with Osmond's method, at 2.47% (95% CI: 1.77–3.17) with the testing history method, and at 9.51% (95% CI: 5.50–13.36) with the LAg+VL algorithm. In Nimule, incidence was 2.25% (95% CI: 1.79–2.82) with Osmond's method, 1.09% (95% CI: 0.51–1.67) with the testing history method, and 2.29% (95% CI: 0.00–4.85) with the LAg+VL algorithm.

CONCLUSIONS: All three estimation methods showed high HIV incidence among FSW in Juba and Nimule compared to the general population in South Sudan and Uganda. These results indicate an urgent need for HIV prevention services for FSW in Juba and Nimule. Of the three methods, LAg+VL is least prone to response bias but is sensitive to assumptions about the MDRI and PFR. LAg+VL produced the highest estimates and its estimates were closer to those from Osmond's method in Nimule than in Juba.

PEC0476

ESTIMATION OF HIV INCIDENCE AMONG MEN WHO HAVE SEX WITH MEN USING ANONYMOUS BIOMETRIC UNIQUE IDENTIFIER SYSTEM IN YANGON, MYANMAR

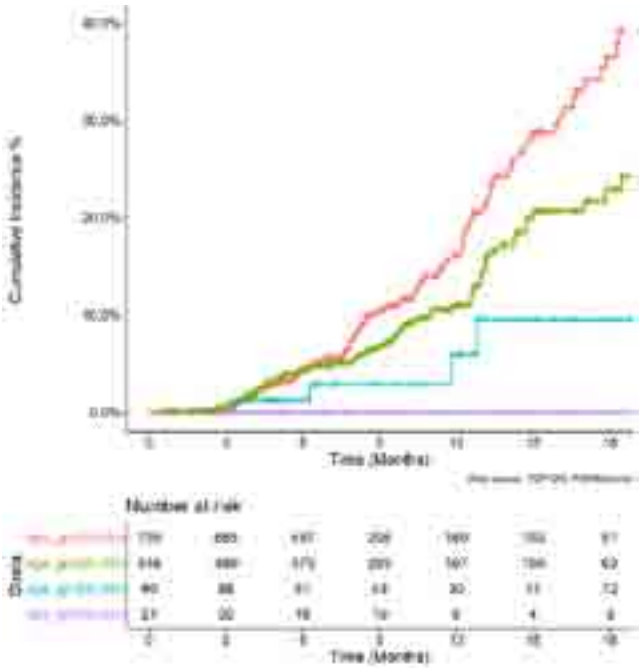
S.T. Thein[1]
[1]Population Services International, Strategic Information Division, Yangon, Myanmar

BACKGROUND: Myanmar is one of the countries with concentrated HIV epidemics among key populations, including men who have sex with men (MSM). Population Services International Myanmar (PSI/Myanmar) runs a Targeted Outreach Program (TOP) drop in center (DiC) for MSM in Yangon. At TOP DiC, MSM can choose to get tested

for HIV with appropriate counseling and linkage to care services. TOP DiC started using a fully anonymous biometric unique identifier system with binocular iris scanners in 2016. This enabled tracking the clients over time without compromising their privacy and anonymity.

METHODS: From HIV testing records in Yangon TOP DiC, the data of MSM who had initially tested negative and then underwent repeated HIV tests from 2016 to 2018 were extracted. From this data, cumulative incidence of new HIV infections was estimated using Kaplan-Meier method.

RESULTS: A total of 1364 MSM had repeated HIV tests during the period and 174 (12.8%) had become HIV-positive within a median time of 297 days [Interquartile range (IQR): 224 days]. The incidence rate was 16.5 per 100 person-years (PY). Estimated cumulative incidence of new HIV infections at 18 months of follow-up was 28.1% [95% confidence interval (CI): 23.4 - 32.5%]. The incidence rates were higher among younger MSM (19.7/100PY in 15-24 years, 15.0/100PY in 25-34 years, 6.8/100PY in 35-44 years). Estimated cumulative incidence at 18 months were 36.5% (95%CI: 28.8-43.4%), 22.9% (95%CI: 16.6-28.8%), and 9.5% (95%CI: 0.0-18.7%) respectively.



[Figure. Estimation of new HIV infections among MSM, Yangon, Myanmar]

CONCLUSIONS: Estimation of new HIV infections among MSM was made possible by the use of biometric unique identifier method, while maintaining client anonymity and confidentiality. This new evidence on disproportionate number of estimated new HIV infections among younger MSM in Yangon has led to successful advocacy of Pre-Exposure Prophylaxis (PrEP) implementation for MSM in Myanmar.

PEC0477

PERIODS OF EXTREME RISK AMONG WOMEN WHO SELL SEX IN ZIMBABWE: ESTIMATING PATTERNS OF HIV INCIDENCE FROM CHANGES IN HIV PREVALENCE OVER TIME

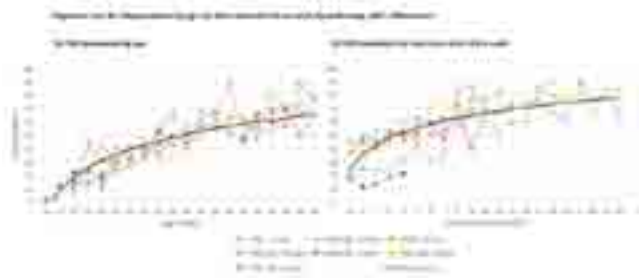
M. de Wit[1], S. Chabata[2], S. Magutshwa[2], S. Musemburi[2], J. Dirawo[2], S. Ali[1], B. Rice[1], L. Platt[1], L. Bansi-Matharu[3], T. Mharadze[2], T. Chiyaka[2], P. Mushati[2], O. Mugurungi[4], A. Mpofu[5], A. Phillips[3], F. Cowan[2,6], J. Hargreaves[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]CeSHHAR, Harare, Zimbabwe, [3]University College London, London, United Kingdom, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]National AIDS Council of Zimbabwe, Harare, Zimbabwe, [6]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

BACKGROUND: HIV risk is high among women who sell sex in Africa. However, very little is known about patterns of HIV incidence because cohort studies are complex to undertake with these mobile, marginalised populations. We explored HIV prevalence by age and by years since start of sex work to estimate HIV incidence among women who sell sex in Zimbabwe.

METHODS: We pooled data from respondent-driven sampling (RDS) surveys covering 23 locations across Zimbabwe, conducted between 2011 and 2017. Each survey recruited 6-10 seeds who distributed two coupons for onward recruitment. RDS diagnostics revealed little evidence of biased recruitment. We plotted HIV prevalence by age and self-reported years since start of sex work. We fitted a logarithmic curve to the pooled data and estimated annual HIV incidence as the average prevalence increase / 1– prevalence at each year: I(t)=(P(t+1)-P(t))/(1-P(t)).

RESULTS: HIV prevalence across all surveys (n=11,711) was 52.9%. HIV prevalence rose from 16.8% among 16-19 year olds to 69.9% among 35-39 year olds. HIV prevalence rose from 39.5% for those in sex work for <2 years, to 73.6% among those in sex work for 16-25 years. We estimated HIV incidence among sex workers as 5.9/100 person-years at risk (pyar) based on prevalence increases by age between 16-35 years. Among 16-19 year olds, incidence was 10.8/100 pyar. Based on prevalence increases by years since start of sex work, we estimated an overall incidence of 12.2/100 pyar during the first 2 years of sex work and 6.0/100 pyar over the first 20 years.



[Figures 1a and 1b: HIV prevalence by age and time since start of sex work, by each study, with a fitted curve]

CONCLUSIONS: Despite limitations, our data suggest a very high incidence of HIV among women selling sex in Zimbabwe, especially among the young and those in early sex work. This indicates there is an important need to engage young people and those in early sex work in services providing targeted interventions to reduce HIV incidence.

NOVEL METHODS/ALGORITHMS FOR DETECTING ACUTE AND RECENT HIV INFECTIONS

PEC0478

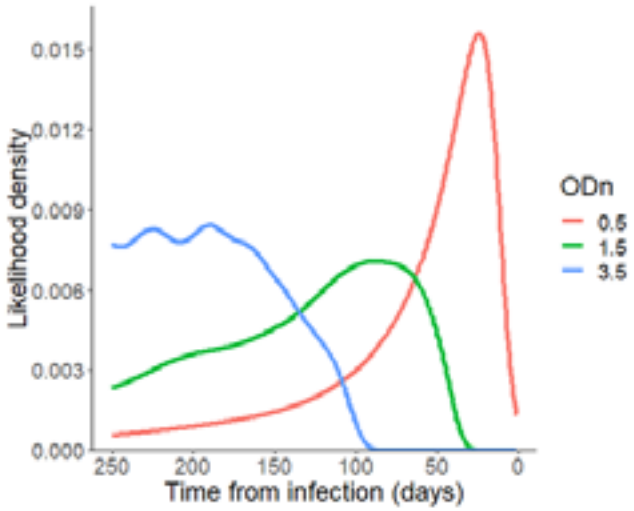
QUANTITATIVE INTERPRETATION OF SEDIA LIMITING ANTIGEN AVIDITY ASSAY FOR HIV RECENCY AT DIAGNOSIS

J.B. Sempa[1], A. Welte[1]
[1]Stellenbosch University, DST-NRF Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), Stellenbosch, South Africa

BACKGROUND: Laboratory based testing for recent HIV infection has become common to estimate HIV incidence from cross-sectional surveys. Individual-level uses are less clear, but numerous studies and pilots of diagnostic services have been returning results of recency tests to individuals. There is considerable interest in using such information to support post-test counselling, disclosure decisions, and contact tracing. The formal information content of individual recency test results, as pertaining to estimation of timing of infection, is disputed.

METHODS: We calibrated a simplistic 'anti-HIV antibody avidity' biomarker progression model (exponential approach to subject-specific asymptote) for the Sedia LAg avidity Elisa assay, to a previously described rich data set from the CEPHIA collaboration. This effectively provides an approximate likelihood function describing the distribution of assay results as a function of time since seroconversion. We considered possible assay values obtained at a first HIV positive test, assuming a uniform prior on seroconversion time since the last negative test, and calculated the infection time posterior.

RESULTS: The informativeness of the Lag results varies significantly depending on the seroconversion interval size and LAg ODn. Figure 1 shows the infection time posteriors for ODn values 0.5, 1.5, and 3.5, obtained on a first positive test performed 250 days after a last negative. Our analysis can vary all parameters to demonstrate diverse scenarios.



[Figure 1. Likelihood density of a specific normalized Optical Density (ODn), using LAg-Sedia assay, after an HIV+ test vs time from infection. The red, green and blue lines are the likelihood density curves for a subject with an ODn of 0.5, 1.5 and 3.5 respectively. Given 3 subjects with 250 days between last negative and first positive HIV results, a subject with ODn = 0.5 has a high likelihood of having been infected 24 days prior to the first HIV positive test, while ODn = 1.5 would be 89 days. For ODn = 3.5, the likelihood of being infected was highest at 190 days prior to their first HIV positive test]

CONCLUSIONS: Infection time estimates for frequent testers cannot be substantially improved with additional recency testing, but for infrequent testers, it is clear that these estimates are substantially improved through the use of quantitative recency testing, rather than just relying on testing history. Such timing information would be expected to strengthen psychosocial aspects of post-diagnosis counselling and management as have already been identified as being of interest, and it is also relevant to studies of early post-infection biology.

PEC0479

RECENTLY ACQUIRED HIV INFECTIONS AND ASSOCIATED FACTORS AMONG MEN WHO HAVE SEX WITH MEN DIAGNOSED AT DUTCH SEXUAL HEALTH CENTRES

I. Slurink[1], F. van Aar[1], S. Parkkali[1], M. Knol[2], T. Heijman[3], H. Götz[4], K. Kampman[5], Y. van Weert[2], B. van Benthem[1], T. van de Laar[6], E. Op de Coul[1], for the RITA surveillance network of sexual health centres
[1]National Institute for Public Health and the Environment, Sexually Transmitted Infections (STI) Department of the Centre for Infectious Disease Control, Bilthoven, Netherlands, [2]National Institute for Public Health and the Environment, Centre for Infectious Disease Control, Bilthoven, Netherlands, [3]Public Health Service Amsterdam, Amsterdam, Netherlands, [4]Public Health Service Rotterdam-Rijnmond, Rotterdam, Netherlands, [5]Public Health Service Twente, Enschede, Netherlands, [6]Sanquin Blood Supply, Virus Diagnostic Services, Amsterdam, Netherlands

BACKGROUND: Recent Infection Testing Algorithm (RITA) surveillance was implemented at Dutch sexual health centres (SHC) in 2014-2017 to support prevention strategies. We explored recent HIV infections (RHI) and associated factors among men who have sex with men (MSM) attending SHC, by comparing two explanatory models.

METHODS: Samples from MSM newly diagnosed with HIV were tested with an avidity assay. Avidity Index (AI) values were AI≤0.75 for RHI (acquired ≤6 months), AI between 0.76-0.84 for indeterminate, and AI≥0.85 for established infection (acquired >6 months). Indeterminate results and AI≥0.85 were reclassified as RHI if an HIV negative test result was registered within 6 months prior to diagnosis. Multivariable multinomial logistic regression was used to analyse risk factors for RHI with
1) established HIV infection and
2) HIV-negative test result as reference group.

RESULTS: In 2014-2017, 128,635 consultations were registered. In total, 1,057 MSM were newly HIV diagnosed (0.8%). Coverage of RITA-testing was 59% (622/1,057), of which 207 (33%) were classified as RHI by avidity and 354 (57%) as established infection. Based on an HIV negative test result in past 6 months, 61 MSM with AI≥0.85 and 26 with indeterminate result were recoded as RHI, and 102 additional RHI were identified, resulting in 54% MSM with a RHI (396/724). In both models, RHI was associated with having an STI in the prior year, multiple sex partners, and no condom use with last sex contact. Additionally, relative to HIV-negative reference group, RHI was associated with low/medium education, non-Western origin, and having a non-Western partner. In contrast, relative to established HIV infection reference, RHI was associated with being of Western origin.

CONCLUSIONS: Percentage of RHI was substantial among MSM attending SHC, indicating ongoing HIV transmission. Differentiation by reference group in explanatory models for RHI is important, as inverse associated factors ((non-)Western origin) were identified. Likely, associations relative to the HIV negative reference group fol-

low those of acquiring HIV infection in general, whereas the comparison with established HIV infection reference rather reflects the testing behaviour of subgroups of MSM. Increased (repeated) HIV testing among MSM at risk should be strongly encouraged for early diagnosis of HIV.

PEC0480

CAN ROUTINE DIAGNOSTIC TEST DISCRIMINATE BETWEEN RECENT AND LONG STANDING HIV INFECTIONS?

P. Patel[1], J. Hall[2], A. Khawar[2], N. Kwame[2], K. Moore[2], I. Scarlett[2], V. Zianta[2], V. Delpech[2], A. Aghaizu[2], D. Bradshaw[2], G. Murphy[1]
[1]Public Health England, National Infection Service, London, United Kingdom, [2]Public Health England, London, United Kingdom

BACKGROUND: Application of high dynamic range immunoassay platforms may transform the ability to identify recent HIV infection in those receiving HIV diagnoses in clinical settings. Interpreting clinical diagnostic test data for evidence of recent HIV infection is not new (seroconversion in paired samples, HIV RNA or p24 Ag positive specimens in absence of anti-HIV) but applying signal strength to infer recency by comparison to results obtained in bespoke HIV recency assays is a relatively new development.

METHODS: Our laboratory receives an aliquot from about 50% of all new HIV diagnoses in England and Wales annually for HIV incidence testing using the Sedia Limiting Antigen assay. Very little data accompanies the initial specimen with linking of patients test results and demographic data is performed later. However, many specimens come with diagnostic test result data. This pilot study used diagnostic Abbott Architect OD/CO values to differentiate recent or long-standing infections using the Sedia LAg assay as the gold standard but can be extended to other assays.

RESULTS: Of the 113 samples, 53were classified long-standing infections (>1.5 ODn) and 60 recent infections (ODn<1.5) by Sedia LAg. Sedia and Architect reactivities were compared by regression analysis. With Architect OD/CO value of 200, 78% (47/60) were classified as recent infection by Sedia, while 17% (10/60) gave Architect OD/CO value of between 200-300. 3 recent infection by Sedia gave OD/CO of between 300-400.Of the long-standing infections by Sedia assay, 83% (44/53) gave OD/CO of >300 in Architect assay, while 7% (4/53) gave architect S/CO of 200-300 and 9% (5/53) gave value under 200.

CONCLUSIONS: The use of serological diagnostic assays to distinguish recent from long-standing infections enables quicker diagnosis and patient management as the need for additional testing using bespoke assays is reduced. The overall correlation between the two assays was disappointing (r2 = 0.60), due to discrepancy in the range of Architect 200-400 OD/CO. However, results below or above this range are strongly indicative of recent or longstanding infection, respectively, minimising the need for additional testing. This work lays a foundation for enhanced analysis of test results to support quicker identification of recent HIV infections.

MONITORING ACUTE HIV INFECTIONS

BARRIERS TO PREP USE AMONG PEOPLE WHO RECENTLY ACQUIRED HIV IN ENGLAND DURING 2018-2019

C. O'Halloran[1], J. Saunders[1], D. Ogaz[1], Q. Enayat[1], A. Brown[1], A. Aghaizu[1], V. Delpech[1]
[1]Public Health England, National Infection Service, London, United Kingdom

BACKGROUND: HIV transmissions are declining in the UK. Using enhanced surveillance of people diagnosed with recently acquired HIV (Surveillance of HIV Acquired Recently: Enhanced, 'SHARE'), we aimed to better understand circumstances leading to HIV acquisition and barriers to HIV prevention in an era of rapid PrEP scale-up.

METHODS: Through record linkage, we identified individuals newly diagnosed with HIV who had a documented negative test in the last year within the same clinic, as well as those with an avidity test at diagnosis indicating recent infection through the recent infection testing algorithm ('RITA recents'). We invited the treating clinicians and patients to complete a questionnaire.

RESULTS: 383 people with recent HIV infection were identified during 2018 and 2019, with 97% identified through documented negative tests in the year preceding diagnosis. Most (79%) were gay and bisexual men (GBM). Of 301 GBM, 43% were aged 25-34 years, 69% white ethnicity, 58% were UK-born, 20% born in Europe outside UK and 7% in Latin America & Caribbean; 53% had a documented anogenital bacterial STI within the same clinic in the last year. Of the 39 heterosexuals, 31% were aged 25-34, 46% were white and 39% black ethnicity; 54 % were UK-born and 21% born in Africa and 28% had a documented bacterial STI within the same clinic in the last year. Questionnaire response rate was 64% (232/383 clinician questionnaires and 43/383 patient questionnaires). Of respondents, 71% (134/190) of GBM had never been on PrEP: of these 41% (55/134) reported the main reason for not being on PrEP as never been offered or unaware of PrEP, 28% (38/134) did not feel at risk, and 13%, (18/134) had declined PrEP. None of the 16 heterosexual respondents had a history of PrEP use: 71% (10) were unaware of PrEP or had not been offered; 29% (4) did not feel at risk.

CONCLUSIONS: As England moves towards HIV elimination, increasing awareness of PrEP among both GBM and heterosexuals and comprehensive assessment of HIV risk and eligibility for PrEP is critical to preventing new HIV transmissions.

PEC0482

ACUTE HIV AT THE TIME OF INITIATION OF PRE OR POST EXPOSURE PROPHYLAXIS: IMPACT ON DRUG-RESISTANCE AND CLINICAL OUTCOMES

K. Johnson[1,2], M. Chen[2], B. Kohn[2], D. Sachdev[1,2], O. Bacon[1,2], S. Lee[1], S. Cohen[1,2]
[1]University of California, San Francisco, United States, [2]San Francisco Department of Public Health, Population Health Division, San Francisco, United States

BACKGROUND: Initiating 2-drug Pre/Post-Exposure Prophylaxis (PrEP or PEP) in the setting of undiagnosed acute HIV (AHI) could lead to anti-retroviral resistance.

METHODS: In our San Francisco City Clinic PrEP/PEP program, patients are tested for HIV using a point-of-care antibody test. If negative, patients are started on prophylaxis and screened for AHI using

pooled HIV RNA (5-10 days turn-around). We used 2-drug PEP until 05/2016. We identified patients who had AHI on the day of PrEP/PEP start, then used our clinical record and surveillance data to describe HIV resistance mutations and clinical outcomes. Study dates were 2014-2018 and 2011-2018 respectively for PrEP and PEP patients.

RESULTS: Of 1,458 PrEP and 2,242 PEP starts, there were 7 cases of AHI among PrEP users (0.50%) and 6 among PEP users (0.30%). All were men who have sex with men (median age 29).

Three patients (23%) were found to have an M184 mutation on initiation of HIV care. All three had genotyping performed on stored serum available from the date of their PrEP/PEP initiation. The stored samples demonstrated wild-type virus prior to PEP/PrEP start, indicating that the M184 mutation developed within 8-12 days of exposure. All 3 patients achieved viral suppression and were most recently on 2-3 class HIV treatment regimens.

Median times for linkage to HIV care, initiation of HIV treatment, and viral suppression in our case series were 7, 15, and 43 days respectively. Details of cases who received two-drug therapy with tenofovir/emtricitabine and had available genotypes are shown (Table 1).

Age (yrs)	Year of AHI diagnosis	HIV viral load (copies/ml)	PrEP/PEP	Genotype data	Time to first care (days)	Time to anti-retrovirals (days)	Time to viral suppression (days)
40	2018	4,194	PrEP	No M184 or K65R mutation	7	7	23
27	2013	668	PrEP	Acquired M184M/I after 8 days on PrEP	7	12	43
29	2018	687	PrEP	No M184 or K65R mutation	4	4	17
32	2018	Unavailable (pool testing not done)	PrEP	No M184 or K65R mutation	3	7	115
26	2018	2,607,865	PrEP	No M184 or K65R mutation	4	4	43
33	2018	661,296	PrEP	No M184 or K65R mutation	5	Unavailable	Unavailable
25	2013	3115	PEP – Tenofovir + Emtricitabine	Acquired M184I after 12 days on PEP	17	131	182
25	2012	113,240	PEP – Tenofovir + Emtricitabine	Acquired M184MIVafter 8 days	8	49	112
34	2012	174,454	PEP – Tenofovir + Emtricitabine	No M184 or K65R mutation	5	15	36

[Table]

CONCLUSIONS: Although rare, AHI in the setting of 2-drug PrEP/PEP initiation can result in M184 mutation within days of exposure. Even with M184, persons with AHI achieve viral suppression quickly when rapidly linked to care. It is unknown how clinical outcomes would change if AHI had remained undiagnosed, underscoring the importance of rapid/accurate diagnosis.

PEC0483

THE UCSF ACUTE HIV COHORT: HIGH VIROLOGIC SUPPRESSION AND LONG-TERM RETENTION RATES IN A CONTEMPORARY SAN FRANCISCO BAY AREA COHORT OF ACUTE HIV-INFECTED INDIVIDUALS RECEIVING IMMEDIATE ART AT DIAGNOSIS

S. Lee[1], T. Henrich[1], M. Gandhi[1], S. Coffey[1], H. Hartig[1], R. Hoh[1], M. Peluso[1], P. Crouch[1], H. Scott[2], S. Cohen[2], D. Sachdev[2], O. Bacon[2], M. Busch[3], C. Pilcher[1], S. Buchbinder[2], D. Havlir[1], S. Deeks[1]

[1]University of California, Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, San Francisco, United States, [3]Vitalant, San Francisco, United States

BACKGROUND: Differences in host immune response by timing of ART initiation may affect the effectiveness of future HIV eradication strategies. Individuals treated during acute HIV have aborted and/or delayed immune responses due to early ART initiation, rapid suppression of virus, and reduced time to develop antigen-specific host immunity. Predisposing psychosocial conditions leading to acute HIV acquisition may also create challenges in accessing clinical care and medications. We sought to establish a San Francisco Bay Area-based cohort of acute HIV-treated individuals eligible for future HIV cure studies.

METHODS: Leveraging the San Francisco Getting to Zero campaign, from 2015-2019 we enrolled HIV-infected individuals (<100 days from estimated date of infection), provided immediate ART (tenofovir/emtricitabine +dolutegravir), linkage to care, and long-term longitudinal follow-up. Participants were referred from Department of Public Health (DPH), community-based organization (CBO), and private health clinic/hospital (PHC) HIV testing sites.

RESULTS: A total of 60 (65% of those screened) were eligible for study, with 43% participants referred from SFDPH, 40% from CBOs, and 17% from PHCs. The proportions of Fiebig I, II, III, IV, V stage disease were 17%, 12%, 7%, 12%, and 53%. The median age was 30; 100% male (98% men-who-have-sex-with-men, 2% heterosexual); 15% African-American; 30% Latino; 20% Asian/Pacific Islander; 21% Caucasian; 3% unstably housed; 33% mental health illness; 13% substance use disorder (primarily alcohol and methamphetamine). Median CD4 count was 505 cells/mm3 and plasma HIV RNA was 5.0 log10copies/mL at diagnosis. The false negative/indeterminate rate of initial Ag/Ab (Architect) and differentiation (Geenius) antibody testing was 27% and 28%, respectively. Six individuals reported taking PrEP at the time of HIV diagnosis. Genotype data (N=50 participants) demonstrated 76% wild-type, 8% possible acquired M184/PrEP, and 16% presumed transmitted resistance (Monogram). The virologic suppression rate was 82% among N=54 participants retained in study by week 24; their current median follow-up is 2.8 (IQR:1.9-3.4) years. There were no differences in retention rates by unstable housing, mental health illness, or substance use disorder in this small sample.

CONCLUSIONS: Early development of a public health/research relationship allowed identification, treatment, and high virologic suppression and retention of acute HIV-infected patients eligible to participate in future HIV interventional cure studies.

SELF-REPORTED ANTIRETROVIRAL THERAPY STATUS VERSUS DETECTABLE BLOOD LEVEL (NIGERIA 2018)

I. Jahun[1], A. Ehoche[2], M. Bronson[3], A. Yakubu[4], I. Dalhatu[5], M. Alagi[5], A. Gambo[2], C. Nzelu[6], J. Tapdiyel[7], O. Bassey[7], H. Patel[8], M. Charurat[9], M. Mahesh[10]

[1]CDC, Epidemiology, Strategic Information and Health System Strengthening, Abuja, Nigeria, [2]University of Maryland Baltimore/Maryland Global Initiative, Epidemiology, Abuja, Nigeria, [3]CDC, Epidemiology and Surveillance Branch, Atlanta, United States, [4]CDC, Science, Abuja, Nigeria, [5]CDC, Epidemiology and Strategic Information, Abuja, Nigeria, [6]Nigeria Federal Ministry of Health, Abuja Nigeria, HIV Division, Strategic Information, Abuja, Nigeria, [7]CDC, Laboratory Branch, Abuja, Nigeria, [8]CDC, International Laboratory Branch, Atlanta, United States, [9]University of Maryland, Epidemiology, Maryland, United States, [10]CDC, Country Director, Abuja, Nigeria

BACKGROUND: The Nigeria HIV/AIDS Indicator and Impact Survey (NAIIS) was conducted in 2018 to estimate the country's progress toward the UNAIDS targets for epidemic control (95% of people living with HIV [PLHIV] know their status; of these, 95% are receiving antiretroviral therapy; and of these, 95% have viral load suppression). We assessed whether self-reported ART status matched detectable blood levels of antiretroviral drugs (ARV).

METHODS: The NAIIS was conducted in all 36 states of Nigeria and the capital city, Abuja. Participants consented to an interview and HIV-related blood tests. In addition to basic socio-demographic questions, participants were asked if they knew their HIV status and if they were on antiretroviral therapy (ART). The survey involved interviewing and HIV testing in the household using the national rapid testing algorithm (Determine HIV-1/2 assay – screening; Uni-Gold – confirmatory) with immediate return of results. HIV positive samples were tested for the presence of antiretroviral (ARV) drugs through collection of dried blood spots using liquid chromatography tandem mass spectrometry. Nucleoside and non-nucleoside transcriptase inhibitor-based ARVs used as first line drugs and protease inhibitors used as second line were tested.

RESULTS: A total of 2,739 PLHIV were identified in NAIIS of which 2,654 (96.9%) provided information about their HIV status and had their blood tested for ARVs. Seventy one percent [95% confidence intervals (CI) 68.7% – 73.3%] reported not knowing their HIV-positive status (newly identified PLHIV) and 29.0% [26.7% - 31.3%] reported knowing their HIV-positive status (known PLHIV). Of the known PLHIV, 89.8% [87.1% - 92.4%] reported being on ART and 10.2% [7.6% - 12.9%] reported not being on ART. Antiretroviral were detected among 24% of newly identified PLHIV [21.8 - 27.0] and 42% of the known PLHIV who reported not being on ART [27.8% - 56.2%].

CONCLUSIONS: Almost one quarter of newly identified PLHIV were already on ARVs and likely knew their HIV status. Use of self-reported ARV and HIV status with laboratory ARV results can help with monitoring national ARV coverage as measured in population based surveys.

PEC0485

WHICH GAPS ARE LEFT TO CLOSE FOR WHOM? RESULTS OF HIV POPULATION SURVEYS IN HOMA BAY, KENYA, 2012 AND 2018

N. Conan[1], R. Nesbitt[1], M. Badawi[1], M. Kimani[2], K. Osuri[3], P. Bondo[3], S. Wanjala[4], E. Szumilin[5], M.L. Chihana[1], H. Huerga[1]

[1]Epicentre, Paris, France, [2]Ministry of Health, National Aids and STI Control Programme, Nairobi, Kenya, [3]Ministry of Health, Homa Bay, Kenya, [4]Médecins Sans Frontières, Nairobi, Kenya, [5]Médecins Sans Frontières, France, France

BACKGROUND: HIV is hyper-endemic in Homa Bay, Kenya. Following a first population survey in Ndhiwa sub-county in 2012, Médecins sans Frontières supported implementation of strategies to improve the HIV cascade of care. Moreover, universal test and treat was implemented in Kenya starting 2016. A second survey was carried out in 2018 to identify progress and remaining gaps.

METHODS: Cross-sectional population-based surveys using cluster sampling and geospatial random selection were conducted in Ndhiwa Sub-County in Homa Bay in 2012 and 2018. Consenting participants aged 15-59 years were interviewed and tested for HIV at home. Viral load and LAg-Avidity EIA assay were done for HIV positive cases. Viral load suppression (VLS) was defined as a HIV-RNA viral load below 1,000 copies/ml.

RESULTS: Overall, 6,076 individuals were included in the 2012 survey and 6,029 in 2018. There was substantial improvement in all cascade of care indicators: awareness of HIV status increased from 59.6% (57.1-62.1) to 93.4% (91.7-94.8) in 2018, p<0.001, ART coverage among the ones who know their status improved from 68.2% (65.0-71.2) to 96.9% (95.6-97.8) p<0.001 and VLS among participants under treatment increased from 82.5% (79.2-85.4) to 95.2% (93.6-96.5), p<0.001. This is consistent with observed trends in HIV incidence (1.9% (1.1-2.7) vs. 0.7% (0.2-1.2). NS). Prevalence decreased from 24% (95%CI: 23.0-25.2) to 17% (16.0-17.9) p<0.001. Among the untested, 62.3% were men and 68.3% were less than 20 years. Women 15-19 years emerged as a priority group with low HIV status awareness (57.1% (35.9-76.0%)). While men and women showed similarly high viral suppression once on ART (92.5% (88.5- 95.2) and 96.3% (94.5- 97.5) respectively), half of unsuppressed women (50.6% (39.7- 61.5%) were unaware of their HIV status.

CONCLUSIONS: These two surveys highlight progress in HIV treatment and prevention in Homa Bay. The increase in VLS and subsequent reduction in people with potential to transmit HIV is in line with a trend in declining incidence. Young women were identified as a priority group to improve status awareness. Key challenges remain, particularly in reaching men and young adults who have never been tested for HIV. Subsequent programing should consider specificities of age and gender to close remaining gaps.

PEC0486

HIV EPIDEMIC DYNAMICS IN NIGERIA: THE NEED FOR LOCATION-SPECIFIC STRATEGIES TO END THE EPIDEMIC IN NIGERIA

O. Amanze[1], G. Ashefor[1], G. Aliyu[1], C. Nzelu[2], C. Agbakwuru[3], M. Alagi[4]
[1]National Agency for the Control of AIDS (NACA), Research, Monitoring and Evaluation, Abuja, Nigeria, [2]Federal Ministry of Health, Strategic Information, Abuja, Nigeria, [3]University of Maryland in Baltimore (UMB), Research and Surveys, Abuja, Nigeria, [4]US CDC Nigeria, Epidemiology and Surveiilance, Abuja, Nigeria

BACKGROUND: Nigeria has been known to have the second largest HIV burden in the world with an estimated 3.4 million people living with HIV, and with conflicting prevalence across the States. The country had in the past relied upon a combination of periodic epidemiological surveys and routinely collected programme data to monitor the trend of HIV in the country; but there were identified limitations with some of these approaches. Consequently, this study aimed to determine the true distribution of Human Immunodeficiency Virus (HIV) disease in Nigeria.

METHODS: In 2018, we conducted the Nigeria AIDS Indicator and Impact Survey (NAIIS), in 36 States of Nigeria plus the Federal Capital Territory (Abuja). NAIIS was a quantitative, cross-sectional, two-stage cluster survey of 88,775 randomly-selected households, sampled from among 3,551 nationally-representative enumeration areas (EAs), and included approximately 230,053 participants, ages 15-64 years and children, ages 0-14 years, from the selected households.

Data collection occurred between July to December 2018, using interviewer-administered structured questionnaire programmed on android tablets. Home-based HIV counselling and testing services were provided to the respondents.

Data was analyzed using SAS. Furthermore, Modelling (Spectrum) was used to estimate HIV burden, incidence and unmet treatment needs.

RESULTS: Of the 230,053 participants, 186,405 were adults (45% males and 55% females); and 43,648 were children (51% males and 49% females). Among the adult respondents, 42% lived in urban areas; while 58% lived in rural areas.

National HIV prevalence was 1.4% (15-49 years), with a burden of 1.9 million persons living with HIV. Seven States have prevalence of 2.0% and above; thirteen States plus the Federal Capital Territory have prevalence between 1.0% -1.9%; and sixteen States have prevalence below 1.0%.

Furthermore, 7 States contribute to 50% of the HIV burden and 13 States responsible for 60%.

Moreover, 8 States contribute more than 50% of new infections. Also, 8 States account for unmet treatment need greater than 30,000.

CONCLUSIONS: HIV epidemic dynamics varies State by State in Nigeria. Therefore, new high level location-specific strategies (focusing on the high burden States) are required to end HIV epidemic in Nigeria by year 2030.

PEC0487

CHARACTERIZING KEY POPULATIONS SERO-CONVERSION RATES: AN ASSESSMENT OF PREVENTION PROGRAMS TOWARDS REDUCING HIV AMONG KEY POPULATIONS IN KENYA

V. Amulega[1], H. Musyoki[1], P. Bhattacharjee[1], J. Kioko[1], J. Musimbi[1], W. Waruiru[2], F. Humwa[2]
[1]Ministry of Health, Division National Aids and STI Control Program, Nairobi, Kenya, [2]University of California San Francisco-Kenya, Surveillance, Nairobi, Kenya

BACKGROUND: Key populations (KP) in Kenya are people who inject drugs (PWID), men who have sex with men/male sex workers (MSM/MSW), and female sex workers (FSW). KP contribute a disproportionately high number of new HIV infections annually despite their small population size. KPs are however often difficult to reach for program service delivery due to stigma and discrimination, higher rates of gender-based violence and police harassment. For those that do access services, it is important to characterize their characteristics, risk behaviors and HIV/STI status including quantifying sero-conversion rates for effective response by programs.

METHODS: The study collected retrospective longitudinal data from 5703 eligible client files, who were accessing services at 24 KP-specific facilities prior to January 2018 regardless of HIV status. We abstracted demographic, behavioral, clinical and laboratory data for eligible KP from client files. We analyzed data from 3153 (55.3%) KPs who were negative at enrollment. Person time years were computed from day of enrollment to the program to December 2018. Sero-conversion time was taken at the midpoint time between the last negative test and the subsequent positive test. Cox regression was used to determine independent factors associated with sero-conversion.

RESULTS: FSWs, MSM/MSWs and PWIDs constituted of 52.1% 24.3% and 23.7% of the sampled respectively. Sero-conversion in person-time years was 1.3%, 2.3%, and 3.3% for FSW, MSM/MSW and PWID respectively . FSWs who had taken prep 3 times prior to enrollment were more likely to sero-convert compared to those who tool once (adjusted hazard ratio [AHR] 3.2, p=0.046). PWIDs who never had sex with another man in the past year were less likely to be associated with sero-conversion (aHR = 0.15, p = 0.001). PWIDs who had 5 sex acts (aHR=26.3, p = 0.011) and 6+ sex acts (aHR = 3.88, p = 0.046 per week) were more likely to sero-convert compared to those who had 1 or less sex act per week.

CONCLUSIONS: Sero-conversion rates seem to be highest among PWIDs. Higher frequency of weekly sex acts were associated with sero-conversion among PWIDs. FSWs who had taken prep 3 time were also likely to sero-convert while in KP Programs.

BACKGROUND: Undisclosed antiretroviral drug (ARV) use among blood donors who tested HIV antibody (Ab) positive but RNA negative (Ab+/RNA-), so-called False Elite Controllers (EC), was previously described by our group. Such undisclosed ARV use represents a risk to blood safety in a country with a growing treated HIV population. We assessed the prevalence of and associations with undisclosed ARV use among HIV-positive donors in South Africa.

METHODS: South African blood donors are screened by self-administered questionnaire, a semi-structured interview and individual donation laboratory testing. HIV-positive donations were classified as acute (Ab-/RNA+), prevalent (Ab+/RNA+), and potential EC (Ab+/RNA-) cases. Prevalent cases were further classified as recent (Ab+/RNA+; Limiting Antigen Avidity [LAg] ODn<1.5) or longstanding (Ab+/RNA+; LAg ODn>1.5). Stored plasma samples from these donations were tested for ARV using qualitative liquid chromatography-tandem mass spectrometry.

RESULTS: Of the 1671 HIV-positive donations detected in 2017, 1250 had plasma samples available for ARV testing. Overall prevalence of undisclosed ARV use was 9.8% (n=122) but differed by HIV classification with 85% (68/80) of potential EC donors compared to 4.9% (54/1108) of prevalent cases (p<0.0001). Among prevalent cases, 5.3% of the recent and 4.9% of the longstanding cases tested ARV positive (p=0.376). None of 62 acute cases tested ARV positive. Undisclosed ARV use was more frequent among donors aged >40 (16.9%) versus <21 (6.8%) years (p<0.0001) and first-time (14.1%) than repeat (2.5%) donors (p<0.0001). Non-disclosure was highest in the KwaZulu Natal province (15.0%). Multivariable logistic regression found ARV positivity to be independently associated with first-time (versus repeat) donor status (aOR = 4.11, 95% CI 2.48 -6.79), age >40 years versus <21 years (aOR=4.02, 95% CI 2.11-7.63) and KwaZulu Natal versus Gauteng province (aOR=2.24; 95% CI 21.34-3.75).

CONCLUSIONS: The 9.3% prevalence of undisclosed ARV use among HIV-positive South African donors is alarming and likely represents a hitherto unrecognized adverse effect of national ARV rollout. Early ARV initiation or infection while on PrEP could lead to low Ab and absent RNA levels, resulting in failure to detect HIV-infected donations and possible transfusion-transmission of HIV. Donor motivations for blood donation with undisclosed ARV use needs further investigation to identify approaches to mitigate this problem.

PEC0489

DISPARITIES IN UPTAKE OF INTEGRASE INHIBITOR-CONTAINING REGIMEN IN THE MODERN HIV TREATMENT ERA, SAN FRANCISCO, USA

L. Hsu[1], N. Hessol[2], S. Schwarcz[1], S. Scheer[1], M. Spinelli[2]
[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of California, San Francisco, United States

BACKGROUND: The introduction of integrase inhibitors (INSTIs) for antiretroviral therapy (ART) has revolutionized HIV care management due to their favorable side effect profile and high potency. Vulnerable populations, including homeless people and people who inject drugs (PWID), could benefit from INSTI ART. We sought to evaluate populations and factors associated with receiving INSTIs using the San Francisco (SF) population-based HIV surveillance case registry.

METHODS: SF residents diagnosed with HIV and reported to the SF Department of Public Health who initiated ART during 2009-2016 were included. Data on ART were collected via chart reviews through November 2019. Time from first ART regimen to an INSTI-containing regimen was compared using Kaplan-Meier curves, with time set to zero if the first regimen included an INSTI. Persons not receiving an INSTI regimen at end of follow-up were censored. Proportional hazard analysis evaluated factors associated with receiving INSTIs, including birth sex, race/ethnicity, transmission category, age, insurance, homelessness, and viral load (time-dependent).

RESULTS: Overall (n=3255), 38% started INSTIs as a first regimen, 29% later switched to INSTIs, and 33% did not receive INSTIs. PWID and homeless people were less likely to initiate INSTIs as a first regimen (30% and 31% respectively). Among those who initiated ART in 2013-2016, 83% received INSTIs compared to 56% in 2009-2012. Median time to INSTIs was 26 months for men who have sex with men (MSM), 45 months for PWID, and 44 months for MSM-PWID (p=0.006). Median time to INSTIs was longer for homeless persons than housed (43 months vs. 30 months, p=0.047).

In multivariate analysis, PWID (Relative Hazard [RH] 0.76, 95% confidence interval [CI] 0.6-0.9), MSM-PWID (RH 0.87, 95% CI 0.8-1.0), and homeless people (RH 0.85, 95% CI 0.7-1.0) had delayed INSTI-containing regimen initiation compared to MSM and housed individuals, respectively.

CONCLUSIONS: Although the majority of persons with HIV received INSTI-based ART in recent years, PWID and homeless persons had delays receiving INSTI-containing regimens, after adjusting for viral load, which may reflect decreased retention in care or provider factors such as concerns about adherence in these populations. Switching to INSTI-based regimens when appropriate could potentially improve viral suppression in vulnerable populations.

PEC0490

TRENDS IN ART REGIMEN MODIFICATIONS AMONG PERSONS WITH HIV IN SAN FRANCISCO, CALIFORNIA, USA, 2001-2016

N. Hessol[1], M. Spinelli[1], S. Schwarcz[2], P. Norton[2], S. Scheer[2], L. Hsu[2]
[1]University of California, San Francisco, United States, [2]San Francisco Department of Public Health, San Francisco, United States

BACKGROUND: The primary reasons for making a modification from one antiretroviral therapy (ART) regimen to another have evolved over time, commensurate with changes in ART, however most studies assessing regimen modification have been clinic or

cohort-based. We evaluated reasons for and factors associated with ART regimen modifications over a 15-year period using a large population-based sample.

METHODS: We used the HIV surveillance database to identify San Francisco residents diagnosed with HIV, who initiated ART during 2001-2016, and who made modifications to their ART regimen. ART prescription data were collected through medical chart reviews with follow-up through November 2019. The four initiation periods were: 2001-2004, 2005-2008, 2009-2012, and 2013-2016 according to year of ART regimen initiation. Regimens were classified by the anchor drug of highest potency: integrase inhibitor, protease inhibitor, and nonnucleoside reverse transcriptase inhibitor. Contingency table analyses, with Cochran-Armitage trend test, measured ART regimen modifications over time.

RESULTS: Among the 5836 adults who modified their regimen, 45% (708/1574) of people who initiated ART in period 1 modified their ART regimen classification, 53% (883/1662) in period 2, 56% (937/1683) in period 3, and 30% (275/917) in period 4 (p for trend<0.001). Compared to those who did not modify their first ART regimen from one class to another, those who modified were more likely to be people who injected drugs (PWID: p<0.0001) and people without private insurance (p<0.001). Among those with known reasons for any treatment modification (n=3209), the most common reasons were: tolerability/toxicity issues (57%), simplification (34%), treatment failure (5%), drug-drug interaction or other conditions requiring ART modification (2%), and access problems (1.5%). Reasons for modifying ART regimens changed over time with more people modifying to simplify and fewer modifying due to treatment failure over time (p<0.001).

CONCLUSIONS: Current ART regimens are simpler, increasingly effective and well tolerated. Therefore the main reason for modification is now simplification aimed to enhance quality of life and adherence, and at the same time to minimize drug toxicity. More frequent modifications among PWID and those without private insurance may be related to greater comorbidities (i.e. hepatitis C among PWID) and/or to address adherence concerns.

PEC0491

TRENDS IN AND PREDICTORS OF ANTIRETROVIRAL THERAPY REGIMEN DURABILITY AMONG PERSONS WITH HIV IN SAN FRANCISCO, USA, 2001-2016

L. Hsu[1], M. Spinelli[2], S. Schwarcz[1], N. Hessol[2]
[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of California, San Francisco, United States

BACKGROUND: HIV antiretroviral therapy (ART) has evolved to be more effective, simplified and durable. ART management is complex and individualized thus modifications may be needed to achieve optimal treatment outcomes. We evaluated time to regimen modification and factors associated with regimen durability using a population-based HIV surveillance registry.

METHODS: San Francisco residents diagnosed with HIV and who initiated ART during 2001-2016 were included. Data on ART prescriptions were collected via medical chart reviews with follow-up through November 2019. Periods of ART initiation were categorized as years 2001-2004, 2005-2008, 2009-2012, and 2013-2016. Time from ART initiation to regimen modification (including simplification or change within drug class) was calculated using Kaplan-Meier techniques. Persons who had no modifications at end of follow up were censored at the date of last chart review, last lab test date or death, whichever was earliest. A separate proportional hazards model for each time period was conducted to evaluate factors associated with regimen durability.

RESULTS: Among the 7047 persons who initiated ART, 71% had a regimen modification. The proportion of ART modifications at two years after initiation was relatively stable across the first three time periods (ranged 28-30%) and was 44% in 2013-2016. People with public insurance or no insurance at time of diagnosis compared to private insurance, were more likely to modify regimens in 2001-2004 and 2005-2008 but the differences diminished in 2009-2012 and 2013-2016. In 2013-2016, initial regimens containing protease inhibitors (Hazard ratio [HR] 1.5, 95% confidence interval [CI] 1.2-1.9) were more likely to be modified and regimens containing integrase inhibitors (INSTI) (HR 1.1, 95% CI 0.9-1.3) were not more likely to be modified relative to nonnucleoside reverse transcriptase inhibitors-based regimens.

CONCLUSIONS: In a city highly specialized in HIV care, a high proportion of persons modified their ART regimens after initiation and these modifications, including simplification, increased in recent years. Although there was initially greater modification among people with public or no insurance, this was not seen in recent years, suggesting improved regimen durability among these vulnerable populations, potentially due to city programs targeted towards these populations and/or greater potency and tolerability of second-generation INSTI regimens.

PEC0492

AWARENESS AND ACCEPTABILITY OF UNDETECTABLE=UNTRANSMITTABLE AMONG A U.S. NATIONAL SAMPLE OF HIV-NEGATIVE MEN, TRANS MEN, AND TRANS WOMEN

P. Carneiro[1], V. Patel[2], D. Westmoreland[3], C. Grov[1,3]
[1]CUNY Graduate School of Public Health and Health Policy, Department of Community Health and Health Policy, New York, United States, [2]Montefiore Health System, Albert Einstein College of Medicine, New York, United States, [3]CUNY Institute for Implementation Science in Population Health, New York, United States

BACKGROUND: While the scientific rigor underlying U=U (undetectable = untransmittable) messaging is vastly endorsed among scientific communities, little is known about its reach and acceptability among the populations to which this messaging is intended. Our study describes socio-demographic characteristics and sexual behavior associated with having heard of U=U and trust in U=U in a U.S. national sample of HIV-negative men, trans men, and trans women.

METHODS: Data were derived from the Together 5000 study, an internet-based U.S. national cohort of men, trans men, and trans women who have sex with men. Six-months after enrollment, participants were invited to complete an optional survey that included questions on U=U (n = 3286). Measures included socio-demographic characteristics, healthcare-related characteristics, and questions pertaining to awareness of and trust in U=U messaging. We explored socio-demographic differences between groups of participants with varying degrees of awareness and trust and built multivariable logistic regression models to explore factors associated with these outcomes. Next, we explored patterns in willingness to engage in various sexual behaviors based on a hypothetical partner's serostatus, PrEP use and viral load, among participants with varying levels of trust in U=U.

RESULTS: In total, 85.5% of participants reported having heard of U=U. Of those having heard about U=U, 42.3% indicated they trusted it, 19.8% indicated they do not trust it, and 38.0% were unsure. La-

tino, Asian, lower income, and Southern participants were less likely to have heard of U=U (p<.05). Having a recent discussion about PrEP with a medical provider (p<.05) or being a former-PrEP user were separately associated with higher trust in U=U (p<.05). Lastly, having trust in U=U was associated with willingness to engage in condomless anal sex under varying hypothetical sexual risk conditions related to partner's serostatus, PrEP use, and viral load.

CONCLUSIONS: We found high rates of U=U awareness; however fewer than half of those aware of U=U said they trust it. Results suggest key communities disproportionately impacted by HIV remain less aware and/or less likely to trust U=U, indicating opportunities for continued HIV education that supports U=U messaging.

PEC0493

IMPROVING RETENTION OF PEOPLE LIVING WITH HIV ON ANTIRETROVIRAL DRUGS THROUGH CONTACT TRACING OF LOST TO FOLLOW UP: LESSON LEARNT FROM NIGERIA

C. Ezeokafor[1], G. Ashefor[1], J. Anenih[1], A. Anosike[1], N. Egwuonwu[1]
[1]National Agency for the Control of AIDS, Research Monitoring and Evaluation, Abuja, Nigeria

BACKGROUND: TNigeria care and treatment programme has recorded significant number of people living with HIV (PLHIV) who are lost to follow up (LTFU). This study aimed at assessing status of contact tracing of PLHIV who are lost to follow up in the Antiretroviral Therapy (ART) sites in Nigeria.

METHODS: This study utilized a cross sectional design. Multi-stage sampling method was used to select 22 public ART sites in 11 states across Nigeria. Participants classified as lost to follow up LTFU from the retrospective cohort folder audit of PLHIV who were in Care and treatment between January 1st, 2013 and December 31st, 2017 were recruited. A systematic sampling technique was used to select Unique ID/ Hospital Numbers of 4,979 LTFU PLHIV. All sampled folders were sorted and information on patients contact details, care and treatment services were collected using a pretested semi-structured questionnaires. Data were analysed for descriptive and bivariate variables using SPSS software version 22.

RESULTS: Greater proportion (66.6%) of the LTFU clients were females while 34.6% do not have any form of education. Almost half (48%) were contacted through phone calls, followed by visiting clients' home (37%). Among 4,979 LTFU clients contacted, more than half (60%) were traceable while 40% were not traceable. More (66.6%) females were traced compared to males (33.4%). By age categorization, majority (71.3%) of the adult clients (25 - 49 years) were traced, while the least (6.3%) contacts traced were children (0-14 years). Amid traceable clients, 35.4% were dead, followed by 24.6% that were alive but have discontinued ART, 22.6% were self-transferred out while 17.4% were still active on ART within the facilities. Of the clients that were not traceable, wrong contact address/ phone number (60%), missing folders (19.0%), phone number not reachable (13.0%) were the major cause.

CONCLUSIONS: The study revealed that number of untraceable LTFU clients were high (40%). Improving quality of records of PLHIV on care and treatment and early tracking of LTFU clients is crucial in bridging the gap of retention in HIV Care and treatment.

MEASURING THE POPULATION-LEVEL IMPACT OF POLICY-LEVEL HIV INTERVENTIONS

PEC0494

EXPERIENCES OF LINKAGE TO CARE AND TREATMENT AMONG PEOPLE LIVING WITH HIV BEFORE AND AFTER A FOCUSED PROVINCIAL TREATMENT AS PREVENTION PROGRAM IN BRITISH COLUMBIA, CANADA

T. Lawson Tattersall[1], T. Wesseling[1], S. Grieve[1], L. Wang[1], N. Bacani[1], C. Tam[1], R. Barrios[1,2], J. Montaner[1,3], D. Moore[1,3], D. Hall[1,2], K. Salters[1,4]
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Vancouver Coastal Health, Department of Family and Community Practice, Vancouver, Canada, [3]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [4]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

BACKGROUND: In 2010, British Columbia (BC) implemented the Seek and Treat for Optimal Prevention of HIV/AIDS (STOP) initiative, expanding HIV testing and timely initiation of and engagement in antiretroviral therapy (ART) to optimize Treatment as Prevention (TasP). We evaluated HIV care experiences, engagement, and therapeutic and clinical outcomes among participants diagnosed with HIV prior to and subsequent to STOP.

DESCRIPTION: From September 2016-August 2018, the STOP Program Evaluation (SHAPE) cohort study recruited people living with HIV, aged 18+, across BC who completed a questionnaire ascertaining sociodemographic information, HIV treatment, and care engagement combined with the Drug Treatment Program. This analysis stratified HIV diagnosis date by prior to (2000-2009) and subsequent to (>2010) STOP implementation. Chi-square and Wilcoxon Rank Sum tests compare engagement outcomes to each time-period. Cox proportional hazards regressions compare time to ART initiation and virological suppression (plasma viral load <200 copies/ml) in each time-period, controlling for sexual orientation, gender, and injection substance use.

LESSONS LEARNED: Of 644 participants, 319 were excluded from analysis due to missing data, starting ART elsewhere, or diagnosis before 2000. Of the remaining 325, 198 (60.9%) were diagnosed prior to and 127 (39.1%) subsequent to STOP. Both periods consisted of mostly men (66.2% vs. 81.9%; p=0.004) with median age of 37 (IQR 31-44) (vs. 38; IQR 29-4 7; p=0.258). The STOP implementation era saw more diagnoses in walk-in and hospital settings (44.9% vs. 39.4% and 20.5% vs. 11.1%, respectively; p=0.04), desire to start ART immediately after diagnosis (74.0% vs. 40.1%; p=<0.001), and use of nurse consultation (41.7% vs. 17.7%; p<0.001), nutritionists (25.2% vs. 13.1%; p=0.006), and social workers (28.3% vs. 16.2%; p=0.008). STOP implementation era participants were timelier to initiate ART (adjusted hazard ratio [AHR] 5.97; 95% CI 4.47-7.97) and reach virological suppression (AHR: 2.03; 95% CI 1.58-2.60). Reduced timeliness exists for transgender and non-binary participants to initiate ART (vs. men; p=0.02) and homosexual participants to reach virological suppression (vs. heterosexual; p<0.001).

CONCLUSIONS/NEXT STEPS Our analysis reveals a reduction in time to ART initiation and virological suppression following HIV diagnosis after implementation of a provincial initiative promoting TasP. Barriers remain for transgender and non-binary participants regarding timeliness of ART initiation.

MONITORING AND EVALUATION OF HEALTH SYSTEMS ALONG THE HIV CASCADE

PEC0495

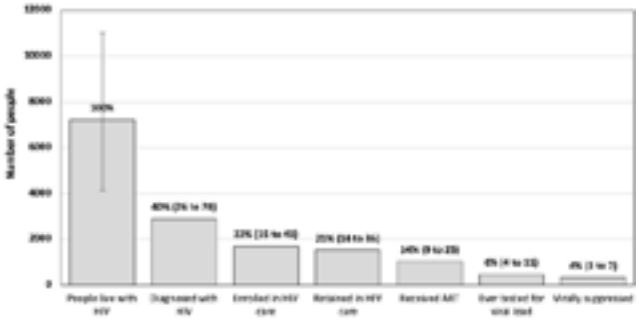
HIV CONTINUUM OF CARE AMONG PEOPLE LIVING WITH HIV IN AFGHANISTAN

M.Z. Harooni[1], A. Mirzazadeh[2], A.A. Atarud[3], A. Rasheed[4], T.B. Aynie[3,3]
[1]United Nation Development Program, HIV Program, Kabul, Afghanistan, [2]Institute of Global Health Sciences, University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [3]United Nation Development Program, Health, Kabul, Afghanistan, [4]Youth Health and Development Organization, Health, Kabul, Afghanistan

BACKGROUND: Afghanistan is facing a concentrated HIV epidemic predominantly among people who inject drugs. Currently,the Afghanistan national HIV program has committed to test and treat strategy for all people living with HIV (PLWH) in the country since 2016. We assessed the HIV continuum of care among people living with HIV in Afghanistan to evaluate the progress towards the 90-90-90 UNAIDS targets.

METHODS: We used the data from national HIV surveillance for 2883 patients who were diagnosed between 1989 and 2018 to assess the HIV continuum of care of people living with HIV in 2018. We excluded 253 patients who reported death for any causes. The estimated number of PLWH in 2018 was estimated by Spectrum model (point and 95% confidence intervals [CI]).

RESULTS: We estimated about 7,200 (95%CI 4100, 11000) PLWH in Afghanistan (Figure 1), of whom only 2883 people (%40, 95%CI 26 to 70%) were diagnosed, 23% (1679 people) were enrolled in HIV care, 21% (1494 people) were retained in HIV care, 14% (1013 people) received ART, 6% (456 people) were tested for viral load after ART initiation, and 4% (300 people) were virally suppressed. In 2019 (from January to November), of the 150 people who diagnosed with HIV, 86% (130 people) started ART.



[Figure 1. HIV continuum of care among people living with HIV in Afghanistan in 2018.]

CONCLUSIONS: Our findings showed less than five percent of people living with HIV in Afghanistan to be virally suppressed. The gaps in HIV continuum of care are major for HIV diagnosis, ART initiation and also viral suppression. While there was some improvement in 2019, addressing barriers in access and using of HIV programs in Afghanistan particularly for key populations are urgently needed to reach the 90-90-90 global targets.

PEC0496

TRENDS IN CHARACTERISTICS AND OUTCOME OF NEWLY DIAGNOSED ADULT HIV-PATIENTS ENROLLED IN CARE IN A LARGE HIV REFERENCE CENTER IN ANTANANARIVO, MADAGASCAR FROM 2010 TO 2016: A RETROSPECTIVE COHORT STUDY

M. Raberahona[1,2], R. Rakotomalala[2], V. Andriananja[1], T. Razafinambinintsoa[2], J. Andriamamonjisoa[2], E. Rakotomijoro[2], E. Rafanomezantsoa[2], R.L. Andrianasolo[2], R.A. Rakotoarivelo[3], M.J.d.D. Randria[1]
[1]University Hospital Joseph Raseta Befelatanana, Infectious Diseases, Antananarivo, Madagascar, [2]Faculty of Medicine, University of Antananarivo, Antananarivo, Madagascar, [3]Faculty of Medicine, University of Fianarantsoa, University Hospital Tambohobe Fianarantsoa, Fianarantsoa, Madagascar

BACKGROUND: The purpose of this study is to describe the trends in profile of newly diagnosed PLWHA enrolled in care, to assess their outcome and to identify factors associated with attrition from care.

METHODS: We conducted a retrospective cohort study including PLWHA of at least 15 years old newly diagnosed from 2010 to 2016 and enrolled in care at the Infectious Diseases Department of the University Hospital Joseph Raseta Befelatanana, a reference center for HIV care in the capital city Antananarivo of Madagascar.

RESULTS: 490 PLWHA were included in the analysis. 67.1% were male. Median age (IQR) at enrollment in care was 29 years (24-38). The proportion of PLWHA aged 40-49 years and > 50 years have significantly increased between 2010 and 2016, respectively from 6.7% to 21.4% (p=0.032 for trend) and from 0% to 11.1% (p=0.002 for trend). 30.8% reported being men who have sex with men with no significant change over time. At enrollment, PLWHA were classified as WHO stage III and IV in respectively 15.7% and 20.4%. The proportion of PLWHA at WHO stage IV at enrollment significantly increased from 3.3% in 2010 to 31% in 2016 (p=0.001 for trend). Median CD4 cell count (IQR) was 273/µl (136-437). The proportion of PLHWA with CD4 cell count <200/µl and <100/µl significantly increased from 10% to 50.8% (p=0.013 for trend) and from 5% to 30.5% (p=0.047 for trend) between 2010 and 2016. 58.7% of PLWHA were retained in care, 11% died and 26.3% were lost to follow-up. The probability of retention in care after diagnosis at 6 months, 12 months, 24 months and 36 months was respectively 76.6%, 71.8%, 65.5% and 61.3%. Age≥40 years (aHR:1.61; 95%CI:1.08-2.40), low level of education (aHR:1.53; 95%CI:1.03-2.28), unspecified level of education (aHR:2.04; 95%CI:1.26-3.28) and unemployment (aHR:1.48; 95%IC:1.03-2.13) were independently associated with attrition from care.

CONCLUSIONS: PLWHA are still enrolled in care at an advanced HIV disease and are increasingly diagnosed late at enrollment over the study period. Retention in care is a major issue within 12 months after the diagnosis. Attrition from care are mostly influenced by sociodemographic rather than clinical factors.

PEC0497

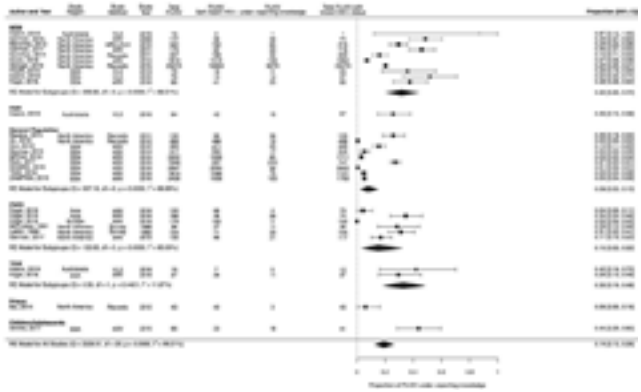
UNDER-REPORTING OF KNOWN HIV-POSITIVE STATUS AMONG PEOPLE LIVING WITH HIV: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Soni[1], K. Giguère[2], M.-C. Boily[1], J.M. Fogel[3], M. Maheu-Giroux[2], D. Dimitrov[4], S.H. Eshleman[3], K.M. Mitchell[1]
[1]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [2]McGill University, Department of Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada, [3]Johns Hopkins University School of Medicine, Department of Pathology, Baltimore, United States, [4]Fred Hutchinson Cancer Research Center, Seattle, United States

BACKGROUND: Measuring progress towards the UNAIDS 90-90-90 goals requires accurate estimates of levels of knowledge of HIV infection. Knowledge of HIV-positive status is often estimated using self-report, although it may be mis-reported by people living with HIV (PLHIV). We aimed to quantify under-reporting of knowledge of HIV-positive status among PLHIV.

METHODS: MEDLINE, EMBASE, Web of Science, Global Health and Scopus databases, IAS conference archives and PHIA datasets were searched to October 2019 for studies providing self-reported and biological/clinical markers of prior knowledge of HIV-positive status among laboratory-confirmed PLHIV. PLHIV with antiretroviral drugs detected, viral load suppression, or prior diagnosis in medical records, but not reporting being HIV-positive, were classified as under-reporting known HIV-positive status. Random-effects models were used to derive pooled estimates of the proportion under-reporting known HIV-positive status. Possible sources of heterogeneity were investigated using sub-group analyses.

RESULTS: Thirty independent study estimates from 24 studies on 39,491 PLHIV were included. Most studies were conducted in the North America (number of estimates [N]=12) or sub-Saharan Africa [N=12], in the general population [N=9] or men who have sex with men [MSM; N=10]). The pooled proportion under-reporting known HIV-positive status was 19% (95% confidence interval: 13%–26%, I^2=99%; Figure). In sub-group analyses, no statistically significant differences in under-reporting were found by continent, study design, interview method, gender (in general population studies) or prior status knowledge assessment method. Under-reporting was higher among MSM (32%, N=10) than the general population (8%, N=9; p=0.0004) and in a subset of North American studies with data by race, under-reporting was higher among Black (18%, N=5) than non-Black (3%, N=3) individuals (p=0.005).



[Figure. Forest plot showing proportion of PLHIV under-reporting known HIV-positive status. MSM = men who have sex with men, PWID = people who inject drugs, SSA = sub-Saharan Africa, FSW = female sex workers, TGW = transgender women.]

CONCLUSIONS: Substantial under-reporting of knowledge of HIV-positive status was found, particularly by MSM. These results could be used to correct self-reported levels of knowledge of HIV-positive status, although biological markers may still underestimate knowledge.

PEC0498

ANTIRETROVIRAL STRATEGIES IN NAIVE AND VIRALLY SUPPRESSED HIV-INFECTED PATIENTS DEPEND ON PATIENTS' GEOGRAPHIC ORIGIN: EXPERIENCE FROM A FRENCH HIV CENTER IN PARIS

R. Palich[1], D. Wetshikoy[2], C. Soulié[3], R. Agher[1], R. Tubiana[1], M.-A. Valantin[1], L. Schneider[1], A. Fayçal[1], C. Katlama[1], L. Assoumou[2]
[1]Sorbonne University, Pitié-Salpêtrière Hospital, AP-HP, Infectious Diseases Department, Pierre Louis Epidemiology and Public Health Institute (iPLESP), INSERM 1136, Paris, France, [2]Sorbonne University, Pierre Louis Epidemiology and Public Health Institute (iPLESP), INSERM 1136, Paris, France, [3]Sorbonne University, Pitié-Salpêtrière hospital, AP-HP, Virology Department, Pierre Louis Epidemiology and Public Health Institute (iPLESP), INSERM 1136, Paris, France

BACKGROUND: We aimed to evaluate antiretroviral (ART) strategies in a French HIV center in naïve and virally suppressed HIV-patients, born in France (PBF) and born in sub-Saharan Africa (PBSSA).

METHODS: This observational single center study has included all the new PBF and PBSSA managed at Pitié-Salpêtrière hospital, Paris, France, from 01/01/2000 to 31/12/2018, with plasma viral load (pVL)>200 copies/mL. Logistic and Cox regression models were used to assessed the impact of origin on ART strategy at initiation and maintenance (pVL<50 copies/mL >24 months), time to first pVL<50 copies/mL and time to the first ART change, adjusted for potential confounders.

	Naive patients (n=1945)			Virally suppressed patients (n=897)		
	PBF (n=1030)	PBSSA (n=915)	Adjusted p-value	PBF (n=509)	PBSSA (n=388)	Adjusted p-value
NNRTI (n=474)	26%	22%	0.42	41%	43%	0.52
PI (n=1021)	47%	58%	0.04	9.2%	18%	<0.001
INSTI (n=363)	24%	13%	<0.001	45%	37%	0.02
Time to first pVL<50 copies/mL	11.7 months	18.7 months	0.68			
Time to first ART change	3.9 months	3.7 months	0.75			
"Drug-reduced" therapies (n=297)				41%	23%	<0.001
Dual therapies (n=179)				23%	16%	0.09
Intermittent triple-drug therapies (n=94)				15%	4.6%	0.01

RESULTS: Overall, 1,945 naïve patients were analyzed. PBSSA were younger (34 vs. 38 years, p<0.001), with more women (59% vs. 14%, p<0.001), with lower CD4 count (240 vs. 339/mm3, p<0.001), and were more frequently CDC C (17% vs. 11%, p<0.001). By multivariate analysis, ART strategy at initiation differed according to birth country: PBSSA received more protease inhibitor (PI)-based ART (HR 1.38; 95%CI 1.01-0.87; p=0.041) and less integrase inhibitor (INSTI)-based ART (HR 0.49; 95%CI 0.32-0.75; p<0.001). Geographical origin, after adjustment for potential confounders, had no impact on the time to reach a first pVL<50 copies/mL (HR 0.97; 95%CI 0.84-1.13; p=0.68), neither on the time prior to the first ART change (HR 1.02; 95%CI 0.87-1.21; p=0.75). When considering maintenance ART strategies, 897 virally

suppressed patients were analyzed, with a similar median duration of viral suppression in the two groups (77.5 vs. 77.0 months, p=0.69). By multivariate analysis, "drug-reduced" ART (mono, dual and 5 or 4 days-a-week therapies) were significantly less frequent in PBSSA (HR 0.46; 95%CI 0.30-0.70; p=0.041).

CONCLUSIONS: Depending on birth country origin, ART strategies at initiation were different in PBF and PBSSA with more PI and less INSTI. In virally suppressed patients, despite similar duration of viral suppression, PBSSA received less "drug-reduced" ART.

PEC0499

SELF-REPORTED ROUTE OF HIV TRANSMISSION THROUGH BLOOD AND BLOOD PRODUCTS UNDER NATIONAL AIDS CONTROL PROGRAMME IN INDIA

S. Jha[1], S. Rajan[1], S. Bhavsar[1], S. Murthy[1], V. Verma[1]
[1]National AIDS Control Organisation, Department of Health and Family Welfare, New Delhi, India

BACKGROUND: The National AIDS Control Programme aims to expand access to safe blood and blood products through a well-coordinated network of transfusion services. The main component of an integrated strategy includes collection of blood only from voluntary, non-remunerated blood donors, screening for all transfusion transmitted infections and reduction of unnecessary transfusion. In continuation of this, to reduce the risk of HIV transmission, National Blood Transfusion Council of India promote 100% voluntary blood donation in all blood banks across the country.

METHODS: The data used for analysis is national programme data from HIV confirmatory sites (Stand-alone Integrated Counselling and Testing Centres, SA-ICTC). Data from financial year 2011-12 to 2018-19 has been used for the analysis. The available data on route of HIV transmission is self-reported, collected during the post-test counselling of confirmed HIV positive at HIV testing centre (SA-ICTC). Data analysis includes (A) State-wise proportion and (B) Three years moving average to smoothen the data points in trend analysis.

RESULTS: Percentage of HIV transmission through the blood and blood products is much lower than other routes of HIV transmission. National level trend shows less than 1% self-reported route of transmission through blood and blood products from 2011-12 to 2018-19. This translate around more than 1,300 in the country. There is around 12% decline in self-reported route of transmission through blood and blood products from year 2011-12 to 2018-19. However, there are seven states reported consistently higher than 1% of HIV transmission through blood and blood products (Chhattisgarh, Delhi, Gujarat, Haryana, Kerala, Uttar Pradesh and West Bengal). In three years moving average, Delhi and Jammu Kashmir constantly reported more than 2% in HIV transmission though blood and blood products from the year 2011-12 to 2018-19. There are 5 states which contributes 67% of total cases (Uttar Pradesh-18%, West Bengal & Delhi-13%, Maharashtra-12% and Gujarat-11%).

CONCLUSIONS: In order to decrease number of self-reported route of transmission through blood and blood products in the high burden states, the programme needs to enhance existing capacity of SA-ICTC counselor and strengthen counselling under programme through induction training and repeated refresher training.

SURVEILLANCE OF DRUG RESISTANCE

HIGH LEVELS OF HIV DRUG RESISTANCE AND EVIDENCE OF TRANSMISSION CLUSTERS WITHIN AND ACROSS KEY POPULATIONS IN PAPUA NEW GUINEA: RESULTS FROM A BIOBEHAVIOURAL SURVEY

A. Kelly-Hanku[1,2], J. Gare[1], J. Chih-Wei Chang[3], B. Willie[1], M. Steinau[3], N. Wagar[3], J. Gabuzzi[1], R. Narokobi[1], S. Pekon[1], R. Boli-Neo[1], H. Aeno[1], M. Kupul[1], S. Ase[1], P. Hou[1], J. Kaldor[2], N. Dala[4], A. Vallely[2,1], S.G. Badman[2], A. Hakim[3]
[1]Papua New Guinea Institute of Medical Research, Sexual and Reproductive Health, Goroka, Papua New Guinea, [2]UNSW Sydney, Kirby Institute, Sydney, Australia, [3]US Centers for Disease Control and Prevention, Atlanta, United States, [4]National Department of Health, Port Moresby, Papua New Guinea

BACKGROUND: HIV drug resistance (DR) is a major threat to reaching UNAIDS 90-90-90 targets. Papua New Guinea (PNG) has the fourth highest prevalence of pre-treatment HIV drug resistance (DR) at 18.4% of the population starting treatment or re-initiating treatment. PNG's epidemic is concentrated among key populations (KP), including female sex workers (FSW), men who have sex with men (MSM) and transgender women (TGW), and shortages of antiretroviral (ARV) drugs are common. However, no data exist on specifically on HIVDR among KPs in PNG.

METHODS: We conducted respondent-driven sampling biobehavioural surveys in Port Moresby, Lae, and Mt. Hagen, PNG from June 2016–December 2017. Venous blood was drawn from 2,955 participants (71% FSW and 29% MSM/TGW) for rapid HIV testing according to the national algorithm. Plasma was tested for HIV viral load (VL) in PNG using GeneXpert. Positive plasma aliquots with VL≥1,000 copies/ml were genotyped at the US Centers for Disease Control and Prevention, Atlanta, using Applied Biosystems™ HIV-1 Genotyping kits.

RESULTS: Among the 355 HIV-positive specimens tested, 205 specimens yielded a VL≥1,000 copies/mL, and 193 were successfully genotyped, 156 from FSW and 37 from MSM and TGW. The majority (n=191) were HIV subtype C; 2 had recombinant form of subtype B, and C. HIVDR to nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors (NNRTIs) and protease inhibitors was detected in 24.9% (n=48), 15% (n=29) and 1.1% (n=2), respectively, and 13.4% (n=26) had HIVDR to both NRTIs and NNRTIs. Among genotyped specimens, HIVDR prevalence was 28.8% among FSW and 10.8% among MSM/TGW. Ten genotypical clusters were found: six from Port Moresby, two from Lae, and two from Mt. Hagen. There were eight clusters among FSW, three among MSM/TGW, with three of these reaching across the KPs.

CONCLUSIONS: KP HIVDR threatens PNG's ability to reach epidemic control. Transmission clusters within and across KP groups highlight interconnected sexual networks that can facilitate HIVDR transmission. Access to routine viral load testing to determine transmitted DR, enhanced adherence counselling, a faster transition to fixed-dose tenofovir/lamivudine/dolutegravir, and a stable ARV supply are important in bringing PNG's HIV and HIVDR epidemics under control.

PEC0501

TRANSMITTED DRUG RESISTANCE AND CARE OUTCOMES AMONG PERSONS NEWLY DIAGNOSED WITH HIV IN SAN FRANCISCO, CALIFORNIA, USA, 2014-2017

M. Chen[1], S.E. Cohen[1,2], S. Pipkin[1], K.A. Johnson[1,2], D. Sachdev[1,2], S. Scheer[1]
[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of California, San Francisco, United States

BACKGROUND: "Treatment as prevention" is an effective HIV prevention strategy which relies on early initiation of antiretroviral therapy (ART). Transmitted drug resistance (TDR) could compromise ART effectiveness. We analyzed HIV nucleotide sequences to assess prevalence and care outcomes of TDR among persons newly diagnosed with HIV in San Francisco (SF).

METHODS: SF residents newly diagnosed with HIV from 2014-2017 and reported to the SF Department of Public Health were included. We included HIV sequences collected within 3 months of diagnosis from individuals with no evidence of prior ART use. The Stanford HIV Sierra Web Service was used to identify mutations. The CDC mutation list for surveillance was applied to determine mutations conferring any resistance to nucleoside reverse transcriptase inhibitors (NRTI), non-NRTI (NNRTI), protease inhibitors (PI) and integrase strand transfer inhibitors (INSTIs). Median time from HIV diagnosis to ART initiation and to viral suppression were estimated using Kaplan-Meier method and log-rank tests comparing those with and without TDR were performed.

RESULTS: Of 1,130 persons newly diagnosed with HIV in 2014-2017, 415 (37%) had an eligible pol HIV sequence reported to HIV registry, 398 with eligible protease and reverse transcriptase (PR/RT) and 144 with integrase gene. Of 398 persons with eligible PR/RT gene, 95 (24%) had at least one resistance mutation; 14% (n=54) had a NNRTI, 11% (n=42) a NRTI, and 4% (n= 14) a PI mutation. The most frequent mutation was K103N (n=35, 9%). Two(0.5%) carried M184V and none had K65R mutation. One person had an INSTI mutation, T66A, which reduces susceptibility to elvitegravir. No significant differences were observed between persons with and without TDR for time to ART initiation (23 vs. 23 days respectively, p=0.95), and viral suppression (80 vs. 89 days, p=0.46).

CONCLUSIONS: We did not find TDR affected HIV care outcomes, a likely effect of rapid availability of potent ART regimens and clinical management in a resource-rich setting such as SF. We identified only two M184V, one integrase and no K65R mutations. Continued TDR monitoring and its clinical impact, and ensuring providers conduct and report genotypic testing for all new patients are critical for optimizing HIV clinical care and effective HIV prevention.

PEC0502

HIGH LEVELS OF HIV DRUG RESISTANCE IN ADULT PATIENTS WITH UNSUPPRESSED VIRAL LOAD, MEASURED THROUGH ROUTINE VIRAL LOAD PROGRAMME MONITORING IN SOUTH AFRICA, 2019

G. Hunt[1,2], K. Steegen[3,4], L. Hans[3,4], N. Cassim[3,4], W. Macleod[5,6], S. Carmona[3,4]
[1]National Institute for Communicable Diseases, Centre for HIV and STIs, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Virology, Johannesburg, South Africa, [3]National Health Laboratory Services, National Priority Programme, Johannesburg, South Africa, [4]University of the Witwatersrand, Department of Molecular Medicine and Haematology, Johannesburg, South Africa, [5]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [6]Boston University, Department of Global Health, Boston, United States

BACKGROUND: HIV drug resistance (HIVDR) surveillance guides selection of optimal antiretroviral therapy (ART) regimens. In South Africa, viral load (VL) monitoring of patients receiving care is performed across 16 laboratories; national VL testing coverage rates are >80% and 13% of 3.3 million people with a VL test performed during 2018 had unsuppressed VL (>1,000 copies/ml). We implemented nationally representative surveillance of HIVDR in adult patients with unsuppressed VL using leftover specimens sourced from patients who had undergone routine VL monitoring.

METHODS: Two-stage sampling was used: first we selected a systematic random sample from all specimens submitted for VL testing at each VL laboratory between May–July 2019. From these, we selected a random sample of unsuppressed VL specimens from adult patients by laboratory for HIVDR testing using next generation sequencing and drug level testing (DLT) using liquid chromatography mass spectrometry. VL results and patient age were extracted from the laboratory information system.

RESULTS: Of the 8202 VL test specimens collected as part of first stage sampling, 1053 had unsuppressed VL. From these, a random sample of 779 unsuppressed VL specimens were selected for further testing. DLT confirmed that 428 (55%) specimens had detectable levels of ART. The proportion of specimens with HIVDR is listed below:

	All specimens (% (95%CI))	Detectable levels of drug (% (95%CI))	Undetectable levels of drug (% (95%CI))
Total Resistance	72.1 (66.78 - 76.86)	85.56 (79.71 - 89.94)	55.6 (46.62 - 64.23)
PI Resistance	2.17 (1.33 - 3.49)	3.14 (1.94 - 5.05)	0.97 (0.31 - 2.96)
NRTI Resistance	48.99 (44.72 - 53.27)	72.69 (66.42 - 78.17)	19.93 (15.6 - 25.12)
NNRTI Resistance	70.51 (64.73 - 75.71)	83.73 (77.67 - 88.39)	54.31 (45.01 - 63.33)

[Table]

CONCLUSIONS: Our survey showed that 72% of patients with unsuppressed VL in the public sector harbor resistance to ART. HIVDR was lower in patients that had undetectable levels of ART, presumably due to lack of drug selection pressure (p<0.0000). Notably, 45% of patients on ART and presenting for routine VL testing had undetectable levels of ART. The use of leftover specimens proved advantageous in that it allowed for proportion to size sampling, and reduced collection time and cost. Laboratory information systems are not reliable systems in which to assess association of HIVDR to clinical and socio-demographic information

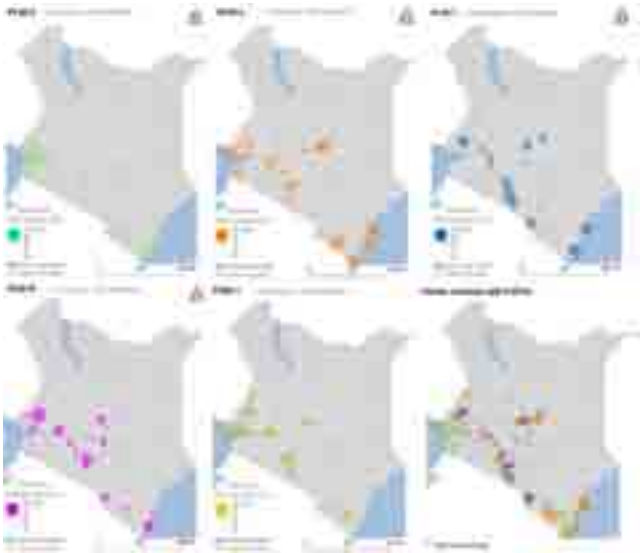
DO SHRINKING HOTSPOTS OF NEW HIV DIAGNOSES SIGNAL EPIDEMIC CONTROL IN KENYA? A SPATIAL-TEMPORAL ANALYSIS (2015–2019)

A. Waruru[1], J. Mwangi[1], M. K. Mugambi[2], V. Ojiambo[3], F. Miruka[1], L. Odero[3], T. N. O. Achia[1], G. Omoro[4], J. L. Tobias[5], P. W. Young[1]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Nairobi, Kenya, [2]Ministry of Health, National AIDS and STI Control Programme, Nairobi, Kenya, [3]United States Agency for International Development, Health Population and Nutrition, Nairobi, Kenya, [4]U.S. Department of Defense, Nairobi, Kenya, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Atlanta, United States

BACKGROUND: By 2020, annual new HIV infections will decrease to <500,000 worldwide as goals for HIV prevention, care, and treatment are achieved. Thus, new strategies will be needed to find undiagnosed HIV-positive persons as countries make progress in HIV epidemic control. We explored whether hotspots of newly HIV-diagnosed were consistently found in roughly the same geographic areas in Kenya and described their magnitudes across five years (2015-19).
METHODS: We analyzed monthly facility-level aggregate routine HIV-testing data reported in fiscal years (FY) 2015-2019. We compared median number of HIV-positive tests across years using the Kruskal-Wallis equality-of-populations nonparametric rank test. We used the Kulldorff spatial-scan Poisson model implemented in SaTScan with a 50-km radius scan window looping over 3000 geocoded facilities to determine whether number of new HIV diagnoses out of the tested were randomly distributed over space or clustered in detectable patterns. We mapped the significant clusters to assess overlaps and shifts in sizes and locations.
RESULTS: Of 7.8 million tested, 242,000 HIV-positive individuals were diagnosed in FY2015; 234, 177, 170, and 162 thousand out of 12.1, 11.9, 12.3, and 9.4 million tested in FY2016, FY2017, FY2018, and FY2019, respectively. Estimated annual diagnoses were 3091, 1935, 1492, 1386, and 1726 per 100,000 tests in each FY (2015 to 2019), respectively (p=0.0001). The number of significant clusters of individuals with new HIV diagnoses increased from 95 in FY2015, to 126 in FY2016, to 133 in FY2017. In FY2018, however, the number of clusters identified dropped to 111 and decreased further to 106 in FY2019 (Figure).



[Figure. Spatial cluster patterns of new HIV diagnoses in Kenya (2015-2019)]

CONCLUSIONS: New diagnoses have decreased especially in high burden areas, yet many clusters overlap. New hotspots may be evidence of accelerated efforts to meet HIV-testing targets. Our findings support the use of geospatial analysis to demonstrate progress toward HIV epidemic control and to focus prevention and testing services where most needed.

PEC0504

SPATIAL CLUSTERING OF SOCIOBEHAVIORAL AND BIOLOGICAL CHARACTERISTICS OF WOMEN WITH UNSUPPRESSED HIV VIRAL LOAD IN A GENERALIZED HYPER-ENDEMIC AREA IN KWAZULU-NATAL, SOUTH AFRICA

A. Soogun[1], A. Kharsany[2], T. Zewotir[3], D. North[3]
[1]University of Kwazulu-Natal/CAPRISA, Statistics, Durban, South Africa, [2]Center for AIDS Programme Research for South Africa, Epidemiology, Durban, South Africa, [3]University of KwaZulu-Natal, Statistics, Durban, South Africa

BACKGROUND: Number of new HIV infections among young women in Sub-Sahara Africa remains exceptionally high, with South Africa accounting for the largest burden.To prevent onward transmission of HIV,it is important to achieve UNAIDS 90-90-90 composite measure of 73% viral suppression among people living with HIV, thus potentially reducing risk of new infections.The aim of this analyses was to spatially map the distribution of women with unsuppressed HIV viral load to help guide the targeting of interventions for immediate linkage to HIV care and scale of treatment and prevention strategies.
METHODS: We analysed data from the HIV incidence Provincial Surveillance System (HIPSS); two sequential cross sectional population based household surveys undertaken in Vulindlela and the Greater Edendale area of KwaZulu-Natal, South Africa. 2014 and 2015 survey enrolled 9812 participants and 10236 respectively. Following informed consent, enrolled participants had their household global positioning system (GPS) coordinates captured, completed questionnaires to obtain demographic, psycho-social behavioural information and had peripheral blood samples collected HIV related measurements. HIV viral suppression was defined as HIV viral load of <400 copies per mL and mapped using ArcGIS software version10.3. Survey logistic regression was used to examine predictors of unsuppressed HIV viral load.
RESULTS: Of the 9812 participants enrolled in the 2014 Survey, 6265 were women and 2 955 (44.1%,95% Confidence Interval (CI) 42.3- 45.9) tested HIV positive and 1372 (46.4%) had a viral load of ≥400 copies per mL. Median age of HIV positive women:32 (IQR) 26-39) years, median age at sexual debut :17 (IQR 16-19) years and median number of lifetime sex partner : 2(IQR 1-4). Of the 10236 participants enrolled in the 2015, 6341 were women and 2948 (45.0%, 95% CI (43.4-46.7) tested HIV positive and 1828 (61.9%) had a viral load of ≥400 copies per mL. Median age:32 (IQR) 26-39) years, median age at sexual debut:18 (IQR 16-20) years and median number of lifetime sex partner: 3 (IQR 2-4).
CONCLUSIONS: A substantial proportion of HIV positive women are virally unsuppressed and there is and urgent need for targeted interventions to link HIV positive women to care and the imperative for rapid scale-up of HIV treatment and prevention programs.

ADVANCES IN PUBLIC HEALTH SURVEILLANCE AND NEW APPROACHES

PEC0505

A CASE-CONTROL STUDY OF RISK FACTORS FOR HIV DRUG RESISTANCE OF PATIENTS HARBOURING ANTIRETROVIRAL DRUG RESISTANCE MUTATIONS IN VIETNAM

D. Vu Quoc[1], A. Nguyen Thi Lan[2], N. Khuu Van[3], L. Nguyen Thuy[2], T. Huynh Hoang Khanh[3], H. Phan Thi Thu[4], N. Do Thi[4], V. Thi Thuy Nguyen[5]
[1]Hanoi Medical University, Department of Infectious Diseases, Hanoi, Vietnam, [2]National Institute of Hygiene Epidemiology, Hanoi, Vietnam, [3]Pasteur Institute of Ho Chi Minh City, Ho Chi Minh City, Vietnam, [4]Vietnam Authority of HIV/AIDS Control, Hanoi, Vietnam, [5]World Health Organisation, Hanoi, Vietnam

BACKGROUND: The HIV epidemic in Vietnam remains concentrated primarily among key populations with the highest prevalence in people who inject drugs (PWID) (21.0%), following by female sex workers (FSWs) (3.2%), and men who have sex with men (2.9%). According to nationally representative surveys of pre-treatment and acquired HIV drug resistance (HIVDR) in Vietnam in 2017, the prevalence of pre-treatment drug resistance (PDR) and acquired drug resistance (ADR) were 5.4% and 2.6% respectively. However, the survey was unable to determine if risk behaviors associated with HIVDR. We conducted a study to identify factors including risk behaviors associated with HIVDR in order to inform public health intervention for HIVDR prevention.

METHODS: A matched case-control study was conducted between August and November 2019. Cases and controls were selected from national HIVDR survey. Case were all adult patients with any HIV drug resistance and controls were selected from patients without HIV drug resistance. Controls were randomly matched with cases on a ratio of 2:1 by sex, age (±2 years), groups of HIVDR (PDR, ADR12, or ADR48) and study sites.

RESULTS: The study included 58 cases and 114 controls. The proportion of patients with history of intravenous drug use was 25% (10/40) in HIVDR groups and 7.6% (8/105) in the control group. The intravenous drug use was associated with increased risk of harbouring antiretroviral drug resistance mutations (OR=3.17; 95%CI 1.20-8.34, p = 0.02). Among male patients, having history of anal sex with men was not associated with HIVDR (OR=0.77, 95%CI, 0.30-1.98, p=0.65).

CONCLUSIONS: Our finding indicated that injecting drug use were associated with HIVDR. This finding has important implication for national HIV programme in designing treatment adherence support for people who inject drugs to prevent HIVDR.

PEC0506

INTEGRATION OF HIV CLUSTER AND EPIDEMIOLOGICAL DATA TO INFORM PREVENTION IN CALIFORNIA

J. Feng[1], D. Sykes[1], P. Peters[1,2]
[1]California Department of Public Health, Center for Infectious Diseases - Office of AIDS, Sacramento, United States, [2]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

BACKGROUND: We examined possible individual and social environmental predictors of molecular clusters of HIV transmission in California. Using multilevel demographic, clinical, and epidemiological data, we calculated expected case clustering rates among the 58 county and three city jurisdictions in support of resource alignment.

METHODS: HIV-1 *pol* sequences reported to the California HIV surveillance system were analyzed with HIV-Trace to identify molecular linkages. The analysis was limited to people diagnosed from 2016-2018 (n=16,504). Clustering was defined as two or more linked sequences with a pairwise genetic distance of ≤ 0.5%. The multilevel analysis accounted for individual characteristics and jurisdiction-level random intercept and fixed effects. Jurisdiction-level characteristics included sociodemographic and housing indicators as well as community viral suppression and care retention. Expected proportions of clustered transmissions in each jurisdiction were obtained by aggregating predicted clustering probabilities over the demographic and transmission mode categories weighted by the categories' proportion in that jurisdiction, and applying exponential transformation to jurisdiction-level logit values.

RESULTS: The proportion of sequences clustering at or below the 0.5% distance threshold was 18.3% (95% Confidence Interval [CI]: 12.3-24.2) in 2016-2018. The proportion clustering in the state's three largest counties, Los Angeles, San Diego, and Orange Counties, was 22.4% (CI: 19.9-24.9), 15.9% (CI: 13.2-18.6), and 23.1% (CI: 19.4-26.7) respectively. Molecular clustering was associated with younger age, white or Latinx race, people who inject drugs, and men who have sex with men or being transgender women. After multivariable adjustment, higher poverty and care retention gaps in a jurisdiction showed positive albeit nonsignificant associations with molecular clustering.

[Figure. Adjusted odds ratios[1] for HIV molecular clustering according to selected individual- and population-level characteristics, California, 2016-2018]

CONCLUSIONS: We observed significantly higher frequencies of molecular clustering among sociosexual subgroups recently diagnosed with HIV in California. We evaluated local variations in clustering rates to inform the allocation of prevention and treatment resources. The socioeconomic gradients in clustering rates were not significant, potentially reflecting the geographic dispersion of linked transmissions.

PEC0507

90-90-90 TARGETS SURPASSED IN THE UK BUT MASK THE NUMBER OF PEOPLE LIVING WITH TRANSMISSIBLE LEVELS OF VIRUS

A. Brown[1], R. Harris[1], A. Presanis[2], c. O'Halloran[1], D. De Angelis[2], V. Delpech[1]
[1]Public Health England, HIV, London, United Kingdom, [2]University of Cambridge, Biostatistics, Cambridge, United Kingdom

BACKGROUND: In the UK, the 90-90-90 targets were surpassed again in 2018 with 94% diagnosed, 97% treated and 97% virally suppressed. However, this: masks the number living with transmissible levels of virus; excludes numbers diagnosed but not in care; and assumes the distribution of viral suppression is identical between patients with and without data reported. We compare the number of people with transmissible levels of virus according to the published 90-90-90 outcome to an "intention to treat" analysis.

METHODS: We use comprehensive national surveillance data reported at HIV diagnosis and every subsequent HIV clinic attendance. Estimates of undiagnosed HIV infection are produced through the multi-parameter evidence synthesis. The number of people with transmissible levels of virus are calculated through adding the estimated number with undiagnosed HIV to the number untreated and not virally suppressed.

For the "intention to treat" analysis, those not linked to care (300) and those not retained in care annually (1,500) were also assumed to have transmissible levels of virus. Additionally, we calculated the proportion of those with missing viral loads in 2018 who were virally suppressed in 2017 and applied it to the number with missing viral load information in 2018.

RESULTS: In 2018, an estimated 103,800 (95% credible interval (CrI) 101,600 to 107,800) were living with HIV in the UK. Using the published scenario, approximately 13,100 people were living with transmissible levels of virus. Of these, 57% (7,500) were undiagnosed, 21% (2,800) untreated and 21% (2,800) virally unsuppressed.

In the "intention to treat" analysis approximately 15,600 people had transmissible levels of virus with 48% (7,500) undiagnosed. This included 1.9% (300) diagnosed in 2018 but unlinked to care, 9.6% (1,500) not retained in care, 18% (2,800) in care but untreated and 22% (3,500) in care and virally unsuppressed. The final UNAIDS targets were 94% diagnosed, 95% treated and 95% virally suppressed.

CONCLUSIONS: Regardless of scenario, the UK meets the UNAIDS targets. Between 13,100 and 15,600 people with HIV have transmissible levels of virus with around half undiagnosed. In addition to testing efforts, strategies to ensure those diagnosed are rapidly linked and retained in care are essential in preventing onward transmission.

PEC0508

PRELIMINARY RESULTS ON THE ACCEPTABILITY EVALUATION OF DUAL HIV/SYPHILIS RAPID TEST FOR THE SCREENING OF HIV & SYPHILIS IN MEN WHO HAVE SEX WITH MEN IN CHECKPOINTLX, LISBON, PORTUGAL

F. Fernandes[1,2], P. Meireles[1], M. Rocha[3,4], R. Guerreiro[3,4], H. Barros[1,5]
[1]EPIUnit - Instituto de Saúde Pública da Universidade do Porto, Porto, Portugal, [2]ACES Baixo Mondego, Figueira da Foz, Portugal, [3]GAT – Grupo de Ativistas em Tratamentos, Lisbon, Portugal, [4]Coalition PLUS Community-Based Research Laboratory, Patin, France, [5]Faculdade de Medicina, Universidade do Porto, Porto, Portugal

BACKGROUND: Dual tests that can be used at point-of-care for simultaneously detecting HIV and syphilis antibodies have been developed, but there is limited data on their acceptability in the field. CheckpointLX offers 15-minute HIV and syphilis testing for men who have sex with men (MSM) performed by trained peers since 2011. A 1-minute dual test was introduced to scale-up HIV and syphilis testing – which accounted for 58.28% of last year's activity – but MSM acceptability is a higher priority to tailor the service, hence an evaluation of the dual test acceptability at CheckpointLX should be performed.

METHODS: Participants who presented to CheckpointLX, filling criteria to be tested to HIV and syphilis were randomly allocated to receive the 15-minute HIV and syphilis testing currently used or to receive the 1-minute INSTI® Multiplex HIV-1/HIV-2/Syphilis Antibody Test, based on the week they visited. Participants were invited to answer an acceptability questionnaire, assessing their willingness to use the test again, feasibility and satisfaction about the test. Data were collected between September 2019 and January 2020, and statistics were performed to describe data and to compare the acceptability of both tests.

RESULTS: 123 MSM were enrolled. The median age was 27 (IQR 12), 77 (75.5%) had a college degree, 63 (61.8%) had a full-time job, and 83 (69.2%) were born in Portugal. 100 (81.3%) received the new dual test and 23 (18.7%) received the ongoing separate test. No sociodemographic differences were found between groups. We found no differences regarding willingness to use the same test again and in the feasibility domains. Regarding satisfaction domain, 94 (94.9%) of dual test would like to use the test again vs. 8 (34.8%) of the separate test group, p<0.001, and 95 (96%) of dual test participants would recommend the test to a friend vs. 18 (78.3%) of the other group, p=0.003.

CONCLUSIONS: Even though these are preliminary results, our data suggest that the dual test acceptance might be higher within MSM testing at CheckpointLX. A higher acceptance associated with a considerable time reduction may contribute to testing scale-up, leading to an eventual increase of new cases detection.

PEC0509

LESSONS LEARNED FROM USING VERBAL AUTOPSIES TO OPTIMIZE MORTALITY DATA IN A HIGH HIV BURDEN SETTING IN SOUTH AFRICA

P. Groenewald[1], J. Joubert[1], M. Maqungo[1], N. Nannan[1], R. Laubscher[1], D. Morof[2], M. Cheyip[2], E. Nichols[3], K. Kahn[4], J. Price[5], F. Bezuidenhout[6], D. Bradshaw[1], NCODV Team

[1]South African Medical Research Council, Burden of Disease Research Unit, Cape Town, South Africa, [2]Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Pretoria, South Africa, [3]Centers for Disease Control and Prevention, National Center for Health Statistics, Hyattsville, United States, [4]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [5]Oxford University, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, [6]Geospace International, Pretoria, South Africa

BACKGROUND: About half of deaths in South Africa occur outside health facilities where cause-of-death information is limited. Many HIV deaths are misclassified, and about 45% of all deaths report vague underlying causes of death. As part of a national cause-of-death validation study, we assessed the use of verbal autopsies (VA) for improving cause-of-death data.

DESCRIPTION: In 27 randomly selected sub-districts across South Africa, enrolled undertakers and Department of Home Affairs offices recruited decedents' next-of-kin to participate in verbal autopsies (2017–2018). We extended the study from 3 to 7 months due to low recruitment. Trained interviewers visited 5768 households and conducted VAs using World Health Organization (WHO) 2016 standardized instruments. Interviews generally lasted 30–60 minutes. Physicians completed the WHO standard medical certificate of cause of death for VAs; these were coded using International Classification of Diseases (ICD-10), and underlying cause of death selected using Iris software.

LESSONS LEARNED: Privacy legislation and need to use undertakers restricted the identification of the newly bereaved next-of-kin and the ability to secure their permission to be approached for interviews. However, 6328 gave interview permission, of those, 5768 could be located, and 5388 (93.4%) agreed to the face to face interview. Recruitment of next of kin during community health care visits or during the mandatory death registration process could improve participation. Of the VAs conducted, 68.3% were assigned a specific and valid underlying cause of death, and 16.6% were assigned an underlying cause of death within an ICD chapter without sufficient specification (e.g., cancer without primary site). Next-of-kin were willing to share the deceased's HIV and TB status and provided rich narratives describing the final illnesses. These contained HIV and TB disease course and treatment information and highlighted treatment discontinuation as an ongoing challenge.

CONCLUSIONS/NEXT STEPS VA was acceptable in South Africa and can produce useful mortality data including on deaths due to HIV and TB. VAs may have the potential to improve national cause-of-death statistics if implementation is determined to be feasible on a broader scale. In high HIV and TB burden settings, strategies are needed to standardize the collection of treatment adherence information.

PEC0510

RECENT HIV INFECTION TESTING AND INDEX TESTING YIELD IN NAIROBI KENYA

S. Welty[1], J. Motoku[2], C. Muriithi[2], W. Waruiru[1], B. Ashanda[1], J. Mirjahangir[1], G. Rutherford[1], B. Rice[3], M. de Wit[3], L. Kingwara[4], D. Njoroge[2], J. Karimi[2], A. Njoroge[2]

[1]University of California, Institute for Global Health Sciences, San Francisco, United States, [2]Eastern Deanery AIDS Relief Programme, Nairobi, Kenya, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]National HIV Reference Laboratory, Nairobi, Kenya

BACKGROUND: Latent antibody (LAg) avidity testing can distinguish recent (in the last 12 months) from long-term HIV infection. Integrating testing for recent infection into routine HIV testing services can provide important information on transmission clusters and identify clients for partner testing. We assessed the feasibility of integrating recency testing into routine HIV testing services (HTS) delivery in Kenya and it's utility in identifying priority clients for index partner testing.

METHODS: We conducted a cross-sectional survey in routine HTS services at 14 Eastern Deanery AIDS Relief Program (EDARP) facilities. We tested new HIV positive clients for recent infection using Maxim® HIV-1 LAg-Avidity EIA and viral load. We abstracted demographic, HIV testing and index partner testing data from clinical records.

RESULTS: From March to October 2018, we offered index partner testing to 532 attendees who were newly diagnosed with HIV. Of these 532, 48 (9.0%) were recently infected. The 48 recently infected clients referred 13 partners (0.27 partners/index patient), and the 485 clients with long-term infection referred 133 partners (0.27 partners/index patient). Of the total 146 HIV-infected index partners referred, 61 (42%) were found to be HIV infected; 30 (49%) had been previously diagnosed. Five (39%) of 13 were partners of clients with recent infection and 56 (44%) of 133 were partners of clients with longer-standing infection (p=NS) were found to be HIV infected. Among those, 4 (31%) of the 13 partners of clients with recent infection were previously undiagnosed, compared to 27 (20%) of the 133 partners of clients with longer-term infection. Twenty-one of the 31 previously undiagnosed HIV-infected index partners consented to recency testing; 13 (62%) had recent infection, and 8 (38%) had longer-term infection.

CONCLUSIONS: We conclude that it was feasible to integrate recency testing into routine HTS. Index testing was an effective way to find previously undiagnosed persons with HIV and clients with recent infection bring in more undiagnosed partners. However, we did not find an association between the proportion of partners testing positive and recent infection in the index cases. Our study had small numbers; more robust studies should be done to evaluate integrating recency testing into routine HTS.

PEC0511

DEVELOPMENT AND APPLICATION OF A DATA-DRIVEN APPROACH TO IDENTIFY SUSPECTED HIV-1 RECENT INFECTION CLUSTERS FOR PUBLIC HEALTH RESPONSE IN VIETNAM, 2019

A. Ernst[1], T.M.T. Tran[2], T.T.H. Bui[2], P.D. Manh[3], K. Curran[4], C. Said[1], S. Welty[1], V.N. Nguyen[3], T.T.H. Nguyen[3], G. Rutherford[1], V.H. Son[3]
[1]University of California, Institute for Global Health, Global Strategic Information, San Francisco, United States, [2]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Center for Global Health, Hanoi, Vietnam, [3]Ministry of Health, Vietnam Administration for HIV/AIDS Control, Hanoi, Vietnam, [4]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Center for Global Health, Atlanta, United States

BACKGROUND: The greatest HIV burden in Vietnam is among key populations in specific geographic regions. To reach epidemic control, Vietnam has implemented rapid test for recent infection (RTRI) within the past twelve months into routine HIV testing services in 10 provinces. Identifying suspected clusters with possible high rates of transmission prompts public health investigation and response.
DESCRIPTION: We identified multiple types of clusters: transmission clusters (via contact tracing, molecular analysis), time-space clusters (geographic grouping of cases), or a single recent infection among priority populations. Stakeholders developed and applied several time-space cluster definitions to determine a threshold for response.
LESSONS LEARNED: From January-August 2019, 402 RTRI-recent HIV cases were identified in 10 provinces. We analyzed data by month, geography, and multiple cluster definitions. With most new diagnoses in two urban provinces, stakeholders agreed that cluster definitions be geographic-specific and field-tested with data.
Using a definition of ≥2 recent cases monthly, provincial-level analysis yielded 48 clusters (average size: 9.27 RTRI-recent cases). District-level analysis, using the same threshold of ≥2 recent cases monthly, identified 40 clusters (average: 4.42 RTRI-recent), with the majority of clusters in Hanoi (n=8, 7 districts) and Ho Chi Minh City (HCMC) (n=30, 12 districts). However, district-level analysis significantly reduced the number of clusters in non-urban provinces, suggesting the need for distinct definitions in high-burden provinces like Hanoi and HCMC. In HCMC, using a definition of ≥6 recent cases monthly, district-level analysis yielded 10 high-volume clusters (average: 9.30 RTRI-recent, 6 districts).
Considering limited resources for response, we developed and applied the following cluster definitions:

1. Hanoi: ≥2 RTRI-recent cases per district monthly;
2. HCMC: ≥6 RTRI-recent cases per district monthly; and
3. National: ≥2 RTRI-recent cases per province monthly.

CONCLUSIONS/NEXT STEPS Using RTRI data, stakeholders developed and field-tested geographic-specific time-space cluster definitions. As health authorities investigate suspected clusters, it is critical to review data routinely in real-time to monitor cluster numbers and trends.
Future evaluations may consider time-space clusters by facility. We recommend that initial cluster definitions be validated using statistical or spatial analysis software and revised accordingly, with input from stakeholders on their capacity to identify and respond to clusters.

PEC0512

INCREASING HIV TESTING YIELD THROUGH INDEX CONTACT TESTING SERVICES TO REACH UNDIAGNOSED PLWHV IN THE SOUTH WEST REGION-CAMEROON

C. Sabastine Anye[1], P. Tih M.[2], A. Pascal Nji[3], D. Felix[1], A. Cynthia Piaplah[1], N. Claude[1], N. Emmanuel[3], M.E. Asongwe[3]
[1]Cameroon Baptist Convention Health Services (CBCHS), Strategic Information/Monitoring and Evaluation, Buea, Cameroon, [2]Cameroon Baptist Convention Health Services, Director, Bamenda, Cameroon, [3]Cameroon Baptist Convention Health Services, Senior Advisor, Bamenda, Cameroon

BACKGROUND: Cameroon, a Central African country is on track to achieving an HIV Epidemic Control, through attaining the first target of the UNAIDS 95-95-95 goals with >70% of PLWHV being aware of their status. In response to improving case identification to reach the last PLWHV, Cameroon scaled up the Index Contact Testing (HIV partner notification) program.
METHODS: This strategy started in 2015 being scaled up across 51 PEPFAR supported health facilities. All newly diagnosed PLWHV from all HIV testing modalities (including the confirmed cases diagnosed in the community) were offered this service after linking them to care. Likewise, the old patients (on treatment for >12 months), unsuppressed viral load cases, and the KPs were offered the partner notification services as well. The index clients were offered different referral methods (either client referral, dual referral, contract and or provider referral methods) of getting their contacts tested after notifying them of HIV exposure.
RESULTS: From the collected data between four project quarters (from October 2018 to October 2019), 1691(n) clients were identified and offered the ICT services as index clients (Females (64%), Males (36%)). Of these index clients offered ICT services, 1560(n) accepted the services offer (Females (64%), Males (36%)), with an overall 92% acceptance rate.

NEW Index Cases		Disclosed	# Notified	# Tested	%Notified Tested	# Tested Positive	Yield	# Linked to ART	% Linked to ART

Children of Index Cases (Age ≤ 15)		632	621	648	103%	20	3%	15	75%
Biological Parents		31	32	36	116%	11	31%	7	64%
TOTAL		1778	1730	1812	102%	299	17%	243	81%

OLD Index Cases		Disclosed	# Notified	# Tested	%Notified Tested	# Tested Positive	Yield	# Linked to ART	% Linked to ART
Index Persons Offered IT Services	803								
Index Persons Accepted IT Services	746								
Sex Partners of Index Cases		723	718	711	98%	136	19%	115	85%
Children of Index Cases(Age ≤ 15)		556	544	643	116%	9	1%	7	78%
Biological Parents		10	12	14	140%	2	14%	2	100%
TOTAL		1289	1274	1368	106%	147	11%	124	84%

[PEC0512 Table]

CONCLUSIONS: HIV Index Contact testing has proven to be an effective strategy towards the achievement of an epidemic control in Cameroon via actively testing the contacts of the already infected HIV patients, especially the contacts of the newly initiated (<12months on treatment) clients and those of clients with an unsuppressed viral load (>1000copies/ml).HIV index testing provided a high yield in infected contacts with HIV, hence scaling up these activity is ideal to improve on case identification, achieving the UNAIDS 95,95,95 goals.

PEC0513

CD4-BASED METRICS TO MONITOR TIMELINESS OF HIV DIAGNOSIS, LOS ANGELES COUNTY, 2013-2018

A. Kim[1], Y. Hu[1], K. Poortinga[1], Z. Sheng[1], C.-M. Kuo[1], S. Kulkarni[1], W. Garland[1], M. Perez[1]
[1]*Los Angeles County Public Health Department, Division of HIV and STD Programs, Los Angeles, United States*

BACKGROUND: HIV is controlled by diagnosing infection soon after HIV seroconversion to ensure that treatment and viral suppression can be achieved early in infection, reducing the likelihood of transmission to others. Metrics for monitoring HIV control do not include measures to evaluate achievement of timely HIV diagnosis on a population level. In the United States, jurisdictions collect immunological data on persons living with HIV (PLWH) for surveillance. This information can be leveraged to monitor timely HIV diagnosis by tracking the percentage of HIV cases with CD4>500 cells/mm^3 at the time of diagnosis.

METHODS: Los Angeles County's (LAC's) HIV surveillance system was used to analyze CD4 results from PLWH diagnosed between 2013-2018. Median and interquartile ranges (IQR) for CD4 levels within 1 month of HIV diagnosis were calculated. CD4 counts were categorized as: <200 cells/mm^3 (i.e., late diagnoses), 200-500 cells/mm^3, and >500 cells/mm^3 (i.e., early diagnoses). Log binomial regression models, controlling for age, gender, race/ethnicity, geography and year of diagnosis, identified factors associated with increased risk for late HIV diagnosis.

RESULTS: Between 2013-2018, 5,335 (54.6%) of 11,467 new HIV cases reported during that period had a CD4 test with 1 month of HIV diagnosis. Median CD4 at HIV diagnosis increased from 385 cells/mm^3 (IQR 193-570) in 2013 to 413 cells/mm3 (IQR 240-605) in 2018. During the 6-year observation period, early HIV diagnosis among individuals diagnosed in each year ranged from 34.0%-36.6%, while late diagnoses ranged from 20.3%-25.6%. The risk of late diagnosis was significantly higher among persons aged 30+ years (Adjusted prevalence ratio [APR] 2.5; 95% confidence interval [CI] 2.3-2.7) vs. persons aged <30 years; Latinos (APR 1.2; 95% CI 1.1-1.4) vs. Whites; and residents in Antelope Valley health district (APR 1.6; 95% CI 1.1-2.4) vs. West health district.

CONCLUSIONS: Timely achievement of HIV diagnosis has improved but remains sub-optimal in LAC. In 2018, only 1 in 3 cases were diagnosed early while 1 in 5 were diagnosed late. Ending the HIV epidemic will require the HIV response to be redirected to ensure age- and culturally-appropriate services are accessible and successful to enable earlier diagnoses, treatment, and viral suppression for all PLWH.

PEC0514

ED-BASED UNIVERSAL SCREENING FOR HUMAN IMMUNODEFICIENCY VIRUS USING AN ELECTRONIC MEDICAL RECORD BEST PRACTICE ALERT

K. Toosi[1], T. Chechi[1], J. Ford[1], M. Otmar[1], N. Tran[2], L. May[1]
[1]*UC Davis Health, Emergency Medicine, Sacramento, United States,* [2]*UC Davis Health, Pathology and Laboratory Medicine, Sacramento, United States*

BACKGROUND: The Center for Disease Control and Prevention (CDC) and the United States Preventive Services Task Force (USPSTF) recommend that all individuals aged 15 to 64 years be screened for human immunodeficiency virus (HIV) regardless of risk factors. Early diagnosis of HIV is associated with earlier initiation of antiretroviral therapy (ART) and subsequent reduction in HIV-related illness and transmission risk.

The purpose of this study was to implement routine opt-out HIV screening in an ED setting through an electronic medical record (EMR) to increase testing of eligible patients.

METHODS: From November 2018 through November 2019, an automated best practice alert (BPA) was implemented in a quaternary care ED in Northern California to identify patients for screening who were undergoing laboratory testing, were between the ages of 18 to 64, had no prior positive HIV test within the EMR, and had not been tested for HIV within the prior 12 months. Patients were screened with an HIV antigen/antibody test with reflex HIV-1/HIV-2 confirmatory testing.

This study included all patients screened by the BPA, in addition to patients who underwent HIV diagnostic testing as part of their clinical work-up. Data are described with descriptive statistics including 95%CI. Comparison between groups was performed using logistic regression, reported as odds ratio with 95%CI.

RESULTS: 14,732 total patients were screened during the study period (mean age 43±14 years; 50% female), with a majority of patients screened using the BPA (14,568, 99%). HIV seropositivity was identified in 108 (0.7%) patients in the BPA group and 46 (0.3%) patients undergoing diagnostic testing. Seropositive patients in the BPA were more likely to be male (OR 4.0 [2.6, 6.3]; $p < 0.001$). 24 (22%) seropositive patients in the BPA group were unaware of HIV status prior to testing; linkage to care was provided for 33 (31%) patients, with 59 (55%) patients having already established medical care.

CONCLUSIONS: Nontargeted opt-out rapid HIV screening in the ED, versus diagnostic testing, was associated with identification of a modestly increased number of patients with new HIV diagnoses, most of whom were identified early in the course of disease and provided with appropriate follow-up medical care.

PEC0515

PROJECT PODER: A COMMUNITY-BASED APPROACH FOR HIV CLUSTER DETECTION AND RESPONSE AMONG HISPANIC MSM AND TRANSGENDER COMMUNITIES THROUGHOUT HOUSTON, TX

M. Garcia[1]
[1]*Tulane University, Social Work, New Orleans, United States*

BACKGROUND: HIV incidence in the US has increased for Hispanic, stabilized for Black, and decreased for White men who have sex with men (MSM). The US government's plan to end the HIV epidemic has emphasized molecular HIV surveillance (MHS) as a strategy to detect

and respond to growing HIV transmission clusters. However, existing medical advances to treat and prevent HIV have not successfully engaged communities of color.

DESCRIPTION: The Houston Health Department was one of four CDC demonstration sites throughout the US to utilize MHS for cluster detection and response for Hispanic MSM and transgender communities. MHS data was based on HIV genetic sequences collected from HIV drug resistance tests. An HIV molecular cluster consists of people living with HIV (PLWH) with a highly similar HIV strain that meets a .05% HIV genetic distance threshold. January 2019, a total of 28 molecular clusters were identified among 126 PLWH. Project PODER's goal was to identify, monitor, and respond to HIV molecular clusters among Hispanic MSM and transgender communities. Strategic Framework: 1. establish partnerships and capacity building stakeholders; 2. monitor and prioritize molecular clusters for investigation; 3. increase HIV testing, treatment as prevention, and PrEP; and 4. address socio-structural HIV-related factors.

LESSONS LEARNED: Historically oppressed and highly marginalized populations were more likely to mistrust the government and significant concerns were raised about the government taking HIV genetic sequences without their consent. The community was alarmed that associating PLWH with a molecular cluster may further stigmatize and result in HIV criminalization or deportation.

Community stakeholders played a critical role in addressing the concerns of the community. A community advisory board (CAB) was established and members were instrumental in developing resources that were culturally informed and linguistically appropriate for Hispanic sexual and gender minorities. A community-based approach supported Social Network Strategy as a peer-based intervention to inform and engage the Hispanic community to access HIV related services.

CONCLUSIONS/NEXT STEPS Structural level outcomes resulted in the health department retraining staff and enhancing access to care for highly marginalized populations. The health department reframed MHS through a strengths-based approach and encouraged people in the community to promote HIV testing.

MEASURING AND EVALUATING QUALITY OF SERVICE PROVISION AND HEALTH OUTCOMES THROUGH PUBLIC HEALTH SURVEILLANCE

PEC0516

MISSED OPPORTUNITIES FOR EARLY HIV DIAGNOSIS IN SOUTH CAROLINA, 2013-2016

S. Weissman[1], S. Chen[2], J. Zhang[2], C. Nkwonta[2], B. Olatosi[2], L. Xiaoming[2]
[1]University of South Carolina, Medicine, Division of Infectious Diseases, Columbia, United States, [2]University of South Carolina, School of Public Health, Columbia, United States

BACKGROUND: Previous studies showed that 73.4% of individuals newly diagnosed with HIV in South Carolina (SC), had visited a SC healthcare facility (HCF) in the years preceding their HIV diagnosis, representing missed opportunities for HIV testing and early diagnoses. Of these individuals 43.4% were diagnosed late, with AIDS. Early HIV diagnosis and antiretroviral initiation are key to ending the HIV epidemic. The current study re-visits the previous investigation to determine if there has been a reduction in late diagnoses and missed opportunities.

METHODS: The SC enhanced HIV/AIDS Reporting System and a statewide all payer HCF database were linked. The HCF data include inpatient (IP), outpatient (OP), and emergency department (ED) visits. Analysis includes individuals diagnosed with HIV in SC from 01/2013-12/2016 and all HCF from 2005 to HIV diagnosis. Late testers were defined as initial CD4<200 cells/mm^3. For late testers, HCF visits within eight years before their HIV diagnosis were included as missed opportunities. For non-late testers, visits within three years were included. We used the two-tailed chi-square statistics with a significant threshold of p<0.05 in SAS to investigate the association between missed opportunities and patient factors. Logistic regression models were used to analyze factors potentially associated with missed opportunities.

RESULTS: From 1/2013-12/2016, 2693 individuals were newly diagnosed with HIV in SC. Of these, 743 (27.6%) were late testers. Overall 1987 (73.4%) had at least one HCF prior to their HIV diagnosis, representing missed opportunities for earlier HIV diagnosis. These 1987 individuals had a total of 12,243 (mean 6.2) HCF prior to the HIV diagnosis, including 10,109 (82.6%) in ED, 990 (8.1%) IP, and 831 (6.8%) OP. The table shows factors associated with missed opportunities.

[Table: Predictors of Having Prior Health Care Visits (Missed Opportunities): Crude and Adjusted Logistic Regression, South Carolina 2013-2016, n=2693]

CONCLUSIONS: Although a decrease from earlier years, >25% of new HIV diagnoses in SC are diagnosed late. Missed opportunities for HIV testing and earlier diagnosis remain a problem.

PEC0517

SHARED DISPARITIES IN THE HIV CARE CONTINUUM AMONG PEOPLE LIVING WITH HIV IN ALAMEDA AND SAN FRANCISCO COUNTIES, USA

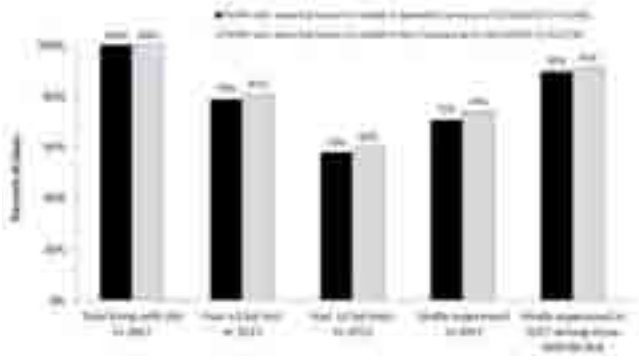
L. Hsu[1], S. Scheer[1], N. Moss[2], E. Wilson[3], D. Allgeier[2], W. McFarland[3], J. Lin[3], M. Yu[2], D. Miller[3], N. Murgai[2]

[1]San Francisco Department of Public Health, HIV Epidemiology and Surveillance Section, San Francisco, United States, [2]Alameda County Public Health Department, Division of Communicable Disease Control and Prevention, Oakland, United States, [3]San Francisco Department of Public Health, Center for Public Health Research, San Francisco, United States

BACKGROUND: Alameda County (AC, including Oakland) and San Francisco (SF) are neighboring counties and are among the 48 US counties accounting for the majority of HIV infections in the US. In both counties, early HIV treatment and viral suppression (VS) are key strategies to eliminate HIV by 2030. Despite shared populations and geographic proximity to one another, HIV public health programs are managed separately. Our objective is to use the framework of the HIV care continuum to identify common disparities and improve regional coordination of the HIV epidemic response.

METHODS: HIV surveillance data from the AC and SF health departments were analyzed to include persons diagnosed by 12/31/2016 who were alive and last known to reside in each county as of 12/31/2017. Linkage to care was defined as having ³1 reported laboratory result in 2017; retention was ³2 laboratory results in 2017; and VS was latest viral load <200 copies/mL in 2017.

RESULTS: There were 5741 persons living with HIV in AC and 12778 in SF. In 2017, linkage to care was 79% and 81%, retention was 58% and 60%, VS was 71% and 74%, and VS among those with any lab report in 2017 was 90% and 91% in AC and SF, respectively (Figure). Populations with lower VS than the overall population included women (87% and 82% in AC and SF, respectively), African-Americans (86% and 84% in AC and SF, respectively), those ages 13-39 in AC (83%-87%) and 25-49 in SF (87%-88%), and trans women in SF (81%).



[Figure. Continuum of HIV care among persons living with HIV, 2017, Alameda and San Francisco counties, USA]

CONCLUSIONS: AC and SF had similar disparities in viral suppression, particularly for women, African-Americans, and younger persons. Analysis of multi-jurisdictional HIV care engagement data can inform regional HIV responses. To end HIV transmission in AC and SF by 2030, coordinated efforts between neighboring counties to improve care continuum outcomes for marginalized populations are needed.

PEC0518

FACTORS ASSOCIATED WITH TESTING FOR HIV AND HEPATITIS C AMONG AT-RISK MEN IN GERMANY

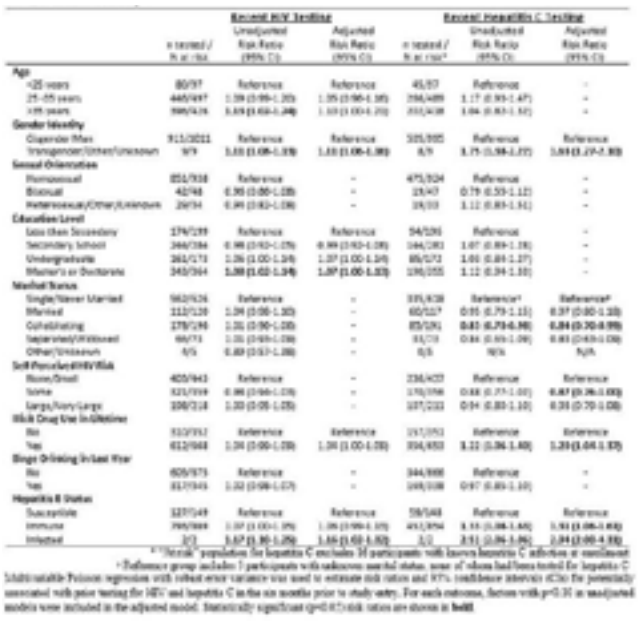
Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]MVZ Labor Krone GbR, Bad Salzuflen, Germany, [4]Uniklinik Köln, Cologne, Germany, [5]University of Bonn, Department of Internal Medicine, Medical Faculty, Bonn, Germany, [6]Institut für Interdisziplinäre Medizin, Hamburg, Germany, [7]Zentrum für Infektiologie, Berlin, Germany, [8]University of Duisburg-Essen, University Hospital, Essen, Germany, [9]Infektiologikum, Frankfurt, Germany, [10]Technical University of Munich, School of Medicine, Munich, Germany, [11]Praxis Hohenstaufenring, Cologne, Germany, [12]Praxis Dr. Cordes, Berlin, Germany, [13]University of Bochum, Center for Sexual Health and Medicine, German Competence Net HIV/AIDS, Bochum, Germany, [14]Praxis Jessen² + Kollegen, Berlin, Germany, [15]Robert Koch Institute, Department for Infectious Disease Epidemiology, Berlin, Germany, [16]University of Bonn, Institute of Virology, Medical Faculty, Bonn, Germany

BACKGROUND: HIV and hepatitis C virus (HCV) have partly shared routes of transmission, including sexual transmission via condomless anal intercourse among men who have sex with men (MSM). Routine screening for both diseases facilitates early diagnosis and treatment, thereby preventing morbidity and onward transmission. We evaluated factors associated with HIV and HCV testing in a German cohort of predominantly MSM.

METHODS: From June 2018 through June 2019, the RV500/BRAHMS study enrolled HIV-uninfected men aged 18-55 years at ten German clinics. Eligible participants reported, in the preceding 24 weeks, either (1) condomless anal intercourse with ≥2 male partners living with HIV or of unknown HIV status or (2) diagnosis of a sexually transmitted infection (syphilis, acute HCV, or anorectal gonorrhea, chlamydia, or Mycoplasma genitalium). Participants completed behavioral questionnaires that included questions about prior experience with HIV and HCV testing. Multivariable robust Poisson regression was used to estimate risk ratios and 95% confidence intervals for factors potentially associated with testing in the previous six months.



[Table. Factors associated with HIV and hepatitis C testing in the last six months during routine care among at-risk men in Germany]

RESULTS: Among 1,020 participants with median age 33.1 (interquartile range 28.6-39.0) years, 1003 (98.3%) reported any lifetime history of HIV testing and 789 (77.4%) reported any HCV testing, including 16 (1.6%) with known HCV infection. Testing within the last six months was reported by 922 (90.4%) and 529 (51.9%) for HIV and HCV, respectively. Recent HIV testing was more common among participants with non-cisgender identity, higher education level, and hepatitis B infection (Table). Recent HCV testing was more common among participants with non-cisgender identity, lifetime history of illicit drug use, and hepatitis B infection.

CONCLUSIONS: Prior screening for HIV and HCV was relatively common in this cohort with known risk factors for infection. Self-perception of risk was not associated with increased testing uptake, highlighting the need for clinicians to employ objective risk stratification methods to identify appropriate testing candidates.

PEC0519

TRANSLATING A SAFETY SIGNAL FOR DOLUTEGRAVIR USE AT THE TIME OF CONCEPTION INTO PUBLIC POLICY FOR WOMEN LIVING WITH HIV IN BRAZIL

L. Neves da Silveira[1], A.A.C.M. Ferreira[1], T.D. Barros[1], G. Mosimann Jr[1], A.S.D. Guarabyra[1], T.C. Morelli[1], V.C.d.S. Lima[1], A.M.B. Beber[1], M. Freitas[1], G.F.M. Pereira[1], F.F. Fonseca[1]
[1]Brazilian Ministry of Health, Chronic Conditions and Sexually Transmitted Infections Department, Brasília, Brazil

BACKGROUND: In Brazil, access to antiretroviral treatment (ART) is universal since 1996; in 2013, treatment was instituted for all people living with HIV (PL-HIV) and since 2017 dolutegravir (DTG) is the preferred ART for initiation scheme for all PL-HIV. In 2018, World Health Organization (WHO) issued a safety signal concerning use of DTG at the time of conception to a possible increase in risk of neural tube defects (NTDs), rare congenital anomalies in Brazilian population. The aim of this study is to describe Brazilian Ministry of Health's (BMoH) response to that alert.

DESCRIPTION: In May 2018, BMoH conditioned the use of DTG in women of reproductive age living with HIV (WL-HIV) to concomitant use of contraceptive methods that do not depend of women's adherence (intrauterine device or tubal ligation). Also changed the ART regimen recommendation for all WL-HIV that did not use one of those contraceptive methods for an efavirenz ART regimen. In parallel, a national study to monitor obstetric outcomes among women exposed to DTG at the time of conception was conducted.

LESSONS LEARNED: The survey to assess WL-HIV who became pregnant on inadvertent use of DTG from January 2015 to May 2018 identified 382 exposures, but no cases of NTD were identified. The referred surveillance is still ongoing after the initial investigation phase. BMoH updated ART recommendations for WL-HIV in December/2019: affirming the preponderant role of DTG as initial ART option, removing the restriction of DTG to concomitantly contraceptive method that does not depend on adherence, reinforcing the need to assess sexual and reproductive health and family planning in every WL-HIV consultation and their sexual partnerships.

CONCLUSIONS/NEXT STEPS The PV will be expanded for the assessment of all obstetric outcomes in WL-HIV, regardless of the ART regimen. Considering the DTG advantages for WL-HIV's health, data from the national survey and studies conducted in other countries, BMoH reinforces the importance of ART choice focused on the autonomy of WL-HIV, empowering them in the therapeutic process. The present challenge is to monitor the impact of the change in ART recommendation on WL-HIV and to increase health professionals' adherence to approach sexual and reproductive health.

PEC0520

VIRAL LOAD SUPPRESSION AND RECENCY OF INFECTION AMONG HIV-POSITIVE SEXUALLY TRANSMITTED INFECTION (STI) SERVICE ATTENDEES

T. Chakezha[1,2], F. Radebe[1], V. Maseko[1], R. Kularatne[1,3], A. Puren[1,4]
[1]National Institute for Communicable Diseases, Centre for HIV and STIs, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [3]University of the Witwatersrand, Department of Clinical Microbiology, Johannesburg, South Africa, [4]University of the Witwatersrand, Division of Virology, School of Pathology, Johannesburg, South Africa

BACKGROUND: We describe antiretroviral therapy status and viral loads among HIV positive STI clinic service attendees. We discuss the implications of the findings for HIV prevention, care and treatment.

METHODS: Cross sectional design. Adults attending two STI clinics conducting sentinel surveillance were enrolled. A nurse-administered questionnaire collected data on demographic and clinical variables was completed for all. Blood specimens were collected for 4th generation HIV serology, plasma VL levels and Limited Avidity Antigen (LAg) assay testing. ART status was determined by self-report. Proportions with VL≥1000 copies/ml determined for those on ART and not on ART respectively. HIV positives were recently infected if not on ART, VL≥1000 copies/ml and LAg assay was recent.

RESULTS: Of 353 STI service attendees enrolled from February - August 2019- median age 28 (interquartile range 24- 35 years), 227 (64.3%) male - 72 (20.5%) were HIV positive . Of the 72 HIV positives, 25 (34.7%) reported were taking ARVs, with 9/21 (36%) and 7/21 (33.3) with valid VL results having VL ≥ 50 copies/ml and VL ≥1000 copies/ml respectively. Of 47 individuals not on ART, 38/44 (86.3%) and 34/44 (77.2%) had VL ≥ 50 copies/ml and ≥ 1000 copies/ml respectively. Of the 34 HIV positives not on ART with VL≥ 1000 copies/ml, 8 (23.5%) were recently infected based on the LAg assay (see Figure 1).

[Figure 1. Study flow]

CONCLUSIONS: HIV positive STI service attendees had high viral loads and about a fifth of those not on ART were recently infected. Better integration of STI screening, diagnosis and treatment with HIV testing, care and treatment is necessary to identify HIV positives who are i) recently infected ii)chronically infected, not on ART and iii)on ART for partner notification and index testing, linkage to ART initiation and adherence support. Planned laboratory measured antiretroviral drug levels will reduce misclassification by ART status.

MODELLING THE POTENTIAL IMPACT OF PREVENTION STRATEGIES ON THE HIV EPIDEMIC

AIDS-RELATED AND NON-AIDS-RELATED MORTALITY AMONG PEOPLE LIVING WITH HIV IN IRAN: FINDINGS FROM A RETROSPECTIVE COHORT STUDY

Z. Gheibi[1], Z. Shayan[2], M. Dianatinasab[3], M. Fararouei[4,1], H. Joulaei[4], A. Mirzazadeh[5,6], M. Shokouhi[7,6]
[1]Shiraz University of Medical Sciences, Department of Epidemiology, Shiraz, Iran, Islamic Republic of, [2]Shiraz University of Medical Sciences, Trauma Research Center, School of Medicine, Shiraz, Iran, Islamic Republic of, [3]Shahroud University of Medical Sciences, Department of Epidemiology, Center for Health Related Social and Behavioral Sciences Research, Shahroud, Iran, Islamic Republic of, [4]Shiraz University of Medical Sciences, HIV/AIDS Research Center, Institute of Health, Shiraz, Iran, Islamic Republic of, [5]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [6]Kerman University of Medical Sciences, HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance Institute for Futures Studies in Health, Kerman, Iran, Islamic Republic of, [7]University of Toronto, Division of Social and Behavioural Health Sciences, Dalla Lana School of Public Health, Toronto, Canada

BACKGROUND: Little is known about the rate of mortality among people living with HIV (PLWH) in the Middle East region. This study estimated the rates of AIDS-related mortality (ARM) and non-AIDS-related mortality (NARM) among PLWH in southern Iran.

METHODS: We conducted a retrospective study using medical/health records from 1997 to 2017. We defined two outcomes using ICD10 codes for cause of death in PLWH: a) ARM, mortalities caused by AIDS or immunodeficiency conditions, and b) NARM, mortalities not directly associated with HIV/AIDS (e.g., cardiovascular diseases, accident, overdose). Cox proportional hazard and competing risk models were used to examine the associated factors of mortality, and then subdistribution hazard ratio (SHR) with 95% confidence intervals (CI) were reported.

RESULTS: Of the 1,160 PLWH, 391 (33.7%) died of whom 251 (64.2%) were ARM. Mortality rates due to ARM and NARM were 38.9 (95% CI: 34.4, 44.0) and 23.2 (95% CI: 19.7, 27.4) per 1,000 person-years, respectively. Associated factors with increased hazard of ARM included: age per one-year increase (SHR 1.02, 95% CI: 1.01, 1.03), late HIV diagnosis (SHR 2.84, 95% CI: 2.12, 3.80), and advanced HIV clinical stages (SHR 7.40, 95% CI: 3.89, 14.07). Associated factors with increased risk of NARM included: male gender (SHR 3.57, 95% CI: 1.16, 11.00), incarceration history (SHR 2.14, 95% CI: 1.04, 4.41), and advanced HIV clinical stages (SHR 0.24, 95% CI: 0.15, 0.38). ART (ARM: SHR 0.09, 95% CI: 0.04, 0.20) (NARM: SHR 0.14, 95% CI: 0.09, 0.23), Pneumocystis Pneumonia (PCP) prophylaxis (ARM: SHR 0.56, 95% CI: 0.42, 0.76) (NARM:SHR 0.64, 95% CI: 0.46, 0.89), and higher CD4 count at diagnosis (ARM: SHR 0.99, 95% CI: 0.97, 0.99) reduced the mortality risk.

CONCLUSIONS: The AIDS-related and non-AIDS-related mortality rates are high among PLWH in Iran. Effective evidence-based strategies should be considered to identify PLWH at earlier stages of the infection, and target those with greater risks of mortality, in particular men, older people, and those with incarceration history.

PEC0522

NATIONALLY REPRESENTATIVE SIMULATION MODEL OF HIV TRANSMISSION CLUSTERS IN THE UNITED STATES

A.M. France[1], C. Gopalappa[2], S. Singh[2], Y.-H. Chen[1], A. Oster[1], Z. Li[1], A. Bingham[1], P. Farnham[1]
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]University of Massachusetts, Department of Mechanical and Industrial Engineering, Amherst, United States

BACKGROUND: Responding to HIV clusters and outbreaks is one of four pillars of the U.S. federal *Ending the HIV Epidemic* initiative. Large HIV transmission clusters in the United States are increasingly recognized through analysis of HIV molecular sequence data reported to the National HIV Surveillance System (NHSS). A simulation model that generates HIV clusters is critical to assess intervention strategies. To date, however, no model has successfully incorporated HIV molecular cluster detection and replicated large HIV clusters. We sought to develop a nationally representative simulation model that replicates clusters observed in NHSS data.

METHODS: We developed a stochastic agent-based network model of HIV transmission among men who have sex with men (MSM) in the United States, incorporating a scale-free network algorithm to replicate sexual transmission networks and adopting a model of HIV progression from CDC's Progression and Transmission of HIV (PATH) model. Using a previously-published algorithm, molecular clusters were identified from HIV transmission networks simulated by the model. We simulated transmission in a population of 7 million MSM and sampled the constructed molecular networks to reflect partial availability (~50%) of sequence data in NHSS. We calculated the median and range of clustering and cluster size across 30 simulations. Model outputs were compared to HIV molecular clusters identified through NHSS during 2015-2017.

RESULTS: In simulation runs, median of 28% (range: 21-38%) of patients with diagnosed HIV were in a cluster. Most clusters were small, with a median of 75% of clusters of size 2 (range: 55-86%), 14% (5-31%) size 3-4, 7% (0-13%) size 5-8, and 5% (0-10%) size > 8. Among people with diagnosed HIV during 2015-2017 for whom a molecular sequence was available in NHSS data, 23% were part of a cluster. Of all clusters observed in NHSS, 64% were of size 2, 25% size 3-4, 8% size 5-7, and 3% size >8.

CONCLUSIONS: The model generated HIV clusters among MSM with a frequency and distribution comparable to that observed in NHSS data. This simulation can replicate the full extent of cluster networks, including undiagnosed infections, which can't be observed in surveillance data, thus providing a critical tool to assess intervention strategies.

PEC0523

MODELLING THE COST-EFFECTIVENESS OF OFFERING PRE-EXPOSURE PROPHYLAXIS TO WOMEN ATTENDING FAMILY PLANNING APPOINTMENTS IN MALAWI

B. Jewell[1], J.A. Smith[1], T.B. Hallett[1]
[1]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom

BACKGROUND: HIV incidence was very high (3.81/100 woman-years) among young women enrolled in a recent randomized trial of HIV risk and contraceptives (ECHO), prompting calls for integration of

family planning and HIV services. One proposed intervention is to offer pre-exposure prophylaxis (PrEP) to any woman attending a family planning visit, while another is to reduce women's unmet need for contraceptives. We modelled the cost-effectiveness of different strategies of increasing PrEP and contraceptive uptake among women attending family planning visits in Malawi.

METHODS: We adapted a pre-existing deterministic, compartmental mathematical model of HIV transmission, contraceptive use, and maternal and HIV outcomes to include age-specific family planning visit attendance, with the potential for uptake of contraceptives and PrEP. The model simulates three intervention scenarios:

(i) PrEP is offered to all women attending family planning visits, with 5-10% age-specific uptake;

(ii) no PrEP is offered but contraceptive use increases such that 20-80% of unmet need is fulfilled; and;

(iii) PrEP is offered to women attending family planning visits concurrent with 20-80% fulfilment of unmet contraceptive need.

Costs (including provision of PrEP, antiretroviral therapy, and contraceptives) and disability-adjusted life-years (DALYs) are measured across time horizons of 5, 10, and 20 years, relative to status quo (no PrEP use and contraceptive use remains at 2020 levels), with 3% discounting.

RESULTS: In Malawi, offering PrEP to women at family planning appointments without increasing contraceptive use would not be cost-effective over any time horizon, while fulfilling any proportion of unmet contraceptive need would be, at $165-290/DALY averted (Table). Combining PrEP and contraceptive uptake would improve cost-effectiveness compared to PrEP alone, but would not be cost-effective overall.

		Cost per DALY Averted		
Scenario		2020-2025 (5 Years)	2020-2030 (10 Years)	2020-2040 (20 Years)
1: PrEP only (offered to women at family planning visits)		$92,063	$24,789	$15,459
2: No PrEP; contraceptive use is increased among women	(a): 20% of unmet need is met	$165	$199	$290
	(b): 40% of unmet need is met	$165	$199	$290
	(c): 80% of unmet need is met	$165	$199	$289
3: PrEP (offered to women at family planning visits) and contraceptive use is increased among women	(a): 20% of unmet need is met	$13,697	$7,160	$4,632
	(b): 40% of unmet need is met	$7,711	$4,430	$2,945
	(c): 80% of unmet need is met	$4,319	$2,596	$1,804

[Table]

CONCLUSIONS: Offering PrEP to all women attending family planning visits is unlikely to be cost-effective in settings without high, generalized HIV incidence or risk targeting. Increasing uptake of contraception is the most cost-effective option for women in Malawi overall.

MODELLING CASH PLUS OTHER PSYCHOSOCIAL AND STRUCTURAL INTERVENTIONS TO PREVENT HIV AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN SOUTH AFRICA (HPTN 068)

M.C.D. Stoner[1,2], J. Edwards[3], D. Westreich[3], K. Kilburn[4], J. Ahern[5], S.A. Lippman[6,7], F.X. Gomez-Olive[7,8], K. Kahn[8,7,9], A. Pettifor[3,2,7], HPTN 068 Study Team

[1]RTI International, Women's Global Health Imperative, San Francisco, United States, [2]University of North Carolina, Carolina Population Center, Chapel Hill, United States, [3]University of North Carolina, Department of Epidemiology, Chapel Hill, United States, [4]Duke University, Duke Global Health Institute, Durham, United States, [5]University of California, Division of Epidemiology & Biostatistics, School of Public Health, Berkeley, United States, [6]University of California, Department of Medicine, San Francisco, United States, [7]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa, [8]INDEPTH Network, Accra, Ghana, [9]Umeå University, Epidemiology and Global Health Unit, Department of Public Health and Clinical Medicine, Umeå, Sweden

BACKGROUND: Combining cash transfer programs with other psychosocial and structural interventions to increase parental support, increase access to school, or provide adolescent sensitive clinic care have had greater impacts on sexual risk behaviors than receipt of cash alone. However, no studies have assessed the impact of combining cash plus other interventions on HIV incidence. We modelled the reductions in HIV incidence associated with combining receipt of the South African Child Support Grant (CSG) increased school attendance, reduced depression, reduced intimate partner violence, increased parental care and receipt of a conditional cash transfer intervention among AGYW in South Africa.

METHODS: We used data from the HIV Prevention Trials Network (HPTN) 068 trial of cash transfers conditional on school attendance in rural South Africa (2011-2015). AGYW aged 13-20 years were followed for up to 4 years, with half randomized to cash transfer and 80% residing in households that received a government CSG regardless of assigned trial arm. We used the g-formula to model the theoretical change in HIV incidence associated with combinations of receipt of a CSG plus all other exposures.

RESULTS: Receipt of the CSG alone and receipt of the conditional cash transfer alone were not associated with HIV incidence. Receipt of a CSG plus parental care had the largest relationship with incident HIV infection when combing the CSG with a single exposure (Risk Difference (RD) -2.6; 95% CI -4.7%, -0.6%). An intervention to provide a CSG combined with increasing parental care and eliminating depression showed the greatest reduction in incident HIV infection with changes in the fewest number of risk factors (RD -3.0%; (95% CI: -5.1, -0.).

CONCLUSIONS: Pairing receipt of a CSG with other interventions addressing social and structural risks experienced by AGYW has the potential to have a greater impact on HIV incidence than receipt of cash alone. Interventions to provide household grants could be combined with interventions to improve parental care and reduce depression to more effectively reduce HIV incidence among adolescent girls and young women in South Africa

PEC0525

IMPROVED PREP EFFECTIVENESS ON NON-DAILY REGIMENS AMONG INDIVIDUALS WITH LOW ADHERENCE: A SIMULATION STUDY USING HPTN 067/ADAPT DATA

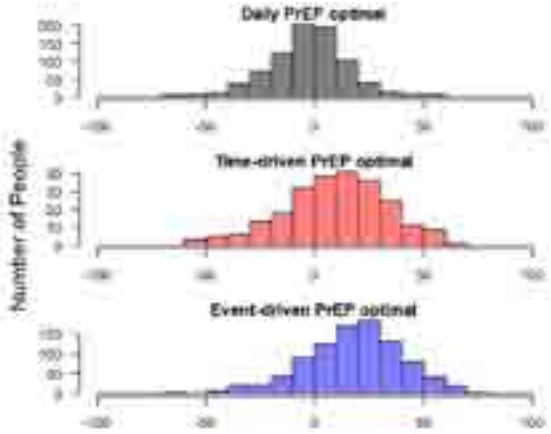
J.R. Moore[1], M.-C. Boily[2], K.M. Mitchell[2], M. Li[1], J.P. Hughes[1,3], D. Donnell[1], S. Mannheimer[4], D. Dimitrov[1,5]

[1]Fred Hutch Cancer Research Institute, Vaccine and Infectious Disease, Seattle, United States, [2]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom, [3]University of Washington, Biostatistics, Seattle, United States, [4]Columbia University, Harlem Hospital and Mailman School of Public Health, New York, United States, [5]University of Washington, Applied Mathematics, Seattle, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP) is effective in preventing HIV, however sub-optimal adherence can limit the effectiveness of daily PrEP. Alternative PrEP dosing may help some individuals improve adherence. HPTN 067 evaluated the pill-taking behavior of two non-daily PrEP regimens: time-driven PrEP (one pill twice per week plus one pill after sex) and event-driven PrEP (one pill before and one after sex).

METHODS: A mathematical model of HIV acquisition was calibrated to sexual activity and pill taking data from men who have sex with men at the Harlem, NY site of HPTN 067. A crossover study was simulated with 2,000 PrEP users in the bottom 20% of adherence to daily PrEP, comparing an initial six months on daily PrEP to successive six-month courses of either time-driven or event-driven PrEP dosing. Correlation between adherence to daily and non-daily regimens was inferred from data on weekly and post-sex pill-taking from the time-driven arm of HPTN 067. Simulated PrEP effectiveness was calculated using the relationship between pill taking frequency and PrEP efficacy derived from the iPrEx and STRAND studies. We identified the most effective PrEP regimen for each individual and simulated it for a six-month follow-up period.

RESULTS: Our analysis suggests that time– and event–driven PrEP minimize HIV risk for 10% and 50% of the low adherence PrEP users, respectively, with better PrEP effectiveness estimated for most users over the follow-up period (see figure). At the population level, predicted PrEP effectiveness rose from 29% to 44% and from 43% to 66% among those for whom event- and time- driven PrEP were optimal, respectively.



[Figure. Absolute % change in effectiveness followup vs initial daily PeEP]

CONCLUSIONS: Our trial simulation results suggest that introducing non-daily dosing may improve PrEP effectiveness for individuals with low adherence to daily PrEP. This approach highlights the potential utility of non-daily PrEP options for individuals at risk.

PEC0526

ATTRIBUTING HEALTH BENEFITS TO TREATMENT AND PREVENTION EFFORTS IN THE HIV RESPONSE: AN ANALYSIS IN SIX U.S. CITIES

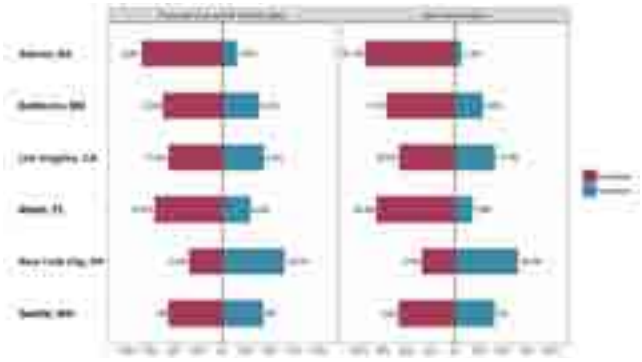
E. Krebs[1], E.A. Enns[2], X. Zang[1], J.E. Min[1], H.A. Duarte[3], B. Nosyk[1], on behalf of the localized economic modeling study group

[1]British Columbia Centre for Excellence in HIV/AIDS, Health Economic Research Unit, Vancouver, Canada, [2]University of Minnesota, School of Public Health, Minneapolis, United States, [3]University of Washington, School of Medicine, Seattle, United States

BACKGROUND: Combination strategies are key to reaching the ambitious goals of 'Ending the HIV Epidemic' in the United States. These strategies generate health benefits through both improved treatment and care for people living with HIV and preventing new infections among uninfected individuals. The distribution of these benefits may vary according to local epidemiological and structural context. In this analysis, we aimed to determine the proportion of health benefits attributable to HIV prevention versus HIV treatment from health-maximizing combination strategies across diverse local microepidemics.

METHODS: Using a dynamic HIV transmission model calibrated for Atlanta, Baltimore, Los Angeles, Miami, New York City (NYC) and Seattle, we assessed the health benefits of implementing highest-valued combinations of evidence-based interventions at publicly-documented implementation levels (drawn from best available evidence) or ideal (90% coverage) scale-up (10-year implementation over a 20-year horizon). Total health benefits for each city were measured in terms of quality-adjusted life-years (QALYs) gained. We then calculated the proportion of QALYs gained due to HIV prevention (through averted and delayed HIV infections) and HIV treatment (through improved treatment access, retention, and adherence).

RESULTS: The proportion of HIV health benefits attributable to treatment varied from 15.3% in Atlanta to 65.0% in NYC (Figure) at publicly-documented levels of combination intervention strategies. At ideal implementation levels, total health benefits gained were always higher; however, the proportion attributable to HIV treatment was reduced in five of six cities, indicating that QALY gains due to scale-up were primarily driven by HIV prevention benefits.



[Figure. Health benefits attributed to combination implementation strategies of HIV treatment and prevention interventions across 6 U.S. cities]

CONCLUSIONS: The proportion of HIV health benefits arising due to the effects of treatment were highest in settings with high levels of epidemiologic control and diminished at higher levels of implementation due to the resulting decreases in prevalence. Understanding to whom benefits accrue may be important in assessing the equity and impact of HIV investments.

PEC0527

MODELING INTEGRATED ANTIRETROVIRAL TREATMENT AND HARM REDUCTION SERVICES ON HIV AND OVERDOSE AMONG PEOPLE WHO INJECT DRUGS IN TIJUANA, MEXICO

J. Cepeda[1], A. Borquez[1], C. Magana[1], A. Vo[1], C. Rafful[2], G. Rangel[3], M.E. Medina-Mora[4], S. Strathdee[1], N. Martin[1]
[1]University of California, Medicine, San Diego, United States, [2]Universidad Nacional Autonoma de Mexico, Psychology, Mexico City, Mexico, [3]El Colegio de la Frontera Norte, Tijuana, Mexico, [4]National Institute on Psychiatry Ramón de la Fuente Muñiz, Mexico City, Mexico

BACKGROUND: The HIV epidemic in Tijuana, Mexico is concentrated in key populations, including people who inject drugs (PWID). Mexico's drug law reform included referral to drug treatment, yet funding was provided for non-evidence based compulsory abstinence programs (CAP) associated with elevated HIV and overdose risk. However, evidence-based opioid agonist therapy (OAT) reduces overdose, HIV transmission, and reincarceration, while improving antiretroviral therapy (ART) outcomes. We assessed the potential impact of scaled-up integrated ART and drug treatment (OAT or CAP) on HIV and fatal overdose among PWID in Tijuana.

METHODS: We developed a dynamic model of HIV transmission, incarceration, and fatal overdose among PWID in Tijuana. We incorporated synergistic benefits of OAT on reducing injecting-related HIV transmission, increased ART recruitment and retention, reducing reincarceration, and averting fatal overdose. We also modeled harms associated with CAP on HIV and overdose. We assessed HIV incidence and fatal overdose over the next decade with the following scenarios: 1) status quo (10% ART among HIV-positive PWID and no drug treatment), 2) OAT scale-up to 40%, 3) ART scale-up (10-fold recruitment) among HIV-positive PWID, 4) scale-up OAT to 40% and ART (10-fold recruitment), 5) scale-up CAP to 40% (no ART scale-up).

RESULTS: OAT scale-up to 40% coverage could avert 33% (95%CI: 19–47%) and 22% (95%CI: 11-28%) new HIV infections and fatal overdoses, respectively, over the next decade. Due to low ART coverage, OAT had marginal impact on averting HIV through its effect on ART recruitment/retention. However, integrating OAT and ART scale-up resulted in synergistic benefits, with the OAT effect on ART recruitment/retention averting 10% more new infections compared to ART scale-up alone. Scaling-up OAT and ART could avert 49% (95%CI: 28-67%) of new HIV infections and one-fifth of fatal overdoses over the next decade. Conversely, scaling-up CAP could increase HIV and overdoses.

CONCLUSIONS: : Integrating ART with OAT scale-up could provide synergistic benefits on ART recruitment/retention, and prevent new HIV infections and fatal overdoses among PWID in Tijuana. Conversely, non-evidence based CAP could lead to major harms. Policymakers should consider the synergistic and multiple benefits of integrated OAT and HIV services on HIV and overdose among PWID.

PEC0528

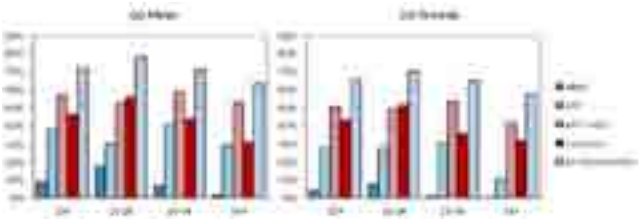
THE EFFECT OF HIV PROGRAMMES IN SOUTH AFRICA ON NATIONAL HIV INCIDENCE TRENDS, 2000-2017

L. Johnson[1], G. Meyer-Rath[2], R. Dorrington[3], A. Puren[4], A. Feizaddeh[5]
[1]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [2]University of Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]University of Cape Town, Centre for Actuarial Research, Cape Town, South Africa, [4]National Institute for Communicable Diseases, Centre for HIV and STI, Johannesburg, South Africa, [5]UNAIDS, Johannesburg, South Africa

BACKGROUND: Recent surveys and longitudinal studies have shown HIV incidence declines at a population level in several African countries. However, these studies have not directly quantified the extent to which incidence declines are attributable to different HIV programmes.

METHODS: We calibrated a mathematical model of the South African HIV epidemic to age- and sex-specific data from antenatal surveys, household surveys and death registration, using a Bayesian approach. The model was also parameterized using age- and sex-specific data on self-reported condom use, medical male circumcisions (MMC), HIV testing and patients receiving antiretroviral treatment (ART). To assess the impact of each programme, model estimates of HIV incidence were compared against the incidence rates that would have been expected had the programme not been implemented.

RESULTS: The model estimated incidence in 15-49 year olds of 0.99% (95% CI: 0.94-1.05%) in 2017. This represents a 56.7% reduction (95% CI: 53.9-59.3%) relative to 2000 (2.27%, 95% CI: 2.25-2.30%), a 39.7% reduction (95% CI: 37.5-41.9%) relative to 2010, and a 70.1% reduction (95% CI: 67.6-72.2%) relative to the incidence that would have been expected in 2017 in the absence of interventions. The reduction in incidence in 2017 due to interventions was greatest in the case of ART and HIV testing (53.7%, 95% CI: 49.6-57.5%) and condom promotion (45.7%, 95% CI: 43.8-48.1%), with MMC having only a modest impact (6.4%, 95% CI: 6.2-6.6%). HIV programme impacts differed significantly by age and sex, with condoms and MMC having their greatest impact in 15-24 year olds, and the overall incidence reduction being greater in men than in women (Figure).



[Figure: Reduction in HIV incidence in 2017 due to HIV programmes]

CONCLUSIONS: HIV testing and ART programmes have together had a substantial impact on HIV incidence trends in South Africa in recent years, while condom promotion has consistently reduced HIV incidence since 2000.

PEC0529

'ENDING THE EPIDEMIC' WILL NOT HAPPEN WITHOUT ADDRESSING RACIAL/ETHNIC DISPARITIES IN THE US HIV EPIDEMIC

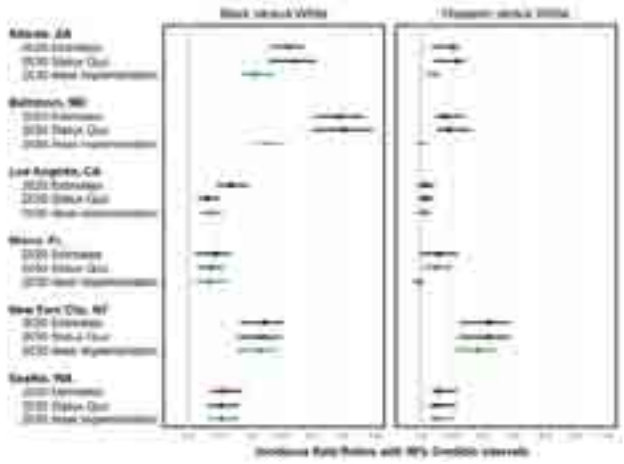
B. Nosyk[1,2], X. Zang[1,2], E. Krebs[2], B. Enns[2], M. Piske[2], C. Behrends[3], C. Del Rio[4], D. Feaster[5], M. Golden[6], B. Marshall[7], S. Mehta[8], Z. Meisel[9], L. Rosen-Metsch[10], A. Pandya[11], B. Schackman[3], S. Shoptaw[12], S. Strathdee[12], Localized Economic Modeling Study Group

[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Weill Cornell Medical College, Healthcare Policy and Research, New York, United States, [4]Emory University School of Medicine, Rollins School of Public Health, Atlanta, United States, [5]University of Miami, Department of Public Health Sciences, Leonard M. Miller School of Medicine, Miami, United States, [6]University of Washington, Department of Medicine, Division of Allergy and Infectious Disease, Seattle, United States, [7]Brown University, School of Public Health, Providence, United States, [8]Johns Hopkins University, Department of Sociomedical Sciences, Mailman School of Public Health, Baltimore, United States, [9]University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States, [10]Columbia University, Department of Sociomedical Sciences, Mailman School of Public Health, New York, United States, [11]Harvard T.H. Chan School of Public Health, Department of Health Policy and Management, Boston, United States, [12]University of California, School of Medicine, Los Angeles, United States

BACKGROUND: Although the tools to reach 'Ending the HIV Epidemic' (EtE) targets are available, there are wide disparities in access to HIV prevention and treatment services in White versus Black and Hispanic populations. Our objective was to define the potential impact of implementing strategies to address racial disparities in HIV incidence, absent additional efforts to curb racial/ethnic disparities in access to HIV/AIDS prevention and treatment efforts.

METHODS: Built off a systematic evidence synthesis and model calibration, we adapted an HIV transmission model to replicate HIV microepidemics in Atlanta, Baltimore, Los Angeles, Miami, New York and Seattle. We focused on unique combinations of evidence-based interventions for each city, delivered at ideal implementation (90% target population coverage), compared to the status quo (access to care held constant at 2015 levels). We projected incidence rates per 100,000 individuals aged 15-64 and calculated incidence rate ratios (IRRs) for Blacks and Hispanics versus White/other under status quo and ideal implementation, from 2020 to 2030.

RESULTS:



[Figure 1. Projected change in the racial/ethnic HIV incidence rate ratio under status quo (black) and ideal combination implementation strategies (green) for six U.S. cities, 2020-2030]

In 2020, estimated IRRs between Blacks and Whites ranged from 1.87 (95%CI:1.21-2.39) (Miami) to 5.85 (5.03-6.66) (Baltimore) (Figure). Between Hispanics and Whites we found a range of 1.16 (0.89-1.45) (Los Angeles) to 3.22 (2.28-3.87) (New York). With combination implementation strategies implemented at ideal levels, Baltimore (39.0%[32.4%-46.2%]), Los Angeles (27.3%[21.7%-35.8%]) and Atlanta (25%[14.6%-31.3%]) were projected to see substantial declines in IRRs between Blacks and Whites by 2030, but IRRs were relatively stable in the other cities. Declines in IRRs were greater for Hispanics, with Miami (0.95[0.75-1.12]), Baltimore (1.01[0.80-1.28]) and Los Angeles (1.12[0.87-1.34]) at or approaching parity with Whites (Figure 1).

CONCLUSIONS: We estimated that disparities in HIV incidence in racial/ethnic groups will not be eliminated without explicit consideration of this factor in public health implementation efforts. Zero discrimination targets have been proposed as part of the National HIV/AIDS strategy, and should be an explicit feature of the EtE strategy.

THE ROLE OF SOCIAL AND SEXUAL NETWORKS IN THE SPREAD OF HIV

PEC0530

NETWORK OF HETEROSEXUAL CONTACTS AND ITS IMPLICATIONS ON HIV INFECTION BASED ON NATIONAL HEALTH BEHAVIORAL SURVEILLANCE (NHBS) SYSTEM DATA OF WASHINGTON DC

S. Das[1,2], R. Medina[3], J. Opoku[1], A. Allston[1,2], I. Kuo[2], M. Kharfen[1], A. Angopian[2]

[1]District of Columbia Department of Health, HIV/AIDS, Hepatitis, STD and TB Administration (HAHSTA), Washington DC, United States, [2]George Washington University, Department of Epidemiology and Biostatistics, Milken Institute of Public Health, Washington DC, United States, [3]University of Utah, Department of Geography, Salt Lake City, United States

BACKGROUND: With an HIV prevalence of 1.8%, DC has made significant progress in reducing new HIV diagnoses over the last 10 years, but the city is struggling to sustain these decreases. Network analysis is a useful tool that can be used to understand sexual and social transmission of HIV. We used the affiliation network analysis among heterosexuals at increased risk of acquiring HIV in DC to understand networks and connectedness.

METHODS: Data from the 2016 National HIV Behavioral Surveillance (NHBS) system among heterosexuals at increased risk in DC was used for this analysis. A total of 747 surveys were collected throughout the cycle. The free social-network analysis package, GEPHI, was employed for all network visualization from adjacency matrix with attributes such as gender and HIV status. We conducted regression analysis to examine the association of selected behavioral and demographic characteristics with HIV infection.

RESULTS: The descriptive characteristics showed 96% of HIV-negative and 100% of HIV-positive participants were Black. Approximately 30% of the HIV-negative and 41% of HIV-positive participants were aged 50 and above. We constructed six connected networks. A total of 24 HIV-positive participants were identified. Seed 1 initiated the largest networks with 426 nodes (16 HIV-positive) followed by seed 4 with 273 nodes (6 HIV-positive). Seed 3 was the third largest network with 36 nodes (2 HIV-positive). Mapping of HIV-positive participants found that all were recruited from 4 zip-codes across DC. Out 24 positives, 11 were located in a single zip-code. The odds of being HIV positive were higher among people with only high school diploma (OR: 5.16; 95%CI: 1.479 - 18.203), those diagnosed with diagnosed mental health condition (OR: 3.037; 95%CI: 1.229 - 7.503) and syphilis (OR: 42.17; 95%CI: 4.0135 - 443.104).

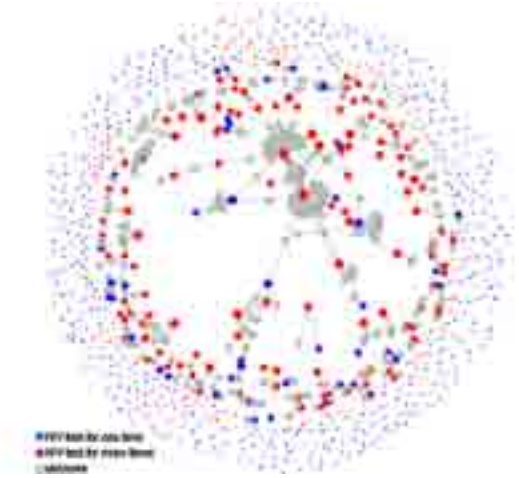
CONCLUSIONS: The study is the first analysis of NHBS data for DC which shows that HIV positives can be identified through networks and HIV positive show spatial clustering. It is also evident that syphilis, diagnosed mental health condition and education have implications on an individual's HIV status. This analysis is an important finding which can be used to drive future intervention and prevention strategies including treatment and PrEP initiatives.

PEC0531

MEN WHO HAVE SEX WITH MEN WHO ARE COLLEGE STUDENTS WITH MORE SOCIAL CONTACTS MORE LIKELY TO HAVE REPEATED HIV TESTING: A LONGITUDINAL STUDY IN NORTHEAST CHINA

Y. Hu[1], H. Wu[2], H. Yan[3], M. Li[2], M. Li[2], W. Shu[2], S.H. Vermund[4], H. Hui[5], H. Li[6]
[1]Capital Medical University, Maternal Care, Child and Adolescent Health, Beijing, China, [2]Capital Medical University, Beijing, China, [3]Heilongjiang Provincial CDC, Harbin, China, [4]Yale School of Public Health, Beijing, United States, [5]Harbin Kongtong Community, Harbin, China, [6]Harbin Kangtong Community, Harbin, China

BACKGROUND: HIV testing promotion is a critical HIV prevention strategy targeting young men who have sex with men. Understanding young people's social networking characteristics could inform HIV testing strategy.
METHODS: We established a longitudinal study of college MSM as users of the Yiyou App, an HIV sero-status query software popular in China. In northeast China (include Heilongjiang province, Jilin province, and Liaoning province) from April 2017 to June 2018, we secured the consented users' social contacts (cross-sectional data) and HIV testing frequency information (longitudinal data), reported by offline HIV testing service dispensary sites. We used multivariable logistic regression and generalized estimated equations to assess predictors of frequency of HIV testing. We visualized the cross-sectional social networking information using Gephi® software.
RESULTS: We enrolled 752 college MSM and their 390 social contacts into the study. High HIV testing-frequency was more likely among men with recreational drug use (past 6 months, aOR=1.65, 95%CI: 1.00-2.71), having >1 HIV self-test (past 6 months, aOR=2.07, 95%CI: 1.43-3.00) and >1 degree of social contact (aOR=4.58, 95%CI: 3.01-6.97). In the longitudinal analysis, from a cumulative 1299 HIV tests, men having >2 HIV tests were more likely in the past six months to report anal sex (aOR=1.75, 95%CI: 1.37-2.24), recreational drug use (aOR=1.67, 95%CI: 1.24-2.24), and having an HIV self-test (aOR=1.3, 95%CI: 1.02-1.65) .



[Figure]

CONCLUSIONS: Active social media contacts, recreational drug use, and prior HIV self-test experience predicted more frequent HIV testing among college MSM, suggesting a potential utility of using online social mobile application to deliver tailored interventions.

PEC0532

SIZE MATTERS: SEXUAL NETWORK SIZE AND RISK OF HIV INFECTION AMONG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER PEOPLE PARTICIPATING IN A PEER-LED HIV SERVICE REFERRAL INTERVENTION IN INDIA

P. Mugundu Ramien[1], G. Shreenivas[1], B. George[1], A.K. Reddy[1], D. Damara[1], N. Murthy[1], J.R. Nagadasu[1], M. Setia[2], J. Baishya[3]
[1]FHI 360, LINKAGES, New Delhi, India, [2]Consultant, Epidemiologist, Mumbai, India, [3]USAID, HIV, New Delhi, India

BACKGROUND: Understanding network characteristics associated with HIV infection and onward transmission is critical for focusing HIV interventions. We assessed associations between self-reported sexual network size and risk of HIV infection among men who have sex with men (MSM) and transgender people participating in a peer-led HIV service referral approach in Krishna district, India.
METHODS: To link previously unreached MSM and trans individuals to HIV services, the LINKAGES project introduced a peer-led strategy called the Enhanced Peer Outreach Approach (EPOA). Participants were asked to report voluntarily on the number of individuals in their current social network with whom they had engaged in anal sex. We conducted logistic and Poisson regression using Stata Version-15, accounting for clustering, to assess associations between sexual network size and HIV serostatus among individuals who received HIV testing as part of the EPOA.
RESULTS: The mean age of the 353 clients who received HIV testing (MSM-287; trans people-66) was 28 years (standard deviation-7.6), and 19.3% tested HIV positive (MSM-19.5%; trans people -18.2%). In multivariate analyses, the network size of HIV-positive individuals was 26% larger ($p<0.05$) than that of HIV-negative individuals. A significantly higher ($p<0.05$) proportion of individuals with a network size of >10 sexual contacts were HIV positive (57.1%) compared to individuals reporting 6–10 (20.3%) or 1–5 (17.7%) contacts. Each unit increase in the reported number of sexual contacts was associated with a statistically significant ($p<0.001$) increase (OR: 1.13, 95% CI: 1.09, 1.17) in the likelihood of receiving an HIV-positive test result. Among MSM, we found that kothis (receptive partners) had a 24% larger sexual network size (RR-1.24; 95% CI 1.11, 1.41; $p<0.001$) than double deckers (both receptive and penetrative partners). Conversely, panthis (penetrative partners) had a 17% smaller (RR-0.83; 95% CI 0.71, 0.97; $p=0.02$) network size than double deckers.
CONCLUSIONS: We found a strong association between the reported sexual network size of MSM and transgender individuals and their likelihood of receiving a positive HIV test result as part of a peer-led service referral strategy. These findings suggest the benefits of targeting HIV services based on self-reported sexual or risk network size, as well as on self-reported risk behavior.

PEC0533

INFLUENCE OF SEROSORTING ON THE POPULATION-LEVEL HIV TRANSMISSION IMPACT OF PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG MEN WHO HAVE SEX WITH MEN (MSM): A MATHEMATICAL MODELING STUDY

L. Wang[1], N. Moqueet[1], A. Simkin[1], J. Knight[1,2], H. Ma[1], N.J. Lachowsky[3], H.L. Armstrong[4,5], D.H.S. Tan[1,2], A.N. Burchell[1,2], T.A. Hart[6,2], D.M. Moore[4,7], B.D. Adam[8], D.R. MacFadden[2], S. Baral[9], S. Mishra[1,2]

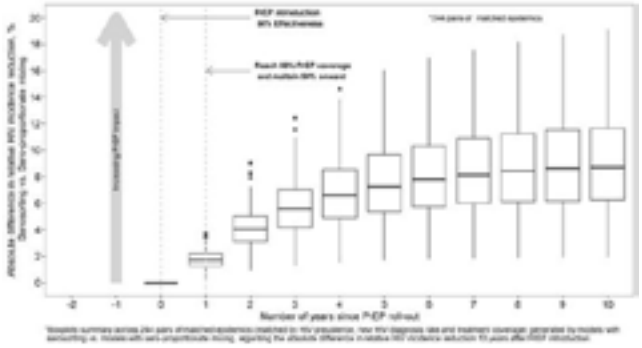
[1]Unity Health Toronto, Toronto, Canada, [2]University of Toronto, Toronto, Canada, [3]University of Victoria, Victoria, Canada, [4]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [5]University of Southampton, Southampton, United Kingdom, [6]Ryerson University, Toronto, Canada, [7]University of British Columbia, Vancouver, Canada, [8]University of Windsor, Windsor, Canada, [9]Johns Hopkins University, Baltimore, Canada

BACKGROUND: HIV PrEP may change serosorting patterns. We examined the influence of serosorting on the population-level HIV transmission impact of PrEP, and how impact could change if PrEP users stopped serosorting, while other men continued serosorting.

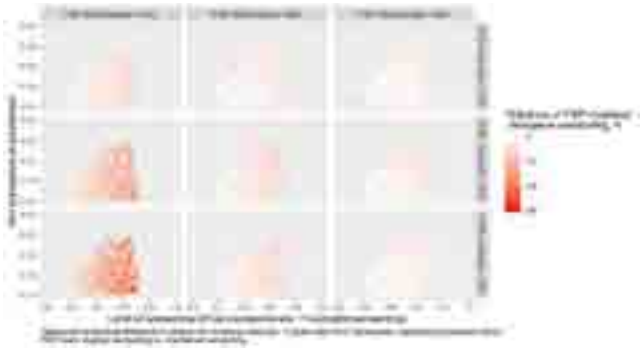
METHODS: We developed a dynamic compartmental HIV transmission model parameterized with bio-behavioural and HIV surveillance data from MSM in Canadian urban settings. We separately fit the model with serosorting and without serosorting (random partner-selection proportional to availability by HIV-status (sero-proportionate)), and reproduced stable HIV epidemics (2013-2018) with HIV-prevalence 10.3%-24.8%, undiagnosed fraction 4.9%-15.8%, and treatment coverage 82.5%-88.4%.

We simulated PrEP-intervention reaching stable coverage by year-1 and compared absolute difference in relative HIV-incidence reduction 10-year post-intervention (PrEP-impact) between: models with serosorting vs. sero-proportionate mixing; 2) scenarios in which PrEP users stopped serosorting vs. maintained serosorting. We examined sensitivity of results to PrEP effectiveness (44%-99%) and coverage (10%-50%).

RESULTS: Models with serosorting predicted a larger PrEP impact compared with models with sero-proportionate mixing (Figure-1), under all PrEP effectiveness and coverage assumptions. PrEP users' stopping serosorting reduced PrEP impact compared with scenarios where PrEP users maintained serosorting: reductions in PrEP impact were minimal (median (inter-quartile-range): 2.1%(1.4%-3.4%)) under high PrEP-effectiveness (86%-99%); however, could be considerable (10.9%(8.2%-14.1%)) under low PrEP-effectiveness (44%) and high coverage (30%-50%)(Figure-2).



[Figure 1. Comparison of PrEP impact on the population-level HIV transmission between models with serosorting vs. models with sero-proportionate mixing.]*



[Figure 2. Influence of PrEP-mediated changes in serosorting on the population-level HIV transmission impact of PrEP by baseline level of serosorting, HIV prevalence at equilibrium, and PrEP intervention condition.]

CONCLUSIONS: Models assuming sero-proportionate mixing among MSM may underestimate population-level HIV-incidence reductions due to PrEP. PrEP-mediated changes in serosorting could lead to programmatically-important reductions in PrEP impact under low PrEP-effectiveness (e.g. poor adherence). Our findings suggest the need to monitor sexual mixing patterns to inform PrEP implementation and evaluation.

PEC0534

OPTIMAL TARGETING FOR EPIDEMIC CONTROL: RESULTS FROM THE LOCAL EPIDEMIC ASSESSMENT FOR PREVENTION (LEAP) MODEL IN CONCENTRATED, MIXED, AND GENERALIZED SUBNATIONAL CONTEXTS

R. Ross[1], A. Dutta[1]

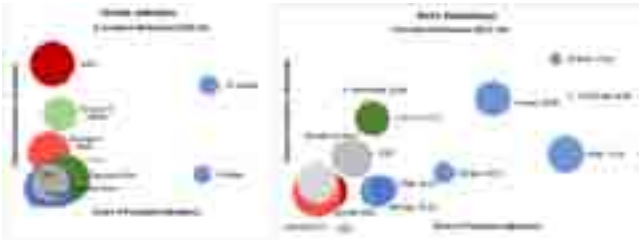
[1]Health Policy Plus, Palladium, Washington, United States

BACKGROUND: As decentralized governments are increasingly responsible for local epidemic control, they must customize HIV interventions to their local context. The USAID- and PEPFAR-supported Health Policy Plus (HP+) project used the Local Epidemic Assessment for Prevention (LEAP) tool to characterize a subnational epidemic, using programmatic, epidemiological, and anthropological information to inform local response. Between 2015-2019, LEAP was implemented in concentrated (Jakarta, Indonesia), mixed (Papua, Indonesia), and generalized (Beira, Mozambique) epidemics.

METHODS: LEAP, designed in MS-Excel, uses subnational (district or province) demographic, epidemiological, behavioral, and programmatic data by sub-population to estimate and project the impact of intervention scenarios on the local HIV epidemic. Subdivisions are defined with differentiation of epidemiological, coverage, and behavioral data and sexual networks among high and low-risk populations. Data sources include integrated bio-behavioral surveillance data, local expert consultation, and anthropological studies. LEAP includes probabilistic sensitivity analysis to account for uncertainty in epidemiological, behavioral, and cost inputs.

RESULTS: In implementing LEAP for the predominantly urban Beira district, Mozambique, population groups are further differentiated by residence into two locations: urban and peri-urban. In Papua, populations are differentiated by three geographic zones: Highlands, Easy to Reach Coastal, and Hard to Reach Coastal. Though Jakarta Province contains five districts, experts suggested that networks, behaviour, and access to interventions varied by socio-economic status not physical location. The LEAP tool was used to model different in-

tervention scale-up scenarios to compare effectiveness and resource needs, Figure 1 illustrates maximum incidence reduction per population group in two of three implementations.



[Figure 1]

CONCLUSIONS: Mathematical models without flexibility to characterize local sexual networks and disaggregate coverage and intervention effectiveness by sub-population group cannot inform programming in the epidemic control and decentralization era. LEAP is driven by local knowledge while applying global evidence, using anthropological data to model sexual transmission reduction. Results provide superior evidence for district/provincial policymakers to tailor the response.

PEC0535

GEOGRAPHIC BRIDGING TIES MAY FACILITATE HIV TRANSMISSION AMONG PEOPLE WHO INJECT DRUGS: A SOCIAL NETWORK ANALYSIS IN THE BALTIMORE REGION

A. Wesolowski[1], S.H. Mehta[1], G.D. Kirk[1], D. German[2], J. Knight[1], C. Latkin[2], G. Lucas[3], B. Genberg[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Health, Behavior & Society, Baltimore, United States, [3]Johns Hopkins University School of Medicine, Infectious Diseases, Baltimore, United States

BACKGROUND: Recent HIV outbreaks, increased overdose mortality and resurgent HCV incidence, all due to changing patterns of opioid use in the US, have increased concerns about a potential reversal in the decades-long decline in HIV incidence related to injection drug use. As the geography of opioid use changes, there is an urgent need to characterize connections between non-urban populations of people using opioids and established urban PWID, as these connections may facilitate HIV transmission from high prevalence urban areas to lower prevalence non-urban settings. The objective of this study was to characterize overlap in urban and non-urban PWID networks in and around Baltimore, Maryland.

METHODS: ALIVE (AIDS Link to the Intravenous Experience) is a community-based prospective cohort of current and former PWIDs ongoing since 1988. ALIVE participants reporting injection drug use in the prior 12 months were eligible for an egocentric social network survey administered in 2018-19. Urban and non-urban networks were defined as uniform geographic locations of the ego and all drug-use ties, whereas bridging networks were defined as any network with discordant residential location (urban vs. non-urban) between the ego and any tie. We compared differences in network properties, HIV suppression and injection-related risk behaviors by geographic characteristics of the networks.

RESULTS: Of the 238 participants, 30% were female, the median age was 51 years, and 59% had urban, 4% non-urban, and 38% bridging networks. Bridging networks were higher density networks (p=0.007), and individuals with bridging networks more often reported injection sharing behaviors (p=0.001) compared to urban and non-urban networks. Compared to PWID with exclusively urban networks, those with bridging networks were more likely to report at least one contact with whom they injected more than one drug (OR=2.07, 95% CI:1.13-3.73). Among urban PWID living with HIV, those with detectable viremia had a higher proportion of non-urban contacts (p<0.0001).

CONCLUSIONS: PWID with more geographically dispersed and connected drug-use networks may be potential conduits of new HIV transmission, through higher risk injection-related behaviors and detectable HIV. Additional research is urgently needed to more robustly characterize the potential for increased HIV transmission among PWID populations with increasing poly-substance use.

THE ROLE OF SYNDEMICS

PEC0536

EXAMINING ASSOCIATIONS BETWEEN SYNDEMIC FACTORS AND HIV-OUTCOMES BY GENDER AND SEXUAL ORIENTATION AMONG WOMEN, STRAIGHT MEN, AND GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN LIVING WITH HIV

K. Closson[1,2], V. Nicholson[1,3], M. Lee[3], K. Card[4], C. Cassidy-Matthews[1,2], T. McLinden[1], M. Marziali[5], J. Trigg[1], L. Wang[1], S. Parashar[1], J.S.G. Montaner[1], A. Gibbs[6,7], T. Hart[8], A. Kaida[3], R.S. Hogg[1,3]
[1]British Columbia Centre for Excellence in HIV/AIDS, Epidemiology and Population Health, Vancouver, Canada, [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [4]University of Victoria, School of Public Health and Social Policy, Victoria, Canada, [5]Columbia University, Mailman School of Public Health, New York, United States, [6]South African Medical Research Council, Gender and Health, Cape Town, South Africa, [7]University of KwaZulu Natal, Centre for Rural Health, School of Nursing and Public Health, Durban, South Africa, [8]Ryerson University, Psychology, Toronto, Canada

BACKGROUND: Little is known about how multiple, co-occurring syndemic experiences affect different populations of people living with HIV (PLHIV). We examined associations between syndemic factors and HIV-outcomes between: women; heterosexual men; and gay, bisexual, and other men who have sex with men (gbMSM) living with HIV (cis and trans inclusive).

METHODS: Using cross-sectional data of 1,000 PLHIV ≥19 years of age accessing antiretroviral therapy (ART) from 2007-2010 in British Columbia, Canada, we assessed associations between a syndemic scores and HIV-related outcomes (from time of interview until December 31st, 2018 or last-contact with the provincial drug treatment program) by gender and sexual orientation. The syndemic score included: any violence (never, ever, in the last 6 months), any sexual violence (ever vs. never), depressive symptoms in the past week (10-item Centre for Epidemiological Studies Depression scale [≥10 indicating probable depression]), post-traumatic stress disorder (ever vs. never), current street drug use (heroin, crack, crystal meth or speedball), and history of excessive drinking (≥2 CAGE score) (range 0-7). Crude and adjusted logistic regression examined associations between syndemic scores and 1) ever viral rebound and 2) average annual ART adherence ≥95% from interview to last-contact, adjusting for age, education, employment, ethnicity and stable housing.

RESULTS: Of 999 participants with complete survey data, 264 (26.4%) were women, 382 (38.2%) were heterosexual men, and 353 (35.3%) were gbMSM. Heterosexual men and women had significantly high-

er median syndemic scores than gbMSM (3 vs. 2, p<0.001). Overall, higher syndemic scores were associated with reduced odds of ≥95% average annual ART adherence from interview until last contact (adjusted odds ratio [aOR]=0.86, 95%CI=0.78-0.95). Among gbMSM, higher syndemic scores were associated with increased odds of viral rebound (aOR=1.30, 95%CI=1.04-1.62) and reduced odds of ≥95% average annual antiretroviral adherence (aOR=0.67, 95%CI=0.55-0.82) from interview until last contact. Associations were not significant for women or heterosexual men.

CONCLUSIONS: We found significant differences in experiences of syndemic factors by gender and sexual orientation. However, higher syndemic scores were only associated with poorer HIV-outcomes among gbMSM, highlighting the need for population-specific adherence supports and additional research examining the unique syndemic experiences of heterosexual men and women living with HIV.

PEC0537

SYNDEMIC EFFECTS OF PSYCHOSOCIAL HEALTH PROBLEMS ON UNPROTECTED ANAL SEX AND THE PREVALENCE OF HIV AND SYPHILIS AMONG MSM AND TG WOMEN IN NEPAL

K. Deuba[1], M.K. Shrestha[2], D.K. Dahal[2], L.R. Pandey[2], R.K. Kharel[3]
[1]Save the Children Stationed at National Centre for AIDS & STD Control, Kathmandu, Nepal, [2]National Centre for AIDS & STD Control, Ministry of Health and Population, Kathmandu, Nepal, [3]National Centre for AIDS & STD Control, Kathmandu, Nepal

BACKGROUND: Men who have sex with men (MSM) and transgender (TG) women experience numerous health inequalities compared to the general population (e.g. HIV infection, sexually transmitted infections, stigma, violence, and discrimination). Although this wide range of health disparities is well documented, significant gaps remain in how psychosocial health problems (injecting drug use, physical abuse and depression) affects risk behaviours among MSM and TG in low-income countries. This study assessed the syndemic effects of psychosocial health problems on unprotected anal sex and the prevalence of HIV and syphilis among MSM and TG women in Nepal.

METHODS: In this quantitative study, 740 MSM and TG women 16 years of age or older, were recruited using respondent driven sampling (RDS) between May 2017 and July 2017 across four districts of Nepal (Kathmandu, Lalitpur, Bhaktapur and Kaski). Information on depression (Center for Epidemiological Studies Depression scale), injection drug use and physical abuse were obtained via the face to face interview. Rapid HIV tests and Rapid Plasma Reagin test performed to assess HIV and syphilis prevalence. Volz–Heckathorn estimator was used to calculate probability weights and RDS-adjusted prevalence. A count of physical abuse (yes vs no), depression (euthymic vs depression) and injection drug use (yes vs no) were calculated to test an additive relationship with unprotected anal sex. Statistically significant associations between independent variables and unprotected anal sex were computed using multivariable logistic regression.

RESULTS: The prevalence of HIV and syphilis was 3.6% and 1.0% respectively. The prevalence of unprotected anal sex was 16% whereas 7% experienced physical abuse and 6% reported injection of drug use in the last 12 months. The burden of depression was high (35%). For each additional psychosocial health problem, the odds of protected anal sex decreased substantially, i.e., by 76% for 2-3 psychosocial health problems (0.24 odds ratio (OR); 95% confidence interval (CI)=0.12-0.47).

CONCLUSIONS: MSM and TG women in Nepal are experiencing multiple psychosocial health problems that also increase the risk of unprotected anal sex. HIV preventive interventions in Nepal should identify and manage the burden of psychosocial health problems among MSM and TG women.

PEC0538

STIMULANT USE AND HIV INFECTION, SUICIDE AND CARDIOVASCULAR DISEASE (CVD) MORTALITY AMONG MEN WHO HAVE SEX WITH MEN (MSM) AND TRANSGENDER WOMEN (TW) IN PERU: A MODELING STUDY

A. Borquez[1], K. Rich[2], M. Farrell[3], L. Degenhardt[3], R. McKetin[3], L.T. Tran[3], J. Cepeda[1], K. Konda[4], A. Silva-Santisteban[4], C.F. Cáceres[4], F. Altice[2], N.K. Martin[1-5]
[1]University of California, Medicine, La Jolla, United States, [2]Yale University, New Haven, United States, [3]University of New South Wales, Sydney, Australia, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]University of Bristol, Bristol, United Kingdom

BACKGROUND: Stimulant use is often high among MSM/TW and has been associated with an increased HIV risk, suicide and CVD mortality. Quantifying the excess disease burden among MSM/TW using stimulants has important policy implications. Using epidemic modeling, we investigated these intersecting health harms among MSM/TW in Lima, Peru, and assessed the impact of prioritizing HIV pre-exposure prophylaxis (PrEP) and harm reduction interventions among MSM/TW who use stimulants.

METHODS: The model represents HIV transmission, CVD and suicide mortality among MSM/TW, differentiating sexual behaviors between four main groups: homosexual and heterosexual/bisexual self-identified MSM, male sex workers and TW. We modeled the increased risk of unprotected anal sex during last encounter obtained from local data (RR=1.35 [95%CI 1.17-1.57]) and used general-population estimates from a global review to model the increased risk of suicide (SMR=6.26 [95%CI 2.84-13.80]) and CVD mortality (SMR=1.83 [95%CI: 0.39-8.57]) among MSM/TW who use stimulants. We estimated the proportion of health harms occurring among MSM/TW who use stimulants in the next year and investigated the ten-year impact (2020-2030) of PrEP prioritization for stimulant-using MSM/TW on HIV, and that of combining PrEP with harm reduction interventions that would halve stimulant use associated risks.

RESULTS: Despite MSM/TW who use stimulants comprising an estimated 9.5% (95%CI: 7.8-11.5) of all MSM/TW in Lima, in the next year, 11% (2.5-97.5% Interval: 10-13%) of new HIV infections, 39% (95%I: 18-60%) of suicides and 15% (95%I: 3-44%) of CVD deaths could occur among this group. Scaling up PrEP among all MSM/TW who use stimulants would prevent 19% (95%I: 11-31%) more HIV infections across 10 years compared to random allocation. Integrating PrEP and an intervention to halve stimulant-associated risks could reduce overall new HIV infections by 20% (95%I: 10-37%), suicide deaths by 14% (95%I: 5-27%), and CVD deaths by 3% (95%I: 0-16%).

CONCLUSIONS: MSM/TW who use stimulants experience a disproportionate burden of HIV infection, suicide and CVD mortality. Prioritizing PrEP based on stimulant use, in addition to sexual behavior or gender identity criteria, could increase its impact. Importantly, as we move towards integration of HIV services, providing comprehensive substance use and mental health care could reduce health disparities among MSM/TW who use stimulants.

UNDERSTANDING THE SPREAD OF HIV THROUGH BEHAVIOURAL STUDIES

PEC0539

ESTIMATING THE CONTRIBUTION OF STIMULANT INJECTION TO HIV AND HCV EPIDEMICS AMONG PEOPLE WHO INJECT DRUGS AND IMPLICATIONS FOR HARM REDUCTION: A MODELING ANALYSIS

J. Cepeda[1], P. Vickerman[2], J. Bruneau[3], G. Zeng[3], A. Borquez[1], M. Farrell[4], L. Degenhardt[4], N. Martin[1]
[1]University of California, Medicine, San Diego, United States, [2]University of Bristol, Bristol, United Kingdom, [3]Universite de Montreal, Montreal, Canada, [4]University of New South Wales, Sydney, Australia

BACKGROUND: Stimulants, such as amphetamines and cocaine, are widely injected among people who inject drugs (PWID). Global systematic reviews indicate stimulant injection is associated with HIV and HCV among PWID. Using these associations, we estimated the contribution of stimulant injection to HIV and HCV transmission among PWID.

METHODS: We developed a dynamic transmission model of HIV and HCV among PWID, incorporating excess injecting and sexual risk among PWID who inject stimulants. We simulated three illustrative settings with different main stimulants injected (amphetamines or cocaine), prevalence of stimulant injecting, and HIV/HCV epidemiology. We calibrated to review data on elevated HIV and HCV among PWID who inject stimulants by class (amphetamines/cocaine). We estimated one-year population attributable fractions of stimulant injection on new HIV and HCV infections, and impact of needle-syringe program (NSP) scale-up among PWID who inject stimulants.

RESULTS: In a setting with low prevalence of stimulant injection (St. Petersburg-like, where 13% inject amphetamine), 9% (2.5-97.5% interval [95%I]: 6-15%) and 7% (95%I 4-11%) of incident HIV and HCV cases, respectively, could be associated with stimulant injection in the next year. With moderate prevalence of stimulant injection (Montreal-like, 34% inject cocaine), 29% (95%I: 19–37%) and 19% (95%I: 16-21%) of incident HIV and HCV cases, respectively, could be associated with stimulant injection. In a high-burden setting like Bangkok (65% inject methamphetamine), 23% (95%I:10–34%) and 20 (95%I: 9-27%) of incident HIV and HCV cases could be due to stimulant injection. If high-coverage NSP increased to 60% among PWID who inject stimulants, this could reduce HIV incidence (by 22-65%) and HCV incidence (by 7-11%) in a decade, but not all excess risk would be removed.

CONCLUSIONS: Stimulant injection contributes to a substantial fraction of HIV and HCV among PWID. NSP scale-up and development of novel interventions among PWID who inject stimulants are warranted.

MODELLING FUTURE HEALTHCARE NEEDS

PEC0540

HIGH LEVEL OF HIV RE-SUPRESSSION FOLLOWING INTENSIVE ADHRENCE COUNSELLING FOR ADULTS ON A PROTEASE INHIBITOR SECOND LINE THERAPY AT AN URBAN HIV CLINIC IN KAMPALA, UGANDA

N. Violet Enid[1,2]
[1]Makerere University Joint AIDS Program, Medicine, Kampala, Uganda, [2]Medicine, Mukono, Uganda

BACKGROUND: Uganda has attained the first two of UNAIDS 90-90-90 goals for HIV epidemic control by 2020. The Uganda Ministry of Health adopted the WHO recommendation of intensive adherence counselling (IAC) for PLHIV who fail to achieve viral suppression , irrespective of whether they are on first or second line ART.. This study sought to determine the prevalence of re-suppression and factors associated with non-suppression of HIV viral load after IAC at Mulago ISS clinic.

METHODS: We conducted a retrospective study on PLHIV aged ≥18 years on second-line ART who received treatment between January 2016 and December 2018 at Mulago ISS clinic. Data on age, gender, baseline and post IAC VL, completion of three IAC sessions, was extracted from the clinic's Open Medical Records System (Open MRS). We determined the prevalence of re-suppression after six months with its 95% confidence interval (CI).

RESULTS: A total of 1,523 adult PLHIV were receiving second line ART of whom 1,046 (68.1%) were female. The median age and baseline CD4 counts were 40 (35-46) years and 229 (81-419) cells/Ul respectively. Average duration on ART was 7.2 (3.28) years. Majority of patients 817 (53.6%) were on Lopinavir/r (LPV/r) with the rest on Atazanavir/r (ATV/r). HIV re-suppression at 6 months following three sessions of IAC was achieved among 1,153 (75.7%, [95%CI: 73-77.8]) patients. Over 14.8% (171) patients failed to achieve VL suppression at one year. After an additional IAC session, 50.3% (86) re-suppressed, 76(44.4%) did not while 4 died and 5 were lost to follow-up. The 76 clients were subjected to a resisitance profile testing and only 11 had protease inhibitor mutations hence switched to thirdline . 65 clients who didnt have pi mutations were matained on second line PI based regimen but eventually suppressed . Additionally, patients who had been on ART for 5-10years were less likely to re suppress.

CONCLUSIONS: HIV viral suppression following IAC for PLHIV on PI- based second- line ART was high but below the UNAIDS 3rd 90 target of 2020. Innovations to improve HIV viral suppression among females and patients who have been on ART for more than 5 years are needed.

PEC0541

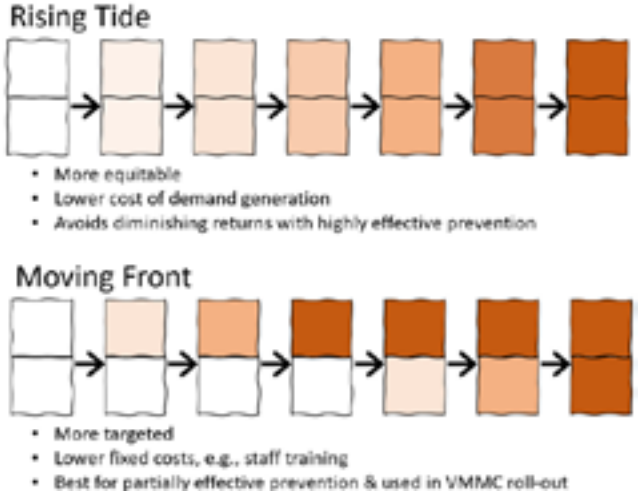
RISING TIDE OR MOVING FRONT? LESSONS FROM VOLUNTARY MEDICAL MALE CIRCUMCISION (VMMC) TO SHAPE THE SCALE-UP OF NEW HIV PREVENTION METHODS IN WESTERN KENYA

A. Bershteyn[1], H.-Y. Kim[1], C. Ngugi[2], R.W. Mbogo[3], E. Mudimu[4], C.C. Kerr[5], A.N. Akullian[5], D.J. Klein[5], R.S. Braithwaite[1], S.M. Mwalili[6]
[1]New York University School of Medicine, Department of Population Health, New York, United States, [2]Kenya Ministry of Health, National AIDS and Sexually Transmitted Infection Control Programme, Nairobi, Kenya, [3]Strathmore University, Strathmore Institute of Mathematical Sciences, Nairobi, Kenya, [4]University of South Africa, Department of Decision Sciences, Pretoria, South Africa, [5]Institute for Disease Modeling, Bellevue, United States, [6]Strathmore University, Center for Health Analysis and Modeling, Nairobi, Kenya

BACKGROUND: Health authorities in sub-Saharan Africa are anticipating new HIV prevention methods such as long-acting prophylaxis. Scale-up of these interventions could cover broad geographies with gradually increasing coverage (a "rising tide") or could focus on high-priority locations with gradually increasing geographic scope (a "moving front"). We analyzed epidemiological and economic factors influencing the optimal scale-up strategy and compared them to past scale-up of VMMC in western Kenya.

METHODS: An agent-based network model of HIV in western Kenya was used to compare the efficiency and effectiveness of HIV prevention with a "rising tide," "moving front," or intermediate approach to scale-up. Key populations such as sex workers were assumed to receive priority access regardless of geography, while access for the general population depended upon clinic catchment area. We varied the intervention effectiveness, scale-up rate, and economic variables including the fixed cost of offering a new service and outreach cost to achieve high coverage. Results were compared to past scale-up of VMMC.

RESULTS: "Moving front" approaches are initially preferable because they prioritize high-incidence catchment areas. At >90% intervention efficacy, "rising tide" approaches can become favorable due to diminishing returns of maximizing coverage when incidence is already declining. Fixed costs such as staff training favor a "moving front" approach, while demand generation costs favor a "rising tide" approach. The optimal balance is a "moving front" that expands when incidence declines or demand generation becomes costly. This is consistent with VMMC roll-out over the past decade, which began in the highest-incidence communities and expanded in geographic scope before maximizing coverage.



[Figure]

CONCLUSIONS: "Moving front" strategies are well-suited to the spatial heterogeneity of HIV in western Kenya. Health authorities have successfully balanced the advantages of "rising tide" and "moving front" approaches when scaling up VMMC. For future interventions, the optimal balance depends on efficacy, fixed costs, and outreach costs.

IDENTIFYING OPTIMAL SERVICE MODELS

PEC0542

CAN WE REDUCE THE FREQUENCY OF CLINICAL MONITORING IN HIV PATIENTS WITH LONG TERM VIROLOGICAL AND IMMUNOLOGICAL SUCCESS?

B. Crabtree-Ramírez[1], J. Sierra-Madero[1], R. Velazquez-Pastrana[1], Y. Caro-Vega[1]
[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Infectologia, Mexico City, Mexico

BACKGROUND: The Mexican ARV program mandates a six month monitoring frequency in people living with HIV (PLWH). It is uncertain if PLWH with virological and immunological success (VIS) need such close follow-up. We attempt to identify the frequency of adverse outcomes (death, AIDS events, non-AIDS events (NAIDS), virological failure (VF) and loss to follow-up (LTFU)) among patients classified as VIS.

METHODS: PLWH adults seen at Instituto Nacional de Ciencias Médicas y Nutrición in Mexico City, since 2000 with at least two years of follow-up were included. Patients were categorized as VIS (at least two years with VL<200c/mL and CD4>350 cells/mL) and non-VIS. Clinical outcomes: death, AIDS, NAIDS, VF (2 consecutive VL determinations >1000c/mL) and LTFU (no clinical visits in >1 year) were compared between groups. We estimated the crude incidence of any event, the distribution of outcomes among VIS and non-VIS and associated factors and time to first event using a Cox model stratified by gender including VIS and characteristics at enrollment

RESULTS: Among 2088 patients, 1099(53%) were classified as VIS and followed by a median of 5.2 years (IQR: 2.5 -8.7), with a median of 2.45 clinic visits per-year (IQR: 2.15-2.8). 518(47%) had at least one outcome with an incidence of 12.5 events/100-person-years: 59% NADEs (70% considered non-serious), 20% VF, 15% LTFU, 4% AIDS and <1% deaths. Among patients classified as non-VIS, 649(66%) events were reported with an incidence of 19.1 events/100-person-years and 49% NADES, 22% VF, 20% LTFU, 6% AIDS and 2.6% deaths. Patients who at entrance to care were ART-experienced and enrolled before 2010 were more likely to have any outcome (HR: 1.23; 1.07-1.42 and HR: 1.65, 1.42-1.94), respectively. Patients with VIS were less likely to develop an outcome (HR: 0.86, 0.74-1.00). Adjusted median time to event, was significantly shorter in VIS women, when compared to VIS men: 52 (95%CI: 44-90) vs 76(95%CI: 67-85) months.

CONCLUSIONS: PLWH with virological and immunological success, naïve and enrolled after 2010 have low risk of unfavorable outcomes and may be candidates to less frequent clinical monitoring. However the strategy must be carefully evaluated among women. Nevertheless, future evaluation of this strategy is warranted.

PEC0543

IMPACT OF RAPID ART INITIATION IN RECENTLY DIAGNOSED PATIENTS IN AN HIV REFERENCE PUBLIC CLINIC OF GUATEMALA

L. Aguirre[1], O. Bonilla[2], C. Brown[3], J.C. Pérez[2], B. Ortíz[2], D. Mercado[2], E. Arathoon[2], B. Samayoa[1]
[1]Asociación de Salud Integral, Guatemala, Guatemala, [2]Clínica Familiar Luis Ángel García, Guatemala, Guatemala, [3]Montefiore, New York, United States

BACKGROUND: The World Health Organization recommends the initiation of antiretroviral therapy (ART) within the first seven days to reduce mortality, morbidity, and transmission of HIV. In Guatemala, a rapid initiation program was implemented in an HIV reference public clinic, aiming to measure the impact on patients with a recent diagnosis.

METHODS: A comparison study was conducted to measure the impact of a rapid initiation ART program at a reference public clinic in Guatemala City, from January 2016 until May 2019, and consisted of two cohorts of newly diagnosed patients: I) before the introduction of the Test and Treat program (Pre-T&T), from January 2016 to June 2017 (N=477) and II) after the introduction (Post-T&T), from September 2017 to May 2019 (N=630). All patients were 18 years and older, never received prior ART, and followed for care in the clinic. A database of demographic and clinical information was extracted from the electronic medical record. The data was analyzed using descriptive statistics, Chi2, and T-student test in the program R, at a significance level of 0.05.

RESULTS: From 1400 patients evaluated, 78.3% (n=1097) met criteria for inclusion. From these, 79.5% were male, 19.0% female, and 1.5% transgender; median age at the time of diagnosis was 28 years old. In the Pre-T&T group, 124 patients initiated ART in a mean of 22.4 days (median:14; IQR:4), 26% (n=124/477) reached a viral load below 200 copies/mL in a mean of 144 days (median:137; IQR:44), and 6.4% died (n=8/124); versus Post-T&T group in which the patients initiated ART in a mean of 5 days (median: 0; IQR:7), 72.5% (n=457/630) reached viral suppression in a mean of 77.8 days (median:84; IQR: 64); and 1.7% died (n=8/456). Statistical differences were observed in all the parameters compared above between the two cohorts (p<0.05).

CONCLUSIONS: It is feasible to implement a rapid initiation program of ART in a clinic from a developing country with the impact of reducing the ART initiation time by 75%, achieving viral load suppression 46% faster and reducing mortality in 4.7%.

PEC0544

BURDEN OF TYPE 2 DIABETES MELLITUS AND ASSOCIATED FACTORS AMONG HIV NEGATIVE AND POSITIVE PATIENTS IN TWO REGIONAL REFERRAL HOSPITALS IN THE MANZINI REGION, ESWATINI

S.K.S. Masuku[1], J. Tsoka-Gwegweni[2], B. Sartorius[3], T.S.B. Maseko[4], F.S. Shabalala[1]
[1]University of Eswatini, Community Health Nursing Science, Mbabane, Eswatini, [2]University of the Free State, Nursing and Public Health, Bloemfontein, South Africa, [3]University of KwaZulu-Natal, Public Health Medicine, Durban, South Africa, [4]University Research Co., LLC, Research Grants, Mbabane, Eswatini

BACKGROUND: Type 2 diabetes mellitus (T2DM) is an emerging non-communicable disease (NCD) in low and middle-income countries (LMICs) in sub-Saharan Africa (SSA) since the rollout of antiretroviral therapy (ART) in Swaziland, the burden of T2DM in human immunodeficiency virus (HIV) infected people and comparison against HIV negative control population has not been evaluated in Swaziland. This study aimed at assessing proximal and distal predictors of T2DM among HIV positive adults in comparison to HIV negative adults.

METHODS: We employed a cross-sectional comparative study design with 498 subjects selected at random in each group. Face-to-face interviews were conducted to obtain socio-demographic and risk factors. Venous blood was collected, fasting blood glucose and 2-hour oral glucose tolerance test. Multivariable logistic regression was used to identify significant determinants of T2DM.

RESULTS: Prevalence of diabetes was 25.6% (95%CI: 22.6 – 28.2). A higher (36.1%; 95%CI: 31.9 – 40.4) prevalence of diabetes was observed in the HIV positive cohort compared to the HIV negative group (14.8%; 95%CI: 11.6 – 17.5). Being ≥40 years posed a higher risk (OR=1.04; 95%CI: 1.00 – 1.07, p=0.04) of developing T2DM compared to those <40 years. Overweight (OR=1.82; 95%CI: 1.06 – 3.10, p=0.029) and obesity (OR=3.73; 95%CI: 2.26 – 6.14, p<0.001) increased the risk of diabetes. Alcohol intake increased the risk of diabetes 15 folds (OR=15.05; 95%CI: 9.03 – 25.11, p<0.001) compared to not taking alcohol. Moderate (OR=0.4; 95%CI: 0.25 – 0.67, p<0.001) and vigorous physical activity (OR=0.1; 95%CI: 0.05 – 0.14, p<0.001) reduced the risk of diabetes. Being HIV positive increased the risk of T2DM (OR=3.43; 95%CI: 2.28 – 5.14; p<0.001) compared to being HIV negative.

CONCLUSIONS: HIV positive cohort had a higher prevalence of T2DM and being HIV positive is a risk factor for T2DM, hence HIV care services need to include T2DM prevention and management.

REACHING AND RECRUITING KEY POPULATIONS FOR HIV SERVICES (ONLINE, OFFLINE, ONLINE-TO-OFFLINE)

PEC0545

TARGETING MEN AS KEY POPULATION TO REDUCE THE BURDEN OF MOTHER-TO-CHILD HIV TRANSMISSION

D. Apagu[1], Y. Tagurum[2]
[1]FCT Primary Health Care Board, Planning Research and Statistics, Abuja, Nigeria, [2]Jos University Teaching Hospital, Community Medicine, Jos, Nigeria

BACKGROUND: About 1.9 million people are living with HIV/AIDS in Nigeria and 100,000 are children who acquired the infection through mother-to-child transmission (MTCT). Over 130,000 new infections were reported in 2018. Hetero-sexual transmission among the general population accounts for most cases of HIV/AIDS. HIV interventions are mostly targeted towards health facilities, focusing particularly on women attending antenatal care (ANC). This approach has excluded men from accessing HIV/AIDS services.
This study aimed at exploring strategy through which men could be better reached with HIV/AIDS intervention to reduce MTCT.

METHODS: Exploratory qualitative study design involving men and women of reproductive age group (15-49 years). The study was carried out in Tunkus, Plateau State, Nigeria. Dahlgren and Whitehead model was used to guide the analysis. Data was collected through focus group discussions (FGDs) and Key informant interviews. Data analysis was based on themes and sub-themes of the study. Direct quotes from the respondents were also used.

RESULTS: Most male respondents welcome HCT in ANC for their partners and are willing to accompany them to the clinic, but complaint of time constraint and the feminine setting of the ANC clinic

where men and women have to sit together contrary to the culture and tradition. This was demonstrated by this respondent:

…"*I will love to carry my wife to the ANC clinic but am very busy, there is no time. The place is also full of women*"… 35 year old male participant.

When asked how men could support their wives regarding PMTCT, particularly couple HCT, majority in both groups are of the opinion that HCT should be done at home.

…." *I cannot do the test in the hospital except at home* "…34 year old respondent.

The female FGD respondents further confirmed the feelings of their partners regarding couple counseling in the ANC

. …"*my husband said he doesn't like the Hospital environment, he said it is meant for women, test should be done at home*"..*A 27 year female respondent*

CONCLUSIONS: Men can be reached with HIV/AIDs services in their homes to scale up the current interventions. Health facilities should be modeled and be gender sensitive when being constructed and organized to accommodate the presence of men.

PEC0546

EVOLVING SOLICITATION PRACTICES AND ITS IMPLICATIONS IN INCREASED VULNERABILITY FOR HIV AMONG FEMALE SEX WORKERS IN INDIA – A MIXED METHOD APPROACH

B. Rakshase[1], P. Saravanamurthy[2], P. Dixit[3], V. Verma[4], B. George[2], S. Rajan[4]
[1]Tata Institute of Social Sciences, School of Health Systems Studies, Mumbai, India, [2]FHI 360, Delhi, India, [3]Tata Institute of Social Sciences, Mumbai, India, [4]National AIDS Control Organisation, Delhi, India

BACKGROUND: The traditional forms of solicitation practiced by Female Sex Workers (FSWs) are undergoing changes. The role of mobile based technology and other social media has become crucial in sex work. Current HIV prevention intervention strategies are not addressing adequately in this changing scenario, for various reasons, including limited evidences. This intervention gap would lead to limited and/or no access of the FSWs to HIV prevention programs, termed as targeted intervention (TI) in India. Hence, the study had systematically documenting the evidences for strengthening the programmatic response.

METHODS: The study was conducted in urban and rural districts of seven states of India in 2018-19, to capture the characteristics of FSWs, irrespective of their association with TIs. Using mix methods, the study aimed to identify current forms of solicitation, analyze condom use and levels of comprehensive knowledge about HIV and associated safe sex practices among FSWs. In qualitative phase 57 key informants' interviews, 26 Focused Group Discussion and 86 In-depth Interviews were conducted. For quantitative phase 1750 survey interviews conducted with primary respondents. Adjusted logistic regression has been used to find out the significant association between dependent and independent variables.

RESULTS: The study found that there are now new physical spaces such as, massage parlors or spas and many different business outfits where solicitation takes place. Further, the use of mobile phones and various social media play prominent roles in solicitation. The study found that the FSWs not linked to the TI program have more inconsistent use of condoms (adjusted odds ratio 1.522 (p=.000)) and also have inadequate knowledge (adjusted odds ratio 1.681 (p=0.130)) There was a 10% difference in condom use between the FSWs associated with TIs (33%) and not associated with TIs (44%).

Condom Use	TI (N=521)	Non-TI (N=1229)
Condom Usage with in last month with paid partner	(77%) 402	810(66%)
Anal sex in the last one month	(21%) 107	250 (20%)
Condom usage during anal sex (Everytime)	(51%) 54	(41%) 102
Oral Sex in last one month	33% (174/521)	50% (610/1229)
Condom usage during Oral sex (Everytime)	43% (75/174)	27% (166/610)
Total	**521**	**1229**

[Table: Use of Condom among Tis and Non-TIs]

CONCLUSIONS: The study identifies various new forms of solicitation including virtual venues. The existing program needs to be modified with new knowledge, information and interventions.

PEC0547

ONLINE INTERVENTION MODEL TO REACH OUT HIDDEN POPULATION AT RISK OF HIV IN INDIA

A. Royal[1], A. Arora[2], A. Vaze[3], S. Acharya[1]
[1]Universitas Gadjah Mada, Department of Public Health, Yogyakarta, Indonesia, [2]ATC Pvt Ltd, New Delhi, India, [3]Ivory Dental Clinic, Indore, India

BACKGROUND: The HIV epidemic has been effectively contained in India. However, there are significant number of people who are at risk of HIV and other sexually transmitted infections, who are beyond the reach of existing healthcare interventions and programs. These people remain hidden due to their cultural and social inhibitions; and fear of stigma due to disclosure of their risky behavior. This hidden population is increasingly reaching out to e-platforms for solutions. The objective of this study was to observe and assess a pilot digital health portal for its effectiveness to reach out hidden, unreached population at risk of HIV & STIs.

METHODS: The marketing data of pilot health portal of a digital health platform (Dr Safe Hands) based in India, from January - December 2018 was collected. Following data was analyzed:

1) Demographic profile of the clients

2) HIV related queries

3) Data related to sexual health counseling, HIV testing and teleconsultations.

The data was analyzed in Google Analytics and MS Excel 3.0

RESULTS: 30,499 HIV related queries were addressed through live chats, emails and telephonic consultations. 81% of the users approached were between 18 - 34 years of age. About 3/5th of the clients were male. Total number of users tested for HIV was 5887 and case detection rate was 1.22%. The sero-positive individuals were telecounselled and linked to local PLHIV networks for care, support and treatment.

CONCLUSIONS: e-platforms have great potential and there is a strong need to promote them as tools to reach out hidden population at risk of HIV in India. However, future evaluations are needed to assess their effectiveness for sustaining them in HIV testing, care and treatment. Also, there is a need to develop protocols and algorithms to assess and assure their quality.

PEC0548

STEALTH HEALTH PROMOTION: THE BENEFITS OF 'UNDERCOVER' HIV AND SEXUAL HEALTH EDUCATION THROUGH DIGITAL COMMUNICATION INNOVATION

C. Williams[1], M. Vaughan[2], K. Price[2], C. Batrouney[1]
[1]Thorne Harbour Health, Melbourne, Australia, [2]ACON, Sydney, Australia

BACKGROUND: In Australia, HIV disproportionately affects men who have sex with men (MSM). In July 2016, the Commonwealth Government of Australia funded a large-scale, innovative project promoting awareness, prevention and management of HIV and STI among MSM in digital environments.

DESCRIPTION: Produced in partnership between leading HIV organisations, ACON and Thorne Harbour Health, the project establishes social media brand Emen8 with website www.emen8.com.au launched May 2017. A native content marketing strategy means Emen8 publishes its own written, video and image content online. Designed to make sexual health information more appealing, sexual health guidance is embedded in content about experiences and conversations reflecting the lives of MSM (cis and trans), covering emotional wellbeing, relationships, travel, entertainment and more. Rather than traditional education, this approach appeals to contemporary ways MSM consume content. Published content and focussed message campaigns are advertised through social media, dating apps and other digital channels using sophisticated audience targeting, maximising message reach and engagement.

LESSONS LEARNED: Until end 2019, Emen8's website attracted 327,407 visitors and 793,751 pageviews. Facebook videos generated 600,771 views while posts achieved 31,747 reactions, 5628 comments and 3675 shares. Average post engagement rate was 1.86% (total engagements per post divided by count of followers at time of post). Subtle integration of sexual health messaging exposes the audience to an ongoing sexual health narrative, aiming to normalise key concepts of prevention, testing and treatment. Discreet mention of these invites the audience to click through to overt educational content. Real-time analytics provide feedback on performance of content, campaigns and advertising, optimising decision-making, budget allocation and informing future content and digital placement direction.

CONCLUSIONS/NEXT STEPS In today's congested digital world, gaining attention for HIV and STI education is challenging. However, results demonstrate our approach achieves this, engaging the audience 20 times more than Facebook's average rate (0.09% per post in 2019). This evidence suggests Emen8's ‚stealth health' approach works. Harnessing digital targeting and communications strategies engages our audience while avoiding message fatigue. While this approach requires balance to avoid unwanted media attention for promotion of homosexuality, risk mitigation around content age restrictions and targeted advertising helps defend the project against attacks.

PEC0549

DETERMINANTS OF TESTING FOR HIV AMONG YOUNG PEOPLE (15-24 YEARS) IN UGANDA. A NESTED SEQUENTIAL MIXED-METHODS STUDY

D. Kalibbala[1,2], S. Kiwuwa Mpungu[3], H. Mberesero[1], W. Muzeyi[1], B. Ssuna[1], A. Katahoire[3], M. Armstrong-Hough[4], J. N. Kalyango[1], V. Musiime[5]
[1]Clinical Epidemiology Unit, School of Medicine, College of Health Sciences, Makerere University, Kampala, Uganda, [2]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [3]Child Health and Development Centre, College of Health Sciences, Makerere University, Kampala, Uganda, [4]University of New York, New York, United States, [5]Makerere University, Department of Paediatrics and Child Health, Kampala, Uganda

BACKGROUND: Globally, young people (15-24 years) contribute to over 30% of new HIV infections yet their HIV testing levels are low. HIV testing among young people in Uganda is lower than the global target despite the progress in enhancing the accessibility of HIV-related health services. We, therefore, sought to explore the experiences of young people regarding HIV testing in Wakiso, a peri-urban district with the highest proportion of young people in Uganda.

METHODS: A nested sequential mixed-methods study was carried from March to May 2019 among 650 young people in Wakiso district. A stratified cluster random sampling approach was used to select 397 rural and 253 urban participants from eight parishes (5 rural and 3 urban). Semi-structured questionnaires were used to collect data from all participants and later, 14 participants were purposively selected for the in-depth interviews. Data were analyzed using STATA 15 and Atlas-ti 8 software. The prevalence of ever testing for HIV was determined and the barriers and facilitators were analyzed using content analysis.

RESULTS: The prevalence of ever testing for HIV was 80.2% (95%CI: 76.9-83.1%). The decision for HIV testing was based on self-evaluation of their risk of HIV infection and the ability to manage the consequences of a positive result. They also mentioned that they are supported by their peers, partners and family members to test for HIV. Fear of injections, loss of confidentiality at testing points, perceptions regarding health facilities as confusing, distant, expensive and staffed by judgmental older health workers were mentioned as factors associated with the low level of HIV testing. Mobile testing points tend to solve some of these problems but introduce lack of privacy and fear of loss of confidentiality because the entire community attends these points.

CONCLUSIONS: The prevalence of HIV testing among young people in Wakiso district is close to the UNAIDS target of 2030. Community outreaches tend to solve many of the challenges that young people are facing at the facility. However, there is a need to make these services community-oriented health-promotion programs to encourage young people to utilize HIV testing sites.

GRAPHIC ARTS AND SOCIAL MEDIA STORYTELLING FOR HIV OUTREACH, EDUCATION, AND LINKAGE TO CARE AMONG RACIAL AND ETHNIC MINORITY YOUTH

A.J. Santella[1,2], R.E. Pérez-Figueroa[3,2], C. Hyden[4,2]
[1]Hofstra University, Health Professions, Hempstead, United States, [2]The Prevention Collaborative, New York, United States, [3]University of Kentucky College of Public Health, Health, Behavior & Society, Lexington, United States, [4]Albert Einstein College of Medicine, Family and Social Medicine, Bronx, United States

BACKGROUND: In the U.S., MSM accounted for 66% of new HIV diagnoses in 2017. In addition, youth ages 13-24 accounted for 21 percent of all new HIV diagnoses. The need exists to provide easily accessible, engaging and informative resources to these communities to promote HIV prevention, testing, and linkages to care. Messages should be tailored and targeted in order to make information relevant to their intended audiences. Graphic novels can enhance learning and the artistic format can facilitate the process for persons with different learning styles and abilities, including for those who have low literacy and/or for whom English is their second language.

DESCRIPTION: With funding from the National Library of Medicine (NLM) HIV/AIDS Community Information Outreach Program, we developed Amigos Y Amantes (AYA). AYA is an educational intervention that features animated, Spanish and English language vignettes that address issues of HIV in the Latinx community through a website platform. We then developed serialized Instagram stories featuring original artwork, under the brand name "Heads or Tails." One story stresses the U=U campaign and the importance of PrEP and the other focuses on risk factors and safety obstacles faced by transwomen. All the stories where developed based on community focus groups. Across all stories, the account has posted almost 650 images, which have received over 36,000 likes and over 1,500 comments. The Instagram audience has over 1,200 followers estimated to be 26% ages 18-24, 36% ages 25-34, and 84% male.

LESSONS LEARNED: Focus group data revealed that Black and Latinx youth (MSM and transwomen) wanted realistic information about dating, sex, and dealing with HIV-related stigma. Youth expressed preference for social media to disseminate messages only when quick and easy to navigate. Content that mixes humor and drama, non-judgmental and culturally sensitive images, and racially and physically diverse characters living various experiences were preferred by the participants.

CONCLUSIONS/NEXT STEPS The next steps are to create a free library of print materials with digital versions available online. This strategy has been endorsed by feedback from consumers. Age-appropriate, culturally diverse vignettes on HIV/AIDS are effective in young sexually, racially, and ethnically diverse populations for facilitating behavior and cognitive change.

PEC0551

HOMELESSNESS, HIV TESTING, AND THE REACH OF HARM-REDUCTION EFFORTS AMONG PEOPLE WHO INJECT DRUGS, SAN FRANCISCO, CALIFORNIA

W. Vincent[1], J. Lin[2], D. Veloso[2], D. Miller[2], W. McFarland[1]
[1]University of California, Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, San Francisco, United States

BACKGROUND: Given that people who inject drugs (PWID) are at increased risk of HIV, public health efforts focus on HIV testing for early diagnosis and harm reduction services, such as syringe exchange programs, for primary prevention. Given the homeless crisis in the US, especially in the San Francisco Bay Area, the present study examined how housing status affects the reach of HIV testing and prevention programming for PWID.

METHODS: Respondent-driven sampling (RDS) recruited 350 HIV-negative PWID, who completed structured interviews in San Francisco. Logistic regression determined whether housing status in the past 12 months ([1] owned/rented, [2] single-room occupancy hotels (SROs), [3] marginally housed (e.g., shelters, with friends/family/partners), [4] outdoors) was associated with getting HIV-tested in the past 12 months and always using sterile needles. PWID who "couch-surfed" (<2%) were categorized as marginally housed.

RESULTS: The majority of PWID had lived outdoors in the last year (58.2%), followed by SROs (21.1%), being marginally housed (12.2%), and owning/renting (8.5%). A majority (63.6%) reported always using sterile needles. PWID who lived in SROs (aOR=3.07, 95% CI: 1.27-7.40, p=0.012) and PWID who lived outdoors (aOR=3.04, 95% CI: 1.40-6.63, p=0.005) had greater odds of being tested for HIV than PWID who owned/rented. PWID who were marginally housed did not differ from PWID who lived outdoors. In separate analyses, PWID who lived in SROs had greater odds of always using sterile needles than PWID who lived outdoors (aOR=3.63, 95% CI: 1.82-7.24, p<0.001).

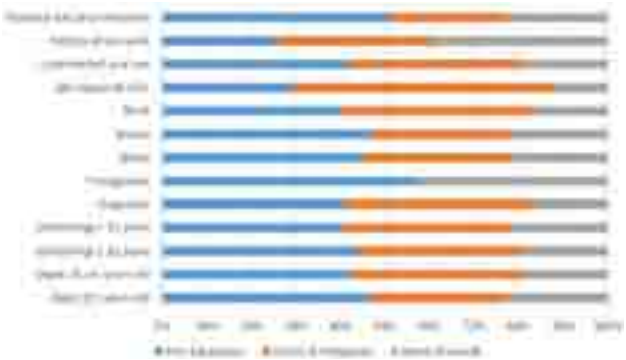
CONCLUSIONS: HIV testing efforts are more likely to reach PWID who live in SROs, where HIV-related programming is often implemented, and PWID who are living outdoors, where PWID might make contact with outreach workers. PWID who owned or rented their homes were at no greater risk of HIV based on sterile-needle use than PWID who were more marginally housed. Although high-risk PWID who own or rent are in the minority, HIV prevention efforts may benefit from finding unique ways of reaching them. Providing PWID with housing is necessary, but these efforts must be combined with public health programming if the goal is to address the HIV prevention needs of PWID.

PEC0552

GO SEEK: REACHING YOUTH AND ADOLESCENTS' MEN WHO HAVE SEX WITH MEN (MSM) AND TRANSGENDER WOMEN (TGW) TO OFFER PREP IN BRAZIL

I. Dourado[1], L. Magno[2], F. Soares[1], F.M. Duarte[1], L.A.V. da Silva[3], C.J. de Melo Santos[1], R. Loreno[2], E. Rufino[2], F. Sarmento Campos[1], W. Mota[4], G. Porto Bispo[1], L.S. de Souza Silva[1], Í. Gomes Ramos[1], D. Greco[5], A. Grangeiro[6], The PrEP1519 Brazil Study Group
[1]Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, [2]Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil, [3]Universidade Federal da Bahia, Instituto de Humanidades, Artes e Ciências Professor Milton Santos, Salvador, Brazil, [4]Universidade Federal da Bahia, Escola de Teatro, Salvador, Brazil, [5]Universidade Federal de Minas Gerais, Departamento de Clínica Médica, Belo Horizonte, Brazil, [6]Universidade de São Paulo, Departamento de Medicina Preventiva, São Paulo, Brazil

BACKGROUND: Our goal is to analyze the strategies applied to reach and recruit adolescents and young key population of MSM and TGW (AYKP) to PrEP. The adjustments required to create a friendly environment to easy their access to PrEP, and creative demands to enable awareness and interest of potential PrEP users. Little is known about the best recruitment strategies to engage AYKP in PrEP. This is the first PrEP demonstration cohort study ongoing in 3 Brazilian cities among AYKP aged 15-19 yo (PrEP1519 study).
METHODS: Methods of recruitment of AYKP to PrEP1519 study involved: the activities of Peer Educators (PE) with youth at venues and schools; the use of social media platforms: Instagram, WhatsApp, dating app and (APPS); and participants' word-of-mouth (WM). Descriptive analysis of recruitment strategies in Salvador site conducted.
RESULTS: From April-December 2019, 446 AYKP of all colors and schooling were reached. Out of those 72% appointments in PrEP clinic (321) and 39.9%(128) enrolled in the cohort (75% in PrEP, 19.5% in other HIV prevention method, 5.5% HIV+ at baseline). PE(35%) and Grindr(34%) recruited most participants. PE recruited more TGW than others strategies (57% vs 42%, p<0.05). APPS-recruitment were associated with recruitees reporting more STI than by PE or WM (58.3%, 29.2%, 12.5%, p<0.01). WM recruited more participants with sex work history than others strategies (39.1%, 26.1%, 34.8%, p<0.05) (Figure 1).



[Figure 1. Description of adolescents' MSM and TGW enrolled in PrEP1519 study by strategy of recruitment. Salvador site, Brazil 2019]

CONCLUSIONS: Well-trained youth PE are very efficient in recruiting AYKP most vulnerable to HIV for PrEP, including TGW, who needs to build trust. Recruitment requires constant monitoring in order to rethink or reinvent new ways when a strategy reaches its limit. Recruitment efficiency also depends on individual and social factors such as risk perception; knowledge of HIV prevention and PrEP; number and type of partners; decision to use or not to use condoms; local contexts-environments and social/personal relationships and social media.

PEC0553

BARRIERS AND FACILITATORS OF ACCESS TO & UTILIZATION OF HIV PREVENTION AND CARE SERVICES AMONG TRANS-WOMEN SEX WORKERS IN THE GREATER KAMPALA METROPOLITAN AREA, UGANDA

T. Ssekamatte[1], J.B. Isunju[1], N. Muyanga[1], E. Buregyeya[1], R. Kibirango Mugambe[1], R. Wanyenze[1], J. Nnakate Bukenya[2]
[1]Makerere University School of Public Health, Department of Disease Control and Environmental Health, Kampala, Uganda, [2]Makerere University School of Public Health, Department of Community Health and Behavioural Sciences, Kampala, Uganda

BACKGROUND: There is evidence that trans-women sex workers are at an elevated risk of HIV infection compared to the general population, and have limited access to HIV prevention services. However, their barriers and facilitators of access to HIV prevention services remains understudied. This study, therefore, focused on understanding the barriers and facilitators of access to & utilization of HIV prevention and care services among trans-women sex workers in the greater Kampala metropolitan area (GKMA), Uganda.
METHODS: This was an exploratory qualitative study among Trans-women sex workers. A total of 22 In-depth interviews, 06 Key Informant Interviews and 09 Focus Group Discussions were used to obtain data from the purposively selected respondents in the GKMA. Data were analysed using thematic analysis under a hybrid of inductive and deductive approaches. Several recurring themes were identified. Informed consent was sought from all the respondents.
RESULTS: The facilitators of access to HIV prevention services included; availability of friendly and trans-competent health care providers at key population clinics; use of a peer-driven system in which a peer acts as a role model to the transwoman as well as their bridge to the health care providers; and availability of a transwoman population or a key population focal person at a health care facility. The barriers to access included; self-enacted stigma; feeling embarrassed to identify as a sex worker, and to mention that they are suffering from an STI; discrimination by not only other clients but also some health care providers and other members of the key population umbrella; low socioeconomic status; stockout of drugs and supplies; high cost of drugs; lack of adequate equipment for treating and diagnosing infections such as anal warts; limited privacy at health care facilities; and limited working hours.
CONCLUSIONS: Whereas there has been progress in addressing the sexual and reproductive health needs and breaking barriers of access to HIV prevention and management services among transwomen sex workers, stigma, discrimination and drug stockouts continue to hamper the utilisation of available services. Therefore, there is a need for the different stakeholders to create an enabling environment for accessing and utilisation of available HIV prevention services.

PEC0554

AN INNOVATIVE STRATEGY FOR INCREASING DEMAND FOR ORAL PRE-EXPOSURE PROPHYLAXIS AMONG FEMALE SEX WORKERS IN MALAWI

F. Gadama[1]
[1]University of Malawi, Medical Department, Blantyre, Malawi

BACKGROUND: In 2018, the Ministry of Health (MoH) in Malawi approved the use of oral pre-exposure prophylaxis (PrEP) for HIV prevention as part of an implementation science project led by FHI 360

and Pakachere Institute for Health and Development with support from the USAID/PEPFAR-funded LINKAGES project. We present the results of efforts to generate demand for PrEP among female sex workers (FSWs).

METHODS: PrEP was delivered as part of a prospective cohort study among FSWs in drop-in-centres (DICs) at Naperi, Chirimba and Bangwe, in Blantyre from February-November 2019. The study intended to enroll 575 HIV-negative FSWs. To facilitate recruitment for PrEP, two peer-led demand generation models were employed. The passive model involved peer-to-peer interpersonal communication (IPC) that was routinely conducted through community outreaches for six months. In the active model, the routine demand generation model was enhanced with peer-to-peer IPC through day and night campaigns at hotspots staggered at two-week intervals over four months. During campaigns-where PrEP messaging merits were discussed, flyers and leaflets distributed, FSWs willing to enroll in the study consented and were provided with HIV prevention services including transportation reimbursement. Those unwilling were offered the MoH core package of HIV services and no monetary incentive was provided.

RESULTS: During the 10-month study period, a total of 460 FSWs were newly initiated on PrEP. Of these, 38% (154/406) were enrolled during the 6-months where the passive demand generation model was used while 62% (252/406) were recruited during the four months of intensified campaigns. The passive model recruited an average of 19 FSWs/month, while in September alone we saw a fourfold jump to 96 FSWs recruited through the active model. There were no differences in demographic, socioeconomic and behavioral characteristics between FSWs recruited during passive and active demand generation models.

CONCLUSIONS: Multiple peer-led demand generation strategies including campaigns increased uptake of PrEP among FSWs, compared to routine passive demand generation strategies only. Campaigns provided opportunity for PrEP messaging to get closer to FSWs preferred settings at hotspots. PrEP programs should consider the use of multiple demand generation strategies tailored to the target populations to increase uptake of PrEP.

PEC0555

OPPORTUNITIES TO INTEGRATE HIV TESTING AND TREATMENT SERVICES IN ALCOHOL AND DRUG TREATMENT CENTRES TO REACH EPIDEMIC CONTROL IN SOUTH AFRICA

J. Burgess[1,2], B. Cummings[3], W. Lucas[4], S. Dada[4], C. Parry[4,5], N. Harker[4,6]
[1]BroadReach Healthcare, APACE - Community Services, Johannesburg, South Africa, [2]US Department of Health and Human Services - Office of Global Affairs, Africa Regional Office, Pretoria, South Africa, [3]US Substance Abuse and Mental Health Services Administration, Center for Substance Abuse Treatment, Pretoria, South Africa, [4]South African Medical Research Council, Alcohol Tobacco & Other Drug Research Unit, Cape Town, South Africa, [5]Stellenbosch University, Department of Psychiatry, Stellenbosch, South Africa, [6]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa

BACKGROUND: Specialist Substance Abuse Treatment Centres (SSATCs) represent an opportunity for integrated services such as HIV testing and counseling (HTS) and treatment services to reach people at risk of or living with HIV. Persons who use drugs (PWUD) who access SSATCs are a potentially critical target group because of the severity of their substance use and they may not routinely access services in other healthcare settings. Little is known about the HIV testing behavior of South Africans admitted for drug treatment. This analysis of national SSATC admission data explores self-reported testing and associated factors to identify coverage gaps and integration opportunities.

METHODS: The South African Community Epidemiology Network on Drug Use (SACENDU) collects routine data to monitor trends in alcohol and drug use. SACENDU data from 2012-2017 was collected from 110 SSATCs, representing 85% of national centres. Logistic regression was performed to examine associations between HTS, demographics and substance of use. Linear regression with cluster was conducted to account for regional clustering.

RESULTS: Of the 87,339 treatment admissions, males were the majority, n=71,641 (82%). 47.5% (n=41,481) of patients reported not conducting HTS in the past 12 months. HTS was reported less frequently by patients whose primary substance of use was cannabis or polysubstances (36.9% and 41.1%, respectively). Patients admitted for alcohol or methcathinone reported low testing rates (55.5% and 51.5%, respectively). None of the substance use sub-groups reported a testing rate above 70%.

Logistic regression showed people who inject drugs had higher odds of HTS (OR=2.860), and those with lower odds of HTS were: 15-19 years (OR=0.593); educational attainment was primary school (OR=0.511); employment status was scholar/learner (OR=0.267); and cannabis as primary substance of use (OR=0.643). All p-values were significant at p<0.000.

CONCLUSIONS: Given the low coverage and decreased odds of self-reported HTS among patients in SSATCs, the integration of HIV services for PWUD should be a priority for South Africa's national HIV strategy. PWUD accessing SSATCs represent an opportunity to motivate behavior change to reduce HIV risk, and identify and link those who are unaware of being HIV-infected to antiretroviral treatment thereby reducing the risk of other health consequences and further transmission.

PEC0556

PREP NEED AND UPTAKE AMONG PEOPLE ON BUPRENORPHINE FOR OPIOID USE DISORDER IN AN URBAN OUTPATIENT TREATMENT CLINIC IN RICHMOND, VA: A CROSS-SECTIONAL SURVEY

L. Beck[1], A.B. Parlier-Ahmad[2], C. Martin[3,4]
[1]Virginia Commonwealth University, Family Medicine and Population Health, Richmond, United States, [2]Virginia Commonwealth University, Psychology, Richmond, United States, [3]Virginia Commonwealth University, Obstetrics and Gynecology, Richmond, United States, [4]Virginia Commonwealth University, Institute for Drug and Alcohol Studies, Richmond, United States

BACKGROUND: People with opioid use disorder (OUD) are disproportionately burdened by HIV due to increased risk behaviors. Pre-exposure prophylaxis (PrEP) is a highly effective intervention to prevent HIV transmission. The US Centers for Disease Control and Prevention (CDC) has issued guidelines for PrEP use in key populations; however, a recent CDC report found that only 18% of PrEP-indicated people are prescribed PrEP. Prior research has investigated HIV treatment adherence in people with OUD, but little is known about PrEP for people in OUD treatment. The objective of this study is to report PrEP need, awareness, and uptake in patients engaged in buprenorphine treatment for OUD.

METHODS: Adult patients at an outpatient substance use treatment clinic were invited to complete a cross-sectional electronic survey between July and September 2019. HIV negative patients on buprenor-

phine who answered questions about PrEP and risk behaviors were included in the study. 2017 CDC criteria determined HIV risk. Gender differences were assessed by Pearson's χ^2.

RESULTS: 137 of 162 participants met inclusion criteria (54.0% women, 46.0% men). The majority of the sample was Black (70.8%), unmarried (68.6%), and unemployed (51.8%). Nine men (14.3%) and 38 (51.4%) women reported same-sex contact. 73.7% (n=101) of the study population met CDC risk criteria based on past year behaviors: 95.0% reported inconsistent condom use, 21.0% engaged in commercial sex, 9.0% shared injection equipment, 8.9% reported a recent bacterial STI, and 4.0% had an HIV+ sexual partner. Of PrEP-indicated participants, 19.0% had heard of PrEP prior to the survey, and only 3 participants reported past year PrEP use. Risk factors and PrEP knowledge/uptake did not vary significantly by gender.

CONCLUSIONS: PrEP uptake in this study is significantly lower than both the general US PrEP prevalence and the CDC's goal of 50%, despite these patients being engaged in medical care and regular buprenorphine treatment. While many campaigns have targeted men who have sex with men and injection drug users in active use, PrEP outreach should also specifically target people with OUD by integrating HIV prevention into OUD treatment.

PEC0557

ONLINE CASCADE OF MSM RECRUITMENT TO A LARGE PREP SERVICE IN RIO DE JANEIRO, BRAZIL

D.R.B. Bezerra[1], T.S. Torres[1], L.E. Coelho[1], C. Jalil[1], E. Carvalheira[1], D. Waite[1], J.R. Grangeiro[1], T. Araujo[1], J. Freitas[1], C. Cerqueira[1], L. Monteiro[1], C. Oliveira[1], L. Kamel[1], N.M. Fernandes[1], S.w. Cardoso[1], B. Hoagland[1], V.G. Veloso[1], B. Grinsztejn[1]
[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

BACKGROUND: Since 2017, Brazil has offered oral FTC/TDF PrEP to high-risk cis/trans men and women at no cost. However, increasing awareness of PrEP services within the young and low income MSM populations remains a challenge. Access to the internet and mobile phones is widely available in Brazil and can be utilized as tools for disseminating information to vulnerable MSM on HIV prevention and testing services. This study describes the online cascade of MSM recruitment to a PrEP service in Rio de Janeiro, Brazil.

METHODS: From Mar-2018 to Oct-2019, advertisements on GSN dating apps (Hornet and Grindr) and social media (Facebook/Instagram) targeting MSM were used to increase HIV and PrEP awareness and to encourage HIV testing. Advertisements included contact information (phone, email, WhatsApp) and invited viewers to contact a peer educator for information on scheduling a HIV risk assessment, testing and referral to PrEP. The success of the online recruitment cascade was assessed based on the number of MSM who:

(1) viewed the advertisement;

(2) contacted the peer-educator; and

(3) received healthcare services.

Participant recruitment costs were calculated by dividing the total advertisement costs by the number of participants who received healthcare services. Comparisons according to the recruitment strategy (dating apps vs. social media) were made using chi-square test.

RESULTS: The online advertisements (all strategies combined) reached approximately 1,500,000 MSM, of those, 0.1%(1270/1,500,000) contacted the peer-educator and 36.3%(462/1270) received healthcare services. Of those who contacted the peer-educators, 44% were recruited using social media, 33% on Grindr and 23% on Hornet. When compared to dating apps, MSM recruited via social media were younger (median age 26[IQR:23-31] vs. 30[IQR:24-37] years-old, p<0.001), non-white (67% vs 55%, p=0.008) and were less educated (completed secondary school or less: 51% vs 38%, p=0.005). The estimated cost for announcements to recruit one participant (USD) were $49.70 on Grindr, $21.18 on Hornet and $15.80 on Facebook/Instagram.

CONCLUSIONS: Social media and dating apps advertisements are an effective means to disseminate online HIV and PrEP information and recruit MSM to PrEP services. Social media advertisements were less expensive and reached more vulnerable MSM.

PEC0558

LOCATION, LOCATION, LOCATION: INCREASING UPTAKE OF HIV SERVICES AMONG KEY AND PRIORITY POPULATIONS IN SLUM SETTINGS: EXPERIENCES FROM TORORO DISTRICT, UGANDA

G. Muzaaya[1], B. Egessah[1], H. Nandudu[1], N. Matsiko[1], I. Mirembe[1], C. Mejia[2], C. Karutu[1]
[1]IntraHealth International, Mbale, Uganda, [2]IntraHealth International, Chapel Hill, United States

BACKGROUND: Pinpointing locations where HIV services are most likely to reach key populations (KPs) and priority populations such as truck drivers is key to linking these populations to HIV care and treatment and promoting adherence to treatment to reach viral suppression. In 2018, the USAID-funded Regional Health Integration to Enhance Services in Eastern Uganda (RHITES-E) Activity, led by IntraHealth International, in collaboration with the Ministry of Health worked with the District Health Team (DHT) in Tororo District, Uganda, to design a comprehensive KP service package including HIV testing and counseling, ART enrollment, STI screening and treatment, and family planning services.

DESCRIPTION: We conducted KP mapping to determine localization of service provision. Bison Health Center III was selected for being in an urban slum surrounded by bars, brew joints, and motels for traders on the Malaba Juba International Highway. From March 2018-March 2019, DHT worked with the health center to identify KP peers to mobilize and counsel the KP community. A retrospective observational cohort analysis using routine patient monitoring data was performed.

LESSONS LEARNED: Within 12 months, peers reached 879 individuals with HIV services. Of these, 75.5% were female sex workers, 10.7% were people who use drugs, 3% were people who inject drugs, 8.5% were truck drivers, and 2.2% were men who have sex with men. The sero-positivity rate was 11% (97/879). All clients were linked to Bison Health Center; 80.4% (78/97) received HIV care at the facility. Of 78 linked to care, 48.7% (38/78) were transferred out by a clinician, 23.7% (18/78) were self-referrals to other health facilities, and 28% (22/78) were lost-to-follow-up. By end of April 2019, only 24.4% (19/78) remained in care at the facility.

CONCLUSIONS/NEXT STEPS Findings indicate that localizing KP services in slums increases uptake of services and engaging peers in mobilization with support from a dedicated health facility team improves responsiveness to services for KPs. A considerable number of KPs do not reach places of referral for care and support and those effectively reached have a low retention rate. This calls for interventions to strengthen linkages, referrals, retention, and treatment outcomes for KPs.

PEC0559

SOCIAL MEDIA INTERVENTIONS FOR QUEER SERVICE SEEKERS OPEN PATH TO REACH HIDDEN AND HARD-TO-REACH KPS IN BANGLADESH

F. Karim[1], L. Rahman[2]
[1]Save the Children, HIV/AIDS Program, Dhaka, Bangladesh, [2]Save the Children, Dhaka, Bangladesh

BACKGROUND: In Bangladesh, internet users have been counted 99 million (61% of the total population) in 2019 (BTRC, 2019). The users are increasing among key populations as it protects their confidentiality. They can communicate with their partners and peers more privately. In a survey interviewing 114 female sex workers (FSWs), 67% found using Facebook, whereas only 13% of general adult women are internet users (GSMA's 2019 Mobile Gender Gap Report). This has begun a new contextual reality for HIV prevention programs as KPs are more likely to avoid physical presence and thus become hidden. The program is experiencing challenges to reach the hidden and hard-to-reach FSWs.

DESCRIPTION: Assuming hard-to-reach FSWs could be reached through online outreach, a Facebook page has been piloted with the information of HIV prevention services including condom promotion, HTS services, and STI treatment. Posts are published to observe the trend of responses. Considering the demography, interests, and behavior of FSWs, the reaching target was defined and the potential audience size was determined as 3,200,000 of general adult women to reach out for the FSWs who have internet access.

LESSONS LEARNED: In six months (July-December 2019), the page got 1756 likes. Analyzing over 70 inbox messages it was found that most of the queries were about HIV testing facilities and privacy. Therefore, KPs like FSWs would not disclose their identity, and the exact figure of FSWs who have internet access would not be easy to determine. But the nature of the inbox showed that there were queers among service seekers having potential risk behaviors. These respondents were connected to peer educators for maintaining further services. Peer educators had analyzed their risk behaviors and enrolled in a virtual mother-list as queer service seekers.

CONCLUSIONS/NEXT STEPS Save the Children is providing HIV prevention services to KPs specially PWID and FSWs. Due to the nature of growing hidden trends, the new reaching strategy is to be devised soon which for the online outreach could be an effective approach. If the Facebook page is promoted to reach the potential audience size of the adult women population, it may bring hidden FSWs under HIV prevention services.

PEC0560

ONLINE OUTREACH AND REFERRAL MECHANISMS IMPROVE HIV CASE FINDING IN NEPAL

K. Bam[1], B. Eveslage[2], A. Sharma[1], D.P. Bhandari[1], P.K. Thakur[1], A. Shrestha[1], R.P. Khanal[1], B. Shrestha[1], R. Wilcher[3]
[1]LINKAGES Nepal/FHI 360, Kathmandu, Nepal, [2]LINKAGES/FHI 360, Washington, DC, United States, [3]LINKAGES Nepal/FHI 360, Washington, DC, United States

BACKGROUND: With a growing majority of Nepalese connected online or through social media platforms, HIV risk has also moved online and outside the reach of traditional physical HIV programs. Going online may help HIV programs realign outreach efforts to additional high-risk networks, leading to improved HIV case finding.

DESCRIPTION: The USAID- and PEPFAR-funded LINKAGES project in Nepal implemented online outreach for social media users at risk of HIV. Outreach staff connected with new clients at virtual hotspots, such as anonymous Facebook groups of sex workers, gay men, and transgender people and on dating apps used by gay/bi men and other men who have sex with men (MSM), transgender people, and sex workers.

Their conversations helped clients determine their sexual health needs and to access services using either a passive e-referral where the clients presented at clinics and mentioned their online referral or by linking them to www.merosathi.net (MeroSathi) where they completed their own risk assessment and booked an appointment for HIV services through an online reservation system. Occasional targeted ads, promotions by social media influencers, and word-of-mouth referrals by key population (KP) community members also generated demand for the MeroSathi website.

LESSONS LEARNED: From October 2018 to September 2019, online HIV outreach staff recorded conversations with 11,991 profiles. Of these, 3,380 completed risk assessments on MeroSathi, 617 booked appointments, and 333 received an HIV test. An additional 918 individuals tested for HIV from a passive e-referral. Twenty-six clients who booked through MeroSathi were newly diagnosed with HIV compared to 17 of those passively referred, producing case-finding rates of 7.8% and 1.9% respectively. While these online approaches contributed only 2.3% of all HIV tests and 4.4% of all HIV positive cases detected by the program, they showed more targeted testing than the standard clinic-based HIV testing that has resulted in 0.7% case finding during the same period.

CONCLUSIONS/NEXT STEPS The higher efficiency of HIV case finding through online outreach, particularly using online booking platforms like MeroSathi, suggests these strategies can be scaled up as part of Nepal's "low test and high yield" approach that will help Nepal achieve 90-90-90 by 2020.

PEC0561

„BE YOU. BE HIV FREE." LESSONS FROM A PREP SOCIAL MEDIA CAMPAIGN FOR YMSM AND TRANSGENDER YOUTH OF COLOR

S. Stafford[1], D. Futterman[1]
[1]Montefiore Medical Center, Pediatrics, Bronx, United States

BACKGROUND: In the US, youth aged 13-24 account for 21% of new HIV infections. PrEP is a highly effective HIV prevention tool but is only used by about 11% of at-risk youth. One reason for low PrEP uptake among youth is their lack of accurate information about PrEP, due in part by PrEP only recently being approved for adolescents by the FDA. Because most PrEP marketing has been adult-focused, there is an urgent need for engaging social marketing that effectively mobilizes at-risk youth to access PrEP.

DESCRIPTION: To inform a new social marketing campaign aimed at promoting PrEP to youth, we commissioned a market research study to identify motivators and barriers to PrEP use among YMSM and trans women of color. A total of 63 YMSM and trans women of color aged 17-24 were recruited and completed online surveys. Each group then participated in a set of focus groups: the first identified issues of concern about PrEP and motivators for using PrEP as well as communications styles and channels most likely to appeal to high-risk youth; and the second tested a number of messages and creative executions.

LESSONS LEARNED: Key research findings included: lack of appreciation for PrEP's effectiveness; significant concerns about side effects; skepticism that youth could afford/access PrEP; and low perceptions of risk for HIV despite admitting to very high-risk behavior. Participants also warned against further stigmatizing LGBTQ youth of color by only depicting them in PrEP marketing materials, and they strongly preferred short video-based education accessible via social media platforms. These lessons informed „Be You. Be HIV Free." a social media-based campaign with short informational videos delivered by peers that direct viewers to a landing site (www.behivfree.com) where they can learn more and directly connect to clinical staff. The workshop will explore in detail the resource investments that went into the campaign and the engagement and PrEP uptake returns on investment.

CONCLUSIONS/NEXT STEPS The campaign had excellent reach and engagement, but the added level of PrEP uptake was disappointing. We will discuss the addition of a peer outreach team to the social media component of the campaign and its effect on PrEP uptake.

PEC0562

DETERMINANTS OF HIV TESTING UPTAKE POST-PREP AMONG HIV-/UNTESTED GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN IN THE UK AND IRELAND 2016-2020; THE SMMASH3 SURVEY

D.E. Strongylou[1], P. Flowers[2], J. Frankis[1]
[1]*Glasgow Caledonian University, Psychology, Glasgow, United Kingdom,*
[2]*MRC/CSO Social & Public Health Sciences Unit, Glasgow, United Kingdom*

BACKGROUND: Frequent HIV testing accompanied by rapid initiation of HIV treatment on diagnosis is critical for preventing new HIV infections among gay, bisexual, and other men who have sex with men (GBMSM). Currently, it is recommended that intensified HIV testing - up to 3 months for HIV negative GBMSM at higher HIV sexual risk - could make HIV elimination achievable. This study examines HIV testing rates alongside factors predicting HIV testing uptake in HIV negative GBMSM in the UK and Ireland.

METHODS: The SMMASH study is a longitudinal cross-sectional online survey of GBMSM in the UK and Ireland conducted in 2016 (SMMASH2) and 2020 (SMMASH3), which examined sociodemographics, biobehavioural HIV sexual risk taking, PrEP use and HIV testing. HIV testing rates were calculated for HIV-/untested GBMSM in SMMASH2 and SMMASH3. Logistic regression was performed to assess factors associated with HIV testing uptake among GBMSM.

RESULTS: 65% (n=1117) of SMMASH3 participants and 60% (n=1796) of the SMMASH2 respondents were tested for HIV in the previous year. However, a lower percentage of GBMSM at higher risk were tested for HIV in 2020 (64%, n=411) compared to 2016 (67%, n=720). The results of the SMMASH3 survey showed that being willing to take PrEP (OR 56.9, p=0.00) was the most important factor predicting HIV testing in the last year followed by considering HIV testing as part of your own clinical routine (OR 22.9, p=0.00). Having condomless anal intercourse (OR 4.84, p=0.001), being worried about a recent sexual episode (OR 4.80, p=0.00) and not having been tested for a long period of time (OR 3.50, p=0.00) significantly predicted HIV testing uptake among GBMSM. Nevertheless, age and being at high sexual risk did not predict HIV testing in the last year.

CONCLUSIONS: Despite PrEP requiring regular HIV testing for health-service users, recent testing has gone down among higher risk GBMSM since the advent of PrEP. Understanding the role of PrEP and other proximal determinants of HIV testing can contribute to the development of more effective strategies to increase HIV testing uptake and eliminate HIV risk among GBMSM.

PEC0563

PREP AND PEP ACCESS IS CHALLENGING: CHANGING THE PARADIGM WITH ONLINE NAVIGATION SERVICES AND A SEXUAL HEALTH COACHING MODEL

L. Lazar[1], A. McCord[1], C. Romero[1], S. Weber[1]
[1]*PleasePrEPMe, San Francisco, United States*

BACKGROUND: HIV prevention education and benefits navigation is essential to help potential PrEP and PEP users access insurance coverage, government programs, and industry-sponsored services. Navigators support clients with understanding PrEP/PEP; help people get into medical care for PrEP/PEP; find assistance programs to cover costs; and provide tailored sexual health information. Navigators can be an important facet of PrEP/PEP uptake and adherence. Online chat navigation provides confidential, anonymous support to people with HIV prevention questions, those with issues accessing PrEP/PEP, as well as to frontline staff assisting clients.

DESCRIPTION: PleasePrEPMe.org is an English and Spanish HIV prevention website featuring: a national provider directory; informational webpages for a variety of communities; and confidential, anonymous live chat services. HIPAA-compliant English and Spanish chat is available Monday - Friday, 9 a.m. - 5 p.m. Pacific Time. PleasePrEPMe navigators utilize the directory, informational webpages, and a client-centered sexual health coaching model (SHCM) to support website visitors in achieving their sexual health goals. Chat supports visitors with questions across the PrEP care continuum.

Partnerships and online promotional outreach has focused on reaching Black and Latinx MSM and transgender women in areas with lower PrEP uptake and fewer resources.

LESSONS LEARNED: Of 1,015 chat interactions in 2019:

- 83.5% were English, 16.3% were Spanish;
- 74% of visitors were potential PrEP/PEP users;
- 24% were clinic/community-based frontline staff;
- 2% were clinicians;
- Topics included (more than one topic may be discussed per chat):
    - Health systems and benefits navigation (49%)
    - PEP, TasP/U=U, and HIV 101 (48%)
    - PrEP basics (45%)
    - The California PrEP Assistance Program (30%)
- 5% of chats required follow-up:
    - Providing local provider lists (35%)
    - PEP needs (29%)
    - Complex insurance issues (10%)
- Average duration: 15 minutes

CONCLUSIONS/NEXT STEPS Online support for health systems navigation can be a conduit of confidential, accurate information often inaccessible due to geography, stigma, misinformation, or lack of resources.

An online SHCM can support a range of information-seekers—from those not yet engaged in prevention care, to staff navigating clients through payment/insurance systems.

PEC0564

USAID HIV/AIDS FLAGSHIP PROJECT: IMPROVING QUALITY AND EXPANDING HIV TESTING AND ART TREATMENT FOR HARD-TO-REACH KEY POPULATIONS IN MYANMAR

Y.M. Thaung[1], L. Htet[1], T.S. Aung[1], K.P. Naing[1], N.N. Aye[1], S. Thura[2]
[1]Community Partners International, HIV/AIDS, Yangon, Myanmar, [2]Community Partners International, Yangon, Myanmar

BACKGROUND: Myanmar has a concentrated HIV epidemic with an estimated number of 252,000 men who have sex with men (MSM) and transgender (TG) persons, 66,000 female sex workers (FSW), and 93,000 people who inject drugs (PWID). HIV prevalence was estimated at 35% among PWID, 14.6% among FSW and 11.6% among MSM. Stigma and discrimination increase the vulnerability and prevent access to HIV prevention, care and treatment services. Services such as harm reduction have traditionally been centered around bigger towns, so KPs living in remote and rural areas have limited access to prevention services.

DESCRIPTION: USAID HIV/AIDS Flagship (UHF) Project implemented the scale-up of HIV prevention, testing and treatment services from September 2017 to September 2019 with the overarching goals of reducing HIV transmission among key populations. UHF project focused on peer-led and community-based prevention interventions, online and social media outreach, tailored harm reduction services for women who use drugs, to reach hidden and higher risk KP in addition to traditional outreach and facility-based services. UHF scaled up mobile activities and community-based HIV service deliveries for KP integrated with existing Community Health Workers (CHW). UHF facilitated differentiated ART initiation at MMT collocated decentralized sites and ART initiation by mobile teams.

LESSONS LEARNED: UHF provided prevention interventions to nearly 75,000 KP, more than 69,000 HTS services and identified more than 93,00 HIV positive cases during 2 years and nearly 5,600 PLHIV were enrolled on ART. UHF provided clinical follow-up and adherence support to nearly 8,300 PLHIV on ART.

CONCLUSIONS/NEXT STEPS Though we have achieved good results, we need to make our efforts to be sustainable and cost effective. The UHF Project is complementary to the existing national response to the HIV epidemic in Myanmar, focusing on the decentralization of services with community-based service-delivery models. The intent of the transition strategy is to intensify on-site HIV service delivery and to establish sufficient capacity, capability, and sustainability of the IP in order to ensure successful, long-term engagement and impact. UHF Project will advocate for the government commitment to capacity building and allocation of resources for HIV program.

INNOVATIVE HIV TESTING STRATEGIES (PEER-LED TESTING, PEER-MEDIATED TESTING, SELF-TESTING WITH AND WITHOUT ONLINE/OFFLINE SUPPORT, USE OF FOURTH-GENERATION AND RECENCY ASSAYS)

PEC0565

"A HORA É AGORA-SÃO PAULO" - HIV SELF-TEST IMPLEMENTATION STUDY: DEFINING WHERE AND HOW TO DISTRIBUTE TESTING KITS TO OPTIMIZE UPTAKE AND DIAGNOSIS AMONG MSM

I. de Paula[1], L.F. Jamal[2], M.C. Gianna[2], M.C. Abbate[3], M. Marques da Cruz[4], R. Zamboni[2], A.A. Cotrim Segurado[5]
[1]Secretaria de Estado da Saúde de São Paulo, Centro de Referencia e Treinamento DST/AIDS, São Paulo, Brazil, [2]Health Secretariat of the State of São Paulo, Centro de Referencia e Treinamento DST/AIDS, São Paulo, Brazil, [3]Health Secretariat of the Municipality of São Paulo, STD/AIDS Program of the Municipality of São Paulo, São Paulo, Brazil, [4]Fundação Oswaldo Cruz, Escola Nacional de Saúde Pública, Rio de Janeiro, Brazil, [5]University of São Paulo, Medicine School, São Paulo, Brazil

BACKGROUND: In Sao Paulo, Brazil, HIV infection is growing mainly among young gays and other men who have sex with men (MSM). One of UNAIDS goals to control the infection is to detect 90% of infected people. Adopting novel strategies to improve testing coverage among key populations is thus warranted. In this implementation study we evaluated the distribution logistics of HIV oral fluid self-tests (HIVST) for MSM living in the city of São Paulo.

METHODS: For this prospective cohort study, we invited MSM over 18 years old who lived in the city. Inclusion was carried out using a digital platform, where the participant could obtain detailed instructions about the study and provide his informed consent. After answering a questionnaire on socio-demographic and behavior data, he was asked to choose where to obtain the HIVST among the following options:

(a) 5 health services with regular working hours;

(b) 2 HIV testing mobile units, operating with alternative schedules in gay-gathering neighborhoods, including afterhours and weekends; or,

(c) a LGBT non-governmental organization (NGO) involved in HIV prevention.

At mobile units, HIVST was offered with a qualified person-to-person approach, with the possibility of kit distribution on site. Study participants could also access a support hotline for guidance counseling, 24 hours a day, 7 days in 7.

RESULTS: From April to December/2018, 7,242 HIVST were digitally requested and 3,450 withdrawn (47.6%) from distribution sites. Preferential sites for HIVST uptake were an HIV/STI specialized healthcare center (20%) and a mobile unit that operates on Sundays at a downtown LGBT gathering area (19,5%). However, the most effective HIVST uptake (rate of withdrawn tests among requested tests) was seen in this mobile unit (74.8% or 1,056 tests altogether). Results from 618/3,450 (17.9%) tests were informed by participants on the digital platform and out of these, only 6 were reported as positive (0.97% prevalence).

CONCLUSIONS: Distribution of HIVST has proved an important tool to increase testing coverage among MSM in São Paulo. Offering the test outside health services and using a qualified person-to-person approach was found to optimize test uptake.

PEC0566

THE ROLE OF INDEX TESTING IN ENDING THE HIV EPIDEMIC: LESSONS LEARNED FROM BHUTAN

L. Khandu[1], W. McFarland[2], N. Choida[1]
[1]Ministry of Health, Department of Public Health, Thimphu, Bhutan, [2]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: Index testing (aka partner notification, contact tracing) can be an effective approach to test persons at risk for HIV, make early diagnoses, link persons to care, and prevent onward transmission. While the approach has existed since the beginning of the HIV epidemic, now is the time to re-examine its role in the "endgame" of getting to zero HIV infections.

As new HIV cases become rare, identifying the source, spread, and partners and children at imminent risk may become increasingly dependent upon index testing.

DESCRIPTION: Bhutan's HIV epidemic has remained low-level since the first case in 1993. Index testing has always played a prominent role in controlling HIV with a steady 30% of all cases identified through contacts. We present lessons learned through three frameworks: couples services, sexual network investigations, and expansion of index testing to social networks, communities, and environments.

LESSONS LEARNED: Among all persons diagnosed with HIV to date in Bhutan (N=663; females 48%, males 52%), 466 were index patients and 197 were contacts. Comparable numbers of women and men are diagnosed through index testing (28% vs. 31%, respectively, p=0.269). All persons diagnosed with HIV were offered and engaged in partner elicitation. On average, each index case named 1.8 partners (leading to an additional 0.3 partners of partners), and 2.9 children. Among partners elicited, 58% were found and tested, with a high yield of 53% HIV-positive. With couples, a key lesson learned was the need for continuous counseling to ensure disclosure and engagement of all partners over time. Sexual network testing holds potential to reach marginalized key populations such as commercial sex partners. Expanding index testing to mobile and community-based events provided confidentiality cover and reached persons with HIV who otherwise would not come to be tested.

CONCLUSIONS/NEXT STEPS From our perspective, we posit that index testing will play a pivotal role in getting to zero infections by 2030. Next steps to strengthen index testing under consideration in Bhutan include improving key population-sensitive services (e.g., for MSM, transgender persons, and female sex workers), integrating recent infection detection into partner services, and implementing HIV self-testing into partner services.

PEC0567

FACILITATORS OF ROUTINE HIV SCREENING AMONG PRIMARY CARE PHYSICIANS: RESULTS FROM AN ONLINE PANEL OF U.S. HEALTHCARE PROVIDERS

M. Pitasi[1], P. Chavez[1], S. Patel[1], B. Emerson[1], E. August[1], E. DiNenno[1], K. Delaney[1]
[1]U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

BACKGROUND: Since 2006, the U.S. Centers for Disease Control and Prevention (CDC) has recommended routine HIV screening in healthcare settings for all persons aged 13-64 years, including at least annual rescreening for persons with ongoing risk for infection. However, more than half of the U.S. adult population has never been tested. Provider-initiated screening is an important component of efforts to improve early diagnosis and end the HIV epidemic in the United States.

METHODS: We analyzed data from DocStyles, a web-based, panel-derived survey of U.S. healthcare providers conducted in 2018, to assess facilitators of routine HIV screening. Eligible respondents were those who actively see patients and have practiced for at least 3 years. Respondents were asked about their knowledge, attitudes, and practices regarding routine HIV screening and what resources would help them order an HIV screening test for more of their patients.

RESULTS: Of 1,004 primary care physicians (PCPs) who completed the survey, 66.7% were male, 44.1% were aged ≥50 years, and 65.9% worked primarily in a group outpatient practice; their median length of practice was 17 years. Half (52.6%) of the PCPs were aware that CDC recommends HIV screening for all patients aged 13-64 years, while less than half (37.1%) endorsed routine screening as the most effective approach, and 40.1% reported that they routinely screen all their patients for HIV. Among the 59.9% of PCPs who do not practice routine HIV screening, the most commonly endorsed resource to help PCPs order an HIV screening test for more of their patients was an integrated laboratory panel that incorporates testing for HIV with testing for other pathogens (sexually transmitted infections or hepatitis C) (52.1%), followed by electronic medical record prompts (40.9%) and training on one or more topics (40.1% overall; 31.6%, recommended laboratory testing algorithm; 13.0%, how to offer an HIV test; 11.5%, how to take a sexual health assessment).

CONCLUSIONS: Most PCPs are not practicing routine HIV screening as recommended, potentially hindering efforts to improve early diagnosis. However, PCPs endorsed a wide variety of tools that, if implemented, could increase provider uptake of routine HIV screening.

PEC0568

HIGH ACCEPTABILITY AND EFFECTIVENESS OF AN ONLINE SELF-SAMPLING INTERVENTION FOR HIV IN GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN AND TRANS WOMEN IN SPAIN

C. Agustí[1], R. Muñoz[1], V. González[1], J. Hoyos[2], E. Muntada[1], S. Moreno[1], P. Romano[1], H. Martínez[1], J. Casabona[1]
[1]Center for Epidemiological Studies of STIs, HIV and AIDS of Catalonia (CEEISCAT), Badalona, Spain, [2]CIBER Epidemiología y Salud Pública, Madrid, Spain

BACKGROUND: The objective of the study was to evaluate the acceptability and effectiveness of an online self-sampling intervention for HIV testing and online consultation of the results addressed to gay, bisexual and other men who have sex with men (GBMSM) and trans women users of websites and online dating applications in Spain.

METHODS: The website www.testate.org was designed to offer the test, consult the results and collect sociodemographic and behavioral information. This was advertised in: Grindr, Scruff, Wapo, PlanetRomeo, Bakala, MachoBB and Trans4men. After signing the informed consent online, the participants requested the delivery of a saliva self-sampling kit by mail and a postage-paid envelope to send the sample to the reference laboratory. Participants received a reminder by SMS to repeat the test at 3/6/12 months. All reactive participants were called by phone. An anonymous acceptability survey was conducted on all participants.

RESULTS:

[Figure 1. Flow chart of the main stages of the study]

From November 2018 to October 2019, self-sampling kits were sent to 2,548 participants (66.6 % return rate). 1,979 participants (77.7%) had a single test, 412 (16.2%) had two, 137 (5.4%) had three and 43 (2.2%) took four tests. 19.1% resided in cities with <50,000 inhabitants. 24.1% had never been tested. 37.9% had not used condom in their last anal relationship. 28.8% had had an STI in the last 5 years. 54 reactive results were detected (3.25%). All were men. 8 were already known positive, one was a false positive, 33 confirmed their result and 31 were linked to care and started treatment. 97.8% would recommend it to a friend. The most identified advantages were comfort and privacy.

CONCLUSIONS: The intervention counted with a high acceptability among the target population. The intervention has been shown to be effective given the high percentages of reactiveness, confirmation and linkage to care observed.

PEC0569

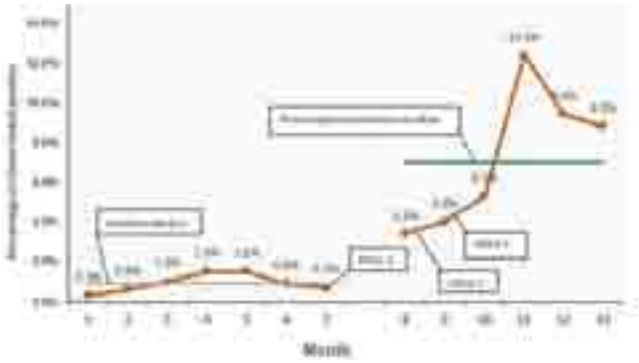
REACHING THE FIRST 90: IMPROVING YIELD FROM ROUTINE COMMUNITY-LED HIV TESTING SERVICES USING A QUALITY IMPROVEMENT APPROACH IN KOGI STATE, NIGERIA

S. Balogun[1], A. Adewole[1], Z. Rufai[1], W. Shaibu[2], P. Adah[2], T. Adeleye[1], E. Nwabueze[1], E. Ijezie[1]
[1]AIDS Healthcare Foundation, Abuja, Nigeria, [2]Kogi State Agency for the Control of AIDS, Lokoja, Nigeria

BACKGROUND: Less than 70% of Nigeria's estimated HIV population of 1.8 million are aware of their status. Shortage of test kits in recent years have led to scaling down of testing services threatening the achievement of the first 90 thereby necessitating innovations for case-finding. Routine community-led testing yield averages 0.8% compared to facility-based testing of 2.0% or more leading to many organizations stopping or scaling down community outreaches. This project aimed at increasing the community-led testing yield to five-folds within a period of 6 months.

METHODS: Using a hybrid of Six Sigma and the Model for Improvement, a multi-disciplinary team including front-line community workers identified challenges with current community testing approach and came up with intervention plans: identification of at-risk sub-population, the use of checklist to screen out people who are less at risk and have had a recent HIV test, and performance payment based on yield. These were implemented in three Plan, Do, Study and Act (PDSA) cycles. The outreaches were conducted in various communities between June and November 2019. Data was collected using routine reporting tools and the outcome plotted on a run-chart.

RESULTS: A total number of 1650 persons were tested with women accounting for 78% (n = 1291) and men 22% (n = 359). Thirty-four percent of the people were young people (n = 555). Of the 92 new HIV positive clients identified (yield of 5.6%), 81 were females (yield of 6.3%) and 11 were males (yield of 3.1%). First month of implementation recorded a yield of 3.4% which rose to peak of 12.4% in the fourth month of the project.



[Figure. Improving yield from community-led HIV testing services]

CONCLUSIONS: The project achieved beyond the set target suggesting that routine community-led testing can be optimized to increase yield. Further evaluation of the impact on linkage to treatment, and retention rate is needed to support wider implementation.

PEC0570

USING MENTOR MOTHER INITIATIVE AS A STRATEGY FOR ACHIEVING PMTCT IN HARD-TO-REACH COMMUNITIES IN NORTH CENTRAL NIGERIA

E.O. Chukwu[1], I.F. Uthman[2], C.E. Awunor[1], G.A. Adesue[3]
[1]Aids Healthcare Foundation, Nursing (Prevention, Care and Treatment), Lafia, Nigeria, [2]Joint United Nations Programme on HIV and AIDS (UNAIDS), UNAIDS, Lafia, Nigeria, [3]Aids Healthcare Foundation, Prevention, Lafia, Nigeria

BACKGROUND: In 2017, 35% of pregnant women in Nigeria received an HIV test, fewer than in 2015 when 42% did. Of those women diagnosed with HIV in 2017, just 30% were on ART. In the same year, 36,000 children became HIV positive, a number that has been rising since 2014. Early infant diagnosis is also extremely low at only 12%. North central Nigeria bears most of these statistical prevalence burden. Mentor Mother Initiative (MMI) intervention was introduced to curb this transmission in Nasarawa State, North Central Nigeria. This article evaluates the effectiveness of this 9-months initiative intervention.

METHODS: 20 mentor mothers with one supervisor who are HIV positive women, passed through the PMTCT cascade with a successful livebirth and baby is HIV negative as a result of the PMTCT intervention and are willing to support others to do same were recruited. They were given package of services which aimed at PMTCT to provide and were sent into hard-to-reach communities in 7 Local Government Areas of the state. Referral/linkage of clients were to 10 ART facilities supported by AHF Nigeria. The intervention initiative lasted for 9 months (January to September, 2019). At the end of the 9 months, the activities of the mentor mothers in the various facilities were compared with that of 2018 in the corresponding months with data been extracted from the PMTCT registers.

RESULTS: During intervention period, 2753 new ANC were recorded as against 1807 in 2018 without MMI intervention. Of these ANC 3.1% (n=2753) were tested HIV positive and were enrolled and linked into care, 53 HEI were linked for ARV prophylaxis within 72hrs of birth and EID within 6-8weeks. 170 index partners were traced and referred for HTS out of which 14.1% (n=170) were tested HIV positive and were linked into ART care.

CONCLUSIONS: MMI is a successful intervention which has led to identification and linkage of HIV positive pregnant mothers especially in rural areas. This initiative intervention should be sustained and be considered in more states and especially rural areas so as to make EMTCT a reality in Nigeria.

PEC0571

INDEX TESTING FINDS MANY PREVIOUSLY UNDIAGNOSED HIV POSITIVE INFANTS AND PREGNANT AND BREASTFEEDING WOMEN IN ZAMBIA

L. Mwango[1], B. Phiri[1], M. Mujansi[1], G. Daka[1], M. Mukubonda[1], S. Njai[2], E. Kabwe[3], R. Tembo[3], K. Nkwemu[4], A. Mwila[4], C. Claassen[5]
[1]Maryland Global Initiatives Corporation Zambia, Lusaka, Zambia, [2]Ministry of Health, Western Provincial Health Office, Chipata, Zambia, [3]Ministry of Health, Lusaka District Health Office, Lusaka, Zambia, [4]U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [5]University of Maryland School of Medicine, Center for International Health, Education, and Biosecurity, Lusaka, Zambia

BACKGROUND: Although Zambia has nearly eliminated mother-to-child HIV transmission, some pregnant and breastfeeding women (PBFW) and their children remain at risk. Targeted strategies are needed to reach these priority populations. We present results from the Community Impact to Reach Key and Underserved Individuals (CIRKUITS) project on index testing for PBFW and their children.

DESCRIPTION: CIRKUITS is a five-year PEPFAR CDC grant awarded to the University of Maryland Baltimore to support HIV case-finding and antiretroviral (ART) linkage for key and priority populations in five districts in Zambia. CIRKUITS community health workers collaborate with health facilities to implement community index testing by tracing all sexual contacts of newly diagnosed HIV persons, including PBFW and their children. PBFW identified as sexual contacts are offered HIV testing, and all children <15 years with an HIV+ biological mother are also tested. All HIV+ persons are supported in linkage to care. We conducted a cross-sectional analysis of aggregated routinely collected program data; outcomes of interest were positivity rates and linkage to ART initiation among women and children aged <15 years.

LESSONS LEARNED: From October 2018 to September 2019, CIRKUITS tested 50,931 adults and children in Zambia. HIV positivity rates were 8% among children <15 years and 26% among adults. Of the 18,309 women aged >15 years who were tested, 6,261 (34%) were HIV-positive, and 5,570 (89%) were linked to care.

Among the women with new HIV diagnoses, 328 were previously undiagnosed PBFW; of these, 324 (99%) were linked to ART. Of the 146 children aged <1 year with mothers with a new HIV diagnosis, 28 were HIV positive, for a positivity yield of 19%. Of these, 24 (86%) were linked to ART. The positivity rate among children aged 1–14 years was much lower (7.8%), but linkage was higher (93%).

CONCLUSIONS/NEXT STEPS Community index testing targeting PBFW and their children identified previously undiagnosed women and children and linked them to care. HIV positivity among infants was high compared to older children, suggesting that many infants are being missed by standard facility-based screening. Further efforts are needed to strengthen HIV services for PBFW and their children.

PEC0572

INNOVATIVE COMMUNITY DRIVEN TESTING STRATEGIES FOR INCREASING HIV CASE FINDING AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN GHANA

S.E. Owusu[1], K. Diaba[2], S.K. Wosornu[3], C. Yalley[1]
[1]Maritime Life Precious Foundation, Programs, Takoradi, Ghana, [2]WAPCAS, Programs, Accra, Ghana, [3]Maritime Life Precious Foundation, Executive Director, Takoradi, Ghana

BACKGROUND: In Ghana, HIV case detection among MSM is low despite targeted interventions implemented by CSOs. Conventional outreach approaches at fixed locations reach large number of MSM but often do not target the high risk and closeted MSM who are living with HIV. Identifying new MSM HIV positives require using more efficient and effective innovative approaches to engage different segments of unreached MSM who are most at risk.

DESCRIPTION: Various innovative approaches were introduced to identify high risk MSM who are HIV positive.

Conventional large group outreach at fixed venues that produced low HIV positive yield were halted and replaced with flexible community-based strategies and cross-cutting initiatives through assessment of MSM according to their risk behaviors and linking them to an appropriate testing strategy.

Outreach workers used peer-driven and multiple testing approaches to reach different high-risk MSM positives in different networks: (1) Social media platforms (Facebook, Grinder, dating apps) were used to reach and engage peers for HTS; (2) HIV Testing took place at homes and/locations identified by and agreed to by peers at their own convenience; (3) Nurses and case managers encouraged MSM who had been initiated on ART to introduce their recent sexual partners to HTS; (4) Testing were conducted within a flexible schedule, using more daytime interventions than the predominantly large-group evening outreach interventions.

LESSONS LEARNED: Trends from programmatic data indicate that HIV positive yield among MSM increased after the introduction of innovative community-driven testing strategies to reaching high risk MSM. Between January and June, 2019, 561 MSM were tested using the conventional large group outreach at fixed venues; 36 MSM (6.4% HIV+ yield) were diagnosed positive. After the introduction of innovative testing interventions, between July and December 2019, 389 MSM were tested and 71 MSM (18.3% HIV+ yield) were diagnosed HIV positive.

CONCLUSIONS/NEXT STEPS Innovative strategies to HIV testing through community-driven approaches is effective and efficient in reaching a high number of MSM who are HIV positive and should be complemented with traditional peer outreach to enhance HIV case finding.

CSOs can adopt multiple tailored and flexible approaches to improve results in reaching, testing and linking MSM who are most at risk.

PEC0573

IMPACT OF PROVIDING FREE HIV SELF-TESTING KITS ON FREQUENCY OF TESTING AMONG MEN WHO HAVE SEX WITH MEN AND THEIR SEXUAL PARTNERS IN CHINA

C. Zhang[1], X. Li[1], H.-Z. Qian[2], L.A. Goldsamt[3], H. Wang[1], D. Koniak-Griffin[4], M.-L. Brecht[4]
[1]Central South University, Xiangya Nursing School, Changsha, China, [2]Yale University, School of Public Health, New Haven, United States, [3]New York University, Rory Meyers College of Nursing, New York, United States, [4]University of California at Los Angeles, School of Nursing, Los Angeles, United States

BACKGROUND: The HIV epidemic is rapidly increasing among men who have sex with men (MSM) in China, yet HIV testing frequency remains suboptimal. HIV self-testing (HIVST) is recommended by the WHO as a complementary approach to site-based HIV testing (SBHT) services in healthcare facilities; evidence is sparse regarding the efficacy of self-testing interventions among Chinese MSM and their sexual partners.

METHODS: This randomized controlled trial was conducted in four cities in Hunan Province, China. Sexually active and HIV-negative MS were recruited from communities and randomly assigned to intervention or control arms. Participants in the control arm had access to routine SBHT services and self-paid HIVST kits; those in the intervention arm were provided with two free finger-prick-based HIVST kits at enrollment and could receive two to four kits every 3 months for 1 year in addition to routine SBHT accessibility. They were encouraged to distribute self-testing kits to their sexual partners. Data were collected through online questionnaires at baseline, 3-, 6-, 9- and 12-month follow-ups. Outcomes examined included the mean frequency of HIV tests among MSM participants and their sexual partners during 12-month follow-up. Z and t tests were performed to compare data.

RESULTS: The sample was composed of 216 MSM, 110 in the intervention and 106 in the control arm. During 12-month follow-up, the total frequency of HIV testing among MSM participants in the intervention arm (mean=3.71) was higher than that in the control arm (mean=1.82, P<0.01). This finding was due to different frequencies of HIVST in two arms (intervention mean=2.19 vs. control mean=0.40, P<0.01); no differences were found in use of SBHT between the arms (1.56 vs 1.41). The total frequency of HIV testing among sexual partners of MSM was higher in intervention than control arm (2.65 vs 1.31; P<0.01), with differences in HIVST also contributing to this finding (1.41 vs 0.36; P<0.01). Use of SBHT remained similar (1.24 vs 0.96).

CONCLUSIONS: Providing free HIVST kits significantly increased testing frequency among Chinese MSM and positively impacted sexual partners within their social networks. This effective intervention has the potential to be easily scaled up through the extensive Chinese public health networks.

PEC0574

THREE COMMUNITY BASED STRATEGIES TO PROVIDE PREVENTION AND TESTING SERVICES TO MSM IN MOZAMBIQUE

M. Cassolato[1], R. Paulo[2], S. Garg[3], C. Belle Fleur[4], E. Pereira[5]
[1]Frontline AIDS, Innovation Team, Hove, United Kingdom, [2]Lambda, Maputo, Mozambique, [3]Frontline AIDS, Hove, United Kingdom, [4]Frontline AIDS, Cape Town, South Africa, [5]Amodefa, Maputo, Mozambique

BACKGROUND: When compared to the general population, in all countries with reliable epidemiological data, men who have sex with men (MSM) are disproportionately affected by HIV. This is true also for Mozambique where the prevalence of HIV among MSM 25 years or older living in Maputo has been estimated at 33.8% (IBBS among MSM, Mozambique, 2011) against a national prevalence of 12.6% (UNAIDS Estimates 2019) for the adult population (15-49). To address this inequity it is vitally important to implement community-based strategies and packages of interventions that can reach MSM in their own communities and provide them with HIV services tailored to their needs.

DESCRIPTION: Funded by the Elton John Aids Foundation, Frontline AIDS implemented a 2.5 year project designed to increase demand and uptake of HIV prevention and testing services by the LGBT populations of Mozambique. At the community level, the project - implemented in the capital city Maputo and in 3 other provinces- provided packages of HIV and STI services through three integrated community- based strategies:

(1) night mobile clinics in settings visited by LGBT people,

(2) LGBT safe spaces and

(3) community outreach done by LGBT peer educators.

An evaluation of all three strategies through focus group discussions and in-depth interviews has been conducted to determine services utilization and preferences of LGBT people.

LESSONS LEARNED: In the period January 2018 to November 2019 the project reached 18708 LGBT people with HIV community based services and conducted a total of 16060 HIV tests. (positivity rate 6%). Of the 18708 LGBT people who accessed the service package, 74% have been reached by a LGBT peer educator and 26% have been reached by a trained health professional. Preliminary findings seem to indicate that in project intervention areas LGBT people are more likely to access HIV services (including HIV testing) when the package is provided by a LGBT peer educator.

CONCLUSIONS/NEXT STEPS Community based strategies designed for and with LGBT people proved to be an effective strategy to provide HIV services to LGBT people in Mozambique,

PEC0575

INCREASING HIV CASE FINDING AMONG KEY POPULATIONS: LESSONS LEARNED FROM IMPLEMENTING INDEX TESTING IN MALAWI

E. Mpunga[1], L. Masankha Banda[1], M. Ruberintwari[1], C. Akolo[1], S. Sikwese[2], G. Trapence[3], D. Chilongozi[1]
[1]FHI 360, Lilongwe, Malawi, [2]Pakachere Institute for Health and Development Communication, Blantyre, Malawi, [3]Centre for Development of People, Lilongwe, Malawi

BACKGROUND: The Malawi Ministry of Health (MOH) has adopted index testing as a strategy for increasing HIV case finding among all populations. We present the experience and lessons learned from implementing index testing among key populations (KPs) under the USAID/PEPFAR-funded LINKAGES project led by FHI 360.

DESCRIPTION: From August to September 2018, LINKAGES began implementing HIV index testing among female sex workers (FSWs) and men who have sex with men (MSM) in six LINKAGES-supported districts in Malawi. Using the MOH-approved training curriculum, KP service providers in drop-in-centers (DICs), including those at referral public clinics, were trained to implement index testing in DICs and outreach mobile clinics. HIV testing services were offered to sexual partners of MSM, FSWs, spouses and clients of FSWs, and biological children of FSWs through mobile outreach services and at DICs. Routine program data were collected and analyzed to understand the contribution of index testing to the LINKAGES' overall case finding.

LESSONS LEARNED: During the two-month implementation period, a total of 267 KP individuals (MSM and FSWs) were offered voluntary partner referral slips as index clients. Of these, 90% (241/267) accepted index testing, and 335 partners were elicited. Among the elicited partners, 49% (164/335) were tested for HIV, and 63% (103/164) tested HIV positive. Of those partners who tested positive, 98% (101/103) were linked to treatment. Under index testing, the case-finding rate among MSM was 93% (88/94) and 21% (15/70) among FSWs, compared to 19% (102/528) among MSM in routine testing for the same period and 27% (477/1,734) among FSWs.

CONCLUSIONS/NEXT STEPS: Index testing generated a higher case-finding rate than routine HIV testing among KPs in Malawi. It also provided an opportunity for KP members to access HIV testing services in preferred and safe settings. Effective KP programming must emphasize and implement index testing as a key innovation for increasing case finding. The project incorporated index testing as routine and promoted provider referral to increase uptake of the service following the early findings. Since FSWs have multiple partners, some of whom cannot be traced, innovative means of partner elicitation and active index case testing should be used.

PEC0576

ASSISTED PARTNER NOTIFICATION: IMPROVING HIV TESTING YIELD TO ACHIEVE THE FIRST 95 TARGET IN LANGO SUB-REGION IN NORTHERN UGANDA

P. Donggo[1], G. Sangadi[1], S. Engulu[1], M. Makumbi[1]
[1]John Snow Inc./USAID RHITES-North Lango Project, Lira, Uganda

BACKGROUND: According to the Uganda Population-Based HIV Impact Assessment, 84 percent of people living with HIV know their status. The Uganda national consolidated HIV prevention, care and treatment guidelines (2018) recommend Assisted Partner Notification (APN) as a critical strategy to achieve widespread testing of those at risk—the first of the UNAIDS 95-95-95 goals. APN provides comprehensive services for persons infected with HIV or sexual transmitted infection, and their partners, with focus on index clients who are newly diagnosed HIV positive, have non-suppressed viral loads and/ or have a new STI or partner.

DESCRIPTION: The JSI-led USAID RHITES-North, Lango project supports health care workers (HCWs) in Lango region to implement APN. The project conducted a phased roll out by training and mentoring HCWs, peer clients and community health workers in 70 health facilities; provided data tools, job aids and telephones. The index clients were line listed and teams consisting of a health worker, counselor and community worker were formed to conduct APN.

LESSONS LEARNED: Between October 2018 and September 2019, Of the 21,081 index clients eligible for APN services, 8,742 (41%) were interviewed; 12,434 partners elicited (an average of 2 partners elicited for each individual); 11,101 (89%) of the partners were notified and offered HIV testing services; 9,427 (85%) of them tested for HIV, and 2,656 (28%) were newly diagnosed as HIV positive. More females (55%) were identified HIV positive through APN, with a higher yield at 30% compared to 1,197 men identified positive with a yield of 27%.

CONCLUSIONS/NEXT STEPS Success of APN depends on good data management systems to identify eligible clients and their partners, and good knowledge and skills among HCWs, peer clients and community health workers. It can enable identification of HIV positive clients. APN identifies persons previously unaware of their HIV-positive status, yet they are sexual partners of newly infected HIV positive individuals, thereby enabling linkage to care and same-day treatment and reducing onward transmission risk. An approach focused on identifying partners of HIV infected persons has the potential to better target testing strategies to identify >95% of people living with HIV in a community.

PEC0577

COMMUNITY-BASED VOLUNTARY COUNSELING AND TESTING IN RURAL SOUTH AFRICA AMONG ADOLESCENT GIRLS AND YOUNG WOMEN

M. Grammatico[1], S.V. Shenoi[1], A.P. Moll[2]
[1]Yale University, New Haven, United States, [2]Philanjalo Care Center, Tugela Ferry, South Africa

BACKGROUND: In sub-Saharan Africa, adolescent girls and young women (AGYW) ages 15 – 24 are at exceptionally high risk for HIV. Community-based voluntary counseling and testing (CBCVT) is a validated strategy to increase HIV awareness and testing uptake. We describe a successful CBVCT strategy to engage AGYW in rural South Africa.

METHODS: Trained community health workers, supervised by a nurse, conducted community-based voluntary and confidential rapid HIV testing and concurrent TB screening in congregate community settings in rural KwaZulu Natal. AGYW identified with HIV were offered confirmatory testing, CD4 staging, individual counseling and referral to care and antiretroviral therapy (ART) according to national guidelines.

RESULTS: CBVCT was performed among 1808 AGYW at community sites including municipality events (n=697), pension pay points (n=348), taxi ranks (n=229), schools (n=122), and home based care visits (n=208). The median age was 20 (IQR 15 - 24) and a high proportion (94.95%) consented to VCT. A third of participants (594, 32.9%) reported first-time HIV testing. Of AGYW who consented to VCT, 114 (6.6%) were HIV positive and linked to public sector facilities for HIV care.

Correlates of HIV-positive status included community testing site (p=0.04) and belonging to the 19-24 age group rather than 15-18yo (p<0.001). Pension Pay Points yielded the greatest proportion of AGYW (24/322 7.5%) with HIV-positive test result, followed by taxi ranks (7.1%) and municipality events (7%). Among all HIV-positive AGYW (n=114), the greatest proportion (45, 39.4%) was identified at municipality events, followed by pension pay points (24, 21%) and taxi ranks (15, 13%).

CONCLUSIONS: AGYW accept HIV testing outside of health care facilities and by non-clinical personnel. Utilizing a variety of community testing sites reaches different demographic groups, including high-risk young women. CBVCT can detect AGYW living with HIV, and may provide an opportunity for engaging hard-to-reach AGYW for HIV prevention interventions including pre-exposure prophylaxis.

PEC0578

INNOVATIVE ENHANCED PEER OUTREACH APPROACH REACHES HIGH-RISK ADOLESCENT GIRLS AND YOUNG WOMEN IN LUSAKA, ZAMBIA

H. Smith[1], M. Gondwe[1], C. Moonga[1], M. Musheke[1], J. Okuku[2], M. Wolfe[3], A. Mwila[2], L. Mwango[4], L. Buumba[1], K. Kaputula[1], K. Chiyenu[1], M. Mujansi[4], J. Chipukuma[4], C.W. Claassen[5], M. Herce[1,6]

[1]Centre of Infectious Disease Research in Zambia (CIDRZ), Lusaka, Zambia, [2]Centers for Disease Control & Prevention (CDC), Lusaka, Zambia, [3]Tackle Africa, Lusaka, Zambia, [4]Maryland Global Initiatives Corporation Zambia, Lusaka, Zambia, [5]University of Maryland School of Medicine, Center for International Health, Education and Biosecurity, Lusaka, Zambia, [6]University of North Carolina at Chapel Hill, Chapel Hill, United States

BACKGROUND: Adolescent girls and young women (AGYW) in Zambia have high HIV prevalence rates (5.7%). Despite increased HIV risk, less than half of Zambian AGYW know their status. Risk factors for AGYW include transactional sex (exchange of sex for material support or other benefits), substance use, and inconsistent condom use. We piloted an innovative, youth-friendly, enhanced peer outreach approach (EPOA) to engage high-risk AGYW networks and promote HIV-testing services (HTS) in an urban compound of Lusaka, Zambia.

METHODS: Working with community partners, we recruited 10 high-risk AGYW aged 15–24 years engaged in transactional sex to act as seeders. We gave each seeder 20 music-themed, non-HIV–branded recruitment coupons featuring the hashtag #utuntu (Bemba for "You should know things") to distribute within her social network. The coupons could be redeemed for HTS at a confidential location during community-based and social venue–based AGYW mobilization. Coupon holders were given (50 Kwacha (~$3.50(USD)) after testing and receiving their results, and seeders received 40 Kwacha (~$2.70 (USD)) for every person who redeemed their coupon. All participants completed a simple risk-assessment form and received condoms and lubricant. All AGYW testing HIV-positive were referred to antiretroviral therapy (ART) services.

RESULTS: During implementation (July–August 2019), 76.5% (153/200) of distributed coupons were redeemed for HTS. Among coupon redeemers, 84.3% (129/153) reported engaging in transactional sex in the last 6 months; another 15.0% (23/153) were classified as high-risk for not using condoms, for using illicit drugs, or for reporting sexually transmitted infection symptoms in the last 6 months. Only one AGYW (0.7%) did not meet high-risk criteria. Of the 153 AGYW tested, 37 (24.2%) were HIV-positive: 5 (13.5%) knew their status and were receiving ART. Of the 32 (86.5%) with new HIV diagnoses, 21 (65.6%) were linked to ART.

CONCLUSIONS: This youth-friendly approach reached high-risk AGYW and identified HIV-positive AGYW who may not access traditional HTS. These results indicate that EPOA strategies may be effective for identifying high-risk and hard-to-reach AGYW for HIV prevention and testing services. Additional investments may be needed to identify complimentary strategies that ensure linkage and retention in care for HIV-positive AGYW after EPOA.

PEC0579

REACHING MALE CLIENTS AND PARTNERS WITH HIV SELF-TEST KITS DISTRIBUTED BY FEMALE SEX WORKERS IN IRAN: ACCEPTABILITY AND EFFECT OF MONETARY INCENTIVES IN A RANDOMIZED CONTROLLED TRIAL

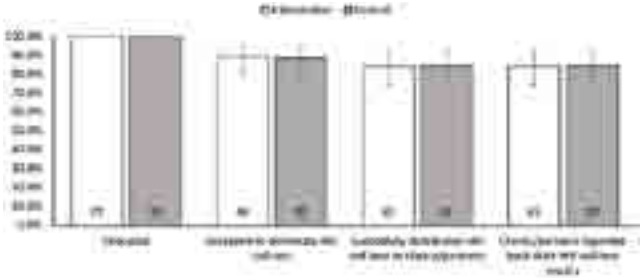
L. Taj[1], T. Amiri[1], S. Sindarreh[2], M. Nasirian[2], R. Khajekazemi[3], S. Hosseini Hooshyar[4], Z. Boroumandfar[5], P. Afsar Kazerooni[6], W. McFarland[7], M. Mohraz[1], A. Mirzazadeh[7]

[1]Iranian Research Center for HIV/AIDS, Iranian Institute for Reduction of High-Risk Behaviors, Tehran University of Medical Sciences, Tropical and Infectious Diseases Department, Tehran, Iran, Islamic Republic of, [2]Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic of, [3]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [4]The Kirby Institute, University of New South Wales, Sydney, Australia, [5]School of Nursing and Midwifery, Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic of, [6]Shiraz HIV/AIDS Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [7]Department of Epidemiology and Biostatistics, Institute for Global Health Sciences, University of California, San Francisco, United States

BACKGROUND: HIV self-testing has great potential to improve early diagnosis among highly stigmatized, hard-to-reach populations. Distributing HIV self-test kits through female sex workers (FSW) may be an effective way to reach male clients. We implemented the "SELFii" study to assess FSW willingness to distribute free self-tests and to the impact of offering monetary incentives on client/partner uptake through a randomized controlled trial (RCT).

METHODS: In an open-label RCT (#IRCT201710039506N1), FSW aged 18+ years were recruited through peer-referral sampling in Tehran and Isfahan, Iran 2019. FSW were randomly allocated into two groups and enlisted to distribute free HIV self-test kits to their clients/partners. The intervention group received monetary incentives (~$2/kit) to distribute kits; the control group received no incentive. Outcomes compared include accepting to distribute, success in distributing, and reporting back their partners/clients test results to the study.

RESULTS: Of 192 eligible FSW initially referred by peers, 156 (81.2%) accepted to participate in the trial. In the intervention arm (N=77), 69 (89.6%, 95%CI 80.6-95.4) FSW accepted to distribute self-tests and 65 (84.4%, 95%CI 74.4-91.7) successfully distributed them and had their clients/partners report back their HIV self-test results (N=65, 84.4%); Of 65 clients/partners 1 (1.5%) tested positive and was later confirmed. In the control arm (N=79), 70 (88.6%, 95%CI 79.5-94.7) FSW accepted to distribute self-tests and 67 (84.8%, 95%CI 75.0-91.9) successfully distributed them and had their clients/partners report back their HIV self-test results(N=67, 84.4%); Of 67 clients/partners 1 (1.5%) tested positive and was later confirmed. Acceptance to distribute self-tests, successful distribution, and client/partner report-back of results was similar in both arms (P>0.05) [Figure 1].



[Figure 1]

CONCLUSIONS: We found high acceptability among FSW to distribute HIV self-test to their clients/partners, and a high acceptability among clients/partners to test themselves. The monetary incentive had no effect on distribution, acceptability, and test reporting outcome measures.

PEC0580

UPTAKE OF HIV TESTING AMONG ADOLESCENTS AND YOUNG PEOPLE ATTENDING PEER-LED COMMUNITY-BASED SEXUAL AND REPRODUCTIVE HEALTH SERVICES IN LUSAKA, ZAMBIA: EARLY RESULTS FROM THE "YATHU YATHU" TRIAL

M.M. Phiri[1], B. Hensen[2], M. Simwinga[1], A. Schaap[1,2], L. Sigande[1], S. Floyd[2], S. Belemu[1], M. Simuyaba[1], K. Shanaube[1], R. Hayes[2], S. Fidler[3], H. Ayles[1,2]
[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Imperial College, London, United Kingdom

BACKGROUND: Adolescents and young people aged 15-24 (AYP) are underserved by available HIV-testing services (HTS). Delivering HTS through community-based, peer-led, hubs may prove acceptable and accessible to AYP, thus increasing HIV-testing coverage. Using data from the pilot phase of a cluster-randomised trial of community-based, peer-led comprehensive sexual and reproductive health services for AYP in Lusaka, Zambia, we describe and explore factors associated with self-reported history of HIV-testing and uptake of HTS through community-based hubs.

METHODS: Twenty clusters across two urban communities were randomly allocated to intervention or standard-of-care. From August–December 2019, AYP in all 20 clusters were enumerated and offered a prevention point's card to enable tracking of services accessed. In intervention clusters, peer support workers, nurses and lay counsellors, provide comprehensive services, including HTS, from centrally-located hubs.At first hub visit, AYP are screened for alcohol use disorders using AUDIT-C and asked their HIV-testing history. We used card data from intervention clusters only to describe: HIV-testing history and uptake of HTS by age, sex, AUDIT-C score, education and marital status, and explored whether these factors were associated with both outcomes.

RESULTS: In the first 4-months of implementation, 5,206 AYP attended a hub; 65% (n=3380) were female. Among AYP self-reporting their HIV-testing history, 69% (n=3461/5013) ever-HIV-tested before their hub visit. Adjusting for age and sex, ever HIV-testing differed by sex, age, educational attainment (Table 1).

Description		Distribution of characteristics (N=5206; N (column%))	Number and % self-reporting previous HIV test (N=3461)*	Number and % HIV testing at the hub (N=3895)+
Overall		5206 (100%)	3461 (69.0%)	3895 (76.0%)
Sex	Male Female	1826 (35.1) 3380 (64.9)	**1134 (64.1)** **2327 (71.7)**	1380 (76.4) 2515 (75.8)
Age	15-19 20-24	3620 (69.5) 1586 (30.5)	**2112 (60.5)** **1349 (88.8)**	2773 (77.3) 1122 (73.0)
Marital status	Never married Co-Habiting /married	4592 (88.2) 614 (11.8)	2942 (66.3) 519 (90.4)	**3506 (77.2)** **389 (66.3)**
Educational attainment	None/Primary Secondary/higher	1263 (24.3) 3943 (75.7)	**662 (54.4)** **2799 (73.7)**	939 (75.5) 2956 (76.1)
At risk of hazardous alcohol use	No Yes	4999 (96.0) 207 (4.0)	3289 (68.3) 172 (86.0)	**3764 (76.4)** **131 (65.5)**

*193 individuals missing data on history of HIV-testing, +80 individuals self-reported HIV-positive

[Table 1]

76% (n=3,895) of AYP attending the hubs HIV-tested (75% via finger-prick HIV-testing; 25% HIV self-testing); including 80% (n=1243/1552) of AYP self-reporting never HIV-testing before visiting the hub. Lower uptake of HTS at hubs was associated with being married/cohabiting and at risk of alcohol use disorders.

CONCLUSIONS: A high proportion of AYP with no history of HIV-testing accessed HTS through community-based hubs. Better targeting of HTS to key groups who may not perceive their risk of HIV needs to be considered.

PEC0581

ASSISTED PARTNER NOTIFICATION HIGHLIGHTS A GAP IN DISCLOSURE AMONG SEXUAL PARTNERS IN LANGO SUB-REGION IN NORTHERN UGANDA

P. Donggo[1], G.E. Sangadi[1], S. Engulu[1], M. Makumbi[1]
[1]John Snow Inc./USAID RHITES-North Lango Project, Lira, Uganda

BACKGROUND: According to the Uganda Population-Based HIV Impact Assessment, 84 percent of people living with HIV know their status. The Uganda national consolidated HIV prevention, care and treatment guidelines (2018) recommend Assisted Partner Notification (APN) as a critical strategy to achieve widespread testing of those at risk—the first of the UNAIDS 95-95-95 goals. APN provides comprehensive services for persons infected with HIV or STDs and their partners. Couples HIV testing is an approach that encourages couples to test together, and to disclose their HIV status to each other during the counseling session. This approach leads to improved outcomes such as linking couples to care, increasing adherence to treatment and reducing stigma.

DESCRIPTION: The JSI-led USAID RHITES-North, Lango project supports health care workers (HCWs) in Lango region to implement APN through assisted HIV PN services where a trained provider helps consenting index patients notify their sexual partner's status and partner's potential exposure to HIV infection. The provider then offers HIV testing to these partner(s). Couples are encouraged to test together, and to disclose their HIV status to each other.

LESSONS LEARNED: Between October 2018 and September 2019, Of the 21,081 index clients eligible for APN services, 8,742 (41%) were interviewed with 12,434 partners elicited (an average of 2 partners elicited for each individual). Among these 1,336 (11%) partners were already on antiretroviral therapy without the knowledge of the index client who was their sexual partner. Of these, 156 (11%) were 15-24 years, 942 (70.5%) were 25-44 years and 238 (17.8%) were above 45 years. Non- disclosure was 2 times higher among younger females aged 15-24 years compared to males in the same age group and 1.6 times higher among older males above 45 years.

CONCLUSIONS/NEXT STEPS The goal of partner testing is to provide HIV testing to undiagnosed persons who are in a relationship with a person diagnosed with HIV. However, lack of disclosure among sexual partners may elicits partner who are already on treatment. HIV positive clients need support to ensure their partners are aware of their HIV status and get tested, and linked to treatment or preventive services.

PEC0582

PEDIATRIC SALIVA-BASED HIV TESTING: ACCEPTABILITY OF HOME-BASED AND PARENT-ADMINISTERED TESTS

J. Neary[1], M. Bulterys[1], E. Awino[2], G. O'Malley[3], A.A. Otieno[4], V.O. Omondi[5], Y. Wang[3], X. Zhai[3], L. Oyiengo[6], D. Wamalwa[7], J.A. Slyker[8], G.C. John-Stewart[9], I.N. Njuguna[4,1], A.D. Wagner[3]
[1]University of Washington, Epidemiology, Seattle, United States, [2]Emory University, Atlanta, United States, [3]University of Washington, Global Health, Seattle, United States, [4]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [5]Kenya Pediatric Association, Kenya Pediatric Research Consortium, Nairobi, Kenya, [6]National AIDS & STI Control Programme, Ministry of Health, Nairobi, Kenya, [7]University of Nairobi, Department of Paediatric and Child Health, Nairobi, Kenya, [8]University of Washington, Global Health, Epidemiology, Seattle, United States, [9]University of Washington, Global Health, Medicine, Pediatrics, Epidemiology, Seattle, United States

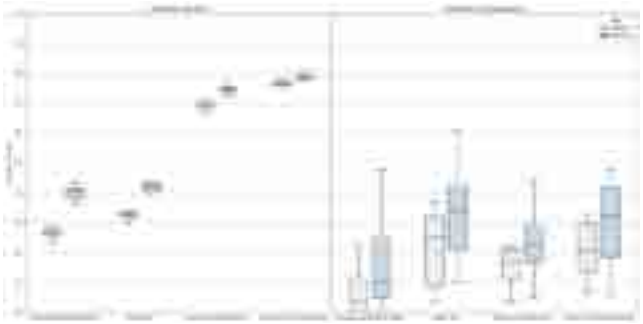
BACKGROUND: Pediatric HIV testing services (HTS) remain suboptimal in many resource-limited settings. The OraQuick oral mucosal transudate test (saliva-based test [SBT]) is validated in pediatric populations 18 months and above. SBT could complement traditional healthcare worker-delivered, facility-based, blood-based HIV testing.
METHODS: A trained qualitative interviewer conducted 4 focus group discussions (FGDs) with healthcare workers (HCW) and 4 with caregivers of children seeking health services in western Kenya. FGDs explored acceptability among HCW and caregivers of pediatric SBT, home- and facility-based SBT use, ideal instruction attributes, and changes to clinic operations anticipated with pediatric SBT. Two reviewers conducted thematic analyses of debrief reports.
RESULTS: Some HCW and few caregivers had heard of SBT. Prior to seeing SBT instructions, both had concerns about saliva volume and potential HIV transmission through saliva, which were mostly alleviated after kit demonstration and instruction. Noted benefits of SBT included usability, avoiding finger pricks, and avoiding HCW exposure. However, lack of caregiver familiarity with SBT was commonly noted. Caregivers urged literacy and language be considered when disseminating information on SBT and generally favored video, pictorial, or in-person instruction.
Benefits of facility-based pediatric SBT included shorter client time, reduced congestion in busy clinics, and higher HTS coverage. Noted challenges of SBT at a facility included ensuring confidentiality.
Benefits of caregivers using SBT at home included shorter time, convenience, privacy, decreased costs, increasing child testing, reduced HCW workload, easier administration, child comfort due to familiar setting, and caregiver belief results. Perceived challenges included not receiving pre-test counseling, disagreements with partners or child neglect, response to positive results, and not trusting results.
Overall, HCW felt that SBT could be used instead of blood-based testing, but saw limited utility for caregivers performing home- or facility-based SBT without an HCW. Caregivers saw utility in home-based SBT, but wanted easy access to HCW to confirm and counsel positive results.
CONCLUSIONS: SBT was generally acceptable to HCW and caregivers and seen as a means to improve waiting time, HTS coverage, and client comfort. Further studies are needed to address concerns related to pre-test counseling and disseminating test information.

PEC0583

MACHINE LEARNING TO IDENTIFY PREDICTORS OF HIV POSITIVITY

E. Orel[1], R. Esra[1], J. Estill[1], S. Marchand-Maillet[2], F.A. Merzouki[1], O. Keiser[1]
[1]University of Geneva/Institute of Global Health, Infectious Diseases and Mathematical Modelling, Geneva, Switzerland, [2]University of Geneva/Viper Group, Department of Computer Science, Geneva, Switzerland

BACKGROUND: High yield HIV testing strategies are needed for epidemic control. We aimed to predict the HIV status of individuals based on demographic and socio-behavioural characteristics.
METHODS: We analysed the most recent DHS surveys from 10 African countries in East and Southern Africa. We trained 4 machine-learning algorithms and selected the best based on the f1 score. Training, validation and, optimization were done on 80% of the data. The model was tested on the remaining 20% and on a left-out country which was rotated around. The best algorithm was retrained on the variables which were most predictive. We studied two scenarios: one aiming to identify 95% of people living with HIV (PLHIV) and one aiming to identify individuals with 95% or more probability of being HIV positive.
RESULTS: Overall 55,151 males (86 variables) and 69,626 females (122 variables) were included. XGBoost performed best in predicting HIV with a mean f1 of 76·8% (± 0·8%) for males and 78·8% (± 0·6%) for females. Among the ten most predictive variables, nine were identical for both sex: longitude, latitude and altitude of place of residence, current age, age of most recent partner, total lifetime number of sexual partners, years lived in current place of residence, condom use during last intercourse and, wealth index. Model performance based on these variables decreased minimally. For the first scenario, 7 males and 5 females would need to be tested to identify one HIV positive person. For the second scenario, 4·2% of males and 6·2% of females would have been identified as high-risk population.



[Figure]

CONCLUSIONS: We were able to identify PLHIV and those at high risk of infection who may be offered pre-exposure prophylaxis and/or voluntary medical male circumcision. These findings can inform the design and implementation of HIV prevention and testing strategies.

PEC0584

FINANCIAL INCENTIVE AND PEER REFERRAL IN PROMOTING DIGITAL SOCIAL-NETWORK DISTRIBUTION OF HIV SELF-TESTING AMONG CHINESE MSM: AN INTERMEDIATE ANALYSIS OF A THREE-ARM RCT

W. Tang[1,2], Y. Zhou[3], X. Li[3], S. Huang[3], H. Jiang[4], Y. Sha[2], D. Wu[2], W. Dai[3]
[1]Dermatology Hospital, Southern Medical University, Guangzhou, China, [2]UNC Project-China, Guangzhou, China, [3]Zhuhai Municipan Center for Diseases Prevention and Control, Zhuhai, China, [4]Guangdong Pharmaceutical University, Guangzhou, China

BACKGROUND: Social network-based HIV self-testing (SN-HIVST), in which an individual is given multiple self-test kits to distribute to people in their social network, is an innovative approach to increase HIV testing among key populations. The purposes of this three-arm RCT were to evaluate the effectiveness of financial incentive (Intervention one) and financial incentive and peer referral (intervention two) in promoting SN-HIVST among Chinese MSM, as compared to conventional SN-HIVST approach (Control group).

METHODS: Eligible MSM were recruited from a digital health platform as indexes and were randomly assigned to one of the three arms in a 1:1:1 ratio. In control group, index MSM were invited to apply for up to five self-test kits (15 USD/kit for deposit, refundable); in intervention group one, the index MSM were given 3 USD for each returned testing result; and in intervention group two, the index MSM were given 3 USD for each returned testing result, and for each successful referral and returned result (by the private application link up to five people for kits application). Both the indexes and the alters (men who received self-test kits from indexed) uploaded a photograph of a completed test result via the digital health platform (ChiCTR1900025433).

RESULTS: From November 1st of 2019 to January 12th of 2020, a total of 120 participants were recruited. Majority were < 30 years old (62%), have attended college (82%), and self-identified as gay (78%). Of them, 42, 41 and 37 were assigned into intervention group one, two, and control group, respectively. The mean number of HIVST kits distributed to the index MSM in the intervention group two was 3.9, which was significantly higher than the other two groups (2.5 and 2.3, P<0.001). Among the distributed kits, 36, 73, and 20 were already returned by alters, and 39% (group 1), 32% (group 2), and 10% (Control) of the alters in the three groups are new testers, of which was 11% for all the index MSM.

CONCLUSIONS: Financial incentive and peer referral may hold promise to promote SN-HIVST and increase HIV testing coverage among Chinese MSM, especially among those who never tested before.

PEC0585

NO MISSED OPPORTUNITIES: INTEGRATING LINKAGE AND PARTNER NOTIFICATION SERVICES INTO VMMC SITES IN TWO DISTRICTS IN KWAZULU-NATAL, SOUTH AFRICA

Z. Linda[1], S. Nyamhuno[1], K. Grabbe[2], C. Laube[2], M. Oladimeji[1], J. Mbulu[3], X. Mbangata[4], M. Mahomed[1]
[1]Jhpiego, Durban, South Africa, [2]Jhpiego, Washington, DC, United States, [3]Department of Health King Cetshwayo District, Empangeni, South Africa, [4]Department of Health Ugu District, Port Shepstone, South Africa

BACKGROUND: Voluntary medical male circumcision (VMMC) is a platform for reaching men who may not otherwise seek HIV testing services (HTS). While HTS yield in VMMC is low (<2% in published estimates), the absolute number of men testing positive is considerable, with millions of VMMC clients receiving HTS across East and Southern Africa per year. Case finding and linkage are central to the HIV response, yet VMMC programs struggle to adopt evidence-based linkage approaches or routinely offer partner notification services (PNS).

DESCRIPTION: In partnership with the South African government and the US Centers for Disease Control and Prevention, Jhpiego introduced enhanced linkage and PNS in Ugu and King Cetshwayo Districts in KwaZulu Natal, South Africa, from October 2018 to September 2019. Men aged ≥15 years presenting to VMMC were offered HTS, and HIV-positive clients were offered active linkage to treatment, and PNS. Men could select passive/self-referral, or assisted referral (provider, contract, or dual) for PNS. Dedicated PNS facilitators linked positive clients with treatment, and traced partners using the selected approach.

LESSONS LEARNED: During the implementation period, the project identified 712 HIV-positive clients out of 35,449 tests (2%); 167 (23%) were newly diagnosed, 6 (1%) had fallen out of care, and 539 (76%) were stable on treatment. Of 173 who needed linkage, 137 (79%) were initiated on treatment; 114 (83%) doing so on the same day. All 712 index clients were offered PNS, and 670 (94%) accepted and elicited a total of 777 contacts (all female). Index clients chose self-referral for 152 contacts (20%) and assisted referral for the remaining 625. Most of the contacts 593/625 (95%) could be reached, and 497 (84%) accepted HTS: 34 (7%) newly tested positive, 397 (80%) were known positive, and 66 (13%) tested negative. Of those newly diagnosed, 33 (97%) initiated ART on the same day.

CONCLUSIONS/NEXT STEPS Linkage and PNS is feasible and acceptable in VMMC; we can improve ART initiation among HIV-positive men and reach their partners for testing through PNS. Providers need training on linkage and PNS, ongoing mentorship to avoid missed opportunities, and encouragement to take actions not traditionally part of standard VMMC service provision. Given low HTS yield and high rates of prior testing among traced contacts, additional consideration is needed to determine whether scaling up PNS is cost-effective in VMMC.

PEC0586

COMMUNITY-LED INDEX CASE TESTING: A PROMISING STRATEGY TO IMPROVE HIV DIAGNOSIS AND LINKAGE TO CARE IN PARTNERS OF KEY POPULATIONS IN NIGERIA

A. Onovo[1], A. Kalaiwo[2], A. Atobatele[2], G. Emmanuel[3], O. keiser[4]
[1]Institute of Global Health, University of Geneva, Global Health, Geneva, Switzerland, [2]USAID, Abuja, Nigeria, [3]Heartland Alliance Nigeria, Abuja, Nigeria, [4]Institute of Global Health, University of Geneva, Geneva, Switzerland

BACKGROUND: The HIV epidemic in Nigeria is concentrated in Key Populations (KP), people who inject drugs (PWID), men who have sex with men (MSM), female sex workers (FSW), and partners of people living with HIV. Due to stigma and discrimination, these groups have poor access to HIV testing services (HTS) and linkage to treatment is challenging. To address this gap, index case testing, targeting sexual contacts and injecting partners of KP index clients, was introduced in 2017.

METHODS: HTS was offered in nightclubs, hotels or community-based ART clinics in Akwa Ibom, Cross River, and Lagos states. Index testing was assisted by peer navigators. In-person and social network

methods were used to mobilize partners of KP. We described the feasibility of implementing index testing, analyzed Partner Notification (PN) delivery models, calculated HIV prevalence among persons who underwent Index Testing, and visualized locations where HIV positive index case testers are confined.

RESULTS: We found that a mixed approach to partner notification was effective. PN was predominantly done through provider referral 5,159 (68.3%) and passive referral 2,278 (30.1%). A total of 3,119 index partners; 1,322 FSW (42.4%), 1,255 MSM (40.2%) and 542 PWID (17.4%) identified 8,989 sexual and injecting partners (average of 2.9 per index client). Among 7,556 (84.1%) who received HTS were first-time testers [79.4% (5,999) of male partners tested]. Of the 3,753 (49.7%) partners tested HIV-positive, 3,492 (93.0%) were enrolled in HIV care. HIV prevalence was 65.5% (1,021/1,557) among females and 45.5% (2,732/5,999) among males, and was disproportionately higher among PWID injecting partners 99.1% (581/586), PWID sexual partners 98.9% (433/438) and MSM sexual partners 95.6% (605/633) in Cross river compared with 71.4% (575/805) in FSW sexual partners. The maps revealed high and low clusters of HIV infection distribution among index case testers by local government areas.

CONCLUSIONS: Including index case testing as part of community-led HTS is feasible and effective, particularly for reaching first-time testers, many male KP and persons not yet diagnosed with HIV. Scale-up of index case testing within community-led HTS for KP is essential for achieving the United Nations 90-90-90 goals.

PEC0587

ACHIEVING THE LAST MILE TO THE FIRST 90 IN URBAN SETTINGS OF UGANDA THROUGH THE SOCIAL NETWORK STRATEGY

F. Akuju[1], F. Namimbi[1], N. Kalema[1], L. Kabunga[1], M.S. Nabaggala[2], G. Anguzu[2], M. Ssuuna[1], J. Kigozi[1]
[1]Infectious Diseases Institute, Makerere University, Health Systems Strengthening, Kampala, Uganda, [2]Infectious Diseases Institute, Makerere University, Statistics Unit, Kampala, Uganda

BACKGROUND: Of the estimated 1.3 million people living with HIV (PLHIV) in Uganda, 85% know their HIV status, (UNAIDS, 2019). To meet the 90-90-90 UNAIDS 2020 cascade targets, the PEPFAR-funded IDI Kampala Region HIV Project implemented an innovative strategy, the social network strategy (SNS), to find the missing 5% contributing to the 6.9% HIV prevalence in Kampala region.

DESCRIPTION: We supported health workers from 48 health facilities in two districts of Kampala and Wakiso to implement SNS from November 2018 to October 2019.

Trained health workers elicited from index clients details of social contacts presumed to be at high risk of contracting HIV based off their: risky sexual behavior; frequent illness; history of loss of a partner to an unknown disease or if their partner was a known PLHIV. The health workers reached these social contacts through phone call or physical tracing, screened them for testing eligibility using the HIV Testing Services Screening Tool, and offered them an HIV test. Newly identified HIV positive social contacts were linked to HIV treatment and the negatives to other prevention services. We performed a descriptive analysis of data to assess SNS feasibility.

LESSONS LEARNED: We elicited 14,795 presumed high-risk social contacts from 7,580 index clients. We reached and invited 12,851 social contacts (86.9%) for an HIV test. Of these, 8,940 (69.5%) were tested for HIV and 1,329 diagnosed as HIV positive, a 15% yield. All the newly diagnosed HIV positive clients were linked to HIV treatment services. A slight variation in uptake of HIV testing was observed by gender with a higher proportion of men 4,316/6161 (70.0%) than women 4,624/6690 (69.1%) testing, however, the difference was not statistically significant (p-value=0.250). On the other hand, testing rates increased with age (167/192 (1.9%)-0-14 years; 412/574 (4.6%) - 15-18 years; 2,391/3,322 (26.7%) – 19 -24 years; 5,970/8,763 (66.8%) – above 24 years), p-value<0.01.

CONCLUSIONS/NEXT STEPS Social Network Strategy (SNS) is an effective approach for HIV case identification among high-risk populations. Integrating SNS alongside other proven testing interventions will help reach more PLHIV with HIV testing and consequently contribute to the 1st 90.

PEC0588

GATHERING RESULT DATA FOR ANALYSIS AND PROVISION OF FOLLOW-UP SUPPORT AS PART OF A NATIONWIDE HIV SELF-TESTING SERVICE IN THE UNITED KINGDOM

W. Howells[1], T. Mukiwa[1], C. Kifetew[1], D. Edwardes[1], I. Green[1]
[1]Terrence Higgins Trust, London, United Kingdom

BACKGROUND: Terrence Higgins Trust ran HIV self-testing pilots in 2016 and 2017 before rolling out the UK's largest free self-testing service in 2018 to expand access to HIV testing.

The service was designed with a clear process for data collection and test result gathering to mitigate concerns that people who test themselves might not receive follow-up support.

DESCRIPTION: Self-test kits are ordered through a dedicated website and delivered by post to any UK address or a click-and-collect point. Tests are available to disproportionately affected populations including men who have sex with men (MSM), black African people (BA) and trans people. Users receive up to two SMS reminder messages to encourage them to report their results through a mobile-optimised web page. Collecting results enables support to be offered to those reporting reactive results and measures the effectiveness of the project. HIV prevention information is provided to those who report a non-reactive result.

The service was free of charge from launch in June 2016 to March 2019. Since April 2019, test kits have cost £15 but users are able to choose a free option if they can't afford to pay. By December 2019, more than 36,000 kits had been ordered.

LESSONS LEARNED: In total, 60% of users reported their results with variance between population groups: 62% for MSM and 50% for BA. Older age groups were more likely to report their results (57% for those 16-25 increasing to 73% for over-65s). Those paying for tests since April 2019 had a significantly higher reporting rate of 67%.

Text message reminders played a vital role in reporting: 51% of those who reported a result did so on the day of the first reminder or the day after, and an additional 17% reported on the day of the second reminder or the day after.

CONCLUSIONS/NEXT STEPS It is possible to achieve a high level of result reporting for analysis of effectiveness and provision of follow-up support for an HIV self-testing service. There are opportunities for research to improve result reporting and to understand better the 40% who declined to report their result, including whether they had used the test or not.

PEC0589

THE KNOWLEDGE, USE AND EXPERIENCE OF HIV RAPID TESTS: A CROSS-SECTIONAL SURVEY TARGETING MSM IN CHINA

J. Han[1,2], Y. Su[1,2], F. Zhang[1,2], Z. Li[1], W. Liao[3], Z. Wang[4]
[1]Beijing Ditan Hospital Capital Medical University, Beijing, China, [2]WHO Collaborating Centre for Comprehensive Management of HIV Treatment and Care Forum, Beijing, China, [3]Red Pomegranate Charity, Beijing, China, [4]AIDS Healthcare Foundation, Beijing, China

BACKGROUND: HIV rapid test has become an important method for early detection of HIV infected people due to its convenience especially for men who have sex with men (MSM) in China. This study aimed to evaluate the knowledge, use and experience of HIV rapid test service including self-testing among MSM in China.
METHODS: With the help of the dating APP for MSM, the participants were conducted by self-designed electronic questionnaires during August to September 2019 in China and analyzed using logistic regression.
RESULTS: A total of 3478 MSM were enrolled in this study, with the mean age of 23.82±4.38. 98.7% (3435/3478) of participants graduated from junior college or above and 41.6% (1446/3478) of them are students. The awareness rate of HIV rapid tests was 83.1% (2891/3478), and the utilization rate was 53.4% (1857/3478). Participants who were older (OR=1.03, 95%CI: 1.01-1.06), with higher education level (OR=1.28, 95%CI:1.10-1.48), with higher average monthly income (OR=1.11, 95%CI:0.99-1.24), had male regular partners (OR=1.35, 95%CI:1.15-1.59), had friends infected HIV (OR=1.78, 95%CI:1.46-2.17), had more sexual partners in the last 3 months (OR=1.16, 95%CI:1.12-1.21) and with higher HIV related knowledge score (OR=1.27, 95%CI:1.20-1.35) were more likely to uptake HIV rapid tests. During the 1624 participants who took HIV rapid tests in the last one year, 55% (893/1624) of them had taken regular HIV rapid tests. But up to 98.2% participants believed regular testing was an effective way to detect HIV early and the willingness to take regular test was up to 98.4%. 83.7% (1360/1624) of participants who took HIV rapid tests in the last year chose self-testing, 83.4% (1134/1360) of them bought detection reagent on the Internet, and the confidence score of self-testing is 8.18±1.77. The main concerns for self-testing were not knowing whether the test results were accurate or not, and whether the reagents were genuine or fake.
CONCLUSIONS: MSM are more willing to conduct self-testing in the HIV rapid tests service. And the Internet is an important way for MSM to obtain testing, which is also a key place for intervention.

PEC0590

USING INDIVIDUAL STATED-PREFERENCES TO OPTIMIZE HIV SELF-TESTING SERVICE DELIVERY PROGRAM AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN MALAYSIA: RESULTS FROM CONJOINT ANALYSIS

R. Shrestha[1,2], H. Alias[2,3], L.P. Wong[2,3], F.L. Altice[2,1], S.H. Lim[2,3]
[1]Yale University, Internal Medicine, New Haven, United States, [2]University of Malaya, Centre of Excellence for Research in AIDS (CERiA), Faculty of Medicine, Kuala Lumpur, Malaysia, [3]University of Malaya, Department of Social & Preventive Medicine, Faculty of Medicine, Kuala Lumpur, Malaysia

BACKGROUND: HIV self-testing (HIVST) has the potential to improve HIV testing uptake and frequency for key populations, like MSM, who experience barriers accessing clinic-based HIV testing. With the characteristics of convenience, privacy, and confidentiality, HIVST may be important in communities of MSM, particularly in Malaysia, who face high rates of stigma, discrimination, and legal challenges. To date, however, research on HIVST in the Malaysian context is non-existent. This study investigated the acceptability of HIVST and preferences about the HIVST service delivery approaches using a standardized stated preference method.
METHODS: A cross-sectional online survey to assess the intention to use HIVST among 550 MSM in Malaysia was conducted between January and April 2019. Participants were recruited using a combination of both online (e.g., social media popular among MSM in Malaysia such as Grindr, Hornet, WhatsApp, Facebook) and offline (e.g., LGBT-friendly NGOs, peer referrals) recruitment strategies. Participants ranked the eight hypothetical HIVST service delivery programs with varied combinations of six two-level HIVST service delivery program attributes (cost, privacy, accuracy, kit collection site, kit type, and support). We used the full-profile conjoint analysis (CJA) approach to assess the acceptability of various hypothetical HIVST service delivery scenarios and to quantify the importance of key hypothetical and known HIVST attributes on acceptability.
RESULTS: The acceptability for HIVST service delivery models ranged from 45.0% to 76.9% with mean acceptability of 56.2% across the eight hypothetical HIVST distribution scenarios. The HIVST service delivery scenario with the highest acceptability had the following attributes: no cost (free of charge), anonymous (name not required to receive HIVST kit), 99-100% effective, home-delivered, finger pricked, and the ability to receive pre-test counseling support using telephone hotline or WhatsApp. The cost associated with HIVST was the most important attribute (relative importance score: RIS=19.3), followed by privacy (RIS=18.4), accuracy (RIS=17.3), kit collection site (RIS=16.9), kit type (RIS=15.8), and support (RIS=12.0).
CONCLUSIONS: Key findings include high levels of acceptability if HIVST distribution programs are optimally organized to accommodate user preferences, notably low-cost models that ensure user anonymity. Consequently, researchers and policy-makers will be better equipped for scale-up of HIVST in key populations, such as MSM, in Malaysia.

PEC0591

SELF HIV TESTING VERSUS SERVICE PROVIDER HIV TESTING: WHAT IS THE WAY FORWARD FOR TERTIARY INSTITUTIONS IN ZIMBABWE?

L.G. Munyonho[1]
[1]Students and Youth Working on Reproductive Health Action Team, Programmes, Harare, Zimbabwe

BACKGROUND: Although commendable efforts have been made in Zimbabwe to make HIV testing readily available and accessible, 1 out of 4 people living with HIV still do not know that they have contracted the virus. Researchers have identified a number of reasons why people may choose not to get tested chief being fears around confidentiality. Self HIV testing has therefore emerged as a panacea to these issues and this study sought to establish student preferences for HIV testing between Self HIV testing and Service Provider HIV testing in 5 tertiary institutions in Masvingo Province of Zimbabwe. Self HIV testing is still on a pilot stage and this study sought to assess levels of readiness for tertiary institutions to roll out Self HIV testing.
METHODS: A pre-tested semi-structured questionnaire was administered to 500 randomly selected students at 5 tertiary institutions in Masvingo Province of Zimbabwe (2 Teacher Training Colleges; 2 Uni-

versities; and 1 Polytechnic). The 500 students (250 male; 250 female) were asked to choose between self HIV testing and service provider HIV testing and to justify their choice.

RESULTS: Whereas 422 students (84, 4 %) preferred Self HIV testing, 78 students (15,6 %) preferred to be tested by a trained service provider. Students who preferred self HIV testing identified breach of confidentiality, lack of a youth-friendly approach to students, and lack of professionalism by college nurses as key deterrents from accessing HIV testing services from the college clinics' providers. They preferred Self HIV testing because of its perceived flexibility on knowing results, ease of access, ability to test partner before sex and increased privacy. Those who preferred service provider HIV testing identified factors like the need for professional counselling, immediate access to treatment and expert guidance on what to do next.

CONCLUSIONS: Student preferences for HIV testing methods are determined by their perceptions and knowledge levels about the testing method in question. Whilst there can be fears of suicidal tendencies among students after the administration of self-test kits, it might be high time tertiary institutions move towards self HIV testing to increase access to HIV testing for early treatment of students living with HIV.

PEC0592

PRACTICABILITY AND PREFERENCES OF BLOOD-BASED VERSUS ORAL-FLUID-BASED HIV SELF-TESTING IN THE HAND OF LESS-SKILLED USERS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

S. Tonen-Wolyec[1], L. Bélec[2], S. Batina Agasa[1], L.F. Kamanga Lukusa[3]
[1]Faculté de Médecine et Pharmacie, Université de Kisangani, Kisangani, Congo, Democratic Republic of the, [2]Université Paris Descartes, Paris, France, [3]National Aids and STI Control Programme, Kinshasa, Congo, Democratic Republic of the

BACKGROUND: The practicability and preferences of the blood HIV self-test (Exacto HIV Test, Biosynex, Strasbourg, France) and the oral-fluid HIV self-test (OraQuick, OraSure Technologies, Inc., Bethlehem, PA) were compared among among less-skilled users in the Republic Democratic of the Congo (DRC).

METHODS: This multicenter cross-sectional study performed between October and November 2019 in Kinshasa and Kindu, DRC used a face-to-face, tablet-based, and semi-structured questionnaires in a directly assisted HIVST approach. Practicability was operationally defined as the successful performance and the correct interpretation of the self-test result. The results were analyzed by the matching tests and by the logistic regression models.

RESULTS: A total of 528 participants were enrolled. The rate of successful performance of HIV self-test was high with blood test (99.4%) and oral-fluid test (99.8%) yielding the absolute difference of -0.4% (95% CI: -2.8 to 1.5; P=0.456). The rate of correct interpretation of the HIV self-test results was 81.3% with blood test versus 80.2% with oral-fluid test (difference=-1.1; 95% CI: -3.0 to 1.2; P=0.532). The misinterpretation was more about invalid tests (20.4% for both types of test). The female gender (aOR=2.3 [95% CI: 1.2 to 3.1]) and the previous knowledge about HIVST (aOR=1.8 [95% CI: 1.0 to 2.9]) were associated with preference for the oral fluid test. However, the history of exposure to HIV (aOR=3.4 [95% CI: 2.1 to 6.0]) were associated with preference for the blood test. Finally, 23% of participants declared that they did not trust the results of the oral-fluid test; 25% said they were afraid when using the lancet; and 88% preferred that both types of tests be available.

CONCLUSIONS: Our field observations show that the blood self-test and the oral-fluid self-test show high and comparable practicability rates. These two approaches appear to be complementary, which leaves users the choice of each test for comparable results.

PEC0593

DIAGNOSTIC ASSESSMENT IN FIELD AND IN LAB OF THE BLOOD-BASED HIV SELF-TEST EXACTO TEST HIV IN THE DEMOCRATIC REPUBLIC OF THE CONGO

S. Tonen-Wolyec[1]
[1]Faculté de Médecine et Pharmacie, Université de Kisangani, Kisangani, Congo, Democratic Republic of the

BACKGROUND: HIV Self-testing (HIVST) has the potential to circumvent the constraints of lack of confidentiality, stigma, discrimination, shortage of counselors and long distances to testing centers. The Democratic Republic of the Congo (DRC) has taken the option of implementing the HIV self-test to boost the first „90" of the UNAIDS 90-90-90 targets by using validated self-test. The objective of this study is to determine the analytical performance and usability characteristics of the Exacto Test HIV (Biosynex, Strasbourg, France) in lab and in field.

METHODS: The performance evaluation was a cross sectional study, and the usability a mixed methods study. For method comparison in lab, INNO-LIA HIV I/II Score (Fujirebio Europe N.V., Ghent, Belgium) was used as the reference test; in field, serological HIV testing was carried out according to the national algorithm of the DR, using Alere Determine HIV-1/2 (Alere Medical Co. Ltd.) and Uni-Gold HIV (Trinity Biotech Manufacturing Ltd.).

RESULTS: In lab, a total of 428 (including 228 positives and 200 negatives) sera were analyzed with Exacto Test HIV self-test, sensitivity was 99.56% (95% CI 98.26-99.86%), and specificity 100% (95% CI 99.80-100%); the concordance was therefore 99.76%. In field, a total of 528 participants took part in the usability study. Of those, 525 (99.43%) found instructions for use easy to follow, 396 (75%) found the finger prick device easy to use, 456 (86.36%) were confident while performing the test, 525 (99.4%) were succeed the performance of the self-test, 503 (95.27) interpreted corrected their self-test result. Finally, in field, sensibility was 99.43% (95% CI 98.34-99.80%), and specificity 100% (95% CI 99.84-100%) yielding the concordance of 99.43%.

CONCLUSIONS: The excellent performance and usability characteristics of Exacto Test HIV self-test make the kit a viable option for HIV self-testing in DRC. To improve the usability of the lancet, the manufacturer should indicate on the instruction for use that the use of the lateral surface of the fingers decreases the pain.

PEC0594

ACCEPTABILITY OF PROVIDER ASSISTED SELF-TESTING AMONG MEN WHO HAVE SEX WITH MEN IN GHANA

M. Owusu[1]
[1]Maritime Life Precious Foundation, Takoradi, Ghana

BACKGROUND: Issues: Anecdotal evidence from Maritime Life Precious Foundation's (MLPF), a civil society organization (CSO) working in with MSM in the western region of Ghana, indicated that some of their MSM clients were refusing HIV testing because of fears of breach of confidentiality and stigma. Although Ghana has

not yet fully rolled out HIV self-testing, MLPF introduced the provider assisted HIV self-testing, using the Ghana health Service approved Oral quick to reach out to these MSM to test and link them to treatment.

DESCRIPTION: Descriptions: During the implementation of this strategy (October 2017 and December 2019), MLPF reached 120 MSM who would only accept HIV testing if they could do the test themselves. Not wanting to lose potential HIV positive MSM, MLPF agreed to guide and support the 120 MSM who were willing to test, read, and interpret their own result and disclose to the counselor. The HIV counsellors and case manager were involved in the process by providing each of them with pre-test and post-test counselling. The 120 MSM were then guided to do the HIV test on their own, interpreted the results and willingly disclosed their results to the counsellors. After further engagement with clients for testing, 79 percent were willing to disclose test result for further support from the case managers and health care workers.

LESSONS LEARNED: Lessons learned: The provider assisted Self-testing strategy was successful in testing all the 120 MSM clients who had opted for self-testing and willing to disclose result. This strategy resulted in a high HIV positivity yield (40 out of 120 clients tested positive). Currently, 32 out of 40 are on ART with 22 virally suppressed. The results indicate that the process of actively involving the client through coaching to self-test, gave them the confidence to accept their status and initiate treatment. Provider assisted Self-testing is feasible and acceptable to MSMs in Ghana.

CONCLUSIONS/NEXT STEPS To ensure total coverage in achieving the first 90 of the 90-90-90 in Ghana, the Government should consider rolling out self-testing.

DEMONSTRATION AND PILOT PROJECTS FOR PREP, PEP, MALE CIRCUMCISION

PEC0595

FACTORS AFFECTING PREP UPTAKE AND TIME TO INITIATION AMONG TRANSGENDER PARTICIPANTS IN THE TRIUMPH PREP DEMONSTRATION PROJECT IN OAKLAND AND SACRAMENTO, CALIFORNIA

J. Sevelius[1], D. Glidden[2], L. Gutierrez-Mock[1], A. Contreras[3], L. Welborn[4], M. Yu[1], R. Grant[1], M. Deutsch[5]
[1]University of California, Medicine, San Francisco, United States, [2]University of California, Epidemiology & Biostatistics, San Francisco, United States, [3]Gender Health Center, Sacramento, United States, [4]La Clinica de la Raza, Oakland, United States, [5]University of California, Family & Community Medicine, San Francisco, United States

BACKGROUND: Transgender people are disproportionately impacted by HIV, yet trials of pre-exposure prophylaxis (PrEP) have largely excluded transgender people. TRIUMPH (Trans Research-Informed communities United in Mobilization for the Prevention of HIV) aims to develop and evaluate a culturally-relevant, community-led PrEP demonstration project to deliver PrEP safely and effectively to transgender and gender non-binary people.

METHODS: TRIUMPH is a trans-specific collaborative between the University of California, San Francisco, and two implementing sites: La Clinica de la Raza, Oakland (a Federally Qualified Health Center), and Gender Health Center (a community-based organization), Sacramento. TRIUMPH utilizes community-led mobilization efforts to increase PrEP knowledge and acceptability, utilizing champions from within trans communities, and clinical integration of PrEP with hormone therapy. The current analysis measures PrEP uptake and time to initiation by first dispensation of PrEP medication.

RESULTS: We enrolled 177 participants; average age was 28 (IQR:23-35), 7% Black, 57% Latinx. Overall, 70% initiated PrEP by week 2 and 90% initiated by week 18. PrEP uptake was 78% in Oakland, 98% in Sacramento, 91% among trans women, 96% among trans men, 70% among non-binary participants. Almost half (47%) rarely/never thought about HIV but 42% reported condomless intercourse in the previous 3 months; 81% were aware of PrEP, interest was low. Univariate analyses revealed more rapid PrEP initiation among participants assigned female sex at birth (P< 0.001), higher socioeconomic status (P<0.001), stronger PrEP interest (P<0.001), higher HIV risk perception (P=0.04), and US-born (P<0.001). White Latinx participants were slower to initiate than other racial/ethnic groups (P<0.001). More participants in Sacramento initiated PrEP and did so more rapidly than those in Oakland (P < 0.001); multivariate analyses indicated that site differences were independent of differences in participant demographics (P<0.001).

CONCLUSIONS: We document rapid PrEP uptake in a young and diverse transgender and gender non-binary cohort with HIV risk. Site differences significantly impact PrEP uptake and time to initiation among TRIUMPH participants. Additional operational barriers within the context of an FQHC likely impact PrEP uptake and time to initiation. Qualitative data collected from both sites will provide additional insight into barriers and facilitators to program implementation and PrEP uptake and initiation among TRIUMPH participants.

PEC0596

OPTIMIZING CARE FOR PEOPLE AT RISK OF ACQUIRING HIV: HEALTH CARE PROVIDERS' PERSPECTIVE OF AN ONLINE PREP CONSULTATION TOOL WITHIN THE SWISSPREPARED PROGRAM

BACKGROUND: The growing demand for oral HIV pre-exposure prophylaxis (PrEP) is a challenge for health care providers (HCPs). In April 2019, SwissPrEPared, a nation-wide program in Switzerland, began with the goal of optimizing care for people requesting PrEP.

The program includes a consultation tool that supports HCPs during PrEP consultations. Seven days prior to their consultation, participants receive a link to an online questionnaire via text message/email that addresses adherence, side effects, co-medications, sexual and mental health. Upon questionnaire completion, their HCP receives a summary of the answers to guide the consultation.

METHODS: In December 2019 we conducted an anonymous survey among 62 HCPs working with SwissPrEPared in eleven institutions in order to evaluate the perceived helpfulness of the tool. The survey contained six multiple-choice and two five-point Likert scale questions.

Question	Answers	Results
Which occupational category do you belong to?	Medical doctor/physician: Nurse: Other:	17/29 11/29 1/29
How many PrEP consultations have you approximately conducted with the SwissPrEPared tool?	None yet 1-10: 11-30: 31-100: >101:	3/29 10/29 6/29 9/29 1/29
How helpful is the SwissPrEPared online tool for your counseling in general? (1 point: not helpful, 5 point: very helpful)	1 point 2 point 3 point 4 point 5 point Missing answer Mean	0/26 1/26 7/26 13/26 4/26 1/26 3.8
With the help of the online tool/questionnaire, were you able to detect a particular health risk which otherwise you think you might have discovered too late or even missed? (you can choose more than one answer)	Yes, Family history of osteoporosis Yes, depression Yes, problematic substance use Yes, side effects of PrEP Yes, adherence problems Yes, lack of vaccination Yes, other (freetext) No, the tool has not yet helped me to discover a particular health risk more quickly	6/26 13/26 14/26 7/26 7/26 3/26 1/26 7/26
Have you already been able to discuss a positive depression screening with your client?	No, I have not yet had any clients with a positive depression screening. No, because it didn`t fit into the PrEP consultation No, because I didn`t know how to speak with the client about it Yes, a few Yes, half/half Yes, almost always Missing answer	11/26 1/26 0/26 6/26 0/26 7/26 1/26
How user-friendly do you rate the SwissPrEpared tool? (1 point: not user-friendly, 5 point: very user-friendly)	1 point 2 point 3 point 4 point 5 point Mean Mean, when >11 consultations	1/26 4/26 5/26 9/26 7/26 3.7 4.4
Do you know the SwissPrEPared recommendations for PrEP prescribers and do you use them in your clinical routine?	Yes, I know them and I use them Yes, I know them, but I don`t use them No, I don`t know them Missing answer	18/26 2/26 5/26 1/26
What was in particular helpful for you, when using the SwissPrEPared tool? (you can choose more than one answer)	It helps me not to forget important points of the consultation It saves time It helps to speak about uncomfortable topics (sexual behavior, substance use, mental health) It helps to keep an overview about the important topics Other points where the tool was helpful in your clinical routine Missing answer	15/26 7/26 12/26 14/26 2/26 1/26

[Table 1: results of the online heath care professionals survey]

RESULTS: The tool was used for 1`377 PrEP consultations. Twenty-nine of the 62 HCPs (46%) answered at least one survey question. Three HCPs who reported that they had not yet used the tool were excluded from further analysis. Amongst all survey respondents, overall helpfulness was rated as a 3.8/5; user-friendliness as a 3.7/5 overall, and 4.4/5 among HCPs who had used the tool in >11 consultations. Nineteen of 26 HCPs (73%) reported that the tool helped them detect health issues in their clients that they would have otherwise discovered too late. The most frequently detected health issues were problematic substance use (14/26) and depression (13/26). Other reported benefits of the tool were: a better overview on important topics (14/26); not forgetting (15/26) or addressing important/uncomfortable topics (12/26); and saving time (7/26).

CONCLUSIONS: Most HCPs that used the tool in SwissPrEPared perceived it as being helpful. It seemed particularly useful in detecting health issues, such as depression and problematic substance use. As a next step the tool will be evaluated by less PrEP-experienced HCPs.

TELEPREP IN LOUISIANA TO REACH THOSE LIVING IN THE RURAL SOUTHERN UNITED STATES

E. Sugimori[1], M. Clement[2], J. Mandani[1], W. Robinson[1,3]
[1]Office of Public Health, STD/HIV Program, New Orleans, United States, [2]Louisiana State University Health Sciences Center, Infectious Diseases, New Orleans, United States, [3]Louisiana State University Health Sciences Center, School of Public Health, New Orleans, United States

BACKGROUND: Barriers to effective HIV prevention with pre-exposure prophylaxis (PrEP) exist for populations who could most benefit from PrEP services, including those living in the rural Southern United States (US). TelePrEP—providing PrEP care through remote conferencing rather than face-to-face encounters—can help overcome structural barriers related to access, such as transportation.

DESCRIPTION: The Louisiana Office of Public Health's TelePrEP program was launched in May 2018 to provide statewide PrEP access by delivering PrEP through telemedicine. The TelePrEP program operates under a collaborative practice agreement in accordance with the Louisiana State Board of Nursing. The program began by accepting inquiries and scheduling patients for encounters using Vidyo two-way video conferencing. Staffing includes two navigators, two Advanced Practice Registered Nurses, a collaborating physician, and a program supervisor. We report data on client engagement for the first 18 months of the program.

LESSONS LEARNED: From May 2018 to November 2019, the TelePrEP Program received 207 inquiries. Of these, 156 (75%) clients were linked to a TelePrEP navigator, 122 (59%) completed intake, 105 (51%) consented and were enrolled, 85 (41%) received a clinical service (e.g. labs, virtual clinical visit), and 73 (35%) were prescribed PrEP. As of November 2019, 39 (19%) patients are engaged in care, of whom 44% are ages 26-35 years, 31% are African-American, 80% are men who have sex with men, and 47% have Medicaid. Although follow-up is suboptimal, the LA TelePrEP program has notably reached clients from all nine regions in LA, and of ongoing-clients, 69% are from rural regions.

CONCLUSIONS/NEXT STEPS TelePrEP in Louisiana is reaching those in rural areas. However, while initial interest is high, further efforts are needed to improve distal steps along this care continuum. To curb the spread of HIV transmission in the rural South, there is a critical need to develop and strengthen alternative implementation strategies such as TelePrEP. The LA TelePrEP program has already been integrated into the End the Epidemic initiative in East Baton Rouge, one of the US Jumpstart high priority counties. Further efforts to bolster TelePrEP, including capacity building, hiring of new support staff, and honing a marketing strategy are underway in Louisiana.

ACCEPTABILITY AND FEASIBILITY OF HIV PRE-EXPOSURE PROPHYLAXIS IMPLEMENTATION AMONG KEY POPULATIONS IN NEPAL

D.P. Bhandari[1], R. Khanal[2], K. Bam[2], P. Thakur[2], A. Shrestha[2], H. Subhani[2], N. Thapa[2], B. Shrestha[2], C. Akolo[3], M. Cassel[4], R. Adhikari[5], M. Sharma[6], A. Bhattachan[7], I. Lohar[8]
[1]LINKAGES Nepal, FHI 360, Technical, Kathmandu, Nepal, [2]LINKAGES Nepal, FHI 360, Kathmandu, Nepal, [3]LINKAGES, FHI 360, Washington DC, United States, [4]FHI 360, Hanoi, Vietnam, [5]Tribhuvan University, Kathmandu, Nepal, [6]National Public Health Laboratory, Kathmandu, Nepal, [7]National Centre for AIDS and STD Control, Kathmandu, Nepal, [8]USAID Nepal, Kathmandu, Nepal

BACKGROUND: In Nepal, key populations (KPs), including female sex workers (FSWs), men who have sex with men (MSM), male sex workers (MSWs), and transgender (TG) women, have been reported to have high rates of HIV infection and gaps in reported consistent condom use (less than 70% across all groups). Pre-exposure prophylaxis (PrEP) could serve as a safe and effective means to prevent HIV infection among these KPs. A demonstration study was conducted by the USAID- and PEPFAR-supported LINKAGES project in collaboration with the national HIV program to assess PrEP acceptability and feasibility among KPs in Lalitpur district.

METHODS: Upon receipt of ethical approval from local and international review boards, a mixed-methods prospective cohort study was conducted November 2018 to June 2019. All eligible, consenting HIV-negative individuals at high risk of HIV identified in HIV testing clinics were offered a generic combination of tenofovir and emtricitabine as daily PrEP. Participants were followed up monthly for three months for HIV, pregnancy, renal function, syphilis, and to assess PrEP adherence. Individual interviews with participants, service providers, and program managers were conducted.

RESULTS: Of 112 eligible KP members, 104 (93%) consented to participate in the study (100% of 27 trans women and 26 FSWs, 87% of 30 MSM, and 88% of 29 MSWs). Average continuation in PrEP throughout the study period was 64%, ranging from a low of 27% among FSWs to a high of 88% among MSWs. During the three-month study period, we observed no HIV seroconversion, no pregnancy, no serum creatinine level changes, and two syphilis-reactive cases. Qualitative findings suggested that PrEP implementation was both feasible and acceptable. Participants cited a perception of personal HIV infection risk as a motivation to accept PrEP. Reasons cited for discontinuation were reported side effects, stigma, alcohol use, and frequent travel.

CONCLUSIONS: In Nepal, PrEP is an acceptable HIV prevention method among KPs. Implementation is feasible and could serve as a valuable complement to existing prevention methods to achieve HIV epidemic control.

HIV PREVENTION USING ORAL PRE-EXPOSURE PROPHYLAXIS IN THE UNITED REPUBLIC OF TANZANIA. RESULTS FROM THE DEMONSTRATION PROJECT

N. Makyao[1], P. Urasa[1], S. Leornard[2], E.J. Mbaga[3], G. Leyna[4], M. Kagashe[1], A. Ramadhan[1], V. Sambu[1], N. Kwesigabo[1], P. Njau[1], M. Leshabari[5], K. Moen[3], S. Likindikoki[6], M. Mizinduko[6], B. Mutayoba[1]
[1]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program, Dodoma, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, Director of Prevention Services, Dodoma, Tanzania, United Republic of, [3]Oslo University, Biostastistics, Oslo, Norway, [4]Ministry of Health, Community Development, Gender, Elderly and Children, National Nutritional Services, Dodoma, Tanzania, United Republic of, [5]Muhimbili University of Health and Allied Sciences, Behavioural Sciences, Dar es Salaam, Tanzania, United Republic of, [6]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: In 2017 and 2019, the Ministry of Health implemented a demonstration project with the aim of informing the Government on feasibility and acceptability of PrEP in Tanzania. It was implemented using both facility lead community outreach and facility HIV services modalities. It was layed in the existing combination prevention interventions for KVPs. Female Sex Workers (FSW), Men who have sex with men (MSM), People who Inject Drugs (PWIDs), vulnerable Adolescent Girls and Young Women (vAGYW), who tested negative for HIV and HIV negative partners of sero-discordant couples, were considered as KVPs.

METHODS: It was done in 21 months that include 3 months of preparing the sites, 12 months of implementation and data collection, and 6 months of data analysis and dissemination. It was longitudinal open cohort with two components namely HIV Self-Testing (HIVST) and PrEP. For PrEP a longitudinal open cohort design was conducted in 9 regions. Data collection was done through routine HIV services monitoring through the National HIV database.

RESULTS: Out of 23,597 clients reached during the implementation of the project, 17,252 (73.1%) were given HIVST kits. 15,401 (89.3%) collected kits through outreach services while 1,851(10.7%) did at health facilities. The positivity rate for the one who returned for confirmation was (552) 4.1%. A total of 7,816 (40%) clients was given PrEP, of which 6,437 (82.4%) received through outreach services and 1,379 (17.6%) from health facilities. Out of 7,816 clients who received PrEP, 6,917 (88.5%) were female and 899 (11.5%) were male. Client aged 20-24 years accounted for a quarter of all clients given HIVST and/or PrEP. Half of PrEP users were self-employed individuals and 69.7 % of had primary education as the highest level of education. The finding also revealed that the uptake for HIVST and PrEP is 30% and 65% respectively.

CONCLUSIONS: There was high uptake of HIVST and PrEP among KVP. The facility lead community outreach services was feasible for both interventions. The majority of the clients were reached through outreach led by a health facility.

Chan School of Public Health, Department of Biostatistics, Boston, United States, [11]Oregon Health and Science University - Portland State University, School of Public Health, Portland, United States

BACKGROUND: Women in sero-different or sero-status unknown relationships wishing to conceive are at a high risk of HIV infection and need strategies to prevent HIV infection.

METHODS: We enrol HIV-uninfected women, 18-35 years with personal/partner plans for pregnancy, not using long-acting contraception, and with a stable partner living with HIV or of unknown-serostatus. Safer conception counselling occurs at each study visit, inclusive of: TDF/FTC as PrEP; partner HIV testing; treatment as prevention; couples counselling; timing-sex to peak fertility; testing and treating sexually transmitted infections; and delaying pregnancy. Data on safer conception strategy uptake for the first 79 non-pregnant participants completing 12 months of follow-up are reported here.

RESULTS: Participants' mean age is 24.6 years [18.1-35.7], the highest level of education is grade 12 (46%), and most (74%) are unemployed. Most (88%) reported having one sexual partner. At baseline, 95% did not know their pregnancy partner's HIV status, 58% had not used a condom during last sexual contact, and 62% suspected their primary partner of infidelity. Only 37% felt likely to acquire HIV. The majority (81%) had not used a safer conception strategy prior to enrolment.

At the six-month visit, condom use decreased to 28% and partner suspected infidelity increased slightly to 65%. Self-perceived HIV risk decreased to 18%. Reported uptake of safer conception strategies was good, with all participants interested in initiating a strategy. PrEP was initiated by 61% and 21% chose timed-sex.

At 12 months/study exit, 28.15% reported condom use, and suspected partner infidelity increased to 68%. Self-perceived HIV risk remained similar at 19%. PrEP remained the most popular strategy at 55% followed by timed-sex at 28%.

CONCLUSIONS: Women wishing to conceive are eager to adopt safer conception strategies. Most were at high risk for HIV acquisition but had low self-risk perception, which decreased with study participation, likely due to counselling and high PrEP uptake. PrEP was the most popular safer conception strategy, followed by timed-sex. These two strategies are within women's control and could explain their high acceptability. Comprehensive counselling and strategy choice are essential to decrease HIV risk for women during the periconception phase.

PEC0601

DECENTRALIZED PREP DELIVERY IN VIETNAM: HIGH PERSISTENCE AMONG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN AT MONTH TWELVE, AND STRONG PREFERENCE FOR COMMUNITY CLINIC SETTING

K. Green[1], P.T. Thu Huong[2], B. Ngoc Vu[1], T. Minh Hung[3], N. Do Thi[4], T. Le Minh[5], K. Do Quang[6], P. Anh Nguyen[7], T. Minh Ngo[8], H. Van Ngo[1], H.A. Doan[1], A. Tran Khanh[1]

[1]PATH, HIV & TB, Hanoi, Vietnam, [2]Vietnam Administration of HIV/AIDS Control, Hanoi, Vietnam, [3]Center for Creative Initiatives in Health and Population, Hanoi, Vietnam, [4]Vietnam Administration of HIV/AIDS Control, HIV & TB, Hanoi, Vietnam, [5]Glink, Ho Chi Minh City, Vietnam, [6]Galant Clinic, Ho Chi Minh City, Vietnam, [7]My Home, Ho Chi Minh City, Vietnam, [8]USAID, Hanoi, Vietnam

BACKGROUND: In March 2017, first ever HIV pre-exposure prophylaxis (PrEP) services were offered in Vietnam as part of the Prepped for PrEP (P4P) pilot enabling same day PrEP enrollment in three key population (KP) owned/led community clinics and four public district HIV clinics in Ho Chi Minh City.

METHODS: P4P followed 1069 men who have sex with men (MSM) and 62 transgender women (TGW) in a rolling enrollment cohort study from March 2017-September 2018. The study assessed the acceptability of PrEP among MSM and TGW by measuring rate of enrollment over time, persistence rates and predictors of persistence, as well as observing clinic enrollment preferences by type (public clinic setting or KP-led clinic). Here we present enrollment and continuation rates, factors associated with PrEP continuation at month 12, and clinic type preference.

RESULTS: The median age of MSM at enrollment was 26, and age 24.5 for TGW. 94.6% of clients opted for PrEP at one of three KP-led clinics. Average monthly enrollment rate was 33 new clients at months 1-3 and 140 at months 9-12. At month 12, PrEP continuation among MSM was 68.8% and 54.8% among TGW. MSM ages 25-30 (aOR 1.43 (95% CI 1.03-1.98) p=0.029) and >30 years of age (aOR 1.87 (95% CI 1.25-2.82) p=0.002) had greater odds of continuing on PrEP, as were those that attained above a high school education (aOR 1.62 (95% CI 1.14-2.30, p=0.007) or had health insurance (aOR 1.57 (95% CI 1.09-2.25) p=0.013). Among TGW, albeit with a limited sample size, those >30 years had greater odds of remaining on PrEP (aOR 5.62 (95% CI 1.05 -29.9) p=0.043).

CONCLUSIONS: We found PrEP to be highly acceptable among MSM and TGW, with a strong preference to receive PrEP at a KP-led clinic. Persistence rates were relatively high for first roll-out of PrEP, however adolescents and young adults were much more likely to discontinue services. Ensuring there is choice in service models, and further differentiating and adapting PrEP delivery among young MSM and TGW seeking PrEP will be essential as part of PrEP scale-up in Vietnam.

PEC0602

SIDE EFFECTS, LIFE TRANSITIONS, AND DISCLOSURE: REASONS FOR ORAL PRE-EXPOSURE PROPHYLAXIS (PREP) DISCONTINUATION AMONG YOUNG WOMEN ENGAGED IN SEX WORK IN UGANDA

S. Mathur[1], G. Mirembe[2], J. Nanyondo[2], W. Nansalire[2], D. Kibirige[2], J. Matheka[3], B. Mwesigwa[2], A. Tindikahwa[2], F. Kiweewa[2], M. Millard[4], E. Akom[5,6], H. Kibuuka[2]
[1]Population Council, HIV and AIDS Program, Washington, DC, United States, [2]Makerere University Walter Reed Project, Kampala, Uganda, [3]Population Council, Nairobi, Kenya, [4]U.S. Army Medical Research Directorate – Africa, Kampala, Uganda, [5]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [6]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States

BACKGROUND: Uptake of PrEP remains far short of global targets and many studies in sub-Saharan Africa report high levels of drop-out. Understanding why individuals may intentionally stop using an effective HIV prevention methodology could orient future programming around PrEP. This study examined the reasons for PrEP discontinuation among young women engaged in sex work.

METHODS: In-depth exit interviews (n=15) and focus group discussions (n=4, 40 respondents) were conducted in Mukono district in Uganda with women who were enrolled in a PrEP demonstration project between December 2017 – July 2019. Thematic data analysis was conducted to identify perceived and experienced challenges around PrEP use and reasons for PrEP discontinuation.

RESULTS: PrEP experience among respondents ranged from 1 - 12 months. Three key themes emerged as reasons for PrEP discontinuation, regardless of time on PrEP: side effects, life transitions, and disclosure. Respondents reported experiencing side effects including headaches, dizziness, blurred vision, nausea, and diarrhea. Most side effects subsided as soon as respondents stopped taking PrEP, but while on PrEP the severity of these side effects interfered with their daily lives and livelihoods. Second, key life transitions such as stopping sex work, settling down with one main partner, and becoming pregnant were also a motivation for PrEP discontinuation. These life transitions shifted the HIV risk perception among respondents and they no longer felt the need for PrEP. Finally, disclosure of PrEP use led to discontinuation. In a few instances, accidental disclosure of PrEP use resulted in rebuke from peers, partners, and family members. Among some participants, the similarity of the PrEP packaging to ART medication for HIV treatment caused persistent fear of being labeled as HIV-positive or revealing their engagement in sex work.

CONCLUSIONS: To enhance uptake of PrEP in similar populations, programs need to provide more supportive counseling to help manage the side effects associated with PrEP. Counseling sessions need to address how to maintain HIV risk reduction strategies during key life transitions. Further, PrEP packaging needs to be de-linked from HIV treatment, and PrEP messaging should aim to create broader awareness to reduce stigma.

PEC0603

UPTAKE OF PRIMARY CARE SIGNIFICANTLY ASSOCIATED WITH PREP RETENTION IN A MID-SIZED U.S. CITY

N. Endreny[1], A. Kaley[2], E. Asiago-Reddy[3]
[1]Cornell University, Ithaca, United States, [2]SUNY Upstate Medical University, Syracuse, United States, [3]SUNY Upstate Medical University, Division of Infectious Disease, Syracuse, United States

BACKGROUND: PrEP engagement and retenion among the most at risk remains challenging. Integration of PrEP services into a primary care environment may enhance retention.

METHODS: In 2014, SUNY Upstate—the largest health care provider covering the mid-sized city of Syracuse, NY and surrounding areas—reformatted their adult and pediatric HIV clinics to become centers for PrEP and HIV primary care. Extensive insurance support and embedded mental health services were offered and the practices were advertised throughout the community. Demographics, appointment and prescription histories were obtained from grant program reports and electronic medical records. All patients were offered to received primary care as well as PrEP at the practice; continuing PrEP was not a requirement to remain in primary care. A proportional hazards model was used to determine factors associated with length of time on PrEP.

RESULTS: Between March 1, 2014 and June 30, 2019, 367 patients presented for PrEP; most were male (308, 83.9%) and reported sex with other men [(MSM) 277, 75.4%]; 66 (18.0%) were Black and 36 (9.8%) were Hispanic/Latino. Most (314, 85.6%) filled a prescription for PrEP and presented to at least one follow up visit; however, 154 (42.0%) ultimately left the program. Median amount of time on PrEP was 161 days. A proportional hazards model demonstrated retention in PrEP care was most strongly associated with being a primary care patient within the adult or pediatric practices where PrEP was prescribed [hazard ratio (HR) for loss to follow up 0.39, p<0.0001]. Lower rates of PrEP retention were associated with sexual orientation other than MSM (HR 1.7, p=0.004), having partners of unknown HIV status (vs. known HIV-positive) (HR 1.6, p=0.004), and being in the lowest age quartile [(≤25 years), HR 1.6, p=0.009]. These factors remained significant after adjusting for patients who reported relocating or transferring with intent to remain on PrEP. Black race, Hispanic/Latino ethnicity, and sex at birth were not associated with time on PrEP.

CONCLUSIONS: Receipt of primary care was strongly associated with a longer time on PrEP in a PrEP program in a mid-sized U.S. city. Scaling up PrEP into primary care practices should be strongly prioritized.

PEC0604

PRE-EXPOSURE PROPHYLAXIS AMONG BRAZILIAN TRANSWOMEN: RETENTION AND ADHERENCE IN 48 WEEKS FOLLOW-UP OF PREPARADAS STUDY

E. Jalil[1], R. Moreira[1], I. Leite[2], T. Torres[1], C. Castro[1], L. Monteiro[1], A.C. Ferreira[1], D. Santos[1], M. Pedrosa[1], P. Leite[1], V. Cattani[1], L. Kamel[1], C. Jalil[1], E. Carvalheira[1], M.D. Gomes[1], B. Hoagland[1], R. Estrela[1], P. Anderson[3], L. Bushman[3], A. Liu[4], S. Wagner[1], V. Veloso[1], B. Grinsztejn[1,1], PrEParadas Study Team

[1]FIOCRUZ, INI, Rio de Janeiro, Brazil, [2]FIOCRUZ, ENSP, Rio de Janeiro, Brazil, [3]University of Colorado, Boulder, United States, [4]UCSF, San Francisco, United States

BACKGROUND: Transgender women are disproportionately affected by HIV in Latin America. Although efficacious, PrEP adherence is a major issue among transwomen. PrEParadas is a demonstration study tailored for transwomen aiming to assess oral PrEP uptake, safety and adherence among transwomen at high risk for HIV in Rio de Janeiro, Brasil.

METHODS: HIV-negative transwomen, aged 18+ years, who reported 1+risk criteria (condomless anal sex in the last 6 months, sexually transmitted infection diagnosis in the last 12 months, transactional sex in the last 6 months, HIV-infected partner in the last 30 days) were enrolled and followed at 4 weeks and quarterly thereafter for 48 weeks. HIV viral load and dried blood spots (DBS) were collected at all follow-up visits. Anal Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) were assessed at w0 and w48. PrEP retention was defined by attendance of w48 visit; PrEP adherence was evaluated by measuring tenofovir diphosphate concentrations in dried blood spots (DBS) at all follow-up visits. We used GEE logistic regression to identify factors associated with high adherence (defined as TFV concentration in DBS correspondent to 4+ doses/week).

RESULTS: 130 transwomen initiated PrEP between Aug-2017 and Dec-2018, 109 (83.8%) were retained at w48. Anal CT and NG prevalence remained similar at w0 and w48 (CT: 7.7% and 8.3%, p=0.79; NG: 9.4% and 8.3%, p=0.88). Overall proportion of high PrEP adherence across all study visits was 57.0% (52.2% at w48). In the univariate analysis, black (OR=0.39 [95%CI:0.17-0.92]) and younger transwomen (OR=0.36 [95%CI:0.16-0.79] had a lower chance of high PrEP adherence across the study but did not remain significant in the adjusted model. Transwomen with high PrEP adherence at w4 had a higher chance of high adherence across the study (aOR=13.90, [95%CI: 6.30-30.87]). There were no HIV seroconversions during follow-up.

CONCLUSIONS: Even in a gender-affirming setting, achieving high PrEP adherence among transwomen remains a challenge, despite high retention, especially for those young and black. Strategies to support early PrEP adherence and to increase knowledge of PrEP as a self-empowering HIV prevention tool may contribute to longer-term PrEP adherence in that highly-vulnerable population.

PEC0605

SIMPLIFYING THE SHANGRING TECHNIQUE FOR VOLUNTARY MEDICAL MALE CIRCUMCISION AMONG PRIORITY ADOLESCENT AND ADULT MEN: RESULTS FROM AN ACCEPTABILITY AND SAFETY STUDY IN TANZANIA

K. Nyalali[1], C. Mejia[2], L. Mphuru[1], S. Aldrige[2], P.D. Lubambi[2], P. Mwakipesile[1], P.W. Sekule[1], D. Simbeye[3], K. Kazaura[3], M. Amuri[3], L. Hinkle[4], J. Hines[4], T. Lucas[4], C. Toledo[4], G.J.I. Lija[5]

[1]IntraHealth International, Dar es Salaam, Tanzania, United Republic of, [2]IntraHealth International, Chapel Hill, United States, [3]US Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]US Centers for Disease Control and Prevention, Atlanta, United States, [5]National AIDS Control Programme, Dodoma, Tanzania, United Republic of

BACKGROUND: Male circumcision (MC) reduces the risk of acquiring HIV infection in heterosexual men by 60%. Accelerating the scale-up of MC in areas with high HIV prevalence and low MC coverage is key in a comprehensive response for HIV epidemic control. MC devices such as ShangRings have the potential to speed up the rollout of MC by making the procedure quicker and easier than surgical circumcision while remaining just as safe. The ShangRing was prequalified by the World Health Organization (WHO) in 2015 as a promising device for circumcision in adolescent and adult males. Based on the WHO's framework for introducing MC devices in countries, IntraHealth International, in partnership with the government of Tanzania, CDC, and Jhpiego, conducted a study to evaluate the acceptability and safety of the ShangRing.

METHODS: We conducted a single-arm, open-label, prospective cohort evaluation of MC using the ShangRing in routine clinical settings between April and July 2019 in two facilities in Shinyanga Region. The recently approved "no-flip" ShangRing procedure was performed on male participants aged 13 years and over. The primary study outcomes included adverse events (AEs), procedure time, pain, healing, and acceptability of the device. Data were collected through observations during placement of the ShangRing and post-procedure surveys.

RESULTS: A total 575 participants were enrolled, of which nine (1.6%) reported AEs due to swelling, displacement, self-detachment, gaping, self-removal, pain, bleeding and infection. The mean procedure and device removal times were eight and six minutes respectively. The proportion of participants with complete wound healing by day 49 was 99.5% while only three participants had delays due to poor personal hygiene. Almost all participants (99.3%) were satisfied and would recommend the procedure to others. The common reasons men opted for ShangRing included the use of topical anesthetic and avoiding sutures.

CONCLUSIONS: ShangRing no-flip technique is safe and acceptable by participants due to its short procedure times and ease of use. However, pre-and post-procedure counseling to strengthen ShangRing circumcision outcomes and back-up surgical procedures in cases of ring placement failures are needed. Active surveillance is also needed to determine device performance at larger scale.

SCALE UP OF PREP

PEC0606

PRE-EXPOSURE PROPHYLAXIS CASCADE AMONG HIV NEGATIVE MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN IN HONG KONG: A TERRITORY-WIDE COMMUNITY-BASED CROSS-SECTION STUDY

N.S. Wong[1], T.H. Kwan[1], K.C.K. Lee[2], S.S. Lee[1]
[1]Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Shatin, Hong Kong, SAR of China, [2]Queen Mary Hospital, Department of Psychiatry, Pokfulam, Hong Kong, SAR of China

BACKGROUND: Pre-exposure prophylaxis (PrEP) provides a new bio-medical means of HIV prevention for individuals at high risk of HIV infection. This study aimed to profile the risk behaviour, PrEP awareness and willingness of self-reported HIV negative men who have sex with men (MSM) and transgender women (TG) in Hong Kong.

METHODS: Socio-demographics and behavioural data of MSM and TG were collected from a territory-wide community-based survey in Hong Kong. HIV-related risk behaviours including engaging in condomless sex, group sex, and chemsex, having multiple sex partners, and recent sexually transmitted infection diagnosis were evaluated. Factors associated with PrEP awareness and willingness were examined separately for MSM and TG in logistic regression models.

RESULTS: Between April and September 2017, 4133 MSM and 104 TG were recruited, with 3044 and 77 being sexually active in the past 6 months, respectively. Of them, 1929 (63%) MSM and 47 (61%) TG with a self-reported HIV negative status in the past 3 months were analysed. Along the cascade, PrEP awareness and experience was 58% and 4% among MSM, and 32% and 2% among TG, respectively. After excluding PrEP-experienced respondents, PrEP willingness was 48% for MSM and 51% for TG. Engagement in chemsex (OR=4.22 for awareness; OR=2.26 for willingness) and condomless anal sex (OR=1.96 for awareness; OR=1.85 for willingness), but not group sex or having multiple sex partners, were significant factors associated with both MSM's PrEP awareness and willingness. Condomless anal sex was the only risk factor significantly associated with PrEP willingness among TG (OR=10.8). Of 60% MSM and 85% TG practiced at least two forms of risk behaviours, 54% and 53% were willing to take PrEP, respectively.

CONCLUSIONS: Only half of MSM and TG at high risk of HIV infection were willing to take PrEP. TG's awareness was especially low, despite their higher level of willingness to take PrEP. Scaling up the coverage along PrEP cascade is needed for individuals at high risk, especially for TG.

PEC0607

CHALLENGES AND OPPORTUNITIES OF PREP (CHOP); A MIXED METHODS STUDY EXPLORING PREP USE, ACCESS AND BARRIERS IN A UK SEXUAL HEALTH CLINIC OUTSIDE LONDON

J. Nicholls[1], A. Lorenc[2], L. Macgregor[1], K. Turner[3], N. Speare[4], L. Harryman[4], J. Kesten[2], J. Horwood[2]
[1]Bristol Medical School, School of Population Science, Bristol, United Kingdom, [2]Bristol Medical School, NIHR ARC West, Bristol, United Kingdom, [3]Bristol Vet School, Infectious Disease Epidemiology, Bristol, United Kingdom, [4]University Hospital Bristol NHS Foundation Trust, Unity Sexual Health, Bristol, United Kingdom

BACKGROUND: We examined knowledge and attitudes towards HIV pre-exposure prophylaxis (PrEP) among attendees at a large, urban sexual health clinic, during the IMPACT trial (England, UK) to ascertain if PrEP impacted on sexual decision-making or perception of risk.

METHODS: All clinic attendees (November 2018 for 12 months) self-identifying as men/trans-persons-who-have-sex-with-men (MSM/TPSM) were sent an electronic questionnaire. Eligibility required completed responses to questions concerning HIV-status and sexual decision-making concerning PrEP use by partners or self; consent to participate; and self-identification as MSM/TPSM. Interviews were conducted with 24 respondents at high risk of HIV acquisition and analysed thematically utilising an inductive approach and integrated with questionnaire data using the 'following a thread' method.

RESULTS: There were 617/2818 eligible respondents.

202/578 (35.0%) HIV-negative respondents had used PrEP of whom 86.1% (174/202) were current PrEP-users. Interviewees reported widespread awareness and enthusiasm for PrEP, which was described as 'life-changing'. Among respondents who had never used PrEP, 145/376 (38.6%) were unaware how to access PrEP and 101/376 (26.9%) could not access the IMPACT trial, of whom 78/101 (77.2%) would have been eligible. Interviewees identified expense and difficulty sourcing PrEP were the main barriers, many of whom would only take PrEP if freely available. Access through the trial was described as 'a gift from the gods'.

379/578 (65.6%) HIV-negative respondents indicated they would be more likely to have condomless sex if taking PrEP, while 472/578 (81.7%) believed taking PrEP would reduce their anxiety about acquiring HIV. 31/39 (79.5%) HIV-positive respondents believed PrEP would reduce anxiety about transmission to their partners.

Interviewee's reported using PrEP flexibly with other risk-reduction strategies, for reassurance during periods of increased HIV risk. PrEP provided 'peace of mind' and reduced fear around HIV testing. PrEP-users were seen as responsible and proactive.

CONCLUSIONS: PrEP awareness was high. However, access was limited by lack of trial places and cost of private purchase. PrEP may lead to increased condomless sex, but many interviewees had good understanding of their HIV acquisition risk and used PrEP as one risk reduction tool of many, as an extra precaution. The reduced fear of HIV transmission and testing should be considered in policy decisions.

PEC0608

WHAT ARE CHARACTERISTICS OF MEN WHO HAVE SEX WITH MEN WHO ARE INTERESTED IN, BUT NOT ON HIV PRE-EXPOSURE PROPHYLAXIS IN THE UNITED STATES? A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Kamitani[1], Y. Mizuno[1], M.E. Wichser[2], A. Adegbite-Johnson[2], J.B. DeLuca[1], D.H. Higa[1]
[1]US Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]ICF International, Atlanta, United States

BACKGROUND: Although 85% of men who have sex with men (MSM) in the U.S. are aware of PrEP, only 25% have used it. By understanding the characteristics of MSM who are interested in but not using it, we may be able to identify sub-populations within this community that need increased access to PrEP. The purpose of this review was to identify characteristics of MSM who are interested in, but not using PrEP.

METHODS: We searched the CDC HIV/AIDS Prevention Research Synthesis cumulative database of HIV prevention literature to identify U.S-based studies published in 2000-2019 that reported factors correlated with interest in using PrEP among MSM who are not using PrEP. Two reviewers independently screened citations, extracted data, and conducted risk of bias assessment using the Newcastle-Ottawa Scale. Discrepancies were resolved through discussion. Meta-analyses were performed to synthesize data.

RESULTS: We screened 2,069 citations and identified 25 relevant studies; the majority had a low-risk of bias and were cross-sectional studies conducted in urban areas. MSM who were interested in PrEP were significantly more likely to be non-white vs.white (OR=1.33, 95%CI:1.12-1.59, k=12, I^2=53.5) or uninsured vs. insured (1.28, 1.06-1.54, 10, 49.5). MSM who perceived benefits of PrEP (2.78, 1.42-5.43, 3, 78.0), were diagnosed with sexually transmitted infections (1.48, 1.06-2.06, 5, 72.4), used substances (1.42, 1.03-1.96, 10, 84.1), engaged in high-risk sexual behavior (1.36, 1.14-1.62, 24, 89.5), or had a high-risk perception (1.33, 1.01-1.76 , 4, 82.3) were significantly more likely than their respective counterparts to be interested in PrEP. Education level, employment status, income, age, HIV-related stigma, and sexual identity were not significantly associated with PrEP interest.

CONCLUSIONS: MSM of color, MSM without insurance, and MSM with HIV-risk were more likely to be interested in PrEP, but not using it. This may imply limited access to PrEP among these vulnerable MSM sub-populations. Study limitations include the inability to conduct meta-analyses on certain predictor variables due to a limited number of studies. This review identifies MSM sub-populations who may benefit from interventions for increasing access to PrEP care.

PEC0609

INTEGRATION OF MINIMUM PREVENTION PACKAGE INTERVENTION (MPPI) MODEL AS A STRATEGY FOR PREP UPTAKE AMONG KEY POPULATION IN CROSS RIVER STATE NIGERIA

B. Edet[1,2], P. Umoh[3], G. Emmanuel[3], R. Abang[3], A. Kalaiwo[4], A. Osilade[3]
[1]Heartland Alliance Nigeria LTD/GTE, Monitoring and Evaluation, Calabar, Nigeria, [2]University of Calabar, Education (Measurement, Evaluation and Research), Calabar, Nigeria, [3]Heartland Alliance Nigeria LTD/GTE, Programs, Abuja, Nigeria, [4]United States Agency for International Development, Programs, Abuja, Nigeria

BACKGROUND: Low uptake of PrEP among key population has been a major concern towards tackling the HIV epidemic in Nigeria. The Minimum Prevention Package Intervention (MPPI) Model is a better strategy that can be used to address the slow uptake of PrEP among key population in Nigeria. This study aims on improving PrEP uptake among key populations in Nigeria. Minimum Prevention Package Intervention (MPPI) is a strategy that aims to improve PrEP uptake among Key Population in Nigeria.

DESCRIPTION: MPPI Model is a strategy that is used to improve HIV services. The components of MPPI Model should be integrated in PrEP services which are the Behavioral (Counseling, Peer Education, Interpersonal communication and outreach sensitization), Biomedical (PrEP screening, Referral and medication) and Structural (Enabling environment to provide the PrEP services). This strategy ensured that at all HIV points, PrEP service is embedded in it.

LESSONS LEARNED: A comparative baseline data was collected between January and April 2019 and MPPI Model implementation period between May and August 2019 in 2 out of 5 One Stop Shop that is implementing comprehensive HIV services in Cross River state. The outcome established that there is inadequate PrEP awareness among the community members (Key Populations), weak referral strategies, rare PrEP screening and poor PrEP adherence were the key bottlenecks. A progression result of 70% improvement shows that embedding MPPI Model into PrEP services will drastically increase the uptake and improve PrEP retention.

CONCLUSIONS/NEXT STEPS MPPI Model strategy was a success in limited sites, the expansion of the MPPI Model is warranted to improve PrEP uptake and some aspects of the MPPI could be adapted to other services to further improve PrEP uptake and achieve reduction in HIV. MPPI model emerged as a one of the key approach that will bring a lasting solution to low PrEP uptake among key population.

PEC0610

UNMET NEED FOR PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG TRANSGENDER WOMEN IN CHINA

Z. Yan[1], J. Lin[2], W. McFarland[2], H. Yan[3]
[1]University of California, Bioengineering, Berkeley, United States, [2]Department of Public Health, San Francisco, United States, [3]Jiangsu Provincial Center for Diseases Control and Prevention, Nanjing, China

BACKGROUND: Transgender women may bear the highest burden of HIV of any population worldwide, and are under-represented in PrEP programs. China's latest national guidelines call for increasing PrEP to reverse the HIV epidemic in populations at highest risk, yet few data exists on PrEP awareness and willingness among transgender women in China. This study aimed to measure these indicators in a community-based sample of transgender women in Jiangsu province, China.

METHODS: From July 2018 to May 2019, a cross-sectional survey was conducted in Nanjing and Suzhou cities of Jiangsu province, China. Participants who were 18 years of age or older and assigned male sex at birth but identified as women or another feminine gender were recruited through respondent-driven sampling (RDS). Analysis focuses on PrEP awareness and willingness to use among 222 participants who were HIV negative or sero-status unknown.

RESULTS: Nearly half (48.2%) of the transgender women surveyed were aged 18-24 years; 31.1% had a university degree or higher. Over half (52.2%) had ever taken hormones; 18.5% had gender-affirming surgery. Over one third (36.5%) reported alcohol use before or during sex in the last year; 34.7% reported ≥2 sexual partners and 27.0% had condomless anal or virginal sex in the last 6 months. PrEP awareness was reported by 33.3%. Willingness to use PrEP (after explaining the intervention) was reported by 49.1%. PrEP awareness was associated with having a university degree or above (AOR 2.77, 95% CI 1.31-5.89) and not using alcohol before or during sex (AOR2.02, 95% CI 1.01-4.09). Those having one (AOR 3.56, 95% CI1.68-7.54) or multiple sexual partners (AOR2.53, 95% CI1.24-5.15) were more willing to take PrEP than those with no partners.

CONCLUSIONS: Transgender women in China are at high risk for HIV and there is an unmet need for PrEP interventions for this group. Our study witnessed low awareness of PrEP, yet substantial willingness to use PrEP. PrEP education and promotion programs should be enhanced for transgender women, especially targeting venues with alcohol use. Meanwhile, implementation research to scale up access and test the effectiveness of PrEP for transgender women is also urgently needed.

PEC0611

UNPACKING THE USE OF ORAL PRE-EXPOSURE PROPHYLAXIS (PREP) AS PART OF THE HIV PREVENTION PACKAGE IN A CLINICAL TRIAL

I. Beesham[1], S. Evans[1], J.M. Baeten[2], R. Heffron[2], J. Smit[1], M. Beksinska[1], L.E. Mansoor[3]
[1]University of Witwatersrand, MatCH Research Unit (MRU), Department of Obstetrics and Gynaecology, Faculty of Health Sciences, Durban, South Africa, [2]University of Washington, Seattle, United States, [3]Centre for Aids Programme of Research in South Africa (CAPRISA), Durban, South Africa

BACKGROUND: The ECHO (Evidence for Contraceptive Options and HIV Outcomes) trial which was conducted at 12 sites in Africa measured HIV incidence among 7829 women randomised to one of three effective contraceptives. PrEP was offered as part of the HIV prevention package throughout the trial, and the trial provided oral PrEP at the Durban, South Africa site part-way through the trial. We present findings below on experiences of women who initiated oral PrEP at the Durban site.

METHODS: All women who initiated oral PrEP on-site at the Durban site were invited to complete an additional structured interviewer-administered questionnaire that probed experiences with using trial-provided PrEP. Women were interviewed approximately three months after initiating PrEP from April to October 2018. Data were entered on REDCap and analysed using Stata. Open-ended questions were coded into categories and descriptively analysed.

RESULTS: In total, 132 (96.4% of 137 women who initiated PrEP on-site) were interviewed. The mean age was 24 years. Twenty-seven (20.5%) women felt they would probably get infected with HIV. Women felt at risk for acquiring HIV due to many reasons including: not knowing their partner's HIV status (24, 18.2%), feeling their partner had other sexual partners (57, 43.2%), not always using a condom when having sex (97, 73.5%) and having had a previous sexually transmitted infection (17, 12.9%). PrEP use was disclosed by 119 (90.2%) women: 46(38.7%) disclosed to partners, 44(37.0%) to friends, and 81(68.1%) to family. In total, 120(90.9%) women heard about PrEP for the first time from ECHO trial staff. Three-quarters (99, 75.0%) elected to continue using PrEP at study exit. Reasons for stopping PrEP included(n=32): side effects (12, 37.5%), partner or family influence (5, 15.6%), forgetfulness (4, 12.5%) and other reasons (11, 34.4%).

CONCLUSIONS: Staff were found to be vital in the delivery of oral PrEP and up to 38% of attrition from PrEP was due to side effects. Most clients disclosed PrEP use. Three-quarters of women continued PrEP at study exit. These findings can be used to inform other trials delivering oral PrEP.

PEC0612

IMPACT OF PREP ON SOCIAL DOMAIN OF QUALITY OF LIFE: A COHORT STUDY

V. Avelino-Silva[1], M. Takada-de-Souza[2], C. Picone[2], M. Prandini[2], L. Monginet-Toledo[2], G. Pimentel[2], S. Gasparini[2], A.P. Silva-Alves[2], P. Parmejani[2], N. Alves-da-Silva[2], M. Santos[2], A. Segurado[1]
[1]Faculdade de Medicina da Universidade de São Paulo, Infectious and Parasitic Diseases, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil

BACKGROUND: HIV pre-exposure prophylaxis (PrEP) has been recently implemented in the public healthcare system in Brazil. Although PrEP efficacy for HIV prevention has been extensively documented, few studies have analyzed its impact on quality of life (QOL).

METHODS: In this cohort study, we included ≥18 years old HIV-uninfected patients receiving a first PrEP prescription in the public healthcare system and applied the WHOQOL-bref questionnaire at baseline and at 7 months after PrEP initiation. The change in QOL scores were explored using Wilcoxon sign rank tests.

RESULTS: 114 PrEP users were included between July/2018 and May/2019. Participants were mostly white (72%) males (97%), with ≥12 years of education (96%) and had median age of 30 years old (range 19-61). Most were men who have sex with men (93%). Condom use in <half of sexual intercourse episodes ≤3 months prior to inclusion was reported by 14%, and 61% reported some illicit/club drugs use ≤3 months prior to inclusion. Baseline and 7-month health perception, overall QOL perception and scores in QOL domains (physical, psychological, social relationships and environment) are presented in Table 1.

QOL measurements	Baseline, N=114	7-month follow-up, N=47	p-value
Overall health perception	75 (75-75)	75 (75-75)	0.635
Overall QOL perception	75 (75-100)	75 (75-75)	0.299
Physical domain	75 (64-86)	79 (68-86)	0.087
Phycological domain	71 (58-79)	75 (63-79)	0.470
Social domain	67 (58-75)	75 (58-83)	0.057
Environmental domain	69 (59-78)	72 (66-84)	0.071

Variables are presented as medians and interquartile ranges
[Table 1.]

QOL measurements at 7 months after PrEP initiation were collected for 60 participants. WHOQOL-bref social domain, which comprises questions on social relationships (friends, relatives, colleagues), sexual life and support from friends, improved from a median score of

67 (interquartile range [IQR] 58-75) at baseline to 75 (IQR 58-83) at 7th-month visit (p=0.057) among 47 PrEP users who reported good adherence (≥4 pills/weeks). Age, race, income and use of illicit and/or club drugs were not significantly associated with change in WHO-QOL-bref social domain score.

CONCLUSIONS: In addition to its documented efficacy for HIV prevention, our findings suggest that PrEP may also improve QOL, especially in the social domain. Favorable effects of PrEP may transcend HIV prevention. These potential benefits should be considered in the context of PrEP referral.

PEC0613

AWARENESS OF AND WILLINGNESS TO USE ORAL PRE-EXPOSURE PROPHYLAXIS IN A COHORT AT HIGH RISK OF HIV INFECTION IN SOUTH-WESTERN UGANDA

S. Kansiime[1], J. Bayigga[1], S. Katana[1], S. Kusemererwa[1], M. Onyango[1], S. Nabukenya[1], G. Mutonyi[1], A. Kakande[1], C.H. Hansen[1], E. Ruzagira[1], P. Kaleebu[1]
[1]Medical Research Council/Uganda Virus Research Institute & London School of Hygiene and Tropical Medicine Uganda Research Unit, Entebbe, Uganda

BACKGROUND: Oral pre-exposure prophylaxis (PrEP) is known to reduce HIV acquisition through sex by nearly 100% when taken consistently. However, many people who could benefit from PrEP are unaware of its existence or cannot access it. We investigated awareness and willingness to use PrEP in a cohort at high risk of HIV infection in South-western Uganda.

METHODS: Participants comprised HIV-negative adults (18-45 years) enrolled in a prospective HIV vaccine preparedness study between July 2018 and October 2019. At baseline, data on demographics, HIV risk, awareness of and willingness to use PrEP, were collected using an interviewer administered questionnaire. A cross-sectional analysis was performed using Poisson regression models with robust variance estimates.

RESULTS: A total of 391 (53% female) participants were enrolled. Of these, 38% (95% CI: 32.9, 42.5) were previously aware of PrEP. Awareness was associated with transactional sex in the past month (RR=1.16, P<0.001), condom use at last sex (RR=1.09, P=0.023), and having electricity in the household (urbanisation indicator) (RR=1.09, P=0.038). 75% (95% CI: 70.6, 79.2) of participants reported willingness to use PrEP. Reported willingness was associated with experience of coerced sex (RR=1.21, P<0.001), having an older (>10 years) sexual partner ((RR=1.11, P=0.075), and non-use or being unsure of condom use at last sex (RR=1.10, P=0.041).

CONCLUSIONS: Prior awareness of PrEP in this population was low. However, willingness to use PrEP was high and associated with presence of high risk behaviour. Efforts to promote and provide PrEP to individuals at high risk of HIV infection in this setting should be fast-tracked.

HOW MEN WHO HAVE SEX WITH MEN PERCEIVE PREP-RELATED SERVICES IN CHINA: A MIXED-METHOD STUDY

C. Lin[1], L. Li[1], J. Liu[2], Y. Li[2]
[1]UCLA, NPI, Los Angeles, United States, [2]Guangdong Provincial Center for Disease Control and Prevention, HIV/AIDS Department, Guangzhou, China

BACKGROUND: Despite the proven efficacy of pre-exposure prophylaxis (PrEP) in HIV prevention, the roll-out of PrEP has been challenging among key populations, including men who have sex with men (MSM). The low acceptability and uptake of PrEP compromise the real-world effectiveness of this promising HIV prevention method. This study sought to understand PrEP acceptability among MSM in China. The data will inform the promotion of PrEP services among MSM.

METHODS: The study was conducted in 2018 in Guangdong Province using a mixed-method approach. An online cross-sectional online survey was conducted with 520 MSM to access their PrEP knowledge, information source, and acceptability. Multiple linear regression was performed to identify the factors associated with PrEP acceptability among HIV-negative MSM. In-depth interviews were conducted with 30 MSM to learn about their concerns and preference regarding PrEP service utilization.

RESULTS: Among the 520 MSM, 489 (94%) self-reported to be HIV-negative. Among the HIV-negative participants, 374 (76.5%) had heard of PrEP before the survey. The most frequently cited channel to learn about PrEP was internet/social media (n=167; 32.1%) and community-based organizations (n=158; 30.4%). Among the 489

HIV-negative MSM, 294 expressed willingness to use PrEP once it is approved in China; 269 were willing to use PrEP daily, and 331 were willing to use before sexual intercourse. Two thirds (n=328) of the HIV-negative MSM accepted PrEP even the protective efficacy is less than 100%; 290 were willing to pay out of pocket for PrEP. After controlling for demographic characteristics, insurance coverage, and risk profile, having mental health symptoms was associated with a lower level of acceptability towards PrEP (β=-0.91; p=0.0477) among the HIV-negative MSM. The challenges to using PrEP included high cost, low accessibility, potential side effect, pill burden, stigma, and lack of protective effect against STI. Primary care-based PrEP services were acceptable, but the protection of patients' confidentiality was a concern.

CONCLUSIONS: Social media could be an efficient channel to disseminate PrEP knowledge. PrEP promotion effort need to address mental health challenges among MSM in order to achieve the best result. The involvement of the primary care systems could help to facilitate PrEP-related service provision.

PEC0615

IS PEP A GATEWAY TO PREP? EXPERIENCE FROM A HIGH VOLUME COMMUNITY HEALTH CENTER

K. Mayer[1], K. Levine[2], C. Grasso[2], K. Biello[3]
[1]Fenway Health/Harvard Medical School, The Fenway Institute, Boston, United States, [2]Fenway Health, The Fenway Institute, Boston, United States, [3]Fenway Health/Brown University, The Fenway Institute, Boston, United States

BACKGROUND: Antiretroviral post-exposure prophylaxis (PEP) after high risk HIV exposure has been recommended for more than 2 decades. Pre-exposure prophylaxis (PrEP) was first demonstrated to be effective a decade ago. The current analyses were designed to assess whether individuals presenting for PEP were likely to transition to PrEP, if they had recurrent high risk exposures.

METHODS: Electronic health record data from patients accessing services in Boston community health center specializing in sexual and gender minority health care between 2010 and 2019 were analyzed to determine the frequency of PEP and PrEP use, secular trends in PEP regimens used, and to evaluate the frequency of the PEP-PrEP transition. Time trend analyses were computed using a chi-square two sample test.

RESULTS: In 2010, 146 unique individuals used PEP, with 17 (11.6%) individuals using it more than once, compared to 2019, when 224 unique individuals used PEP, with 53 (23.7%) using it more than once (p=.004). Increasingly, regimens included tenofovir, so that by 2016, all PEP regimens were tenofovir-based, with the majority of courses (76.9%) by 2019 consisting of 2 drugs, and when a third drug was used, it was always an integrase strand transfer inhibitor. PEP users in 2019 were predominantly White (66.5%), non-Latinx (81.3%), male (85.7%), non-heterosexual (88.8%), and aged between 25 and 39 (55.4%). In 2011, only 11 (8.7%) PEP users initiated PrEP within the same year after PEP, while by 2019, 224 (89.3%) did (p<0.001). No PEP users in 2019 became HIV infected. Of 4089 patients with an active PrEP prescription in 2019, 3 became HIV-infected, all of whom were likely to have been recently infected prior to the time of PrEP initiation.

CONCLUSIONS: Over the past decade, the use of PEP and PrEP has significantly increased at a Boston community health center, with an increasing percent of individuals using PEP recurrently, and transitioning from PEP to PrEP. The low HIV incidence among PEP and PrEP users suggests that PEP promotion and facilitated triage to PrEP has the potential to impact HIV spread.

PEC0616

ADOPTION OF HIV PRE-EXPOSURE PROPHYLAXIS AMONG WOMEN AT HIGH-RISK OF HIV INFECTION IN KENYA

C. Bien-Gund[1], P. Ochwal[2], N. Marcus[1], E. Bair[1], S. Napierala[3], S. Maman[4], K. Agot[5], H. Thirumurthy[1]
[1]University of Pennsylvania, Philadelphia, United States, [2]Impact Research and Development Organisation, Kisumu, Kenya, [3]RTI International, San Francisco, United States, [4]UNC Gillings School of Public Health, Chapel Hill, United States, [5]Impact Research and Development Organization, Kisumu, Kenya

BACKGROUND: Young women in sub-Saharan Africa (SSA) account for a quarter of new HIV infections worldwide. In order to reduce incident HIV infections, in May 2017, Kenya became the first country in SSA to scale-up the availability of oral pre-exposure prophylaxis (PrEP). We evaluated the prevalence and predictors of PrEP use among a cohort of high-risk HIV-negative women in the Nyanza region of Kenya.

METHODS: We analyzed PrEP use over a 12-month period among HIV-negative women participating in an ongoing cluster randomized controlled trial of an HIV self-testing intervention (NCT03135067). HIV-negative women aged ≥18 years with ≥2 sexual partners in the past 4 weeks were eligible. Women in intervention clusters received multiple HIV self-tests for distribution to sexual partners while women in control clusters received mutliple referral vouchers for clinic-based testing. Participants completed a baseline questionnaire assessing socio-demographic characteristics, sexual behavior, and HIV risk. PrEP use was assessed at baseline, 6 months, and 12 months. The primary outcome was PrEP use at any of the study visits. Univariate and multivariate logistic regression were conducted to identify baseline characteristics associated with PrEP use.

RESULTS: Between June 2017 and August 2018, 2,091 participants were enrolled in the study, of which 2,087 had complete baseline data and were included in the analysis. 138 (6.6%) reported PrEP use during the first year of the study. At study initiation, 1.7% indicated PrEP use, which increased to 3.3% at 6 months, and 4.9% at 12 months. In multivariate analyses, PrEP use was associated with a recent STI diagnosis (AOR 4.9, 95% CI 2.0-12.0), having an HIV-positive primary partner (AOR 5.4, 95% CI 2.7-10.8), having regular transactional sex in the past 12 months (AOR 2.2, 95% CI 1.0-4.7), and being a female sex worker (AOR 2.2, 95% CI 1.3, 3.8).

CONCLUSIONS: In the early stages of the national PrEP rollout in Kenya, PrEP appears to be reaching women at high risk of HIV infection. PrEP uptake increased modestly among HIV-negative women in Kenya during a 12-month period, however, overall uptake was low. There is need for interventions that can increase PrEP uptake among women who are at risk of HIV acquisition.

PEC0617

LONG-TERM RETENTION IN HIV PRE-EXPOSURE PROPHYLAXIS CARE AMONG PATIENTS IN RHODE ISLAND, UNITED STATES, 2013-2018

J. Tao[1], R.J. Williams[2], M. Maynard[3], M. Montgomery[2], S. Napolean[3], C. Chu[3], E. Silva[3], A. Almonte[3], C. Sosnowy[1], B. Rogers[1], A. Nunn[4], P. Chan[1]
[1]Brown University, Infectious Diseases, Providence, United States, [2]Brown University, Department of Medicine, Providence, United States, [3]The Miriam Hospital, Infectious Diseases, Providence, United States, [4]Brown University, Behavioral and Social Sciences, Policy and Practice, Providence, United States

BACKGROUND: Retention in HIV pre-exposure prophylaxis (PrEP) care is critical for effective PrEP implementation. However, limited studies have reported long-term retention in PrEP care in the United States. We analyzed clinical data from a major PrEP program to evaluate retention in PrEP care and explore factors associated with PrEP discontinuation.

METHODS: All cis-gender patients presenting to the Rhode Island PrEP clinic from 2013-2018 were included in this study. Descriptive analyses were performed to present demographics and behavioral characteristics. We conducted Cox Proportional Hazard regression to analyze PrEP retain in care over the five year period. Discontinuation was defined as no clinical visit after the last visit within 98 days, which was defined as the median of time intervals between each follow-up. The entry point was the date of individuals' first PrEP visit, and the end point was either the date of discontinuation or the end of this study (Dec, 31, 2018). Confounding variables were identified using directed acyclic graphs (DAGs) and a priori.

RESULTS: Of 502 cis-gender PrEP patients, the median age was 31 years old (interquartile range [IQR]: 25, 43). The majority were male (96%), White (65%), non-Hispanic (82%), insured (99%), and having a college degree or above (64%). African American and Hispanic/Latino were 7% and 18% of this study population, respectively. Of these individuals, 53% were retained in care by Year1, 37% by Year2, 30% by Year3, and 18% by Year4, and 1% by Year5. Being one-year older (crude hazard ratio [cHR]: 0.98, 95% confidence interval [CI]: 0.97, 0.99) and having a college education or above (adjusted hazard ratio [aHR]: 0.73, 95% CI: 0.57, 0.94) were less likely to discontinuation. Females had a 1.68 (cHR: 1.68, 95% CI: 1.01, 2.79) times of risk being discontinued than male. Being either heterosexual (aHR: 3.57, 95% CI: 1.66, 7.70) or bisexual (aHR: 2.71, 95% CI: 1.90, 3.86) was associated with having a higher risk of being not retained in care than people who had same-sex partners only.

CONCLUSIONS: The majority of PrEP users were discontinued during five-year follow-up. Future studies should determine why individuals were not persistent and develop intervention to improve PrEP care outcomes.

PEC0618

UPTAKE AND SEROCONVERSION RATES AMONG KEY AND PRIORITY POPULATIONS SCREENED FOR PRE-EXPOSURE PROPHYLAXIS IN KAMPALA, UGANDA

E. Nasuuna[1], F. Namimbi[1], J. Wanyama[1], M. Ssuna[1], A. Muganzi[1], P. Kyambadde[2], J. Kigozi[1]
[1]Infectious Diseases Institute, Makerere University College of Health Sciences, Outreach Department, Kampala, Uganda, [2]Most at Risk Populations' Initiative, Mulago Hospital, Kampala, Uganda

BACKGROUND: Pre-Exposure Prophylaxis (PrEP) is effective in reducing HIV transmission among populations at high risk of acquiring HIV. Individuals must perceive their risk and faithfully take the daily PrEP. We report the uptake and seroconversion rates among key and priority populations (KP/PPs) on PrEP in Kampala, Uganda.

METHODS: Clients that attended three PEPFAR supported clinics were followed up from August 2017-September 2019. KP/PPs were: discordant couples, female sex workers (FSW), men who have sex with men (MSM), fisherfolk, non-injecting or injecting drug users. A client was eligible for PrEP if: HIV negative, at substantial risk of acquiring HIV (sex work, irregular condom use, multiple partners, recurrent STIs) with normal renal function (creatinine clearance ≥ 60ml/min). Clients were screened using the national PrEP eligibility tool and counselled. Those that accepted provided consent and were initiated on PrEP (TDF/3TC) at the clinic or in the community; followed up monthly and retested for HIV every 3 months. Seroconversion was defined as testing HIV positive after testing negative while on PrEP. Descriptive analysis was done using frequencies/percentages and incidence rate calculated.

RESULTS: A total of 9,878 clients tested HIV negative [Females 6,203 (62.8%); 4,133 (41.8%) young adults 10 to 24 years]. Those eligible for PrEP were 7,381 (74.7%) [Females 4,749 (64.3%), young adults 3,307 (44.8%)]. Majority 6424(87%) accepted, and were initiated on PrEP [Females 4,205 (65.5%), young adults 2,863 (44.6%)]. Uptake was highest among the discordant couples 429 (99%), transgender people 29 (91%) followed by the FSW 3936 (88%), MSMs 1106 (82%).
There were 15 clients that seroconverted, an incidence rate of 7.4 per 100 person years. FSW 10 (66%), 3 (20%) MSMs, 1 (7%) drug user and 1 (7%) DC. Seroconversion was associated with suboptimal adherence. 10 (67%) were taking drugs intermittently, 5 (20%) stopped due to side effects and new partners. The average time on PrEP was 8.2 months (range 3-17). Retention at 12 months was 11%.

CONCLUSIONS: PrEP uptake was suboptimal among KP/PPs. Apparent seroconversions were few, but those lost to followup may have higher seroconversion rates. Further research is needed to understand barriers and develop strategies to improve uptake and adherence to PrEP.

PEC0619

RATES AND RISK FACTORS OF SEXUALLY TRANSMITTED INFECTIONS AMONG MALES USING PRE-EXPOSURE PROPHYLAXIS (PREP)

R. Hechter[1], K. Bruxvoort[1], H. Zhou[1], J. Jones[2], R. Contreras[1], D. Ling Grant[1], C. Schumacher[3], W. Towner[1]
[1]Kaiser Permanente Southern California, Department of Research & Evaluation, Pasadena, United States, [2]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, [3]Johns Hopkins University School of Medicine, Center for Child and Community Health Research, Department of Pediatrics, Baltimore, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP) is an important element of HIV prevention. However, the increasing incidence of sexually transmitted infections (STIs) among men who have sex with men may compromise the long-term success of PrEP. We examined the rates and correlates of STIs in a cohort of males using PrEP in an integrated healthcare system in United States.

METHODS: We assessed rates of genital and extragenital syphilis, chlamydia, and gonorrhea in males ≥ 14 years old initiating PrEP between 2014-2017 in Kaiser Permanente Southern California. New STIs within 12 months following PrEP initiation were ascertained through laboratory test results in electronic health records. Multivariable logistic regression was used to assess the odds ratios and 95% confidence intervals for factors associated with testing positive for one STI vs. none and ≥ 2 STIs vs. none during the follow-up period.

RESULTS: Of the 4,998 males initiating PrEP, 4,767 individuals received at least one STI test. There were 890 men (17.8%) who tested positive for one STI and 466 (9.3%) had ≥ 2 STIs during follow-up. There were 338 new syphilis infections among 15,478 screening tests (2.2%), 852 (4.2%) gonorrhea and 913 (4.5%) chlamydia infections among 20,215 gonorrhea/chlamydia tests. In multivariable analysis, having a history of STIs in the 6 months prior to PrEP initiation was the strongest predictor of testing positive for STIs after PrEP initiation, followed by having an addiction medicine department visit in the prior 6 months. Blacks and Hispanics (vs. Whites) had 48% and 33% increased odds of STIs. Those aged ≥35 years were less likely to have a new STI (vs. 14-24-year-olds), as were those who lived in a neighborhood with >75% of adults with a high school diploma.

Characteristics		Odds Ratio (95% confidence intervals) One STI vs. none	Odds Ratio (95% confidence intervals) ≥ 2 STIs vs. none
Age at PrEP initiation, vs. 14-24 years old	25-34 years	0.90 (0.71-1.14)	0.88 (0.64-1.20)
	≥35 years	**0.78 (0.61-0.99)**	**0.51 (0.36-0.70)**
Race/ethnicity, vs. non-Hispanic White	Asian	1.26 (0.95-1.68)	1.02 (0.68-1.52)
	Black	**1.48 (1.07-2.04)**	1.06 (0.67-1.68)
	Hispanic	**1.33 (1.10-1.61)**	1.10 (0.85-1.42)
Proportion of adults with a high school diploma in census block	> 75% vs. < 50%	0.66 (0.44-0.99)	0.60 (0.36-1.01)
History of STIs in the prior 6 months	Yes vs. No	**3.51 (2.92-4.22)**	**5.40 (4.25-6.86)**
Having ≥ 1 visit to addiction medicine department in the prior 6 months	Yes vs. No	1.61 (0.85-3.04)	**3.28 (1.45-7.42)**

[Table. Demographic and clinical characteristics associated with testing positive for STIs during follow-up in multivariable analysis.]

CONCLUSIONS: Among an insured population, disparities exist in rates of STIs acquired while on PrEP. Targeted interventions may benefit youth, minorities and those with a STI history.

PEC0620

CURRENT USE AND REFERRAL FOR PREP AMONG PARTNERS OF HIV DIAGNOSED PERSONS CONTACTED BY PARTNER SERVICES PROGRAMS, UNITED STATES: PRELIMINARY ANALYSIS OF 2018-2019 DATA

M.S. Mulatu[1], H. Zhang Kudon[1], W. Song[1], M. Rorie[1], S. Rao[1]
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

BACKGROUND: HIV partner services (PS) provide an opportunity to link HIV-negative partners to prevention services, including pre-exposure prophylaxis (PrEP). However, the extent to which PrEP services are integrated into PS programs is not well known. This preliminary analysis examines current use of PrEP and referral to PrEP providers among HIV-negative partners contacted by PS programs at Centers for Disease Control and Prevention (CDC) funded health departments.

METHODS: The CDC funds 60 state and local health departments to implement HIV prevention programs, including PS. Health departments report client-level data (demographics, geographic location, HIV testing and outcomes, and linkage to care) on named sexual and/or needle-sharing partners. In 2018, the data requirements were expanded to include current PrEP use and referral to PrEP providers. We analyzed data reported by 39 health departments that had implemented the new requirements during July 2018–June 2019. Descriptive and multivariable logistic regression analyses were conducted to determine the extent of and associated factors for current use of and referral for PrEP among HIV-negative partners.

RESULTS: PS programs tested 3,112 partners for HIV; 2,068 (66.5%) of them tested HIV-negative. Information on PrEP was reported for 1,167 (56.4%) of HIV-negative partners. Of these, 139 (11.9%) were already using PrEP. Blacks (7.6%; aOR=0.61, 95% CI=0.38–0.96) compared to whites (13.1%)) and women (7.5%; aOR=0.52, 95% CI=0.32–0.83) compared to men (13.2%) were less likely to be on PrEP. Partners residing in the West (20.2%; aOR=2.18, 95% CI=1.30–3.68) were more likely than those in South (7.9%) to be on PrEP. Among those who were not on PrEP, 254 (24.7%) were referred to PrEP providers. Partners residing in the Midwest (43.3%; aOR=2.33, 95% CI=1.52–3.59) and West (39.9%; aOR=2.08, 95% CI=1.33–3.23) were more likely than those in the South (24.0%) to be referred to PrEP providers.

CONCLUSIONS: Only one-third of HIV-negative partners contacted through PS programs were using PrEP or referred to PrEP providers. The gap in PrEP services may be wider among population groups and regions disproportionately affected by HIV. Further research is needed to identify and address the barriers to integration of PrEP services in PS programs.

PEC0621

REFERRAL LINKAGE TO PRE-EXPOSURE PROPHYLAXIS (PREP) CARE IN AN INTEGRATED HEALTHCARE SYSTEM

K. Bruxvoort[1], C. Schumacher[2], J. Jones[3], W. Towner[1], R. Contreras[1], D. Ling Grant[1], R.C. Hechter[1]
[1]Kaiser Permanente Southern California, Department of Research & Evaluation, Pasadena, United States, [2]Johns Hopkins University School of Medicine, Center for Child and Community Health Research, Department of Pediatrics, Baltimore, United States, [3]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States

BACKGROUND: Successful PrEP referral linkage is important for PrEP uptake scale-up in populations at risk of HIV. We examined PrEP referral linkage, PrEP prescription and initiation, and factors associated with linkage to PrEP consultation in an integrated healthcare system in the United States.

METHODS: We identified individuals referred for PrEP from 2014 to 2018 at Kaiser Permanente Southern California using electronic health records and assessed the proportion of individuals with a follow-up PrEP consultation (linkage), the proportion receiving a PrEP prescription, and those fulfilling the prescription (initiation). Demographic and clinical correlates of referral linkage were analyzed using multivariable Poisson regression with robust standard errors.

RESULTS: There were 4,766 individuals who received a PrEP referral, of whom 90% were male, 37% were White, and 33% were Hispanic. The median age was 32 (range 17-77). The number of individuals referred for PrEP increased each year from 163 in 2014 to 1,771 in 2018. The majority of referrals were made by Family Medicine (55%) or Internal Medicine (34%) departments. About 75% (n=3,594) of referred individuals were linked to a PrEP consultation, most of whom received a PrEP prescription (99.6 %) and initiated PrEP (97.2 %). Individuals of age ≥25 years, those living in a neighborhood having ≥50% adults with a high school diploma, or those having alcohol use disorder were were more likely to be linked to PrEP consultation, while those with high-deductible insurance and Medicare were less likely to be linked (Table 1). There was no evidence of disparities in PrEP linkage by race/ethnicity.

Characteristics		Adjusted Relative Risk (95% Confidence Interval)
Age at PrEP referral, vs. 14-24 years old	25-34 years	1.18 (1.11, 1.25)
	≥35 years	1.22 (1.15, 1.29)
Insurance type, vs. Commercial without high deductible	Medicare	0.72 (0.59, 0.88)
	Medicaid	0.97 (0.90, 1.05)
	High-Deductible Plan	0.82 (0.78, 0.86)
Proportion of adults with a high school diploma in census block, vs. <50%	50-75%	1.04 (1.01, 1.08)
	>75%	1.13 (1.03, 1.24)
Alcohol use disorder in previous 6 months	Yes vs. No	1.18 (1.05, 1.32)

[Table 1: Demographic and clinical characteristics associated with PrEP referral linkage]

CONCLUSIONS: We observed suboptimal PrEP referral linkage but very high PrEP initiation among individuals successfully linked to PrEP consultation in an insured population. Equipping frontline providers to prescribe PrEP as well as other targeted interventions to improve referral linkage may facilitate scale-up of PrEP uptake.

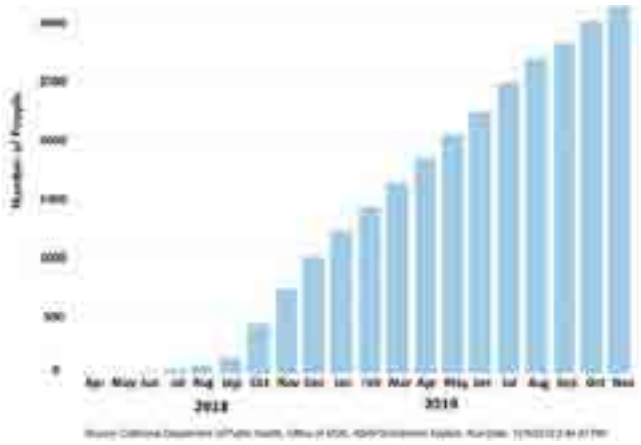
PEC0622

THE CALIFORNIA PRE-EXPOSURE PROPHYLAXIS ASSISTANCE PROGRAM: LESSONS LEARNED DURING AN INITIAL EXPANSION OF SERVICES

P. Peters[1,2], A. Nakamura[1], A. Barraza[1], K. Wu[1], S. Robinson[1], M. Ramos[1]
[1]California Department of Public Health, Office of AIDS, Sacramento, United States, [2]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

BACKGROUND: HIV Pre-Exposure Prophylaxis (PrEP) is highly effective at preventing HIV infection, but access is often limited for people with low income. The California PrEP Assistance Program (PrEP-AP) seeks to remove financial and structural barriers to PrEP access.

DESCRIPTION: PrEP-AP covers medical out-of-pocket costs for both uninsured and insured people who are eligible based on income. Coverage includes PrEP-related clinical services, laboratory tests, and access to sexually transmitted infection treatment. PrEP-AP supplements PrEP medication access provided through manufacturer assistance programs and covers the provision of post-exposure prophylaxis (PEP).



[Figure. California Pre-Exposure Prophylaxis Assistance Program (PrEP-AP) enrollment, 2018 - 2019]

	Active enrollment in PrEP-AP	HIV Diagnoses in California, 2017
Gender		
Cisgender men	2,775 (95%)	4,138 (87%)
Cisgender women	82 (3%)	526 (11%)
Transgender women	45 (2%)	72 (2%)
Transgender men	3 (0.1%)	5 (0.1%)
Unknown	4 (0.1%)	0 (0%)
Age (years)		
18 - 24	305 (10%)	914 (19%)
25 - 34	1,461 (50%)	1,710 (36%)
35 - 44	691 (24%)	1,005 (21%)
45 - 64	358 (12%)	1,040 (22%)
≥ 65	98 (3%)	81 (2%)
Race/Ethnicity		
Hispanic/Latinx	1,236 (42%)	2,232 (47%)
American Indian/Alaska Native	7 (0.2%)	18 (0.4%)
Asian	260 (9%)	344 (7%)
Black/African American	211 (7%)	802 (17%)
Native Hawaiian/Other Pacific Islander	11 (0.3%)	12 (0.3%)
White	1,065 (37%)	1,245 (26%)
Multiple races	40 (1%)	138 (3%)
Unknown	83 (3%)	0 (0%)
Geographic region of residence		
Southern California	2,545 (87%)	3,053 (64%)
Bay Area	268 (9%)	859 (18%)
Central Valley	11 (0.4%)	503 (10%)
Other regions	100 (3%)	376 (8%)

[Table. Demographic characteristics of people enrolled in the California Pre-Exposure Prophylaxis Assistance Program (PrEP-AP) and number of people with an HIV diagnosis in California in 2017.]

LESSONS LEARNED: From April 2018 – November 2019, active enrollment increased to over 3,000 people (Figure) of whom 58% were uninsured, 38% had commercial insurance, and 4% had Medicare. Comparisons between PrEP-AP enrollees and people with HIV diagnosis in California in 2017 identified several groups with low PrEP-AP enrollment (Table). Potentially under-enrolled populations included cisgender women, young people (age 18 – 24 years), black/African Americans, and people residing in the Central Valley. Several programs have been introduced to address these lessons learned including state-funded PrEP navigation projects that focus on under-enrolled populations. To address confidentiality concerns for young people and other groups, an enhancement to allow PrEP-AP enrollment without using family or partner's health insurance is planned. To improve access in the Central Valley, PrEP-AP introduced a telemedicine PrEP option in September 2019.

CONCLUSIONS/NEXT STEPS PrEP-AP has expanded access to PrEP in California but several populations may be under-enrolled. New enhancements have been introduced and can be evaluated to address these remaining barriers to PrEP.

PEC0623

ACCESS TO PRE-EXPOSURE PROPHYLAXIS OF HIV IN EASTERN EUROPE CENTRAL ASIA REGION

M. Kornilova[1], G. Roshchupkin[2], V. Djuma[2]
[1]Alliance for Public Health, Monitoring and Evaluation, Kyiv, Ukraine, [2]Eurasian Coalition on Male Health, Tallinn, Estonia

BACKGROUND: There is lack of studies about pre-exposure prophylaxis (PrEP) in Eastern Europe Central Asia(EECA). From what is known to date, in EECA PrEP is not adequately addressed. We conducted a baseline assessment in 2018 in 17 EECA countries, and at that time only Georgia and Ukraine had an on-going pilot projects on PrEP for MSM covering 100 clients each with the plans for scale-up in 2019. Other countries such as Moldova, Kazakhstan, Kyrgyzstan and Russia planned to introduce PrEP by 2019. We have reassessed the situation in the end of 2019 to see if the access to PrEP improved.

METHODS: 17 countries participated in the survey: Albania, Armenia, Azerbaijan, Belarus, Bulgaria, Georgia, Hungary, Estonia, Latvia, Macedonia, Moldova, Kazakhstan, Kyrgyzstan, Russia, Slovakia, Ukraine, Uzbekistan. The study utilized mixed methods of data collection: desk review of the official regulating documents and on-line structured questionnaire followed by the semi-structured in-depth interviews. First assessment was conducted in July-September 2018, second – December 2019.

RESULTS: Out of 17 countries assessed in 2019 only three - Georgia, Ukraine and Moldova have PrEP programs, that are covering 1000 clients in Ukraine, which is 3.5 times less than has been planned, 200 in Georgia and few clients in Moldova. The situation in other 14 countries hasn't changed and no PrEP had been introduced. Among the main barriers preventing countries from initiating PrEP and negatively impacting scale-up we identified insufficient level of knowledge among medical professionals and clients creating lack of demand; luck of financial and human resources including reluctance to provide a governmental funding; high level of stigma and discrimination, significant disconnection between potential users and key gatekeepers, excessive medicalization of service.

CONCLUSIONS: PrEP is still poorly available in EECA region. Among 17 countries participated in assessment by the end of 2019 only 3 had PrEP programs. Scale up is also not going as fast as planned. The main limiting factors are lack of demand from the community and lack of knowledge among medical professionals. Facilitators - informational support for promotion and demand creation, advocacy support, endorsement from professional society, cooperation with governmental and non-governmental stakeholders, international technical and financial aid.

PEC0624

PREVALENCE OF STIS AMONG ADOLESCENT MEN WHO HAVE SEX WITH MEN (MSM) AND TRANSGENDER WOMEN (TGW) AT HIGH RISK OF HIV INFECTION IN A PREP MULTISITE STUDY IN BRAZIL

D. Greco[1], U. Tupinambas[1], M. Westin[1], Y. Martinez[2], M. Greco[3], A.P. Silva[3], A. Granjeiro[4], M. Depallens[5], L. Miranda Marques[6], G. Barreto Campos[6], L. Magno[7], I. Dourado[8], The PrEP1519 Brazil Study Group
[1]Federal University of Minas Gerais, Internal Medicine, Belo Horizonte, Brazil, [2]Federal University of Minas Gerais, Pos-Graduate Programe Infectious Diseases, Belo Horizonte, Brazil, [3]Federal University of Minas Gerais, Belo Horizonte, Brazil, [4]Sao Paulo University, Saúde Pública, São Paulo, Brazil, [5]Federal University of Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, [6]Federal University of Bahia, Campus Anisio Teixeira, Vltória da Conquista, Brazil, [7]Universidade Estadual da Bahia, Epidemiologia, Salvador, Brazil, [8]Federal University of Bahia, Saude Coletiva, Salvador, Brazil

BACKGROUND:

PrEP is safe and highly effective in reducing HIV acquisition risk among MSM and TGW. However, concerns remain that risk compensation in PrEP users may lead to decreased condom use and increased incidence of STIs, specially among adolescents for whom data is still scarce. Our objective is to present preliminary data on baseline STI prevalence and behavioral risk factors in a cohort of adolescent (15-19 y.o) MSM and TGW PrEP participating in a research study in three Brazilian cities.

METHODS: Recruitment started in April 2019 in Belo Horizonte, Salvador and São Paulo (Southeast Brazil). We assessed baseline prevalence of syphilis (Rapid Test and/or FTA-Abs and VDRL), chlamydia and gonorrhea (NAAT of pharyngeal, rectal and urethral swabs) and Hepatitis A, B, C (Anti-HAV, HBsAg, Anti-HBc/antiHBs and Anti-HCV respectively). Behavioral data was collected through structured questionnaires.

RESULTS: Data were been presented below:

Demographic data at enrollment (n=289)	
Variables	**%**
Age (>18 years)	55.3

Gonorrhea (193)	18.7
Chlamydia (93)	14

[Figure. Demographic data at enrollment (n=289)]

CONCLUSIONS: There are several barriers regarding PrEP use for adolescents at risk for HIV and this research project is the first in Brazil dealing with them. Our preliminary data on sexual behavior and on HIV and STIs are worrisome. On the former, especially the percentage of condomless anal sex and the use of chem sex (mainly alcohol). On the latter, the prevalence of HIV of 4.6%, especially considering that almost half of the recruited are between 15 and 17 years; the high prevalence of Syphilis (active or previous contact): 17.7% and of gonorrhea (18.7%), as both conditions facilitate HIV transmission; Hepatitis A: 86.1% susceptible which is unacceptable considering that vaccination is available free of cost at the public health system and the known role of sexual transmission of this virus. These preliminary findings reinforce the importance of studying in depth this population and the need to facilitate access to all combined prevention tools, including PrEP for this age bracket.

PEC0625

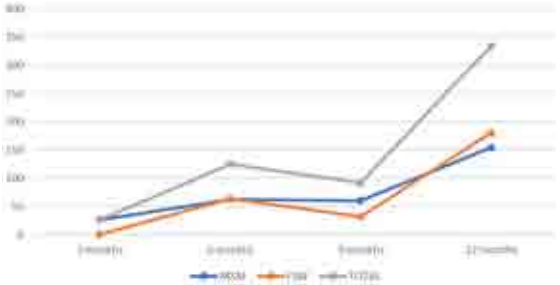
INCREASING KNOWLEDGE OF PRE-EXPOSURE PROPHYLAXIS AMONG KEY POPULATIONS LED TO INCREASED UPTAKE IN BOTSWANA

T. Dima[1], W. Dikobe[1], R. Kereng[1], O. Komotere[1], C. Akolo[2]
[1]FHI 360, Linkages Across the Continuum, Gaborone, Botswana, [2]FHI 360, Linkages Across the Continuum, Washington DC, United States

BACKGROUND: The use of pre-exposure prophylaxis (PrEP) is vital to attaining HIV epidemic control among key populations (KPs) and their sexual partners. The second Behavioral and Biological Surveillance Survey (BBSS2) showed awareness of PrEP is low among KPs (6.6% FSWs; 13.4% MSM). However, there was an increase in HIV prevalence 13.1% in 2012 to 19.1% in 2017 amongst MSM. We implemented PrEP for KPs in a community-based setting.

DESCRIPTION: From October 2018 to September 2019, the PEPFAR/USAID-funded LINKAGES project provided PrEP to KPs using differentiated service delivery models including mobile outreach, drop-in centers, and community-based clinics in Maun, Kasane, Gaborone, Selibe-Phikwe, Palapye-Serowe, and Francistown. PrEP, provided as part of a combined prevention strategy, was offered to all eligible KPs. Peer outreach workers (POWs) were trained on explaining PrEP to KPs and provided information, education, and communication (IEC) materials about PrEP during demand creation activities. They also applied a risk-assessment tool to all KP individuals accessing services through the program and referred those at high-risk with a recent HIV negative or unknown result for further screening and assessment for PrEP eligibility. Eligible KPs were offered and started on PrEP, then linked to a peer navigator (PN) for support.

LESSONS LEARNED: PrEP uptake was slow at first; only 26 MSM enrolled in the first three months. At six months, uptake increased five-fold to 125. At 12 months, 334 had enrolled (Figure 1). After one year, a cumulative total of 576 KP members had been initiated on PrEP.



[Figure 1. PrEP uptake over time, October 2018 to September 2019]

CONCLUSIONS/NEXT STEPS: Scaling up demand for PrEP, particularly among FSWs, by improving knowledge, training POWs and peer navigators, distributing IEC material, and accompanying referrals for those who did not enroll the first time helped improve PrEP uptake among KPs.

PEC0626

STAKEHOLDER PERSPECTIVES ON PROMISING INTERVENTIONS TO IMPROVE PRE-EXPOSURE PROPHYLAXIS (PREP) COVERAGE FOR HIV PREVENTION IN LESOTHO: A PARTICIPANT-RANKED PREFERENCES STUDY

J. Chebet[1], R. Chase[2], S. McMahon[2,3], P. Geldsetzer[4]
[1]University of Arizona, College of Public Health, Tucson, United States, [2]Heidelberg University, Heidelberg Institute of Global Health, Heidelberg, Germany, [3]Johns Hopkins School of Pulic Health, Baltimore, United States, [4]Stanford University, Department of Medicine, Stanford, United States

BACKGROUND: Slow uptake and high discontinuation rates persist as major obstacles to realizing the potential of Pre-Exposure Prophylaxis (PrEP) in changing the trajectory of the HIV epidemic in sub-Saharan Africa. This study aimed to determine which interventions relevant stakeholders view as being most promising to increase PrEP coverage in Lesotho.

METHODS: This study was conducted between March and May 2019 among stakeholders across the health system (N=155). Policy makers (n=4) and implementing partners (n=3) were recruited based on their direct involvement in the development and/or implementation of the national PrEP program. Health providers (n=51) delivered direct PrEP services. End-users were sampled from facility records and selected to participate based on current (n=55) or previous PrEP use (n=36), or PrEP decline (n=36). End users were predominantly young women and included, among others, female sex workers and migrant workers. Participants sorted barriers and interventions for PrEP uptake and retention into pre-selected categories of incremental salience (very, somewhat, and not important). Participants then ranked barriers and interventions in the most salient categories in ascending order of importance separately for men and women. Ranked preferences were treated as voting data and analyzed to identify the Smith Set: smallest set of candidates where each candidate in the set would win a two-candidate election against any candidate outside the Smith Set.

RESULTS: Overall, community-based HIV testing was prioritized as the most helpful intervention to improve overall PrEP uptake, and stigma was ranked as the biggest barrier to PrEP retention. However, gendered differences in preferences emerged, with participants selecting lack of PrEP awareness, and fear of HIV testing as the biggest barriers for uptake for women and men, respectively. For men, factors of daily life and medication regimen were also ranked as significant barriers for retention, and an increase in the quantity of PrEP prescribed was prioritized as an avenue to improve men's retention in a PrEP program.

CONCLUSIONS: Eliciting participant perspectives allowed us to quantify policy-level and end-user priorities. Findings from this study can be applied to the current PrEP scale-up in Lesotho, and more broadly inform emerging PrEP programs in Southern Africa.

PEC0627

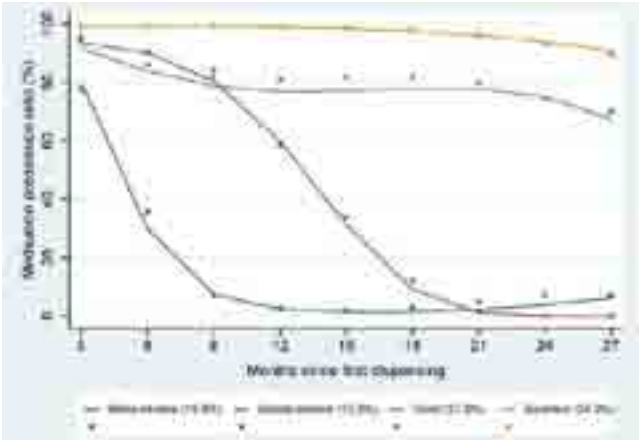
LONG-TERM PATTERNS OF PREP ADHERENCE AND ASSOCIATION WITH HIV SEROCONVERSION IN A LARGE-SCALE IMPLEMENTATION STUDY IN NEW SOUTH WALES (EPIC-NSW), AUSTRALIA

F. Jin[1], R. Guy[1], J. Amin[2], S. Vaccher[1], B. Bavinton[1], C. Selvey[3], I. Zablotska[4], J. Holden[3], K. Price[5], B. Yeung[1], S. Clackett[1], E. Ogilvie[1], A. McNulty[6], D. Smith[7], A. Grulich[1], Expanded PrEP Implementation in Communities New South Wales (EPIC-NSW) research group
[1]University of New South Wales, The Kirby Institute, Sydney, Australia, [2]Macquarie University, Department of Health Systems and Populations, Sydney, Australia, [3]NSW Government, Ministry of Health, Sydney, Australia, [4]Sydney University, Westmead Clinical School, Sydney, Australia, [5]AIDS Council New South Wales, Sydney, Australia, [6]Sydney Sexual Health Centre, Sydney, Australia, [7]North Coast HIV/Sexual Health Services, Lismore, Australia

BACKGROUND: Adherence is critical to the success of HIV PrEP. We report patterns of long-term PrEP adherence and the association with HIV seroconversion in a population-based implementation study in NSW, Australia.

METHODS: EPIC-NSW was an open-label study of daily oral PrEP which recruited from March 2016. Adherence was measured using drug dispensing logs. We defined PrEP discontinuation as a ≥120-day period without PrEP coverage assuming daily dosing. Long-term adherence patterns were identified using group-based trajectory modelling (GBTM) and named by the shape of adherence trajectory. Multinomial regression was used to determine predictors of adherence trajectories and Cox regression to describe the association with HIV seroconversion.

RESULTS: Among 9586 participants who were dispensed PrEP, 6460 (67.4%) were followed for at least nine months by April 2018 and were included in this analysis. Participants were mostly male (98.7%), and identified as gay (92.5%), with a median age of 35 years (IQR: 29-44). Over a median of 19 months of follow-up, PrEP discontinuation occurred in 1942 participants (30.1%). Among these, 292 (15.0%) restarted PrEP later. Four distinct groups were identified using GBTM ("Steep decline", "Steady decline", "Good adherence", and "Excellent adherence", Figure).



[Figure]

Participants in the "Steep decline" group (15.4%) were younger, and at baseline more commonly reported recent crystal methamphetamine use, and a recent STI diagnosis (p<0.001 for both). Overall HIV incidence was 0.92 per 1000 person-years (95%CI: 0.48-1.77; n=9), and was highest in the "Steep decline" group (4.92 per 1000 person-years; p=0.001). No participants in the "Excellent adherence" group seroconverted.

CONCLUSIONS: A minority of participants stopped PrEP early and were at increased risk of HIV infection. They were more likely to be younger and report an episode of STI or methamphetamine use prior to PrEP initiation. Strategies to encourage adherence to PrEP among those at high-risk of HIV should be investigated.

PEC0628

ASSESSING PREP DEMAND AND PREFERENCES TO PROMOTE SCALE-UP AMONG MSM AND MALE SEX WORKERS IN INDIA: A DISCRETE CHOICE EXPERIMENT

P.A. Newman[1], V. Chakrapani[2], M. Cameron[3], M. Shunmugam[2], S. Rawat[4], D. Baruah[4], S. Roungprakhon[5], R. Scarpa[3]
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [3]University of Waikato, Waikato Management School, Hamilton, New Zealand, [4]The Humsafar Trust, Mumbai, India, [5]Rajamangala University of Technology Phra Nakhon, Computer Science, Bangkok, Thailand

BACKGROUND: India has the third largest HIV epidemic globally, with 20-fold higher prevalence among MSM vs. general population. With PrEP demonstration projects being planned, empirical evidence on community demand and preferences can be applied to promote scale-up. We conducted a survey and discrete choice experiment (DCE) to assess demand and preferred PrEP attributes among MSM in India.

METHODS: From 12/2016-03/2017, participants recruited by peer outreach workers from hotspots/cruising areas in Mumbai and Chennai completed an interviewer-administered survey in community-based organization offices. DCE was conducted on Android tablets using choice scenarios of 5 hypothetical, multi-attribute PrEP cards with Tamil/Marathi text and illustrative graphics. In 8 successive double-rounds of choice scenarios, participants chose their "best" and "worst" product out of 5, and then out of 3 remaining cards, using a drag-and-drop technique on the Tablet screen. Additional items assessed demographics, sexual practices, sex work, and willingness to use PrEP. We fitted full ranking data to a multinomial logit likelihood function using the rank-exploded logit model. We then estimated marginal willingness-to-pay (mWTP) and odds ratios from regression coefficients for each attribute, with sub-group analysis by sex work.

RESULTS: Among 200 MSM (mean age, 26.5 years [SD 6.5]; 66.5% < college-degree education), 67.5% reported condomless anal sex, mean number of partners = 6.0 (SD 4.0) (past month), 15.0% forced sex (past year). Half (49.0%) engaged in sex work. Overall, 77.0% indicated willingness to use PrEP. Efficacy had the greatest marginal effect on choice (high vs. moderate, AOR=5.7, 95% CI 4.5 7.3), followed by side effects (none vs. minor, AOR=2.0, 95% CI 1.8 2.4), and dosing (on-demand vs. daily, AOR=1.6, 95% CI 1.5 1.7), with venue (private vs. government hospital) nonsignificant. Sex workers had higher preference for efficacy, and non-sex workers higher preference for on-demand PrEP and preference for government hospitals.

CONCLUSIONS: Educational and social marketing interventions emphasizing high PrEP efficacy and minimal side effects, and programs providing choices of intermittent or daily dosing in both government and private hospitals/clinics will support PrEP uptake among at-risk MSM, including male sex workers. Demonstration projects should monitor uptake/non-uptake, adherence, and evolving preferences to support evidence-informed PrEP scale-up among MSM in India.

PREP USE AND EVOLUTION OF SEXUAL BEHAVIOR FOR MSM IN COHMSM-PREP, A COMMUNITY-BASED COHORT IN WEST AFRICA (ANRS12369 - EXPERTISE FRANCE)

A. Eubanks[1,2], L. Sagaon-Teyssier[1,2], M. Mimi[1,2], B. Dembélé Keita[3], C. Anoma[4], E. Dah[5,6], E. Mensah[7], G. Maradan[1,2], M. Bourrelly[1,2], M. Mora[1,2], L. Riegel[8], D. Rojas Castro[1,8], I. Yaya[9], C. Laurent[9], B. Spire[1,2], CohMSM-PrEP Study Group

[1]Aix Marseille University, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]ARCAD-SIDA, Bamako, Mali, [4]Espace Confiance, Abidjan, Cote D'Ivoire, [5]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [6]Association African Solidarité, Ouagadougou, Burkina Faso, [7]Espoir Vie Togo, Lomé, Togo, [8]Coalition PLUS, Community Research Laboratory, Pantin, France, [9]IRD, INSERM, Univ Montpellier, TransVIHMI, Montpellier, France

BACKGROUND: Although PrEP is being introduced in Sub-Saharan Africa, access remains difficult for MSM. In West Africa, PrEP rollout faces unknowns such as the impact of PrEP on sexual behavior and adherence. We sought to explore the evolution of PrEP use and sexual behavior among West African MSM.

METHODS: In 2017, CohMSM-PrEP, a cohort in Mali, Cote d'Ivoire, Burkina Faso, and Togo, added PrEP to their prevention package. Quarterly follow-up includes the choice of PrEP scheme (daily or on-demand) and the collection of socio-behavioral data. Outcomes included: 1) PrEP use (correct, suboptimal, poor, and no-PrEP), 2) condomless anal sex (CAS) in the last 3 months (yes/no); 3) condomless receptive anal sex (CRAS) during last sex (yes/no); 4) number of male partners (0, 1, and ≥2). Generalized estimating equations (GEE) were used to investigate whether these outcomes changed over time, while adjusting for confounders like country, age, education and PrEP scheme.

RESULTS: 555 MSM were included. PrEP use and sexual behavior concerned 1752 (M3-M15) and 2296 (M0-M15) analyzable questionnaires, respectively. PrEP use decreased during follow-up for correct (aOR:0.70, 95%IC:0.49-0.99, p-value:0.046), suboptimal (aOR:0.45, 95%IC:0.23-0.87, p-value:0.019) and poor use (aOR:0.46, 95%IC:0.31-0.70, p-value:<0.001). When compared to daily users, on-demand users were less likely to use PrEP correctly (aOR:0.32, 95%IC:0.21-0.48, p-value:<0.001) and more likely to use it poorly (aOR:3.82, 95%IC:1.97-7.39, p-value:<0.001). Over time, however, no difference in PrEP use was found between PrEP schemes. Concerning sexual behavior, participants were less likely to have either 1 partner (aOR:0.44, 95%IC:0.28-0.69, p-value:<0.001) or ≥2 partners (aOR:0.63, 95%IC:0.40-0.98, p-value:0.040): i.e. they were more likely to declare no partners. No significant trend for CAS or CRAS was found.

CONCLUSIONS: Globally, PrEP use appears to be coherent and evolve with sexual behavior: less partners and less risk leads to less PrEP use. However, more attention should be given to on-demand users, who seem to struggle to take PrEP correctly. Even though risk behavior seems to remain stable, its frequency remains elevated in this population. This, coupled with low adherence and the absence of other forms of prevention, could compromise PrEP's efficacy and put on-demand users at risk for HIV exposure.

PEC0630

PREDICTORS OF PRE-EXPOSURE PROPHYLAXIS UPTAKE AMONG YOUNG SEXUAL MINORITY MEN AND TRANSGENDER WOMEN IN NEW YORK CITY: A P18 COHORT SUBSTUDY

C. LoSchiavo[1,2], J. Jaiswal[3,2,4], S. Singer[5,2]

[1]Rutgers School of Public Health, Health Behavior, Society, & Policy, Piscataway, United States, [2]Rutgers School of Public Health, Center for Health, Identity, Behavior & Prevention Studies (CHIBPS), Newark, United States, [3]University of Alabama, Tuscaloosa, United States, [4]Yale University, Center for Interdisciplinary Research on AIDS, New Haven, United States, [5]Rutgers Graduate School of Applied and Professional Psychology, New Brunswick, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP), a highly effective form of HIV prevention available since 2012, is still not widely used by those who could benefit. While many studies have examined disparities in access and uptake by demographic factors such as gender and race/ethnicity, fewer studies have examined psychosocial factors such as medical mistrust, PrEP-related stigma, and other beliefs about PrEP. This study examined the demographic and psychosocial factors associated with current PrEP use in a diverse sample of sexual minority men and transgender women in the New York City metropolitan area.

METHODS: The mixed methods Health-Related Beliefs Study took place within the P18 Cohort Study, a prospective cohort study exploring syndemic development in a racially/ethnically and socioeconomically diverse sample of young adult sexual minority men and transgender women. A total of 202 P18 Study participants who were HIV-negative were enrolled in the quantitative study portion. The CASI (computer-assisted self-interview) measured sociodemographic variables, healthcare access and utilization, medical mistrust, PrEP awareness/uptake, and various beliefs about and experiences with PrEP.

RESULTS: Almost all participants were aware of PrEP, but only 23.2% were currently taking PrEP. There were no significant differences in current PrEP use based on key sociodemographic factors such as age. race, health insurance status, and healthcare utilization. PrEP use was less common among those with greater endorsement of HIV/AIDS „conspiracy beliefs" and more mistrustful beliefs about medications. In adjusted regression models, PrEP use was significantly more likely among those who received PrEP info from a healthcare provider and those who believed that they might contract other STIs if taking PrEP made their condom use decrease. Additionally, PrEP use was significantly less likely among those who don't like taking pills if they're not sick, have concerns about remembering to take a daily pill, and are not sure if everyone should take PrEP.

CONCLUSIONS: PrEP is a key component of HIV prevention, but individuals' experiences with and beliefs about PrEP may impact their likelihood of PrEP uptake. Providers should educate all eligible patients about PrEP, and make space to discuss medical mistrust, conspiracy-type beliefs, and other beliefs or concerns that are barriers to PrEP use.

PEC0631

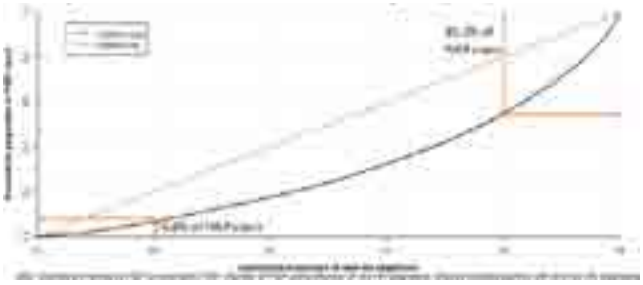
MEASURING NATIONAL DISPARITIES IN PRE-EXPOSURE PROPHYLAXIS (PREP) USE IN US COUNTIES RELATIVE TO PREP NEED IN 2018

F. Mouhanna[1,2], P. Sullivan[3], R. Mera Giler[4], A. Derryck Castel[2], E. Pembleton[3], C. Jaggi[3], M. Kramer[3], P. McGuiness[4], A. Julius Siegler[1]
[1]Emory University Rollins School of Public Health, Department of Behavioral Sciences and Health Education, Atlanta, United States, [2]The George Washington University Milken Institute School of Public Health, Department of Epidemiology, Atlanta, United States, [3]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States, [4]Gilead Sciences, Pharmacovigilance & Epidemiology, Foster City, United States

BACKGROUND: PrEP is an effective biomedical HIV prevention method when adherence and coverage are high, but its use is unevenly distributed across the United States (US). Lorenz curves provide an easy-to-implement metric for health inequalities with diverse potential applications in the HIV prevention field. We sought to measure disparities in PrEP use by US county relative to new HIV diagnoses, a proxy for PrEP need.

METHODS: Lorenz curves compare the distribution of PrEP across counties to an ideal 'line of equality' that assumes PrEP is being prescribed proportionally to the number of new HIV diagnoses in all counties. Lorenz curves were used to compare the cumulative proportion of overall PrEP use to that of new HIV diagnoses by county, ranked by PrEP-to-need ratio (PnR) (Figure 1). PnR is calculated as the number of prevalent PrEP users in 2018 divided by new HIV diagnoses in 2017. We also calculated the Gini coefficient of inequality. Data on PrEP use were obtained from Symphony Health national pharmacy records' aggregator.

RESULTS:



[Figure 1. Lorenz curve of PrEP users versus new HIV diagnoses by county in the U.S. in 2018]

The Lorenz curve demonstrated a large variability in PrEP distribution between counties after adjusting for inequalities in new HIV diagnoses (Gini=0.38198). When ranking counties by PnR, persons living in counties that accounted for the lower 20% of new HIV diagnoses had only 6.6% of PrEP users, while persons living in counties that accounted for the top 20% of new HIV diagnoses had 45.3% of PrEP users.

CONCLUSIONS: PrEP use relative to its need is limited in some counties and highly concentrated in others in the US. This indicates that geography is closely linked to access and may serve as a proxy for structural-level factors. Our findings support policies and programs targeting underserved areas in need for PrEP scale up that may be able to adopt successful strategies from areas with higher PrEP uptake.

PEC0632

AWARENESS ABOUT AND WILLINGNESS TO USE LONG-ACTING INJECTABLE PREP (LAIP) AMONG PEOPLE WHO INJECT DRUGS

R. Shrestha[1], E. DiDomizio[1], R. Kim[1], F. Altice[1], J. Wickersham[1], M. Copenhaver[2]
[1]Yale University, Internal Medicine, New Haven, United States, [2]University of Connecticut, Allied Health Sciences, Storrs, United States

BACKGROUND: Long-acting injectable pre-exposure prophylaxis (LAIP) is being developed as an alternative to the oral form of pre-exposure prophylaxis (PrEP) currently prescribed to individuals at high-risk for HIV infection. People who inject drugs (PWID) are an important target population for the use of LAIP as it has the potential to eliminate concerns of poor adherence to daily oral PrEP. Our study aims to understand the willingness of PWID to use LAIP over daily oral PrEP.

METHODS: Between July 2018 and October 2019, 234 participants were recruited from an inner-city addiction treatment program in New Haven, CT. HIV-uninfected individuals who reported high-risk behavior were asked to completed a questionnaire assessing their knowledge and awareness of daily oral PrEP and LAIP. After a brief description of LAIP, participants were asked about their willingness to use and concerns related to uptake of LAIP. Bi-variate and multivariate analyses were employed for data analysis.

RESULTS: From the sample, 67.1% and 25.6% of participants reported having heard of daily oral PrEP and LAIP, respectively, and 25.6% had ever used daily oral PrEP for protection against HIV. A high proportion of participants (76.9%) voiced worries about long-term side-effects as a potential barrier to uptake for LAIP. Male PWID had lower odds of being willing to use LAIP as compared to females (aOR=0.459, p=0.018). Having visited primary care physician was associated with almost three-fold odds (aOR=2.919, p=0.023). Having high perceived HIV transmission risk (aOR=3.255, p=0.007) and having ever used daily oral PrEP (aOR=3.284, p=0.017) were associated with over three-fold odds of willingness to use LAIP compared to their counterparts.

CONCLUSIONS: This is the first quantitative study to assess the willingness of PWID to use LAIP. Our findings showed that PWID who visit the doctor often and who perceive themselves at high-risk for HIV transmission were more likely to be willing to use LAIP. A majority of participants were concerned with the potential side-effects of LAIP, outlining the need for more information and education on this form of PrEP. Results of this research are fundamental for guiding future efforts for the implementation of a program to incorporate LAIP into preventive medicine for PWID.

PEC0633

FACTORS ASSOCIATED WITH INTEREST IN COMMUNITY PHARMACY DELIVERED PRE-EXPOSURE PROPHYLAXIS AMONGST A COHORT OF PATIENTS SEEKING HIV TESTING: A RETROSPECTIVE COHORT STUDY

M. Lopez[1], N. Koreie[2], S. Wong[1], A. Chimezie[1], J. Cocohoba[2]
[1]Mission Wellness Pharmacy, San Francisco, United States, [2]University of California, Clinical Pharmacy, San Francisco, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP) uptake has been lower than desired in specific populations. California state legislation will soon allow pharmacists to initiate and furnish PrEP without

a prescription, and in other states pharmacists may work under collaborative agreements to furnish PrEP under protocol. Mission Wellness Pharmacy (MWP) provides pharmacy-based HIV, Hepatitis C, sexually transmitted infections (STI) testing and a PrEP program in collaboration with the San Francisco Department of Public Health. The goal of this project was to examine sociodemographic factors associated with interest in a community pharmacy based PrEP program in a cohort of persons who presented to the pharmacy for HIV testing.

METHODS: This is a retrospective cohort study of persons who received rapid HIV testing at Mission Wellness Pharmacy from 3/1/2017 – 4/1/2018, prior to implementation of the One Stop PrEP program. Social and demographic factors were collected for all patients receiving testing. Patients were also asked whether they viewed the pharmacy as a place to receive PrEP. Fisher's exact and Student's T-tests were used to determine associations between demographic/risk factors and interest in pharmacy-based PrEP.

RESULTS: Of 94 persons who presented for HIV testing 3% were taking PrEP and only 53% had heard of PrEP. 81% positively viewed pharmacies as a place to obtain PrEP. There were no statistical differences in pharmacy-driven PrEP interest by gender (p=0.48), having a primary care provider (p=0.44), insurance (p=0.74, none vs. public vs. private), or high-risk sex in the last year (p=0.12). Patients with a higher number of sex partners were more likely to be interested in pharmacy based PrEP (p=0.04). Patients who identified as African American were more divided about their interest (56% interested) as compared to other race/ethnic groups (p=0.04).

CONCLUSIONS: One strategy to encourage PrEP uptake is to provide services in less traditional settings. There was a high degree of interest in community pharmacy based PrEP in a population with varied demographic backgrounds who received HIV testing services in a pharmacy. Pharmacy PrEP programs can potentially reach a wide variety of persons at risk and will be an important point of access in PrEP scale up.

BARRIERS TO UPTAKE AND USE OF ORAL PREP AMONG FSW IN BLANTYRE, MALAWI

j. chinele[1], E. Mgoli1[1,2], G. Kumwenda 1[3], M. Kamtimaleka[2], T. Mnenula1[2], S. Sikwese1[4], F. Gadama2[5], C. Akolo3,[6], C.,. Akolo3[6], D. Chilongozi[2]
[1]Pakachere IHDC, Projects, Blantyre, Malawi, [2]Pakachere IHDC, Clinical, Blantyre Malawm, Malawi, [3]Pakachere IHDC, Programs, Blantyre, Malawi, [4]Pakachere IHDC, Administration, Blantyre, Malawi, [5]FHI 360, Clinical, Blantyre, Malawi, [6]FHI 360, Operations, Lilongwe, Malawi

BACKGROUND: Ministry of Health in Malawi approved the delivery of oral pre-exposure prophylaxis (PrEP) for HIV prevention in 2018. This was followed by the roll-out of the PrEP implementation science project under the USAID/PEPFAR-funded LINKAGES project in February 2019 which aimed to assess acceptability, feasibility and uptake of oral PrEP among female sex workers (FSWs). We present barriers affecting uptake and use of PrEP among FSWs from a qualitative study conducted in Blantyre.

METHODS: Qualitative study using in-depth interviews (IDIs) explored perceptions about PrEP among FSWs unwilling to take PrEP. Participants were recruited from drop in centres at Chirimba, Naperi and Bangwe PrEP study sites in Blantyre. Seven IDIs were conducted among recruited study participants who self-identified as FSW; aged 18 and above; tested HIV negative; and eligible but unwilling to enroll in PrEP. Consent was obtained from all participants and ethical approval obtained from relevant authorities. Data were digitally recorded, transcribed and analyzed thematically to identify barriers of uptake.

RESULTS: Between February and November 2019, 841FSW were screened for PrEP. Out of these, 474 FSW were eligible and enrolled in the study. Of those enrolled, 24 FSW were unwilling to initiate PrEP while 450 FSW initiated on PrEP. Of those initiated, 210 discontinued PrEP. Several factors affected uptake and continuation. These include; myths and misconceptions regarding PrEP; perception that PrEP negatively affects sexual drive as well as fear that HIV treatment will be ineffective if they seroconvert while on PrEP. Other factors included anticipated stigma from sexual partners and peers in case of PrEP being mistaken for HIV treatment, lack of motivation to take PrEP, perceived pill-burden and fear of blood draws for associated tests. One of the recurring reasons for default for those who discontinued PrEP was mobility. This affected follow-up visits and adherence. Despite the barriers, all participants acknowledged the risk of HIV in their personal lives due to indulgence in unprotected sex and multiple concurrent sexual partners.

CONCLUSIONS: Understanding barriers to PrEP uptake is critical in supporting the development of communication and demand creation interventions that address specific reasons that affect decision to initiate on PrEP.

PEC0635

RETENTION IN CARE OUTCOMES AMONG KEY POPULATIONS RECEIVING HIV PRE-EXPOSURE PROPHYLAXIS IN HAITI

M. Leonard Galbaud[1], E.J. Pericles[1], E. Emmanuel[1], S. Smith[2], F. Jean Louis[1], J.W. Domercant[1]
[1]Institut, Pour la Santé, la Population et le Développement (ISPD), Pétion-Ville, Haiti, [2]Programme National de Lutte contre le VIH/SIDA du Ministère de la Santé Publique et de la Population (PNLS/MSPP), Pétion-Ville, Haiti

BACKGROUND: The HIV prevalence in Haiti is 2% among the general population but rises up to 4% in prisoners, 8% in FSW and as high as 18,2% in MSM. To reach the goal of zero new HIV infections by 2030, the National AIDS Control Program launched the pre-exposure prophylaxis (PrEP) in 2019, as part of HIV prevention services offered to key populations (KP) and other high-risk groups in Haiti. This study aims to evaluate PrEP use and retention in care outcomes in KP in Haiti.

METHODS: Medical records of clients screened for PrEP eligibility between March and December 2019 from 8 KP friendly health facilities in Port-au-Prince Haiti, were abstracted. Clients either self-referred or were offered PrEP by clinicians or peer educators, based on known risk factors: Men having sex with men (MSM), female sex workers (FSW), serodiscordant couples (SDC)... Follow-up visits were scheduled every 1–3 months. Clients who did not return within 60 days of a scheduled follow-up visit were considered no longer retained in the program. Cox proportional hazard regression was used to identify factors associated with time to PrEP discontinuation.

RESULTS: A total of 330 clients were medically evaluated for PrEP. The median age was 27 years (interquartile range 10 years). About 32.7% of the participants are identified as MSM, 25.8 as FSW, 18.2 as SDC and 23.3 as others. At enrollment, 3.3% (11/330) were diagnosed with syphilis and 5.8% (19/330) with other sexually transmitted infections. Among the clients who initiated PrEP, median follow-up time was 68 days (range 45–134). The cumulative incidence of discontinuing PrEP services at 6 months was 21% (70/330). MSM, SDC

and FSW were significantly less likely to be retained (adjusted hazard ratio [aHR]:0.16, 95% confidence interval [CI]:0.09–0.29; aHR:0.41, 95% CI:0.22–0.76; aHR:0.31, 95% CI:0.15–0.64 respectively) compared to non-KP clients presenting high risk behaviors. One Client (0.3%) became infected with HIV during the six-month period after being prescribed PrEP.

CONCLUSIONS: Retention in PrEP care was suboptimal among KP in Haiti. Further research is needed to identify the individual, social and structural factors that may impede or enhance retention among KP receiving PrEP care.

PEC0636

KNOWLEDGE OF EVENT-DRIVEN PRE-EXPOSURE PROPHYLAXIS (ED-PREP) AMONG PREP-EXPERIENCED GAY AND BISEXUAL MEN IN AUSTRALIA

B.R. Bavinton[1], C. Chan[1,2], S. Vaccher[1], M. Holt[2], I. Zablotska-Manos[3,4], A. Grulich[1]
[1]The Kirby Institute, UNSW Sydney, Sydney, Australia, [2]The Centre for Social Research in Health, UNSW Sydney, Sydney, Australia, [3]Sydney Medical School - Westmead, University of Sydney, Sydney, Australia, [4]Western Sydney Sexual Health Centre, Sydney, Australia

BACKGROUND: Event-driven PrEP (ED-PrEP) has recently been endorsed in global and national PrEP guidelines as an effective alternative to daily dosing. However, there has not yet been widespread community education about ED-PrEP in Australia. In a sample of PrEP-experienced gay and bisexual men (GBM), we assessed knowledge about ED-PrEP in the absence of community education campaigns.

METHODS: In October/November 2019, 2,164 previous participants of the EPIC-NSW PrEP trial were invited to participate in an optional survey ≥12 months after PrEP became available via public subsidy. Participants were asked if they were aware of ED-PrEP, followed by three multiple-choice knowledge questions: number of pills to take before sex; minimum time before sex to take the loading dose; number of days after last episode of sex that one pill should be taken per day. Associations were examined with multivariate logistic regression; we present adjusted odds ratios (aOR) and 95% confidence intervals (95%CI).

RESULTS: 1,305 men completed the survey. Median age was 35, 92.8% identified as gay and 80.9% were currently taking PrEP. Over two-thirds (n=888, 68.1%) were aware of ED-PrEP. Only 56 of these men (6.3%) used ED-PrEP in the previous 6 months. ED-PrEP-aware men were no more willing to take ED-PrEP than unaware men (43.2% vs 42.0%, p=0.664). Being more socially engaged with gay men (aOR=1.2, 95%CI=1.1-1.4, p<0.001), believing in the efficacy of ED-PrEP (aOR=1.5, 95%CI=1.2-2.1, p=0.004) and higher income (aOR=1.8, 95%CI=1.2-2.6, p=0.004) were associated with ED-PrEP awareness. Of the 888 ED-PrEP-aware respondents, only 109 (12.3%) answered all three knowledge questions correctly, 296 (33.3%) answered 1-2 questions correctly, and 483 (54.4%) answered all questions incorrectly, including 306 (34.5%) respondents who answered "I don't know" to all three questions. The question on how many days after last sex a pill should be taken was the most likely to be incorrect (75.8%). Correct knowledge was higher among ED-PrEP users than non-users (46.4% vs 10.3%, p<0.001).

CONCLUSIONS: Despite most respondents being aware of ED-PrEP, knowledge of dosing requirements was poor. Lack of knowledge about ED-PrEP use was more common than incorrect answers. Community education about ED-PrEP is critical.

PEC0637

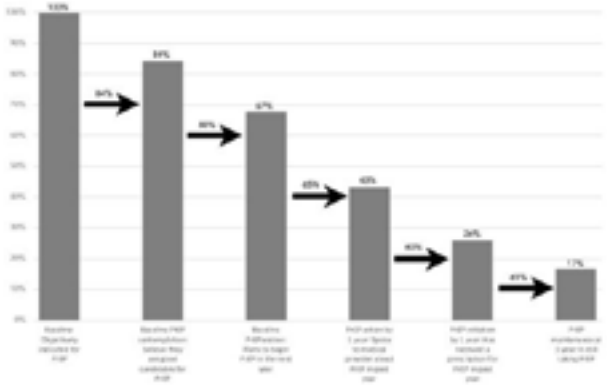
MOVEMENT ALONG THE PREP CASCADE IN A LONGITUDINAL US NATIONAL COHORT OF SEXUAL MINORITY INDIVIDUALS

M.L. Mehrotra[1,1], D.A. Westmoreland[2], V.V. Patel[3], C. Grov[2]
[1]University of California, Epidemiology and Biostatistics, Berkeley, United States, [2]CUNY Graduate School of Public Health & Health Policy, CUNY Institute for Implementation Science in Population Health, New York, United States, [3]Albert Einstein College of Medicine, Division of General Internal Medicine, New York, United States

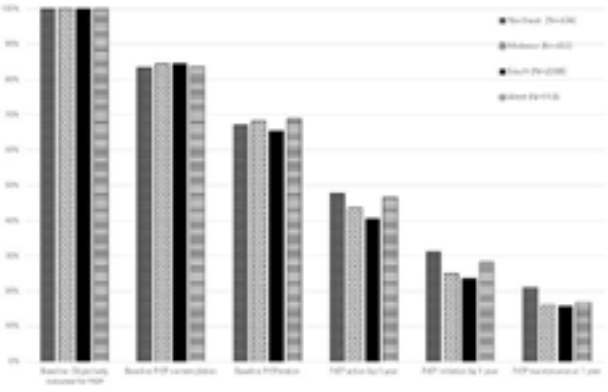
BACKGROUND: Widespread scale-up of PrEP is essential for reducing HIV incidence, but PrEP uptake remains low. The PrEP cascade outlines the necessary steps to maximize PrEP's impact and helps highlight potential intervention targets to improve PrEP implementation.

METHODS: The Together 5000 Study is an internet-based, U.S. national cohort of PrEP-eligible men and trans persons who have sex with men who were not taking PrEP at enrollment. Using longitudinal data from baseline and year one follow-up (N = 4,229), we assessed five steps of the PrEP cascade—PrEP contemplation, PrEParation, PrEP action, PrEP initiation, and PrEP maintenance over the course of one year. We compared the PrEP cascades by region, gender, and race, and identified factors associated with PrEP initiation using unadjusted logistic regression.

RESULTS: After one year, 1092 (26%) participants had initiated PrEP, 709 (17%) were still using PrEP, and 117 (4%) were no longer clinically indicated for PrEP. The largest gap in the cascade was between PrEP action and PrEP initiation (Figure 1).



[Figure 1. The 1 year PrEP cascade in the Together 5000 Study (N=4229)]



[Figure 2. 1 year PrEP cascade by region]

We found differences in the PrEP cascades by U.S. region (Figure 2), but not by gender and race. Baseline characteristics associated with lower odds of PrEP initiation at year one include: not having a college

degree (OR:0.60 [0.52, 0.69]); earning <$20,000/year (OR: 0.67 [0.57, 0.78]); not having health insurance (OR: 0.68 [0.57, 0.81]); having very low food security (OR: .81 [0.68, 0.97]); and not having a primary care doctor (OR: 0.66 [0.57, 0.76]).

CONCLUSIONS: Healthcare access is a major barrier to PrEP implementation.

PEC0638

MIDDLE AND HIGH SCHOOL STUDENT ACCESS TO HIV PREVENTION EDUCATION AND PRE-EXPOSURE PROPHYLAXIS (PREP) IN OAKLAND, CALIFORNIA SCHOOL-BASED AND COMMUNITY HEALTH CENTERS

I. Bertolini[1], E. Gardner[1]
[1]*Oakland Unified School District, Community Schools and Student Services, Oakland, United States*

BACKGROUND: In May 2018, the US Federal Drug Administration approved daily oral pre-exposure prophylaxis (PrEP) for adolescents. However, lack of information, adolescent's inability to navigate the healthcare system, and physicians unwillingness to prescribe PrEP are all barriers to PrEP use by adolescents at risk of HIV. To address this gap, the Oakland Unified School District (OUSD) developed comprehensive sexual health education curricula, with HIV prevention methods inclusive of PrEP, and partnered with 16 School Based Health Centers (SBHC) to provide PrEP to students at school.

DESCRIPTION: Sexual Health Education is delivered in 6th, 7th and 9th grade, including information about PrEP and access to sexual health services. Student knowledge is evaluated through a pre and post assessment. OUSD's SBHCs are operated by six Federally Qualified Health Agencies that provide medical care to students and family members ages 12-24, including prescriptions to same-day PrEP. Ten physicians who provide care to adolescents in SBHCs completed a survey assessing PrEP prescriptions, provider's willingness to prescribe PrEP, and challenges in supporting students to access and adhere to PrEP.

LESSONS LEARNED: During 2017-2018, 7,500 students received OUSD's Sex Education. High School students reported a 19% increase and middle school students reported a 25% increase in knowledge of where and how to access sexual health services. The same school year, 7,249 reproductive health visits occurred in 16 SBHCs; 1522 (21%) of the visits were for HIV screening and 1667 (23%) were for other STI screenings. Most (98.8%) SBHC providers reported they prescribe PrEP but cited challenges with insurance coverage, understanding of minor consent laws, inadequate patient follow up, and patient phobia of needles for HIV screening.

CONCLUSIONS/NEXT STEPS School-based access to PrEP is feasible, acceptable and readily available to young people at school. Opportunities to improve our program include expanding health education, providing professional development to providers to increase willingness to prescribe PrEP, and implementing best practices for student adherence to PrEP. OUSD has created a model that can be adapted by other urban school districts and used successfully to have an impact on overall student wellness.

PEC0639

EXPERIENCES OF ACCESSING HIV PRE-EXPOSURE PROPHYLAXIS (PREP) FOLLOWING INCLUSION ON AUSTRALIA'S SUBSIDISED MEDICINE SCHEME

K. Ryan[1,2], D. Murphy[3,4], J. Asselin[2], M. Traeger[2], C. Bell[5], L. Owen[6], M. Stoove[2], E. Wright[1,2], The PrEPX Study Team
[1]*Alfred Health, Department of Infectious Disease, Melbourne, Australia,* [2]*Burnet Institute, Melbourne, Australia,* [3]*UNSW, Kirby Institute, Sydney, Australia,* [4]*University of Sydney, Dept. of Gender and Cultural Studies, Sydney, Australia,* [5]*Royal Adelaide Hospital, Clinic 275, Adelaide, Australia,* [6]*Statewide Sexual Health Service Tasmania, Hobart, Australia*

BACKGROUND: Little is known about the impact on participants of transitioning from accessing PrEP via a study to accessing PrEP in health care services. We report on experiences of accessing PrEP in the year following inclusion of PrEP on Australia's list of subsidised medicines.

METHODS: PrEPX, a population level intervention study, provided PrEP in three Australian states from July 2016 to national subsidisation of PrEP in April 2018. PrEPX participants (99% gay, bisexual men) were invited to complete an online survey in April 2019. We describe experiences related to PrEP access and use in the year following national subsidisation. Multivariate logistic regression identified covariates associated with continuing PrEP at a non-study clinic. Thematically analysed free text responses to an open-ended question described experiences of post-study PrEP access among all respondents.

RESULTS: Of 4849 PrEPX participants, 1383 (28%) completed the survey, 1277 (92%) reported any post-study PrEP use, and 1161 (84%) were currently using PrEP. Among those reporting post-study PrEP use, few (18%) changed their PrEP provider clinic. Factors associated with changing to a new clinic included age <30years (aOR2.0 95%CI:1.3523.96), not having all anatomical sites tested for STIs at most recent non-study appointment (aOR2.52 95%CI:1.53-4.15), taking a break from PrEP in the previous three-months (aOR1.44 95%CI:1.01-2.07), and not reporting a positive experience at the most-recent non-study clinic (aOR3.91 95%CI:2.31-6.61) or pharmacy visit (aOR1.55 95%CI:1.02-2.35).

Free-text responses indicated a range of negative experiences when attempting to access PrEP in the community, especially when seeking PrEP from doctors and pharmacists with little previous experience providing PrEP. Also, despite these participants having previous experience of PrEP, and perceiving that PrEP was becoming normalized within their communities, many expressed concerns that might affect their continued use, such as side effects, toxicity, cost, and expressed interest in non-daily dosing.

CONCLUSIONS: Most survey respondents transitioned to subsidised PrEP with little change to their PrEP access or patterns of use. However, those who changed PrEP provider had poorer experiences and receiving less thorough sexual-health care. Negative reactions from doctors and pharmacists also suggest a need for increased training for service providers.

PEC0640

DAILY AND EVENT-DRIVEN PRE-EXPOSURE PROPHYLAXIS REGIMENS AND RETENTION LEVEL IN REAL LIFE: A MULTICENTER RETROSPECTIVE COHORT STUDY IN TAIWAN

A.P.-L. Chen[1,2], S.W.-W. Ku[3], I.Y.-H. Chu[4], Y.-T. Chu[2], C.-T. Fang[1]
[1]National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan, Province of China, [2]Taipei Veterans General Hospital, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [3]Taipei City Hospital Renai Branch, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [4]London School of Hygiene and Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom

BACKGROUND: Taiwan implemented daily and event-driven (ED) pre-exposure prophylaxis (PrEP) in 2016 and 2018 respectively. While both regimens have been proved effective among men who have sex with men, the data of their retention rate in real life remains scarce.

METHODS: This multicenter retrospective cohort study was conducted in the PrEP clinics of three hospitals in Taiwan from August 2018 to December 2019. The demographic characteristics and laboratory data were collected at first visit and quarterly follow-ups. PrEP clients were categorized into daily, ED, and mixed (defined as switching between daily and ED regimens more than twice) users. We defined the level of retention based on the number of visits yearly: high (>4), medium (2-3), and low (<2).

RESULTS: Of 541 clients visiting the PrEP clinics, six were diagnosed with HIV at first visit, and 35% did not initiate PrEP. There were 344 clients started PrEP (with a total follow-up of 2,418 person-months); 40% used daily, 44% used ED, and 16% were mixed users. No participant was seroconverted during follow-up.

The mixed users were significantly younger (P<0.001), with longer follow-up time (P<0.001) than the other two groups. Daily PrEP users reported previous use of post-exposure prophylaxis more frequently (P=0.004). Mixed PrEP users had the highest retention level (Ps<0.001) (Figure).

CONCLUSIONS: Our study suggested switching between daily and ED PrEP regimens was not uncommon and did not decrease the retention rate in real life. More efforts should be addressed to facilitate such practice.

	Daily (n=137)	Event-Driven (n=150)	Mixed (n=57)	P value
Male (%)	134 (97)	150 (100)	57 (100)	0.14
Age (Mean±SD)	33.8±8.1	33.4±7.9	28.0±5.8	<0.001 (ANOVA)
Partner with HIV (%)	17 (12)	10 (7)	6 (11)	0.01
Partner with UVL (%)	13 (9)	8 (5)	5 (9)	0.13
Condomless Sex (%)	115 (84)	111 (74)	46 (81)	0.34
History of PEP (%)	44 (32)	27 (18)	9 (16)	0.004
History of syphilis infection (%)	22 (16)	15 (10)	10 (18)	0.22
History of chemsex (%)	38 (29)	27 (18)	11 (23)	0.21
Total follow-up time (person-month)	903	989	526	<0.001 (ANOVA)

[Table. Demographic characteristics of 344 PrEP users in the study.]

PEC0641

BEYOND LABS AND DRUGS: THE COMPREHENSIVE COSTS OF REAL-WORLD PREP IMPLEMENTATION AND SCALE-UP IN ZAMBIA

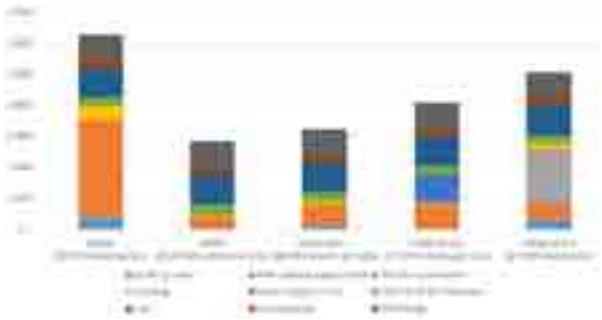
C. Hendrickson[1,2,3], L. Long[1,2,4], C. van Rensburg[1,2], D. van de Vijver[3], C. Claassen[5], M. Njelesani[6], C. Moyo[7], H. O'Bra[8], B. Nichols[1,2,4]
[1]Health Economics and Epidemiology Research Institute, Wits Health Consortium, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, Johannesburg, South Africa, [3]Erasmus University Medical Center, Department of Viroscience, Rotterdam, Netherlands, [4]Boston University, Department of Global Health, School of Public Health, Boston, United States, [5]Center for International Health, Education and Biosecurity (CIHEB), Institute of Human Virology, University of Maryland School of Medicine, C, Lusaka, Zambia, [6]USAID DISCOVER - Health, John Snow, Inc., Lusaka, Zambia, [7]EQUIP, Lusaka, Zambia, [8]United States Agency for International Development, Lusaka, Zambia

BACKGROUND: Pre-exposure prophylaxis (PrEP) is effective at preventing HIV infection, but PrEP cost-effectiveness is sensitive to PrEP implementation costs- for which there is limited data. Preliminary studies indicate that, in addition to direct delivery cost, PrEP provision requires substantial demand creation and user support to encourage PrEP initiation and persistence. We estimated the cost of providing PrEP in Zambia through different PrEP delivery models.

METHODS: We estimated the annual cost of providing PrEP per client for five delivery models: two key population (adolescent girls and young women (AGYW) and men-who-have-sex-with-men (MSM)) and three integrated (operated at primary healthcare centres). Program start-up, provider, and user support costs were based on program expenditure data and number of PrEP sites and clients in 2019. PrEP clinic visit costs were based on micro-costing at two PrEP delivery sites. We took a guidelines-based approach for visits, labs and drugs assuming fidelity to the expanded 2018 Zambian PrEP guidelines for 12-months of PrEP. Costs are in 2018 USD.

RESULTS: The annual cost/PrEP client varied greatly by program type, from <USD300 (MSM) to USD650 (AGYW). Even between the integrated programs there was substantial variation(USD310-USD500). Cost differences were driven largely by volume (clients initiated/

model) which impacted the relative costs of program support and technical assistance assigned to each PrEP client. Service delivery costs were a key component in the cost of PrEP, representing 18%-63% of total costs. Reductions in service delivery costs per PrEP client are expected with further scale-up.



[Figure. Average cost/PrEP client per year; 2019]

CONCLUSIONS: The results show that accessing vulnerable, marginalised populations at substantial risk of HIV infection is likely to cost more than originally assumed even when integrated into full service delivery models. Improved data on patient level resource usage (e.g. drugs, labs, visits) and outcomes (e.g. initiation, persistence) is required to take the next step in estimating expected annual cost of PrEP provision in Zambia.

PEC0642

MINI FREQUENT PREP INFORMATION GROUP SESSIONS HELP RETAIN A HIGH RISK MSM ON PREP FOR LONGER PERIOD OF TIME

M. Akolo[1], J. Kimani[2], R. Gichuki[3], J. Osero[4], L. Gelmon[2], A. Kibera[4]
[1]PHDA, Clinical, Nairobi, Kenya, [2]PHDA/University of Nairobi/Manitoba, Nairobi, Kenya, [3]AMREF, Nairobi, Kenya, [4]Kenyatta, Nairobi, Kenya

BACKGROUND: In Sub Saharan African countries, MSMs have 19.3 folds higher odds of being HIV infected compared with the general population. Kenya MSM have a HIV prevalence of 18.2. PrEP protects up to 90% of HIV infection in those who adhere well. However retention of high risk MSM on PrEP in Kenya has proved to be a challenge
METHODS: This was an experimental design, 168 MSM were initiated on PrEP and simple randomly assigned to either control or treatment arm. Both arms were followed for six months to measure retention on PrEP. Control arm received PrEP as per the government guidelines without any intervention, while the intervention arm had 30 minutes group sessions prior to PrEP refills on each visit that ensured they knew name of PrEP agent, time to swallow in relationship to meals, PrEP side effects, importance of not missing PrEP appointment and strategies to use to ensure they take their pills without fail. The participants who completed the study accessed an endline questionnaire and their baseline responses were compared to their endline responses, McNermar's test was used to check for significance in consistency of their responses
RESULTS: At month six the intervention arm had 58/84(69.0%) MSM still taking PrEP compared to control arm at 16/84(19.0%) irrespective of all 168 being active at the facility and reporting high risk sexual behavior. The study showed no significant difference (p=1) among the control arm participants in ability to identify PrEP agent at baseline (25%) and end-line (25%). However the intervention arm demonstrated significant difference from 45.2% to 98.7% at baseline and end line respectively on ability to identify PrEP agent. At month six 96.8% intervention arm participants knew how to take PrEP in relation to meals compared to 31.2% control arm. While only 8.6% in intervention arm compared to 31.3% control arm had missed taking PrEP pill, 5% intervention arm compared to 34% control arm had missed at least one PrEP appointment. Regression analysis was done and presented in the attached table.
CONCLUSIONS: Policy makers should adopt PrEP mini group sessions to enhance PrEP retention among MSM

PEC0643

HIGH ADHERENCE TO PREP FOR HIV PREVENTION AMONG ADOLESCENTS MEN WHO HAVE SEX WITH MEN (AMSM) AND TRANSGENDER WOMEN (ATGW) IN BRAZIL

L. Magno[1,2], I. Dourado[2], F. Soares[2], M. Eustórgio-Filho[2], D. Ferraz[3,4], E.M. Zucchi[5], T. Fonseca[2,1], P. Caires[1], P. Massa[3], R.G. Vieira[6], M. Westin[7], U. Tupinambas[7], D. Greco[7], A. Grangeiro[3], The PrEP1519 Brazil Study Group
[1]Universidade do Estado da Bahia, Departamento de Ciências da Vida, Savador, Brazil, [2]Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, [3]Universidade de São Paulo, Departamento de Medicina Preventiva, São Paulo, Brazil, [4]Fundação Oswaldo Cruz, Escola Fiocruz de Governo, Brasília, Brazil, [5]Universidade Católica de Santos, Programa de Pós-Graduação em Saúde Coletiva, Santos, Brazil, [6]Universidade de São Paulo, São Paulo, Brazil, [7]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

BACKGROUND: Maintaining a high level of adherence to daily PrEP is a challenge for AMSM and ATGW. Rates of adherence in "real-world" settings remain largely unknown for this group. Our goal is to estimate PrEP adherence among adolescent's key populations in Brazil.
METHODS: Data are from PrEP1519, a first PrEP demonstration cohort study among AMSM and ATGW aged 15-19 yo ongoing in three Brazilian cities, and collected between March-December, 2019. The outcome "self-reported adherence" was categorized in taking <16 (low) and ≥16 pills (high) and measured at two cross sectional periods of the cohort: 1) past 30 days after PrEP initiation and 2) in the last 30th days of use reported by each participant in the last study visit. Descriptive and bivariate analysis conducted.
RESULTS: 205 MSM (89.3%) and TGW (10.7%) aged 15-17 yo (13.7%) and 18-19 yo (86.3%), at least completed study visits at 4 weeks after PrEP initiation. 70.7% (145) self-reported PrEP adherence in 1st measure: 93.1% (CI 95%: 88.9-97.2) high adherence, and slight differences between MSM vs TGW (93.9% vs 86.7%), those engaged in commercial sex vs no (96.1% vs 92.4%), those 15-17 yo vs 18-19 yo (94.1% vs 93.0%) and those reporting unprotected anal sex vs no (94.7% vs 93.1%). There was no difference in demographic profile for those with and without (30%) adherence data. For the last 30 days of PrEP use reported in the last study visit, 90.9% (100) of 110 participants self-report adherence: 94.0% (CI 95%: 89.2-98.7) high adherence, with a similar pattern as for the 1st measure, except for a lower adherence observed among those engaged in commercial sex (83.3% vs 94.5%). No HIV infection detected in 10 months of PrEP enrolment.
CONCLUSIONS: High rates of PrEP adherence were estimated in PrEP1519 study. It may be explained by youth friendly clinics and peer-navigation strategies to retain participants, used in the study. Despite high adherence rates, TGW and those engaging in commercial sex need more attention. Results indicate the feasibility of AMSM and ATGW adhering to daily PrEP, and suggests the pertinence of expanding PrEP offer to adolescents within the Brazilian National Health System.

PEC0645

PREP AS A LAYERED SERVICE FOR DREAMS AND OTHER AGYW IN ZAMBIA: INSIGHTS FOR ROLLOUT FROM THE USAID DISCOVER-HEALTH PROJECT

M. Njelesani[1], M. Nyumbu[1], L. Cicciò[1], C. Madevu-Matson[2], A. Fullem[2], M. Chikuba-McLeod[1]
[1]JSI Research & Training Institute, Inc., Lusaka, Zambia, [2]John Snow, Inc., Boston, United States

BACKGROUND: The USAID DISCOVER-Health Project (DISCOVER), implemented by JSI Research & Training Institute Inc (JSI), supports the Ministry of Health to improve access to and utilization of quality HIV services in Zambia. DISCOVER is among the first MOH-partners to rollout PrEP after May 2018 scale-up approval, and is the partner currently providing oral PrEP services to AGYW in DREAMS districts, using product donated for DREAMS by Gilead Sciences.
DESCRIPTION: Shortly after MOH PrEP scale-up approval, DREAMS PrEP ARVs arrived in-country, requiring DISCOVER to rollout DREAMS PrEP services with both speed and prudence. Three months into program implementation, we undertook a rapid program review to inform future program direction. Below are the challenges/lessons-learned, and the mid-course corrections implemented to improve program effectiveness.
LESSONS LEARNED:

#	Challenge	Course-Correction
1.	Staff not competent to provide PrEP	Training, intensive mentorship and supportive supervision for staff (lay/clinical), to assure quality service-provision across the care-continuum
2.	Limited bandwidth among ART providers to add-on all PrEP service delivery.	Trained RMNCH providers with Option B+ training to provide PrEP (off-site or integrated into FP/MCH services).
3.	Over-crowded clinics - PrEP adding to congestion.	Layered PrEP services onto a successful pre-existing service-mix, off-site, at DREAMS centres.
4.	Staff/provider biases about AGYW taking PrEP – some judgmental/ disapproving.	Retrained/mentored staff, increasing PrEP knowledge-levels and improving interpersonal communication competencies.
5.	High PrEP demand from non-DREAMS AGYW	Obtained flexibility to use DREAMS centres and Gilead product to provide PrEP to non-DREAMS AGYW. Win-win: higher enrolment of older AGYW into DREAMS
6.	Challenging environment for AGYW on PrEP at start-up – delayed official launch of PrEP delayed start-up of community awareness activities for a supportive environment for PrEP	Provided targeted support to AGYW facing parent/guardian PrEP-related challenges; and supported MOH to launch PrEP and develop a national HIV prevention campaign: Zambia Ending AIDS
7.	No competent/motivated peer-mentors for community-based support to AGYW on PrEP.	Recruited DREAMS graduates as peer-mentors/mobilizers. Already HIV-prevention champions. Contributed to program success.

[Table]

CONCLUSIONS/NEXT STEPS Layering PrEP onto successful pre-existing DREAMS-centre-based services provided greater HIV-resilience for AGYW at substantial HIV-risk, while use of program data for mid-course correction increased program effectiveness.

PEC0646

MEN-WHO-HAVE-SEX-WITH-MEN HIV PREP PREVENTION CASCADES ACROSS EUROPE: FINDINGS FROM THE EUROPEAN MSM INTERNET SURVEY 2017

A.J. Schmidt[1], F. Hickson[1], U. Marcus[2], D. Rojas Castro[3], P. Weatherburn[1], The EMIS Network
[1]London School of Hygiene & Tropical Medicine, Sigma Research, London, United Kingdom, [2]Robert Koch Institute, Berlin, Germany, [3]Coalition PLUS, Paris, France

BACKGROUND: Men-who-have-sex-with-men (MSM) are the sub-population at greatest risk of HIV in Europe. HIV pre-exposure prophylaxis (PrEP) has great potential to interrupt transmission. Prevention cascades have been proposed to focus primary HIV prevention programmes on the most commonly unmet needs. We constructed a PrEP cascade for MSM and compared it across 43 countries using data from the European-MSM-Internet-Survey-2017.
METHODS: EMIS-2017 was a multi-language, self-completion on-line survey (10/2017–01/2018) recruiting 122,495 MSM without discrepant data in 50 countries, of whom 109,344 (89.3%) were without diagnosed HIV. We constructed a 5-step PrEP cascade: awareness (heard of PrEP); knowledge (key facts); intention to use (very likely to use PrEP if affordable/accessible); accessibility (tried to get PrEP); current use (daily/on demand). We applied the cascade to multiple countries with different denominator populations of non-HIV-diagnosed MSM (100%): (A) all; (B) reporting two or more episodes of condomless anal intercourse with a non-steady partner, past 12 months (objective risk); (C) disagreeing with 'The-sex-I-have-is-always-as-safe-as-I-want-it-to-be' (subjective risk).
RESULTS: Among men not diagnosed with HIV, 21.1% met the behavioural and 13.2% the subjective risk measure.
Among all men not diagnosed with HIV, awareness was 58.2%, knowledge 32.6% (56.1% of the previous step), intention to use PrEP 10.2% (31.1%), accessibility 4.6% (44.8%), and 3.1% (67.7%) used PrEP daily or on demand. Across 43 countries, variation was large for all steps: awareness 26.7–82.7%; knowledge 11.2–54.6%; intention 1.3–21.9%; accessibility 0.3–12.6%; current use 0–8.4%. The table shows the five steps for the subgroups objectively and subjectively at risk of HIV infection. Among those with objective or subjective risk behaviour, all the cascade steps were better met than among the broader group.

	(A) MSM without diagnosed HIV (N=109,344)		(B) Objective risk MSM not diagnosed with HIV, who had condomless intercourse with 2+ non-steady male partners in the last 12 months (N=23,128)		(C) Subjective risk: MSM not diagnosed with HIV who disagreed To The sex I have is always as safe as I want it to be' (N=14'442)	
	% of all	% of last step	% of all	% of last step	% of all	% of last step
Capacity to benefit	100.0	--	100.0	--	100.0	--
Awareness	58.2	58.2	66.6	66.6	68.3	68.3
Knowledge	32.6	56.1	44.6	67.1	48.7	71.3
Intention	10.2	31.1	23.7	53.0	32.3	66.3
Accessibility	4.6	44.8	14.0	59.2	25.5	79.0
Current use	3.1	67.7	10.7	76.3	23.3	91.5

[Table]

CONCLUSIONS: Awareness and practical knowledge, but also intention to use PrEP among men with objective or subjective HIV risk are currently major gaps in the MSM HIV PrEP cascade. EMIS-2017 data allows the comparison of prevention data across multiple countries/ cities.

PEC0647

INCREASING PREP UPTAKE THROUGH HTS COUNSELOR SENSITIZATION, INTEGRATED SCREENING, AND CLIENT EDUCATION

E. VanderWal[1], M. Mirira[2], N. Lukhele[3], H. VanderWal[4]
[1]Kettering College of Medical Arts, Kettering, United States, [2]University of Stellenbosch, Stellenbosch, South Africa, [3]University of Zimbabwe, Harare, Zimbabwe, [4]Wright State University, Boonshoft School of Medicine, Dayton, United States

BACKGROUND: PrEP (Pre-Exposure Prophylaxis) serves as a powerful new tool for reducing HIV infection for at-risk populations and moving toward epidemic control. In early 2019 in Eswatini, however, few patient education resources existed for PrEP. In some cases, PrEP was seen as a service only for key populations. In response, The Luke Commission (TLC) designed and implemented a PrEP uptake plan. TLC provides free HIV/AIDS testing and treatment in Eswatini as part of a comprehensive healthcare platform reaching over 95,000 patients annually through mobile medical hospital outreaches and at a fixed site in central Eswatini.

DESCRIPTION: TLC integrated PrEP into its healthcare platform through a four-pronged strategy. First, HTS counselors were sensitized to the availability of PrEP for at-risk clients who tested nonreactive (NR). Next, PrEP screening questions were incorporated into a comprehensive patient assessment tool. Third, SMS invitations were designed for index partners, inviting them for a wellness check with TLC that included education about PrEP. Finally, HIV+ clients returning to TLC for a followup visit were invited to bring their partner to the visit.

LESSONS LEARNED: Initial uptake of PrEP was high in the early months of the initiative; however, one-month retention was low as many clients did not return for a first refill. In response, TLC adjusted strategy to focus on more extensive education and counseling about consistent use of PrEP. By including a private code in SMS invitations, indexed HIV-negative clients were identified to counselors without stigma as potential candidates for PrEP.

[Figure. PrEP initiations]

CONCLUSIONS/NEXT STEPS Following the strategy above, TLC initiated 1,862 clients on PrEP between March and November 2019. Providing increased training for staff and analyzing potential entry points to screen for and encourage PrEP initiation significantly increased the number of PrEP patients identified and initiated.

PEC0648

ONLY HALF OF GAY, BISEXUAL AND OTHER MSM MEETING HIGH RISK CRITERIA ACCEPTED REFERRALS TO PREP SERVICES IN TORONTO AND VICTORIA, CANADA: PRELIMINARY FINDINGS FROM THE PRIMP STUDY

D.H.S. Tan[1], K. Fisher[2], S. Mohammed[3], N. Fawcett[4], A. Chris[4], B. Clarke[4], Z. Tengra[5], L. Mitterni[5], C. Fraser[6], M. Selfridge[7], W. Stark[7], S. Bannar-Martin[7], M.W. Hull[3], the PRIMP Study Group
[1]St. Michael's Hospital, Division of Infectious Diseases, Toronto, Canada, [2]University Health Network, Division of Infectious Diseases, Toronto, Canada, [3]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [4]Toronto Public Health, Toronto, Canada, [5]Hassle Free Clinic, Toronto, Canada, [6]Cool Aid Community Health Centre, Victoria, Canada, [7]Vancouver Island Health Authority, Victoria, Canada

BACKGROUND: To maximize the public health impact of HIV pre-exposure prophylaxis (PrEP), health systems should actively link those at greatest HIV risk to PrEP services.

METHODS: PRIMP is a multi-centre Canadian implementation science effort to link gay, bisexual and other men who have sex with men (gbMSM) to PrEP through a cascade of steps: 1) identify gbMSM meeting high-risk criteria, 2) recommend PrEP, 3) client acceptance of the recommendation, 4) referral to PrEP services, 5) PrEP clinic attendance, 6) PrEP initiation, and 7) retention on PrEP. We documented this PrEP cascade among gbMSM seen at eight sexual health facilities in Victoria and Toronto between 12/2018-11/2019. Sequential patients were categorized according to a hierarchy of risk criteria (infectious syphilis, rectal gonorrhea/chlamydia, HIRI-MSM (high incidence risk index for MSM) score ≥25, recurrent post-exposure prophylaxis (PEP) use, 'other') and the proportion completing each subsequent step was tabulated using program data or chart review.

RESULTS: Numbers (% of previous step) of gbMSM meeting each of steps 1-4 are shown in the Table. Common reasons that PrEP was not recommended to gbMSM meeting criteria included already being on PrEP (25.9%) and being HIV-positive (1.4%), although another 4.6% were not offered PrEP for unclear reasons. PrEP was only accepted by 50.2% of clients. Reasons for refusal were similar in Victoria and Toronto, and most commonly related to clients not believing themselves to be at risk for HIV acquisition.

Cascade step	Toronto	Victoria	TOTAL
STEP 1. IDENTIFIED	771	617	1388
STEP 2. PrEP RECOMMENDED	653 (84.7)	292 (47.3)	945 (68.1)
Not recommended; HIV+ or on PrEP	72 (9.3)	307 (49.7)	379 (27.3)
Not recommended; other reason	46 (6.0)	18 (2.9)	64 (4.6)
STEP 3. ACCEPTED PrEP	322 (49.3)	152 (52.1)	474 (50.2)
Declined; Doesn't feel at risk	103 (15.8)	56 (19.2)	159 (16.8)
Declined; Concerned about side effects	17 (2.6)	8 (2.7)	25 (2.6)
Declined; other reason	211 (32.3)	76 (26.0)	287 (30.3)
STEP 4. REFERRED FOR PrEP	322 (100)	151 (99.3)	473 (99.8)

[Table]

CONCLUSIONS: Despite implementing routine procedures at sexual health clinics to recommend PrEP to gbMSM meeting evidence-based criteria, only half of clients were referred. Interventions to aid men in recognizing risk for HIV are urgently needed.

PEC0649

ESTABLISHING A ROBUST PRE-EXPOSURE PROPHYLAXIS (PREP) IMPLEMENTATION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN (AGYW) IN THE DREAMS PROGRAM 2017-2019: THE KENYAN SUCCESS STORY

R.P. Oluoch[1], J. Thiomi[2], L. Otiso[2], P. Patel[3]
[1]Centers for Disease Control and Prevention (CDC), Division of Global HIV and Tuberculosis (DGHT), Nairobi, Kenya, [2]LVCT Health, Nairobi, Kenya, [3]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis (DGHT), Atlanta, United States

BACKGROUND: The Determined, Resilient, Empowered, Aids free, Mentored and Safe (DREAMS) program provides a package of evidence-based HIV prevention interventions including Pre exposure prophylaxis (PrEP) for adolescent girls and young women (AGYW) ages 18-24 years. Kenya DREAMS program pioneered the use of PrEP when there was limited programmatic experience on PrEP implementation among AGYW. We describe the processes, strategies, and lessons leant from the Kenya DREAMS PREP program for possible replication.

DESCRIPTION: A systematic multi-step process inclusive of government, donors, implementing partners, civil society and communities working together was employed. The processes embraced stakeholder input and buy-in and included (1) information gathering and learning from PrEP demonstration projects, PrEP users and other studies; (2) capacity building for implementing partners and health workers (3) facility readiness assessment and commodity needs assessment and distribution strategy; (4) development of materials and tools for service provision, monitoring and evaluation (5) strategies for mobilization; awareness and demand creation. The model of service provision was jointly decided upon by the respective implementing partner and the sub county health officials.

LESSONS LEARNED: Round table discussions with PrEP users from demonstration projects provided valuable inputs for implementation approach. A cascade approach to capacity building for health workers and facility management created demand for service provision. The push strategy adopted for commodity distribution to central facilities ensured proper control. Two models of service provision were employed: facility approach where services are integrated into existing services, and community based where the safe space platform (a non- challenging environment) are used for service provision. The safe space approach is preferred by the AGYWs for PrEP services. There has been an upward trend in uptake of PrEP from 3,444 in 2017 to 6,589 in 2018 and 14,004 as of September 2019.

CONCLUSIONS/NEXT STEPS Successful PrEP implementation among AGYW in Kenya can be attributed to the use of a systematic and collaborative approach to implementation and roll out. The safe spaces platform is more feasible for PrEP implementation as it ensures continuous assessment for the AGYW needs and support. The DREAMS experience was used to inform PrEP roll out among the general population nationally.

SCALE UP OF PEP AND MALE CIRCUMCISION

PEC0650

AN INTEGRATED APPROACH TO CUSTOMARY MALE INITIATION PRACTICES IMPROVES ACCESS TO MALE CIRCUMCISION SERVICES IN EASTERN CAPE, SOUTH AFRICA

N. Igaba[1], S. Groove[1], K. Moyo[1], M. Lambane[2], M. Phohole[1], S. Hlongwane[1], S. Khama[2], Y. Govender[2], C. Bonnecwe[3]
[1]Right to Care, Pretoria, South Africa, [2]PSI, Johannesburg, South Africa, [3]National Department of Health, Pretoria, South Africa

BACKGROUND: Every year in South Africa, thousands of young males participate in Customary Male Initiation (CMI); a significant part of the rite of passage from boyhood to manhood. Safe Male Circumcision is part of the CMI activities of AmaXhosa males in the Eastern Cape Province (EC). We implemented an integrated Voluntary Medical Male Circumcision (VMMC) model into the existing CMI culture.

DESCRIPTION: Right to Care (RTC) and Population for Service International (PSI) implement a VMMC program in five districts (Amathole, Alfred Nzo, OR Tambo, Buffalo City and Chris Hani) in Eastern Cape, South Africa. Integrated CMI support model involved; community entry and stakeholder engagement, advocacy community campaigns, pre-screening of initiates for chronic illnesses; Safe Male Circumcision procedure, Follow-up at day 2 and day 7, adverse events management, and monitoring and evaluation. Dis-aggregated data was collected as per programmatic requirements using standardized National Department of Health (NDoH) tools. Data was captured and stored in a PEPFAR cloud data storage system called DATIM. This data was analyzed using descriptive data analysis, in particular, univariate analysis.

LESSONS LEARNED: Table 1. Results before and after implementation of integration of CMI model in EC, SA.

	Before implementation of integrated model of CMI support		After implementation of integrated model of CMI support	
	Q1 of FY 2016	Q1 of FY 2017	Q1 of FY 2018	Total Q1 of 2016, 2017 and 2018
Total number of males circumcised	2393	4328	37909	44630
Circumcised males between the age of 15-34 years (age pivot)	1784	3413	33338	38535

[Table]

After implementation of the CMI support Model, there was an increase in total number of males circumcised from 6,721 (Q1 of 2016 &2017) to 37,909 (Q1 of 2018). the number of males between the age of 15-34 years (target group) also increased from 5,197 to 33,338 between the two periods. Integrating VMMC in existing CMI activities may have improved access to VMMC services and presented an opportunity to reach the target males between 15-34 years.

CONCLUSIONS/NEXT STEPS The findings of this study indicate that integrated approached to CMI improves access to circumcisions among males 15-34 years, also known as age pivot. This intervention presents an opportunity to reach sexually active males in this pivot age group and subsequently bring immediate impact in reduction of HIV incidence in EC province. Introducing similar model in traditional circumcising communities may increase uptake of VMMC among 15-34 years old.

PEC0651

INNOVATION FOR A SUSTAINED COUNTRYWIDE VOLUNTARY MEDICAL MALE CIRCUMCISION (VMMC) SCALE-UP IN ZAMBIA

R. Kamboyi[1], A. Kaonga[1], O. Chituwo[2], T. Chisenga[1], P. Lukonde[3], J. Zulu[1], T. Mwamba[4]

[1]Ministry of Health, Public Health, Lusaka, Zambia, [2]CDC Zambia, Biomedical Prevention Services, Lusaka, Zambia, [3]Ministry of Health, Clinical Care, Lusaka, Zambia, [4]Clinton Health Access Initiative, Public Health, Lusaka, Zambia

BACKGROUND: Voluntary Medical Male Circumcision (VMMC) has been shown to be effective in reducing the acquisition of HIV by 60% (UNAIDS,2007). Zambia is a high HIV burden country with an HIV prevalence of 13.3% (ZDHS 2018) and began scaling up VMMC for HIV prevention in 2007. MC Prevalence in Zambia according to ZDHS, 2013/14 was at 21.6% and only increased to 27.1% in 2016 (ZAMPHIA 2016).

DESCRIPTION: In 2016 the program began holding more advocacy meetings with community leaders (Traditional, Civic and religious) and conducting roadshows with music artists. VMMC campaign periods were extended from one month to two months for each of the three school holiday periods. Community volunteers were recruited and oriented to mobilize clients for VMMC. More VMMC providers were trained and deployed to conduct outreach and static VMMC services while ensuring a steady supply of VMMC commodities. Community mobilizers and providers were reimbursed a minimum daily allowance of $6 for their transport and lunch during outreach activities. Program coordination and management data were done through the already existing Ministry of Health structures both at national and sub-national levels.

LESSONS LEARNED: Since program inception, there was a steady increase in the number of annual VMMCs performed from 304 in 2007 to 173,992 in 2012. This trend continued up to 2015 when 222,000 VMMCs were performed in a single year bringing the total number of circumcisions to 1.2 million in 9 years. However, when the above strategies were implemented in 2016 numbers exponentially increased from 312,000 in 2016 an average of 485,000 VMMCs per year from 2017 to 2019 bringing the total of VMMCs conducted in only 4 years (2016-2019) to 1.8 million. This already translates into 88% achievement of the country target (2 million) for 2016 to 2020, with a year to go.

CONCLUSIONS/NEXT STEPS Factors associated with increased VMMC uptake in Zambia included: advocacy with various community opinion leaders; minimally incentivized community mobilizers; deployment of more providers; extension of the campaign periods and a steady supply of commodities. Innovative demand and service delivery approaches are key to improving VMMC uptake.

PEC0652

KENYA'S EXPERIENCE WITH INTRODUCTION OF DEVICES INTO VOLUNTARY MEDICAL MALE CIRCUMCISION PROGRAM (2009-2019)

N. Owuor[1], E.O. June[2], C. Laube[3], Z. Mwandi[4], J. Kataka[5], P. Musingila[2], A. Juma[6]

[1]Jhpiego, Programs, Nairobi, Kenya, [2]US Centers for Disease Control and Prevention, Kisumu, Kenya, [3]Jhpiego, Washington DC, United States, [4]Jhpiego, Nairobi, Kenya, [5]Centers for Health Solution, Siaya, Kenya, [6]National STD/AIDS Control Program, Ministry of Health, Nairobi, Kenya

BACKGROUND: From 2009 to 2018, Kenya assessed the PrePex (elastic collar compression) and ShangRing (collar clamp) devices as outlined in the WHO framework for clinical evaluation of male circumcision devices, to explore their utility within the country's voluntary medical male circumcision (VMMC) for HIV prevention programme.

DESCRIPTION: The ShangRing and PrePex devices were first introduced in Kenya in 2009 and 2013, respectively, through implementation pilots (n=40 and n=427, respectively) assessing effectiveness, safety and acceptability. Their safety and operational requirements were further evaluated under active adverse event surveillance (AAES): PrePex in 2016 (n=2,048) and ShangRing in 2018 (n=1,051). Both devices were endorsed for open-ended roll out. Since endorsement, 76 PrePex circumcisions were conducted with one adverse event (AE) (non-fatal tetanus) reported while 194 ShangRing circumcisions have been done with no reported AEs.

LESSONS LEARNED: In pilot studies, both devices were effective, safe and well-accepted. The moderate/severe AE rate in the PrePex pilot was 5.9% (25/427) compared to zero for ShangRing (0/40). Follow up studies showed that ShangRing takes one week and PrePex two weeks longer to heal than conventional surgical circumcision. Under AAES, both devices were well accepted with moderate/severe AE rates of 0.2% (5/2048) for PrePex and 0.3% (3/1,051) for ShangRing, both within Kenya's acceptable rate of 2.0%. Due to a higher risk of tetanus among PrePex clients identified globally, Kenya in 2017 adopted the new WHO recommendation for 2 doses tetanus toxoid (TT) immunization starting 6 weeks prior to device placement. This became an operational challenge to PrePex roll-out. For ShangRing, stock out of some frequently used device sizes was a challenge.

CONCLUSIONS/NEXT STEPS Though PrePex circumcision is simple and effective, requirement for TT immunization prevented its scale up. ShangRing device is safe, simple and effective. In boys 10-14 years old, ShangRing could help eliminate penile glans injuries and urethral fistulas associated with deep stitches during surgical circumcision. The roll-out of ShangRing to scale would confer great public health benefits.

PEC0653

BALANCING PRIORITIES: QUANTITY VERSUS QUALITY WITHIN A VOLUNTARY MEDICAL MALE CIRCUMCISION PROGRAM OPERATING AT SCALE IN ZIMBABWE

V. Murenje[1], B. Makunike Chikwinya[1], J. Hove[2], T. Munyaradzi[3], S. Xaba[4], J. Mandisarisa[5], M. Holec[6], V. Chitimbire[2], M. Tshimanga[3], S. Barnhart[6,7,8], C. Feldacker[6,8]
[1]International Training and Education Centre For Health (I-TECH), Harare, Zimbabwe, [2]Zimbabwe Association of Church-Related Hospitals (ZACH), Harare, Zimbabwe, [3]Zimbabwe Community Health Intervention Project (ZICHIRe), Harare, Zimbabwe, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]U.S. Centers for Disease Control and Prevention (CDC), Harare, Zimbabwe, [6]International Training and Education Center for Health (I-TECH), Seattle, United States, [7]University of Washington, Department of Medicine, Seattle, United States, [8]University of Washington, Department of Global Health, Seattle, United States

BACKGROUND: Since 2013, the local ZAZIC Consortium implemented an integrated voluntary medical male circumcision (VMMC) program in 13 districts in partnership with the Zimbabwe Ministry of Health and Child Care (MOHCC). ZAZIC achieved over 350,000 VMMCs with few reported adverse events (AEs). Ministries and donors set increasingly ambitious VMMC targets and require cost reductions. Qualitative study explores whether intense pressure to do more with less influences program quality. Results inform VMMC program improvement.

METHODS: Key informant interviews (KIIs) with seven site-based VMMC program officers and nine ZAZIC roving-team members were conducted in August 2019. Interviews covered adherence to VMMC standards, demand creation innovations, reaching targets, adverse events, client follow-up and overall program quality. Interviews were recorded, transcribed, and analyzed using Atlas.ti 6.

RESULTS: VMMC teams work nights and weekends in diverse settings using locally-adapted strategies to achieve ambitious targets. Rotating teams of trained VMMC providers ensures continuous service delivery to meet demand. In challenging outreach settings, VMMC procedure safety is prioritized and additional quality assurance (QA) measures help ensure client safety, especially among adolescents. However, KIIs noted three areas where pressure to reach targets and cut costs may compromise safety. First, VMMC teams combine individual and group counselling sessions, potentially reducing client understanding of critical wound care instructions. Second, shortcuts within key infection control practices (handwashing, scrubbing techniques, and preoperative client preparation) may speed VMMC procedures; mild or moderate infections attributable to these shortcuts may be underreported. Lastly, emphasis on numbers at reduced program cost diminishes team commitment to the resource-intensive client follow-up needed to identify complications. In combination with KI observations that circumcision-related stigma reduces client care-seeking behaviours, AEs may be identified late or not reported, lessening program quality.

CONCLUSIONS: The pursuit of ambitious VMMC targets and cost reductions may lead to compromised VMMC service quality. Cost-saving best practices in VMMC should be considered; however, prioritizing costs may have a corrosive effect on the culture of safety. Safeguards must optimize risk reduction over productivity. Increased quality assurance efforts that assure provider adherence to guidelines, encourage AE reporting, and promote quality service provision would balance efforts to increase VMMC productivity at lower cost.

PEC0654

YIELDS FROM VOLUNTARY MEDICAL MALE CIRCUMCISION DATA QUALITY AUDIT: A CASE OF ZAMBIA

J. Zulu[1], W. Mwanza[1], R. Kamboyi[1], T. Mwamba[2], F. Mpasela[2], N. Sinyange[3]
[1]Ministry of Health, Public Health, Lusaka, Zambia, [2]Clinton Health Access Initiative, Lusaka, Zambia, [3]Zambia National Public Health Institute, Lusaka, Zambia

BACKGROUND: Male Circumcision reduces chances of males acquiring the HIV virus through heterosexual intercourse by 60%. Zambia has implemented VMMC since 2007 and uses two data collection systems; the Partner Reporting System (PRS), and in 2013 indicators were introduced in the Health Management Information System (HMIS). This was to ensure collection of all VMMC data including health facilities not supported by partners. In April 2015, a comparative analysis of the 2014 data revealed a large discrepancy between HMIS and PRS (PRS reported 37% more circumcisions). A national data audit was conducted to verify the discrepancy, determine the causes, make recommendations and implement possible solutions.

DESCRIPTION: Purposive sampling of the districts and health facilities was done in five provinces, guided by program data targeting four high-volume facilities (two static and two outreach/mobile) in each of the four selected districts in the province. Client intake forms and registers were reviewed for number of VMMCs performed, comparing them with the PRS and the HMIS in each of the facilities for April-September 2014. Key informant interviews were conducted with providers and supervisors at health facility, district and provincial levels.

LESSONS LEARNED: The audit revealed non availability of source documents at service delivery points, aggregated non-granular data reported by the PRS which could not be traced to the facility and there were poor data capturing and handling practices at service delivery points. This was combined with a weak linkage between program implementation teams and monitoring and evaluation. Recommendations were made to leave source documents at facilities, disaggregate data when reporting and foster linkage between providers and Health Information Officers. There was a marked improvement in 2018 with HMIS reporting 476,396 MCs above the PRS's 257,056.

CONCLUSIONS/NEXT STEPS A large data discrepancy between reporting systems was verified in 2014. A comprehensive monitoring and evaluation system for VMMC requires frequent audits with collaboration from partners, government and all levels of the health system. The discrepancies in the 2014 VMMC data, served as a call-to-action for strengthening the HMIS as the official source of VMMC data. Recommendations from this exercise laid the foundation for data quality improvement, which has been realized in following years.

PEC0655

UPTAKE AND OUTCOMES OF A NOVEL COMMUNITY-BASED POST-EXPOSURE PROPHYLAXIS (PEP) PROGRAM IN RURAL KENYA AND UGANDA

J. Ayieko[1], M. Petersen[2], E. Charlebois[2], J. Peng[2], F. Opel[1], M. Nyanduko[1], J. Kabami[3], M. Kamya[3], E. Bukusi[1], C. Koss[2], D. Havlir[2]
[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]University of California, Berkeley, United States, [3]IDRC, Kampala, Uganda

BACKGROUND: Post exposure prophylaxis (PEP) is a highly effective and complimentary approach to PrEP for HIV prevention; however, in Africa, PEP for sexual exposures is infrequent, under-advertised and highly dependent on access to HIV clinical care sites. We assessed demand, feasibility, acceptability, uptake, adherence and outcomes in a pilot study of a clinic-based patient-centered community program for persons seeking PEP after high-risk sexual exposures.

METHODS: We conducted this pilot study in 5 rural communities in Kenya and Uganda after population-level HIV testing and HIV risk assessment linked to clinics with PrEP programs (SEARCH Trial:NCT01864603). We assessed barriers to PEP in the population and then implemented an intervention that addressed these barriers, building on existing in-country PEP protocols. Additional intervention components were (a)PEP availability 7 days/week, (b)PEP hotline staffed by providers, (c)option for home medication delivery, and (d)facilitation to start or re-initiate PrEP as clinically indicated after PEP completion. The PEP regimens were atazanavir/ritonavir, lamivudine, tenofovir(ATZ/r/3TC/TDF) or dolutegravir(DTG/3TC/TDF). We measured adherence by self-report using three-day recall. Adverse events were measured using DAIDS scale. Successful "PEP completion" was defined as self-reported adherence over 4 weeks of therapy with post-PEP HIV testing.

RESULTS: A total of 124 persons sought PEP; 66% were female, 24% were ≤25 years, and 42% were fisherfolk. Of these, 20% reported exposure with an HIV-discordant spouse, 72% with a new or existing relationship, 7% from transactional sex, and none from rape. 12% of all visits were conducted off-site; 35% of participants had ≥1 off-site visit. No severe/serious adverse events were reported; 7% reported mild nausea, dizziness or malaise that resolved spontaneously. 97% of participants were retained at four week follow-up with 86% reporting adherence over all follow-up visits. 95% were HIV-tested at week 4 follow-up and 88% at week 12. Overall, 85% met the definition of PEP completion. There were no HIV seroconversions.

CONCLUSIONS: Participants in an integrated PEP/PrEP pilot based at community clinics, reporting high-risk exposures, completed PEP with high adherence, few side effects, and no seroconversions. Community-based PEP is an underutilized, on-demand option that compliments PrEP for HIV prevention and expands the reach of current prevention strategies.

PEC0656

ASSOCIATION BETWEEN VOLUNTARY MEDICAL MALE CIRCUMCISION AND HIV RISK COMPENSATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Gao[1], T. Yuan[1], H. Qian[2,3], G. Wu[4], L. Ouyang[4], M. Yu[5], X. Meng[6], S.H. Vermund[2], H. Zou[1,7]
[1]Sun Yat-sen University, Shenzhen, China, [2]Yale School of Public Health, New Haven, United States, [3]Shanghai Jiao Tong University, Shanghai, China, [4]Chongqing Municipal Center for Disease Control and Prevention, Chongqing, China, [5]Tianjin Municipal Center for Disease Control and Prevention, Tianjin, China, [6]Wuxi Municipal Center for Disease Control and Prevention, Wuxi, China, [7]University of New South Wales, Sydney, Australia

BACKGROUND: Voluntary medical male circumcision (VMMC) reduces HIV infection among heterosexual men and, likely, among men who have sex with men (MSM). There are concerns about risk compensation—increased high risk sexual behaviors from a decrease in perceived risk post-VMMC. We reviewed available evidence on the association between VMMC and condom use and number of sex partners among both heterosexual and homosexual men.

METHODS: We searched PubMed, Embase, and Cochrane Library for studies published before April 25, 2019. Interventional and observational studies were included if they contained original quantitative data describing the association between VMMC and condom use and/or the number of sex partners among men. Studies were excluded if circumcision was ritual/religious. We used Mantel-Haenszel random effects model to calculate pooled odds ratio (OR) and 95% confidence interval (95%CI). We assessed risk of bias using the Cochrane Handbook of Systematic Reviews of Interventions and the Newcastle-Ottawa Scale.

RESULTS: A total of 116,330 men from 33 eligible studies (37 different population samples, including 39,647 MSM and 76,683 heterosexual men) were included in our analysis. Pooled effects showed no association between VMMC and condomless sex (OR 0.98, 95%CI:0.85-1.12; k=33; I^2=87.2%) and no association between VMMC and multiple sex partners (OR 1.07, 95%CI:0.95-1.21; k=28; I^2=87.2%). Post-surgery data did not find evidence of VMMC-associated risk compensation either among heterosexual(condomless sex: OR 0.95, 95%CI:0.81-1.12; k=25; I^2=89.6%; multiple sex partner: OR 1.07, 95%CI:0.92-1.25; k=22; I^2=87.4%) or MSM(condomless sex: OR 1.08, 95%CI:0.96-1.21; k=8; I^2=0%; multiple sex partner: OR 1.04, 95%CI:0.97-1.12; k=5; I^2=0%). VMMC was associated with decreased odds of condomless sex in the last sexual encounter (OR 0.82, 95%CI:0.70-0.97; k=12; I^2=80.2%).

CONCLUSIONS: The promotion of circumcision as an HIV preventive measure does not appear to increase risky sexual behaviors in both heterosexual and homosexual men. Education is of vital importance to the scaling up of VMMC programs.

INTEGRATING STI, SEXUAL AND REPRODUCTIVE HEALTH AND HBV AND HCV SERVICES IN HIV PREVENTION PROGRAMMES

PEC0657

INCIDENCE RATE OF SEXUALLY TRANSMITTED INFECTIONS IN ADOLESCENT YOUNG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN USING PRE-EXPOSURE PROPHYLAXIS IN THAILAND

W.N. Songtaweesin[1], S. Kawichai[1], P. Panichnantakul[2], J. Moonwong[1], N. Wacharachaisurapol[3,1], T. Pankam[4], T.R. Cressey[5,6,7], T. Theerawit[1], S. Teeratakulpisarn[4], N. Phanuphak[8], T. Puthanakit[1,9], CE-PID - TRC Adolescent Study Team
[1]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Bangkok, Thailand, [2]McGill University, Department of Anatomy and Cell Biology, Faculty of Medicine, Montreal, Canada, [3]Chulalongkorn University, Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Department of Pharmacology, Faculty of Medicine, Bangkok, Thailand, [4]Thai Red Cross AIDS Research Center, Anonymous Clinic, Bangkok, Thailand, [5]Chiang Mai University, PHPT/IRD UMI 174, Faculty of Associated Medical Sciences, Chiang Mai, Thailand, [6]Harvard T.H Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [7]University of Liverpool, Department of Molecular and Clinical Pharmacology, Liverpool, United Kingdom, [8]Thai Red Cross AIDS Research Center, Prevention, Bangkok, Thailand, [9]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand

BACKGROUND: Scale-up of pre-exposure prophylaxis (PrEP) in Thailand has led to growing concern of a consequential increase in the incidence of sexually transmitted infections (STIs). Our aim was to describe STI incidence rates and their associated factors in adolescent PrEP users in Thailand.

METHODS: Participants were included from a cohort of adolescent men who have sex with men (MSM) and transgender women (TGW) receiving an HIV prevention package including (1) a daily oral TDF/FTC PrEP regimen (2) routine STI screening and (3) HIV risk reduction counseling. Urine and anal swab nucleic acid amplification screening tests for Neisseria gonorrhea (NG) and Chlamydia trachomatis (CT) and syphilis serology were performed at baseline and month 6 following PrEP initiation. PrEP adherence, number of sex partners and self-reported consistent condom use were analyzed for associations with STI incidence using Poisson regression. PrEP adherence was categorized by TFV-DP concentrations in dried blood spot samples (fmol/punch) into poor (<350), moderate (350-700) and good (>700).

RESULTS: Between March 2018 and June 2019, 200 adolescents (147 MSM, 53 TGW) with a median age of 18 years (IQR 17-19) were enrolled. At baseline, 84% reported inconsistent condom use in the past month. Baseline prevalence of any STIs was 23% (95%CI 17, 28). STIs included 30 CT, 15 syphilis, and 9 NG, all but 2 were asymptomatic. All received STI treatment. Self-reported consistent condom use in the past month increased from 16% to >50% at months 3 and 6 follow-up (p<0.001). Of 144 adolescents who received STI screening at month 6, there were 17 new episodes of STIs, all were asymptomatic. STI incidence rate was 25.2 per 100 person-years (95%CI 14.7, 40.3).
Associated factors with STI incidence were self-reported >2 sex partners in the past month (adjusted RR 4.2, 95%CI 1.0-18.1) compared to none, and moderate (adjusted RR 3.5, 95%CI 1.1-11.5) compared to poor PrEP adherence.

CONCLUSIONS: Despite increased rates of condom use during PrEP program participation, incidence rates of STIs among adolescent MSM and TGW remained high. Most STIs were asymptomatic, therefore routine STI screening and treatment should be integrated into HIV prevention packages to maximise sexual health benefit of high-risk adolescents.

PEC0658

UTILITY OF PSA TO ASSESS SELF-REPORTED PROTECTED SEX AMONG HIV DISCORDANT COUPLES

A. Matubu[1], S. Kasuso[1], F. Mhlanga[1,2], S. Gitome[3], B. Mateveke[2], N. Mgodi[1], C. Murombedzi[1], P. Musara[1], G. Chareka[1], C. Chasakara[1], J. Kitagawa[4], T. Chirenda[1], C. Smith[4], M. Chirenje[1,2,4], J. Brown[5]
[1]University of Zimbabwe, College of Health Sciences - Clinical Trials Research Centre, Obstetrics & Gynaecology, Harare, Zimbabwe, [2]University of Zimbabwe College of Health Sciences, Obstetrics & Gynaecology, Harare, Zimbabwe, [3]Centre for Microbiology Research, Kenya Medical Research Institute, Nairobi, Kenya, [4]University of California, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [5]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: Understanding sexual practices among HIV discordant couples desiring pregnancy is critical for designing effective safer conception programs. Self-reported sexual behavior may be biased, thus use of objective biomarkers of sexual activity, such as prostate specific antigen (PSA), may be beneficial. We measured the utility of, and agreement between self-reported sexual behavior and PSA testing in the context of a safer conception study for HIV discordant couples in Zimbabwe.

METHODS: Discordant couples desiring conception were enrolled in a prospective, non-randomized, safer conception study and offered a choice of one or more HIV prevention strategies (antiretroviral therapy, oral pre-exposure prophylaxis, vaginal insemination, semen washing). Couples were followed for 12 months. At each monthly visit, data were collected on sexual behaviors including condom use during the past 48 hours, and a clinician-collected vaginal swab was used to test for PSA using ABAcard®p30. Monthly visits were carefully timed to occur outside of the female fertile period, when all couples were counselled to use condoms 100% of the time.

RESULTS: Twenty-three HIV discordant couples were followed from April 2017–June 2019; in 12 of the couples the female partner was HIV-positive. Median age was 31 years for females, 34 years for males. Couples completed a total of 216 monthly visits with no loss-to-follow-up. The majority (71.4%) of vaginal swabs tested negative for PSA (n=152/216). However, half of the couples (n=13/23; 57%) had one or more positive PSA test results (median=2, IQR=2-3), for a total of 64 (29.6%) positive PSA tests. Among patient-visits with a positive result, 20.3% occurred when the participant reported no sex during the past 48 hours, and 46.9% when the participant reported 100% condom use.

CONCLUSIONS: PSA testing provided an objective measure of condom use among discordant couples trying to conceive, showing that half of the couples had condomless sex and the majority of these couples misreported condom use. This is of concern given the high HIV transmission risk among discordant couples. Programs designed to measure exposure and transmission risk would be advised to adopt rapid, objective biomarkers such as PSA to improve accuracy of measurement.

PEC0659

INCREASED SYPHILIS TESTING AND TREATMENT UPTAKE AMONG TRANSGENDER WOMEN CLIENTS WITH FREE TESTING AND SAME-DAY TREATMENT AT TANGERINE COMMUNITY HEALTH CLINIC IN BANGKOK, THAILAND

K. Samitpol[1], R. Janamnuaysook[1], P. Getwongsa[1], A. Chancham[1], J. Kongkapan[1], T. Amatsombat[1], J. Rueannak[1], P. Srimanus[1], J. Peelay[1], O. Nampaisan[1], R. Sungsongkiat[1], M. Avery[2], S. Mills[2], R. Vannakit[3], P. Phanuphak[1], R. Ramautarsing[1], N. Phanuphak[1]
[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]FHI 360, LINKAGES, Bangkok, Thailand, [3]Office of Public Health, USAID Regional Development Mission Asia, Bangkok, Thailand

BACKGROUND: Syphilis could enhance HIV acquisition and syphilis/HIV co-infection are common among key populations, including transgender women (TGW). Thailand's Universal Health Coverage (UHC) provides free HIV testing but not syphilis testing. We explored syphilis testing uptake before and after it was made available free of charge, as well as linkage to syphilis treatment before and after same-day treatment was provided, among TGW at Tangerine Clinic in Bangkok, Thailand.

METHODS: Tangerine Clinic offers gender-affirming care and sexual health services. TGW could access free twice-a-year HIV testing under UHC. Free syphilis testing was provided through the USAID LINKAGES program since October 2017. Same-day benzathine penicillin injection for syphilis became available in January 2018. We examined uptake of syphilis testing, syphilis and HIV prevalence, and linkage to treatment, as well as TGW characteristics who received syphilis-related services from November 2015 to October 2019.

RESULTS: Of 2,926 TGW clients, 1,738 (59.4%) had syphilis testing with prevalence of 9.3%. HIV testing uptake was 94.4% and 9.5% were tested HIV-positive. Syphilis/HIV co-infection was found among 52 TGW (3.0%) out of 1,715.

In the pre-free syphilis testing period (November 2015-September 2017), 64.7% of the clients were tested. In the post-free syphilis testing period (October 2017-October 2019), 57.7% of the clients were tested. Syphilis prevalence among TGW tested when the testing was free was 10.8%, which was significantly higher than 5.1% prevalence among those tested when it was not free (p=<0.001). TGW who tested when syphilis testing was not free were more likely to be employed than those tested when it was free (79.0% vs. 69.7%, p=<0.001), although more than half shared similar age group and education.

In the pre-same-day treatment period (November 2015-December 2017) 47.7% received treatment with unknown timeframe. In the post-same-day-treatment period (January 2018-October 2019) 81.2% were able to get treated, which is significantly higher (p=<0.001) and the majority of them received same-day treatment or within 1 week.

CONCLUSIONS: We found high prevalence of syphilis and syphilis/HIV co-infection among TGW. Treatment rate also increased with same-day linkage. National HIV program should integrate free syphilis testing and same-day treatment as part of comprehensive health service package for TGW.

PEC0660

TEMPORAL TRENDS IN POSTPARTUM LONG-ACTING REVERSIBLE CONTRACEPTION (LARC) UPTAKE AMONG WOMEN LIVING WITH HIV IN ZIMBABWE, 2012-2018

L.A. Hunter[1], E.L. Sibanda[2], L.J. Ralph[3], M.-S. Kang Dufour[4], N.S. Padian[1], A. Mushavi[5], F.M. Cowan[2,6], S.I. McCoy[1]
[1]University of California, School of Public Health, Berkeley, United States, [2]Centre for Sexual Health and HIV/AIDS Research (CeSHHAR), Harare, Zimbabwe, [3]University of California, Bixby Center for Global Reproductive Health, San Francisco, United States, [4]University of California, Division of Prevention Science, San Francisco, United States, [5]Ministry of Health and Child Care, Harare, Zimbabwe, [6]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

BACKGROUND: Zimbabwean women living with HIV (WLHIV) experience higher rates of unintended pregnancy and maternal mortality than HIV-negative women. Long-acting reversible contraceptives (LARC) are highly effective at preventing pregnancy, yet demand remains low. Additionally, many clinicians impose unnecessarily restrictive eligibility criteria that prevent WLHIV from accessing LARC. In light of LARC scale-up in Zimbabwe over the past decade, including programs strategically targeting postpartum women, we examined temporal trends in postpartum LARC uptake from 2012-2018, both overall and among WLHIV.

METHODS: We used three serial population-based cross-sectional surveys conducted in 2012, 2014, and 2018 to elucidate changes in postpartum LARC uptake. Women with infants born 9-18 months before each survey were randomly sampled from catchment areas of 157 health facilities offering PMTCT services. We restricted our sample to biological mothers ages 16-49 (n=26,315). Participants self-reported their current (postpartum) contraceptive use; HIV serostatus was directly measured for >90% of participants. We estimated prevalence differences (PD) in LARC use across survey years using generalized linear models and generated stratified estimates by HIV status.

RESULTS: Postpartum LARC use doubled between 2012 and 2014 (4.4% vs. 10.6%). This increase was larger among WLHIV (5.4% in 2012 vs. 14.6% in 2014; PD: 9.2; 95% confidence interval [CI]: 6.4, 11.9) than among women without HIV (4.2% vs. 10.0%; PD: 5.8; CI: 4.3, 7.3). However, the difference in LARC use between WLHIV and women without HIV was attenuated between 2014 and 2018, during which time LARC use modestly decreased among WLHIV (14.6% in 2014 vs. 11.6% in 2018; PD: -3.0; CI: -7.6, 1.6) but remained constant among women without HIV (10.0% vs. 10.0%; PD: 0.0; CI: -2.3, 2.3). The interaction between survey year and HIV status was significant (p<.04).

CONCLUSIONS: After doubling between 2012 and 2014, postpartum LARC uptake stagnated among women without HIV and decreased among WLHIV between 2014 and 2018. Additional research is necessary to understand supply- and demand-side factors underlying overall low uptake of LARC and the recent decrease in postpartum LARC uptake among WLHIV in order to inform strategies to increase access to methods to prevent unintended pregnancy.

PEC0661

INTEGRATION OF HIV AND SYPHILIS SCREENING IN INDIA: CURRENT SCREENING PATTERNS IN STI CLINIC ATTENDEES AND PREGNANT WOMEN (PW)

R. Sindhu[1], A.K. Puri[1], S.P. Bhavsar[1], V. Yadav[1], S. Shah[2], S.S. Venkatakrishnan[2], Y. Bansal[2], S. Garg[2], U. Chawla[2]
[1]National AIDS Control Organisation, Basic Services Division, New Delhi, India, [2]William J. Clinton Foundation, New Delhi, India

BACKGROUND: STI/RTI control is an effective strategy for preventing HIV transmission and would support achievement of the country's AIDS elimination goal. The National AIDS Control Organisation (NACO) and the National Health Mission (NHM) also jointly administer the prevention of vertical transmission of HIV & Syphilis program and universalised screening of PW in 2014. However, Syphilis screening of the estimated ~30 million PW lags behind HIV screening by 33%. Further, no recent estimates of syphilis prevalence for non-ANC populations exist. This paper examines screening patterns for individuals attending Designated STI/RTI Clinics (DSRCs) and PW arriving at public HIV testing facilities (ICTCs), in order to support program intervention design and strengthen integration.

METHODS: Program data from April 2018 to March 2019 across ~1,160 DSRCs and ~31,800 ICTCs was analysed to quantify HIV and Syphilis screening rates and reactivity. Screening gap was defined as difference between HIV and Syphilis screening rates (against estimated PW). General Clients (GCs) were defined as non-ANC individuals who did not self-identify into an HIV high risk-group. PW syphilis reactivity was not reported due to on-going national data-cleaning exercise.

RESULTS: Of the ~4.8 million GCs (Men:34%, Women: 66%) arriving at DSRCs, 63% were screened for syphilis, and 0.54% were found reactive (Men: 0.95%, Women: 0.3%). Only 45% GCs were referred for HIV screening, with 0.3% found reactive (Men: 0.57%, Women: 0.23%). At these rates, up to 7,985 and 9,675 cases of HIV and Syphilis respectively could have been missed due to incomplete screening. At ICTCs, 10.1 million fewer PW were screened for syphilis than HIV. Screening gap varied widely across facilities - 54% at screening ICTCs, 31% at confirmatory ICTCs, and 70% at public-private-partnership ICTCs.

CONCLUSIONS: As the country moves towards HIV/AIDS elimination, it is critical to shift focus from testing to treat, to testing to prevent and ensure integrated health service delivery. 100% HIV and syphilis screening for individuals attending DSRCs and ICTCs, especially for PW will help fast-track this. A few interventions the program can explore are – introducing universal HIV screening at DSRCs and syphilis screening at ICTCs, strengthening coordination between NHM and NACO, and utilising Dual HIV/Syphilis RDTs.

DEVELOPING TAILORED AND COMPREHENSIVE SERVICES FOR SPECIFIC KEY AND VULNERABLE POPULATIONS

THREE YEARS OF A HIV/STI PREVENTION PROGRAM THROUGH GEOLOCATION APPS IN BARCELONA, SPAIN

M. Alarcon Gutierrez[1,2,3], M. Fernández Quevedo[4], R. Guayta-Escolies[5,6], M. Alberny Iglesias[7], R. Ruiz Riera[8], P. García de Olalla[1,3]
[1]Agència de Salut Pública de Barcelona, Servei d'Epidemiologia, Barcelona, Spain, [2]Universitat Autonoma de Barcelona, Departamento de Pediatria, Obstetricia y Ginecologia y de Medicina Preventiva, Cerdanyola del Vallès, Spain, [3]Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [4]Agència de Salut Pública de Barcelona, Preventive Interventions and Programs Service, Barcelona, Spain, [5]Consell de Col·legis de Farmacèutics de Catalunya, Barcelona, Spain, [6]Universitat Ramon Llull, Facultat de Ciências de la Salut Blanquerna, Barcelona, Spain, [7]Institut Català de la Salut, Departament de Salut, Generalitat de Catalunya, Gerència Territorial de Barcelona, Barcelona, Spain, [8]Generalitat de Catalunya, Departament de Salut, Direcció Estratègica Atenció Primària, Barcelona, Spain

BACKGROUND: Men who have sex with men (MSM) are a high risk population to get sexually transmitted infections (STI). New prevention strategies for reaching hidden populations are needed. The aim of this study was to determine the response rate, acceptability and effectiveness of a program who offers rapid STI testing through dating Apps.

METHODS: We offered rapid STI testing (HIV, syphilis and hepatitis C) by sending private messages on gay Apps from December 2015 until September 2019. Main outcomes were: response rate between contacted users; acceptance as proportion of favorable responses between responders; and effectiveness as the proportion of users who attended our centers between contacted users. Sociodemographics, sexual behaviors and App usage variables were collected from the users who attended our centers. A descriptive analysis was carried out. To identify associated variables to the messages's response, multivariate logistic regression was used. Adjusted Odds ratio (ORa) and 95% confidence intervals (CI) were calculated.

RESULTS: 5,221 individual messages were sent. The response rate reached 32.9% (N=1,720), acceptance was 86.2% (N=1,483) and effectiveness 8.3% (N=458). Additionally, 3.2% (N=169) received online counselling about sexual health. Factors significantly associated with the response of the message in multivariate analysis were: displaying a picture in the App without bare chest or abdomen (OR: 1.42; CI:1.16-1.74), connection schedule at the moment of the message or during last hour (OR:1.62; CI:1.21-2.15) and sent message after 5 pm (OR:1.21; CI:1.01-1.45). Among tested users 37.5% (n=446) had not taken a HIV test for over a year, 21.7% (n=97) had any STI diagnosis during previous year, 43.4%(n=194) had reported anal sex without condom with non-steady partners, and 41.8% (n=187) had consumed drugs for having sex. Positive testing for HIV was 1.8% (n=1), syphilis 2.7% (n=9) and hepatitis C 0.3% (n=1).

CONCLUSIONS: The response rate, acceptance and effectiveness observed in this program indicates that this strategy was a useful tool for promoting STI testing among the MSM population. This program was capable of reaching Apps users with high prevalence of STI, who engage in risky sexual behaviours, consume drugs during sex, and do not routinely take the HIV test.

PEC0663

FACTOR ANALYSIS OF HIV PREVENTION INTERVENTIONS FOR HIGH-RISK ADOLESCENT GIRLS AND YOUNG WOMEN IN THE DREAMS (DETERMINED RESILIENT EMPOWERED AIDS-FREE MENTORED AND SAFE) PROGRAM IN UGANDA (2016-2019)

R. Apondi[1], A.C. Awor[1], R. Wanyenze[2], H.S. Kiyingi[1]
[1]Centers for Disease Control and Prevention, Kampala, Uganda, [2]Makerere University, School of Public Health, Kampala, Uganda

BACKGROUND: Combined evidence-based HIV prevention interventions targeting adolescent girls and young women (AGYW) have not been evaluated. United States President's Emergency Fund for AIDS Relief -funded DREAMS, provides evidence-based HIV prevention interventions, targeting high-risk AGYW aged 10-24 years in 15 high (>7%) HIV prevalence districts in Uganda. We identified latent factors that may help reduce HIV incidence among AGYW.

DESCRIPTION: We analyzed DREAMS Uganda program data collected January 2016 to September 2019. We included 81,762 AGYW confirmed HIV negative at least 12 weeks after enrolment followed in an open cohort design who were tested for HIV sero-conversion. We conducted exploratory factor analysis leading to theory driven grouping as follows: Group A: Biological prevention (condoms and contraceptive methods); Group B: Social Protection (economic strengthening services, parenting support and communication and relationship skills); Group C-Keep Girls in School (education subsidy, school-based HIV and violence prevention); and Group D, post violence care. We then developed possible variable combinations from groups A, B, C and D and conducted confirmatory factor analysis, with varimax rotation maintaining only items with factors loading alpha >0.6; the analysis produced a 14-item, four factor scale.

LESSONS LEARNED: Table-1: Rotated Factor Pattern for Standardized Loadings Model of Prevention Packages, Uganda DREAMS Program 2016-2019

	Factor 1 Risk Reduction	Factor 2 Girl Empowerment	Factor 3 Resilience	Factor 4 Post Violence Care
A	0.94170			
A+D	0.90122			
A+B	0.83636			
C		0.95257		
C+D		0.84763		
B			0.94720	
B+D			0.86908	
D				0.93840
Variance (% variance)	6.73 (49%)	3.14 (23%)	1.98 (14%)	1.25 (9%)

[Table]

Confirmatory factor analysis yielded four factors explaining approximately 95% of the variance in the data. Factor-1, (Risk Reduction) accounts for 49% of data variance extracting biological and post violence care interventions highest; Factor-2 (Girl Empowerment) explains 23% of data variance extracting social protection and post violence care interventions highest. The overall observed incidence rate was 0.113/100PY (CI 0.09-0.131).

CONCLUSIONS/NEXT STEPS Our results suggest that risk reduction and girl empowerment combination interventions may have the highest impact on HIV incidence reduction among high-risk AGYW. They will be important variables to consider when investigating the overall impact of DREAMS prevention activities in the cohort.

PEC0664

ACCELERATED HIV INCIDENCE REDUCTION AMONG HIGH-RISK ADOLESCENT GIRLS AND YOUNG WOMEN IN DREAMS (DETERMINED RESILIENT EMPOWERED AIDS-FREE MENTORED AND SAFE) IN UGANDA (2017–2019)

R. Apondi[1], I. Sebuliba[2], L.J. Nelson[1], J. Cheptoris[3], S. Kyobutungi[4], S. Alamo-Talisuna[1], M. Okwero[1], A. Nakirijja[5], J. Hegle[6], H.S. Kiyingi[1]
[1]Centers for Disease Control and Prevention, Kampala, Uganda, [2]Makerere University, School of Public Health - Monitoring and Evaluation Technical Support, Kampala, Uganda, [3]Ministry of Health, Kampala, Uganda, [4]United States Agency for International Development, Kampala, Uganda, [5]Makerere University Walter Reed Project, Kampala, Uganda, [6]Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: HIV prevalence among Ugandan adolescent girls and young women (AGYW; aged 10–24 years) is four times higher than among male counterparts. We enrolled AGYW into DREAMS (Determined Resilient Empowered AIDS-free Mentored and Safe), an evidence-based HIV prevention program that targets high-risk AGYW. We evaluated the AGYW population effect of providing prevention in a layered approach on HIV incidence among AGYW aged 15–24 years.

DESCRIPTION: We collected program data from DREAMS beneficiaries receiving a multi-pronged combination of prevention interventions along with their parents/caregivers, sexual partners, and communities in 15 districts with high (>7%) HIV prevalence and AGYW population in Uganda (January 2016–September 2019). Districts were grouped by homogeneous HIV characteristics in three geographical clusters. Overall, 237,432 AGYW confirmed HIV negative at least 12 weeks after enrollment were followed in an open cohort design. They received prevention interventions by risk profile and risk-based HIV testing. Using the AIDS Impact Model in SPECTRUM version 5.76, we modeled the expected HIV incidence rates (IR) for AGYW population without DREAMS inputs in the three DREAMS clusters. We then compared the expected HIV incidence rates with observed rates in the DREAMS program (January 2017–September 2019).

LESSONS LEARNED: DREAMS program observed 178 new HIV infections over 77,860.45 person years (PY), with median follow-up of 0.729 PY. Across all three clusters, observed IR was lower than modeled IR, with the highest difference in Central 2 cluster (69%) and the lowest difference in the Mid-Northern cluster (25%). The overall observed incidence rate (IR) was 0.23/100 PY (95% confidence interval [CI]: 0.20–0.26), which was 45% lower than overall modeled IR of 0.41/100 PY (95% CI: 0.40–0.43).

	Baseline - SPECTRUM 2016		SPECTRUM 2017-2019 (A)		DREAMS 2017-2019 (B)		% difference (A-B)/A
	Cases/ Denominator	IR/100 PY (95% CI)	Cases/PY	IR/100 PY (95% CI)	Cases/PY	IR/100 PY (95% CI)	
Overall	3262/ 636,900	0.51 (0.50-0.53)	8525/ 2,014,350	0.42 (0.41 - 0.43)	178/77, 860.45	0.23 (0.20 - 0.26)	45
Mid Northern	1015/ 230,500	0.44 (0.41- 0.47)	2653/ 731,700	0.36 (0.35 - 0.38)	97/35, 340.91	0.27 (0.22 - 0.33)	25
Central 1	975/ 149,340	0.65 (0.61- 0.70)	2709/ 464,050	0.58 (0.56 - 0.61)	44/10, 999.70	0.40 (0.29 - 0.54)	31
Central 2	1271/ 257,060	0.49 (0.47- 0.52)	3163/ 818,600	0.39 (0.37 - 0.40)	37/ 31519.85	0.12 (0.08 - 0.16)	69
Abbreviations: IR, incidence rate; PY, person-years; CI, confidence intervals.							

[Table 1: Modeled expected HIV incidence rates compared to observed rates in DREAMS (Determined Resilient Empowered AIDS-free Mentored and Safe), for adolescent girls and young women aged 15–24 years in Uganda (2017–2019)]

CONCLUSIONS/NEXT STEPS DREAMS implementation decreased new HIV infections by 40% among high-risk AGYW in high HIV prevalence districts. Targeting high-risk AGYW with layered HIV prevention interventions not only protects AGYW from HIV but also may decrease population-level incidence and accelerate HIV epidemic control.

PEC0665

REDUCING HIV RISK VIA STRENGTHENING RESILIENCE IN MSM IN CHENNAI AND MUMBAI, INDIA: A RANDOMIZED CLINICAL EFFICACY TRIAL

S. Safren[1,2], B. Thomas[3], K. Biello[4,2], K. Mayer[2,5], S. Rawat[6], A. Dange[6], C.A. Bedoya[7,8], S. Menon[9], V. Anand[6], V. Balu[3], C. O'Cleirigh[8,7,2], S. Swaminathan[3,10], M. Mimiaga[4,2]
[1]University of Miami, Psychology, Miami, United States, [2]Fenway Health, The Fenway Institute, Boston, United States, [3]National Institute for Research in Tuberculosis, Chennai, India, [4]Brown University School of Public Health, Providence, United States, [5]Harvard Medical School, Boston, United States, [6]Humsafar Trust, Mumbai, India, [7]Massachusetts General Hosptial, Psychiatry/Behavioral Medicine, Boston, United States, [8]Harvard Medical School, Psychiatry/Psychology, Boston, United States, [9]Sahadoran, Chennai, India, [10]World Health Organization, Geneva, Switzerland

BACKGROUND: Men who have sex with men (MSM) in India are a key population at risk for HIV acquisition and transmission. They are also an extremely marginalized and stigmatized population, facing immense psychosocial stressors and socio-cultural challenges. Self-acceptance appears to be key to fostering resilience in this population. Current HIV prevention intervention programs in India have not focused sufficiently on these issues, and are largely driven by condom promotion and HIV testing.
METHODS: 608 MSM (mean age=26.2, SD=6.3; baseline STI prevalence=33%, HIV prevalence=9.5%) with risk for HIV acquisition or transmission from Chennai and Mumbai, India were equally randomized to either standard HIV/STI testing, or standard HIV/STI testing and a self-acceptance based psychosocial HIV prevention intervention, consisting of group (4-session) and individual (6-sesson) counseling. Primary outcomes included self-reported number of past-month condomless anal sex (CAS) acts and STI incidence at 12-months. Hypothesized mediators related to resilience included self-acceptance and self-esteem. $\chi 2$ tests were used to examine group differences in annual STI incidence, and negative binomial and linear mixed effects models were performed to examine group differences in changes in CAS acts and the hypothesized mediators, respectively, over 4 time-points (baseline, 4-, 8- and 12-months).
RESULTS: A significant interaction ($\chi 2$=40.29, 3df, p<.0001) indicated that the intervention group had a 56% larger reduction in CAS acts from baseline to 4 month follow up (95%CI=35%-71%, p<.0001) and 72% larger reduction from baseline to 8 (95%CI=56-82%, p<.0001) and 12 (95%CI=53%-83%, p<.0001) month follow up compared to control group. Additionally, the intervention group had a larger improvement in resilience: the self-acceptance and self-esteem variables, compared to the control group (both p's<.01). Of those HIV-negative at baseline, 12-month incidence (n=470) was 3.8% (post-hoc exploratory analyses=no significant main effect for the intervention).
CONCLUSIONS: An intervention focused on fostering resilience and reducing CAS was efficacious in reducing CAS, and hypothesized mediators self-acceptance self-esteem in high risk Indian MSM. However, annual STI incidence did not differ. HIV prevention intervention programs for this key population should consider addressing mental health needs in this way, potentially also integrating PrEP to augment this effective psychosocial intervention for effective HIV control in India.

PEC0666

DISABLED PERSONS' KNOWLEDGE ABOUT HIV INFECTION AND THEIR ACCESS TO HIV/AIDS INFORMATION AND SERVICES IN AFRICA: A SYSTEMATIC REVIEW

I. Olufadewa[1,2], M. Adesina[2,1,3], M. Ekott[2], O. Adeyemo[2], O. Iyiola[2]
[1]University of Ibadan, College of Medicine, Ibadan, Nigeria, [2]Slum and Rural Health Initiative, Research Academy, Ibadan, Nigeria, [3]Universal Care for Africa Foundation, St. Louis, United States

BACKGROUND: While several studies have explored the disabling consequences of HIV/AIDS and reported a higher risk of HIV transmission among people with disabilities, there has been no consensus evidence on disabled persons' knowledge about HIV infection and their access to HIV/AIDS information and services in Africa. We conducted a systematic review of the literature to also enable the government, funders, and partners to make better evidence-informed decisions on HIV/AIDS interventional programs for disabled persons.
METHODS: An electronic search of 9 databases (PubMed, Google Scholar, SCOPUS, Web of Science, HINARI, Cochrane Library, JURN, CINAHL, and DOAJ) was conducted. We also searched the references of eligible studies and sent emails to six authors for other relevant peer-reviewed studies to include in this systematic review. All studies were screened independently by two reviewers using the eligibility criteria and relevant data was synthesized and analyzed in accordance with the PRISMA guideline.
RESULTS: Eighteen studies (15 qualitative and 3 mixed method) comprising 5,709 people with disabilities (ranging from physical to intellectual disabilities) conducted across Africa met the eligibility criteria. Most studies found low levels of knowledge about HIV among disabled persons, with females tending to have lower levels of knowledge than males. There were huge gaps in the knowledge base of persons with disabilities, including the misconception that HIV infection could occur through mosquito bites. Also, there was poor access to HIV services among disabled persons: most of the deaf respondents reported difficulties in communicating with healthcare staff, print materials were not adapted for the blind and those with physical impairments were often unable to access health centers. These challenges were similar across many African countries except for some favorable experiences in accessing HIV services reported in Uganda and Zambia, where disability-tailored services were offered by some NGOs and government facilities.
CONCLUSIONS: Disabled persons have poor knowledge of HIV/AIDS and have been historically marginalized in their access to HIV information and services in Africa. There is an urgent need for training of healthcare workers and targeted interventions focused on enhancing communication through concrete examples, visual representations, and a gestural system (sign language) for inclusive HIV/AIDS programs.

PEC0667

PACT: A RANDOMIZED CONTROLLED TRIAL TO EVALUATE EFFECTIVENESS OF IMPLEMENTING A COUPLE-BASED HIV/STI PREVENTION INTERVENTION FOR MEN IN COMMUNITY CORRECTIONS IN NEW YORK CITY

L. Gilbert[1], D. Goddard-Eckrich[1], T. Hunt[1], E. Wu[1], M. Chang[1], N. El-Bassel[1]
[1]*Columbia University, Social Intervention Group, NY, United States*

BACKGROUND: Although accumulating research indicates that men in community correction programs (CCPs) and their female partners are at disproportionately high risk of acquiring HIV and other STIs, to date, no couple-based HIV or STI prevention interventions have been implemented for this population. This study evaluated the effectiveness of implementing a 5-session couple-based prevention intervention, compared with a 1-session counseling, testing, and referral (CTR) program, in reducing HIV and STIs as well as condomless intercourse among men in CC and their female sexual partners.

METHODS: A randomized clinical trial was conducted from July 11, 2013 through May 17, 2016. Participants were drug-involved men mandated to community corrections and their female sexual partners (n = 230 couples or 460 individuals). Participants were recruited from various CC sites in New York, New York, and randomized into either the PACT (Protect And ConnecT) intervention condition or the HIV CTR control condition (n = 115 couples or 230 individuals in each arm). Analysis of outcomes used an intent-to-treat approach. Repeated measures on sexual behaviors in the past 90 days were collected to assess behavioral outcomes at baseline and 3, 6, and 12 months. Biological indicators of HIV and STIs were collected at baseline and 12 months.

RESULTS: The mean (SD) age of participants was 35.0 (12.8) years, and most participants (341 [74.1%]) self-identified as African American. Compared with the control participants, PACT participants had 33% fewer acts of condomless vaginal and/or anal intercourse with their main partner (incidence rate ratio [IRR], 0.67; 95% CI, 0.45-0.99; P = .04), 70% fewer acts with other partners (IRR, 0.30; 95% CI, 0.12-0.74; P = .009), and 40% fewer acts with all sexual partners (IRR, 0.60; 95% CI, 0.42-0.85; P = .005) and fewer sexual partners in the past 90 days (IRR, 0.74; 95% CI, 0.61-0.88; P = .001) over the follow-up period. At 12 months, HIV and STI incidence did not differ significantly between the 2 arms.

CONCLUSIONS: The PACT intervention appeared to reduce risky sexual behaviors, such as condomless intercourse; this finding suggests that a couple-based HIV and STI prevention intervention program may curb HIV and STIs among men in CCPs.

PEC0668

ASSOCIATION BETWEEN GENDER, SEXUAL ORIENTATION AND HEALTHCARE ACCESS IN AGEING ADULTS: A CROSS-SECTIONAL STUDY

M.R. Furst Crenitte[1,2], L.R. de Melo[1], W. Jacob-Filho[1], T.J. Avelino-Silva[1,3]
[1]*University of Sao Paulo, Division of Geriatrics, São Paulo, Brazil,* [2]*Universidade Municipal de São Caetano do Sul, Medical School, São Paulo, Brazil,* [3]*Faculdade Israelita de Ciencias da Saúde Albert Einstein, São Paulo, Brazil*

BACKGROUND: Health indicators show that Lesbian, Gay, Bisexual, Transgender, and related communities (LGBT+) are subject to significant disparities regarding health services utilization. Few studies have addressed the subject, especially in older LGBT+ adults. Our aim in this study was to examine the association between gender, sexual orientation, and healthcare access in ageing adults.

METHODS: We designed a cross-sectional study including Brazilian participants aged ≥50 years (Aug2019-Dec2019). We circulated an anonymous online health survey to collect the data. The study was approved by the local institutional review board and requested free and informed consent for participation. Our dependent variable was poor healthcare access, measured using the Primary Care Assessment Tool (PCATool-Brasil; score=0-10, 0=worst) and defined as the lowest score quintile. Our independent variables were gender (cisgender man/woman, transgender man/woman, transvestite, non-binary gender, other) and sexual orientation (heterosexual, homosexual, bisexual, pansexual, other). We grouped participants as non-LGBT+ or LGBT+ and investigated their association with poor healthcare access in a multivariable logistic regression model, stratified according to dependency in the public healthcare system and adjusted for possible confounders.

RESULTS: We included 5,838 participants. Overall, the median age was 60 years, 4,020 (69%) were female, and 1,064 (18%) were LGBT+. We found 60 adults (1%) living with HIV in the non-LGBT+ group and 135 (13%) in the LGBT+ group. A total of 259 (24%) LGBT+ adults answered that their primary care physicians were unaware of their gender identity or sexual orientation. The mean PCATool-Brasil score was 5.8 (±2.0) in the non-LGBT+ and 5.2 (±2.1) in the LGBT+ group. PCATool-Brasil scores under 4.0 defined the lowest quintile of healthcare access. Non-LGBT+ and LGBT+ groups had 882 (18%) and 322 (30%) of participants with poor healthcare access, respectively. After multivariable analysis, we verified that being LGBT+ was independently associated with poor healthcare access both in participants not dependent in public healthcare services (prevalence ratio [PR]=1.43; 95% confidence interval [95%CI]=1.21-1.71) and in those dependent (PR=2.60; 95%CI=2.07-3.27).

CONCLUSIONS: Being LGBT+ was independently associated with poor healthcare access in Brazilian ageing adults. Policymakers should be aware of the barriers facing this population and structure more inclusive healthcare systems.

PEC0669

HIV POST-EXPOSURE PROPHYLAXIS FOLLOWING SEXUAL VIOLENCE: WHO ARE THE VICTIMS MISSING THE TIME WINDOW FOR PREVENTION?

I. Nisida[1], M.-I. Boulos[1], L. Cuello[1], A. Segurado[1], V. Avelino-Silva[1]
[1]*Faculdade de Medicina da Universidade de São Paulo, Infectious and Parasitic Diseases, Sao Paulo, Brazil*

BACKGROUND: Sexual violence (SV) is a widespread and under-reported public health problem. Prophylaxis for sexually transmitted infections is an essential part of care for SV victims. However, post-exposure prophylaxis (PEP) for HIV can only be administered when patient admission occurs within 72 hours of the SV episode.

METHODS: In this cross-sectional study, we compared SV victims who sought care ≤72h or >72h after the SV episode. We analyzed demographic, clinical, and SV-related variables using chi-squared tests, Wilcoxon Rank-Sum tests, and a multivariable logistic regression model.

RESULTS: We included 482 SV victims who visited a specialised unit at a university hospital in Sao Paulo, Brazil, between 2000 and 2018. Overall, 208 victims (43%) sought care >72h after the SV episode; demographic, clinical, and SV-related characteristics are presented in

Table 1. SV victims who missed the time window for HIV PEP were younger, less educated, and more often male, of black/mixed race, and physically or mentally disabled. They also more frequently described suffering chronic/repeated assaults at or near home, perpetrated by known persons. Although victims seeking care ≤72 hours of the SV episode suffered physical intimidation more frequently, verbal intimidation was more common in those seeking care >72h. Only a minority of victims (19%) reported the SV episode to the police. In a multivariable logistic regression including age, sex, race, schooling years and physical/mental disability, male sex (OR=1.79, 95%CI 1.15-2.79; p=0.011), black/mixed race (OR=1.63, 95% CI 1.06-2.52; p=0.026) and education (OR per additional schooling year 0.94, 95%CI 0.89-0.99, p=0.024) remained significantly associated with admission >72h after SV.

Variables	Total, N=482	Admission ≤72h after SV, N=274	Admission >72h after SV, N=208	p-value
Female sex (%)*1	350 (73)	216 (79)	134 (65)	0.001
Age ≤13 years old (%) 14-17 years old (%) ≥18 years old (%)	19 (11-28) 152 (32) 70 (15) 260 (54)	22 (15-29) 60 (22) 34 (12) 180 (66)	15 (9-26) 92 (44) 36 (17) 80 (38)	<0.001 <0.001
Race/skin color*2 White/Asian (%) Black/mixed (%)	 341 (71) 136 (29)	 205 (76) 66 (24)	 136 (66) 70 (34)	 0.021
Schooling years*3	8 (4-11)	10 (6-11)	8 (2-11)	<0.001
Physical/mental disability (%)*4	36 (8)	14 (5)	22 (11)	0.023
Chronic/recurrent violence*5	101 (21)	11 (4)	90 (44)	<0.001
Assault at/near home	165 (34)	55 (20)	110 (53)	<0.001
Known perpetrator*7	200 (45)	74 (29)	126 (67)	<0.001
Type of intimidation Verbal (%) Physical (%) Cold weapon (%) Firearm (%)	 181 (38) 353 (73) 28 (6) 44 (9)	 78 (28) 216 (79) 21 (8) 29 (11)	 103 (50) 137 (66) 7 (3) 15 (7)	 <0.001 0.001 0.046 0.203

Table 1:

CONCLUSIONS: SV victims who missed the time window for HIV PEP were more often male and socially vulnerable individuals. They were also at a higher risk of domestic sexual abuse. Policy makers should prioritise this population in interventions aiming to improve access to timely medical care.

PEC0670

INTEREST IN THE DELIVERY OF HIV PREVENTION SERVICES THROUGH A GEOSOCIAL NETWORKING APP AMONG MEN WHO HAVE SEX WITH MEN IN CHINA

L. Wang[1], A. Siegler[2], G. Mi[3], D. Zhang[3], F. Yu[3]
[1]Emory University/Danlan Beijing Media Limited, Beijing, China, [2]Emory University/Rollins School of Public Health, Atlanta, United States, [3]Danlan Beijing Media Limited, Beijing, China

BACKGROUND: The growing HIV burden among Chinese men who have sex men (MSM) is partially due to the low use of HIV prevention services. Blued, a widely used social networking app for MSM, has approximately 40 million registered users. Alternative service delivery models through such an app may improve the uptake of preventive services among Chinese MSM.

METHODS: We used data from a large, cross-sectional survey of Chinese Blued users, focusing on items that explored willingness to use HIV prevention interventions through the app. Eligible MSM were aged over 18 years and geolocated in survey deployment areas. Four online services were considered: HIV home tests and condoms mailed to an individual's residence, online HIV risk screener, and pre-exposure prophylaxis (PrEP) referral to local providers. We used univariate and multivariate assessments to explore factors associated with the willingness to use each service.

RESULTS: A total of 4,266 participants were in the final analysis. Most participants (89.2%) had an interest in using at least one online HIV prevention service through Blued (67.4% in HIV home test mailing, 59.2% in condom mailing, 57.1% in online risk screener, and 32.8% in PrEP referrals). About 20% of participants who had never tested for HIV and 37% did not test for HIV in the past six months indicated they would order HIV testing kits online. 26.9% of participants who had inconsistent condom use in the past six months said they would use a condom mailing service. MSM who were young, had higher education, used recreational drugs, or had tested for HIV in the past six months were more likely to use online HIV prevention services. Previous PrEP knowledge was strongly associated with willingness to use a PrEP referral service.

CONCLUSIONS: The availability of HIV prevention services in online contexts is of high interest to MSM, especially to those who are not currently accessing those services. This indicates a substantial promise of this strategy, if even a fraction of users that state willingness would eventually uptake such prevention services. Online and geosocial networking platforms have enormous user bases, and it is essential for public health programs to appropriately leverage them.

PEC0671

HEALTH CARE ACCESS AND PROGRAMMATIC GAPS: FACILITATORS AND BARRIERS FOR MEN HAVING SEX WITH MEN (MSM) IN RURAL INDIA

S. Bangar[1], U. Mohan[2], S. Kumar[3], A. Mahapatra[4], S. Singh[2], R. Kohli[5], A. Verma[5], V. Verma[6], P. Saravanamurthy[7], B. George[7], S. Rajan[8], S. Sahay[5]
[1]ICMR-National AIDS Research Institute, Epidemiology, Pune, India, [2]King George's Medical College, Department of Community Medicine, Lucknow, India, [3]All India Institute of Medical Sciences, Department of Community & Family Medicine, Bhopal, India, [4]ICMR-Regional Medical Research Center, Epidemiology Division & CPIO, Bhubaneswar, India, [5]ICMR-National AIDS Research Institute, Social and Behavioral Research, Pune, India, [6]National AIDS Control Organisation, Evaluation & Operational Research, New Delhi, India, [7]FHI 360, Linkages-India, New Delhi, India, [8]National AIDS Control Organisation, Ministry of Health and Family Welfare, New Delhi, India

BACKGROUND: Despite the „Link Worker Scheme" under India's national program, many men having sex with men (MSM) remain unreached, especially in rural India. This study explored issues around health care access among MSM in rural settings of India.

METHODS: Eight FGDs, 20 KIIs and 20 IDIs were conducted in 4 rural (R) sites from Maharashtra (MH), Odisha (OR), Madhya Pradesh (MP) and Uttar Pradesh (UP) of India between 2018 and 2019.

RESULTS: Lack of ambient services was the major reason for not accessing government health setting:*"I go to a government hospital it will get unnecessarily advertised. We don't get good treatment too over there in the government hospital" (*MH-R-ID-01). Fear of stigma transformed into fear of breach of confidentiality was evident. *"...they get fear to go hospital because they know that in hospital will not maintain confidentiality because they are local people. If society will know about them then family life will disturbed"* (OR-R-KI-04). Government targeted intervention services did not seem to be optimally advertised as people showed lack of information about it: *"There is no such center [/HIV testing center/] here, and if so then I do not*

have knowledge about it. This test [/HIV test/] may happens in the government hospital but I do not have much knowledge about it" (MP-R-ID-10). Lack of MSM focused health services emerged as gap: *"For our gay community, there is no health facilities for us. Yes, in our village ASHA and Anganwadi workers are there but they basically work for ladies. If we MSM face some health problem then we cannot tell them. Because in our village we cannot say to ASHA Didi"* (OR-R-ID-01), *"...If Government will give one person from our community, then we can openly tell them about our entire health problem"* (OR-R-ID-01).

CONCLUSIONS: Primary barriers to access were lack of knowledge, program invisibility in rural settings, beliefs, and quality of services, stigma experienced, at government health facilities. There is a need for establishing MSM friendly health clinics to improve health care access in rural MSMs. Stigma reduction activities for acceptance of MSM in the rural health setting requires structural interventions.

PEC0672

REACHING SOUTH AFRICAN MEN AND YOUTH WITH MOBILE HIV COUNSELLING AND TESTING OVER SEVEN YEARS: A RETROSPECTIVE, LONGITUDINAL STUDY

P.J. Smith[1], H. Green[2], D. Joseph Davey[2,3], M. Cornell[3], L.-G. Bekker[1]
[1]University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, [2]University of California, Department of Epidemiology, Los Angeles, United States, [3]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa

BACKGROUND: Although HIV testing rates have improved, many South Africans remain unaware of their seropositivity, negatively impacting progress towards universal HIV treatment. Mobile clinics offering HIV counselling and testing (HCT) are cost effective, have high acceptability, and offer timely testing to people who experience barriers to conventional healthcare services, thereby increasing access to HIV care.

This study analysed data from a mobile clinic operating in high HIV disease burdened, limited-resourced settings in Cape Town, South Africa.

METHODS: Patients ³12 years registered with their fingerprint at the mobile clinic which offered a wellness service, including HCT and chronic disease screening with a trained counsellor in Cape Town. Patients who tested HIV positive were referred for physical assessment by a nurse and were referred to HIV care. Trained counsellors contacted HIV-positive patients telephonically and encouraged them to attend HIV care. We used multivariable logistic regression to describe correlates of new HIV diagnoses adjusting for gender, age and year.

RESULTS: Between 2008 and 2016, 43,938 individuals (50% male; 29% <25 years; median age=31 years) tested at the mobile clinic, where 27% of patients (66% of males, 34% of females) reported being debut HIV testers. Overall, 2,743 (6%) people were newly diagnosed HIV-positive and overall HIV prevalence was 12% (10% male, 13% female). Males not previously tested for HIV had higher rates of HIV positivity (11%) than females (7%). Over half (55%, n=1,343) of those previously diagnosed HIV-positive had not initiated ART. Males had lower CD4 counts than females. Being between age 35-44 compared with 12-18 years (aOR = 5.24, 95% CI = 4.13, 6.65), reporting STI symptoms (aOR = 2.40, 95% CI = 1.95, 2.95), and reporting TB symptoms (aOR = 3.98, 95% CI = 3.47, 4.58) were associated with higher odds of a new HIV positive diagnosis.

CONCLUSIONS: Mobile HIV testing services can be used to reach individuals who may not visit conventional clinic facilities, including men living with HIV not previously tested. Differentiated mobile HCT can be used as part of an HIV prevention and treatment toolkit for HIV control among harder to reach populations, such as men and young people.

PEC0673

EFFECTS OF VITAMIN D AND CALCIUM SUPPLEMENTATION ON BONE MINERAL DENSITY AMONG THAI YOUTH USING DAILY HIV PRE-EXPOSURE PROPHYLAXIS

K. Pornpaisalsakul[1,2], W.N. Songtaweesin[2], S. Tepmongkol[3], P. Wongharn[2], S. Kawichai[2], S. Anugulruengkitt[1,2], T. Puthanakit[1,2], CE-PID – TRC Adolescent Study Team
[1]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand, [2]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Faculty of Medicine, Bangkok, Thailand, [3]Chulalongkorn University, Department of Radiology, Faculty of Medicine, Bangkok, Thailand

BACKGROUND: Tenofovir disoproxil fumarate combined with emtricitabine (TDF/FTC) is used for HIV pre-exposure prophylaxis (PrEP). TDF may affect bone mineral density (BMD), particularly in youth whom are a stage of peak bone mass accrual. The objective of this study was to evaluate the effects of vitamin D and calcium supplementation on BMD among Thai adolescents receiving daily PrEP.

METHODS: This open-label randomised trial was conducted in adolescents aged between 15-24 years. Participants were randomised to Arm A who received once daily TDF/FTC plus vitamin D and calcium supplementation with meals twice daily (600 mg of elemental calcium and 200 units of cholecalciferol) while Arm B received once daily TDF/FTC only. PrEP takers were defined as taking at least 2 tablets/week (TFV-DP level of >350 fmol/punch). Adherence to calcium/vitamin D supplementation was defined as taking >50%. Lumbar spine (L2-L4) BMD was evaluated by dual energy X-ray absorptiometry (Hologic Horizon Bone Densitometer) at baseline and at 6 months after PrEP initiation.

RESULTS: From March to September 2019, 100 youth (67 MSM and 33 TGW) with a median (IQR) age of 18 (17-20) years were enrolled. At entry, median (IQR) BMD z-score was -1.6 (-2.5 to -0.9), 36% had low BMD (Z-score<-2). Median amount of calcium intake from nutrition diary was 167 mg/day, 39% of participants had vitamin D deficiency, defined as 25(OH)D level<20 IU/mL.

As of December 2019, 47 participants had completed 6-months follow up. Of these, 30% were PrEP takers and 52% had good adherence to vitamin D supplementation. Median(IQR) change of lumbar spine BMD z-score at 6 months was slightly higher in arm A +0.41(0.08-0.51) compared to arm B +0.28(0.09-0.49) (p=0.33). There was a trend of higher increase in BMD-score among adolescents with vitamin D deficiency who received vitamin supplementation; arm A +0.48 (0.06-0.50) compared to arm B +0.23(0.09-0.52), p=0.81.

CONCLUSIONS: Thai youth who received a daily TDF/FTC PrEP regimen had low intake of calcium. There was an increment of BMD z-scores over 6-months among youth who received vitamin D/calcium supplement vs. controls. There were no immediate adverse effects of concern regarding bone health among adolescent PrEP users.

PEC0674

DEVELOPING A COMMUNITY SITE CATERING FOR KEY POPULATIONS IN BARBADOS

N. Rambarran[1], M. Rapley[1]
[1]*Equals Barbados, St Michael, Barbados*

BACKGROUND: In Barbados, it has been suggested that key populations (KPs) (men who have sex with men (MSM) and transgender persons) do not optimally utilise national HIV services, partially due to the perception that they would encounter stigma and discrimination. In order to increase access and utilisation of HIV services, the lesbian, gay, bisexual and transgender plus (LGBT+) civil society organization (CSO) Equals Inc. opened a community site specifically geared towards KPs.

DESCRIPTION: Equals, with funding with the USAID supported LINKAGES project, and in close collaboration with the Barbados Ministry of Health and Wellness, began offering HIV services in July 2017 at their safe space located in a residential building in a quiet neighbourhood conducive to privacy. Initially only weekly HIV and STI testing by Ministry personnel and psycho-social counselling by a private psychologist was available. This has expanded to free HIV/STI testing by certified peers and psycho-social counselling twice a week, PrEP provision, HIV treatment and care and gender affirming hormone provision. The safe space is also the site Tuesday to Saturday for any persons in the LGBT+ community to utilise, along with available desk top computers and food preparation facilities.

LESSONS LEARNED: Outreach workers and an active online and social media presence has resulted in an average 20 persons accessing HIV and STI services each month. Since opening, over 40 persons have benefited from psycho-social counselling, and outreach workers have interacted with over 400 Individuals, around 45% of whom have gone on to have HIV testing. Approximately 10% of the new national HIV diagnoses are made at Equals. Additionally, the site has also enrolled over 50% of the PrEP patients in the country and has seen rapid uptake of its shared HIV care.

CONCLUSIONS/NEXT STEPS Having a discrete private site specifically geared to meet the needs of KPs can increase their access to essential health services, and this is bolstered by having effective in-person and virtual outreach. Collaboration with the national HIV program is essential to ensuring success, and may be the key to ensuring sustainability in light of dwindling international donor funds.

PEC0675

PATIENT`S PREFERENCE AND PERCEPTION OF EHEALTH SUPPORT OPTIONS: A PILOT STUDY FOR THE VITAL TRIAL (VIRAL LOAD TRIGGERED ART CARE IN LESOTHO)

R. Scherrer[1], N. Bachmann[1], T.I. Lejone[2], M. Kopo[2], M. Lerotholi[3], N.D. Labhardt[1]
[1]*Swiss Tropical and Public Health Institute, Clinical Research Unit, Department Medicine, Basel, Switzerland,* [2]*SolidarMed, Swiss Organization for Health in Africa, Butha-Buthe, Lesotho,* [3]*Ministry of Health of Lesotho, Maseru, Lesotho*

BACKGROUND: Differentiated service delivery models (DSDM) aim at personalizing and thereby optimizing care for increasing numbers of people living with HIV taking antiretroviral therapy (ART). The viral load (VL) triggered ART care in Lesotho (VITAL) trial will assess an automated DSDM where patients are followed-up based on their last VL result, their comorbidities and preference. This pilot study serves to inform the VITAL trial by assessing patient's preferences and perception of different eHealth support options.

METHODS: We assessed eHealth preferences of adult patients attending routine ART visits at a rural clinic in Lesotho. Participants choose among the following options of eHealth support: communication of VL result by SMS, phone calls for adherence counselling in case of a VL≥1000/copies/mL and the option to request call-backs by a nurse. Automated calls for symptomatic tuberculosis screening were tested on site. Participants were asked to rank three options of adherence support: counselling by phone, ART-intake reminders by SMS and adherence counselling at the clinic. After six weeks participants were followed-up and their perception of the chosen eHealth support was assessed.

RESULTS: Among 112 participants (74% female), 17 patients came for routine VL blood draw and 13 came with a recent result of a VL≥1000/copies/mL. Everyone due for routine VL measurement requested the result to be communicated by SMS. All participants with a recent unsuppressed VL requested additional adherence counselling by phone call. In case of high VL, adherence support by phone calls was preferred, followed by ART intake reminders and standard counselling at the clinic. 75 participants (67%) received and finished an automated tuberculosis screening call, thereof 71 (95%) appreciated it. Among 56 participants with completed follow-up at submission, 54 (96%) would appreciate to have the nurse call-back option in the future.

CONCLUSIONS: eHealth options offered in this pilot study were perceived very positively. Receiving the VL result directly by SMS was appreciated and in case of an unsuppressed VL getting adherence counselling by phone was the preferred option. The VITAL trial will assess if an automated DSDM providing these options at a large scale will result in better clinical outcomes and cost-effectiveness.

PEC0676

EXPANDING THE REACH OF PRE-EXPOSURE PROPHYLAXIS TO TRANS AND NON-BINARY COMMUNITIES IN THE SAN FRANCISCO BAY AREA: DEVELOPMENT AND EVALUATION OF THE STAY STUDY PREP CAMPAIGN

C.S. Rodriguez[1], J. Vinson[2], E. Palafox[3], J. Halfin[3], A. Liu[2], E.C. Wilson[1], J. Rapues[4], S. Pardo[4], J. Ayankoya[4], S. Arayasirikul[1]
[1]*San Francisco Department of Public Health, Trans Research Unit for Equity, San Francisco, United States,* [2]*San Francisco Department of Public Health, Bridge HIV, San Francisco, United States,* [3]*Tri City Health Center, TransVision Program, Fremont, United States,* [4]*San Francisco Department of Public Health, San Francisco, United States*

BACKGROUND: Trans and non-binary (T&NB) people are a population at high risk for HIV acquisition, yet have been largely ignored in the biomedical prevention response. While PrEP awareness is critical to promote uptake, there are no best practices in developing tailored public health campaigns focused on T&NB people and PrEP.

DESCRIPTION: The STAY Study is one of the first PrEP demonstration projects in the US, aimed at increasing access, uptake and adherence to PrEP for T&NB people in the San Francisco Bay Area. The STAY Study developed a social marketing campaign involving 12 diverse Bay Area T&NB social influencers (see figure). The STAY campaign harnessed the power of PrEP to show the diversity, beauty, vibrancy, and resilience of T&NB communities, rather than to employ messaging that sensationalizes HIV and the promise of prevention. For example, "Adding PrEP to your daily routine will not lead to huge

changes in your life, but it will help you STAY magical." Social influencers developed and incorporated their own personal messages about PrEP with engaging hashtags. The campaign was featured on our website (www.staystudy.org), posters/palmcards, and distributed via social media.

[Figure]

LESSONS LEARNED: We evaluated campaign acceptability via computer-assisted survey among 153 T&NB participants enrolled in STAY. Almost all participants were aware of PrEP (98.1%), and 38.9% had seen the campaign. Among all participants, most found the campaign to be attractive, informative, and appropriate for T&NB people (83%, 88%, and 83%, respectively). Eighty-three percent reported they could see themselves in the STAY campaign, giving credence to how important community engagement is and prioritizing diversity in developing PrEP campaigns.

CONCLUSIONS/NEXT STEPS Tailored campaigns to increase PrEP awareness are critical to engaging people underserved in the HIV response. Future campaigns with T&NB communities may do well to reflect diversity in the community and acknowledge the limitations along with the promise of biomedical HIV prevention.

PEC0677

HOTSPOT LISTING, VALIDATION AND SIZE ESTIMATION OF KEY POPULATION IN NIGERIA: PROGRAMMATIC MAPPING APPROACH IN 10 STATES

C.C. Ejeckam[1], K. Green[2], M. Okpara[3], G. Ashefor[4], A. Adeshina[5]
[1]Centre for Global Public Health, Program, Abuja, Nigeria, [2]Centre for Global Public Health, Country Coordinator, Abuja, Nigeria, [3]Centre for Global Public Health, Community Mobilization, Abuja, Nigeria, [4]National Agency for the Control of AIDS, Strategic Knowledge Management, Abuja, Nigeria, [5]Centre for Global Public Health, Monitoring and Evaluation, Abuja, Nigeria

BACKGROUND: The United Nations World meter algorithm estimates that Nigeria has a population of 203,732,121,(updated as at January 13th, 2020). In a country this size, determining the size and locations of members of Key Populations (Female Sex workers (FSWs), Men who have Sex with Men(MSM), People who Inject Drugs(PWIDs)), are critical steps in HIV epidemic control. There are many different approaches in determining the size of key population. CGPH adopted the programmatic mapping method.

DESCRIPTION: Programmatic mapping involves a two sequential data collection steps known as level one (L1) and level 2(L2). During L1, information on geographic locations where Key populations congregate (listing), characteristics of spots, estimate number of KPs found, their risk behaviors, networking patterns, HIV prevention service access, etc. were collected from key informants. During L2, key informants' interviews were conducted at identified spots across the 10 study States. In L2, primary key informants who are members of key population group operating in spot validated information collected during L1.

LESSONS LEARNED: 32,566 KI interviews were conducted in Level One (L1).16,563 active spots (8877 FSW spots, 4349 MSM spots, 3837 PWIDs) were identified. Kaduna State had the highest number of FSW spots (1,629) while Taraba state has the least (346). Highest MSM spots were in Kano State (2,012) and Imo State has the least (56). Kaduna State has the highest PWID spots (857) while Edo state has the least (45). 80% of FSW spots in Kaduna are non-brothel based, 91% of MSM spots in Kano are streets and homes while 65% of PWID spots in Kaduna are streets.

Total number of FSWs estimated across the 10 states stood at 118,171. Anambra state had the highest number of FSWs with 36,607 and Enugu state had the least estimated FSWs with 3,824. Total number of MSM estimated at physical locations was 44,355 across the 10 states. Kano state had the highest number of MSM with 20,144.Total number of PWID estimated at 49,876.

CONCLUSIONS/NEXT STEPS Programmatic Mapping helps to determine the size of Key population groups and their locations in areas where program could reach them.Result from this study will inform the review of the national prevention strategy.

PEC0678

6-MONTH OUTCOMES OF A SOCCER INTERVENTION FOR HIV PREVENTION FOR YOUNG SOUTH AFRICAN MEN AGED 18-29 YEARS

M. Rotheram-Borus[1], S. Rabie[2], E. Almirol[3], J. Stewart[4], M. Tomlinson[4]
[1]Univ. of CA, Los Angeles, United States, [2]Stellenbosch University, Stellenbosch, United States, [3]UCLA, Los Angeles, United States, [4]Stellenbosch University, Cape Town, South Africa

BACKGROUND: Current HIV prevention strategies often exclude men, are located in health settings underutilized by men, and use formats that are not appealing to men. In South Africa, the country with the highest HIV rate globally, men are additionally challenged by drug abuse, unemployment and a culture of alcohol and violence. Soccer is utilized as a community-level intervention for young, South African men.

METHODS: All men aged 18-29 years old in 30 township neighborhoods in Cape Town, South Africa were randomized by neighborhood to either a soccer league (SL, n=788) or a control condition (CG, n=423) and more than 82% were followed-up 6 months later. Weekly soccer practices and games were used to teach young men skills to reduce the risk of HIV transmission, substance use and to refrain from interpersonal violence. On the soccer field, random, weekly, rapid drug/alcohol tests were collected. Longitudinal mixed models were used to evaluate the intervention's effectiveness over 6 months.

RESULTS: Mean age of men was 23.4 (SD 4.8) years old, with an average of a 10th grade education completed. Within 6 months, the SL group reported less violence towards women than the CG (OR=0.37, 95% CI 0.28-0.49), yet the CG reported a higher income than the

SL (OR=2.59, 95% CI 1.87-3.59). Though the number of concurrent sexual partners, times arrested, and depressed mood significantly decreased from baseline to six months over time, there was no significant difference by intervention effect. For the SL group only, SL increased HIV testing from baseline to 6 months (40.5% at baseline, 47.9% at 6 months), tested less positive for alcohol (34.3% at baseline, 28.2% at 6 months), and had a 50% lower rate of mandrax use (20% vs 31%) over time.

CONCLUSIONS: For the first 6 months of the intervention, we found modest findings in the SL group compared to CG. These effects we found over time, yet not by intervention, may be due to the brief amount of time. The following 6 months will be focused on vocational training that we anticipate will increase the likelihood of employment in the intervention group.

PEC0679

SECONDARY DISTRIBUTION OF HIV SELF-TESTING KITS IN DIFFERENT CLINICAL SETTING: A COHORT STUDY IN ZAMBIA

C. Mulubwa[1], P. Mee[2], L. Sigande[1], M. Neuman[2], B. Hensen[2], A. Mwinga[1], K. Hatzold[3], B. Chiti[1], M. Simwinga[1], C. Johnson[4], E.L. Corbett[5], H. Ayles[2,1]
[1]Zambart Project, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, Clinical Research Department, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [3]Population Services International (PSI), Washington, DC., United States, [4]World Health Organization, Department of HIV, Hepatitis and STIs, Geneva, Switzerland, [5]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

BACKGROUND: In sub-Saharan Africa, knowledge of positive HIV status remains lower for men than women. Secondary distribution of HIV self-test (HIVST) kits can reach previously untested adults. We describe uptake, and linkage to confirmatory testing and post-test HIV care and prevention services following partner-delivered HIVST from antiretroviral (ART) and antenatal (ANC) clinic services.

METHODS: All clients attending ART (regardless of ART duration) and ANC (regardless of HIV status) clinics were offered HIVST kits for secondary distribution. Consenting ART/ANC clients were interviewed at recruitment and one-month. Partners reported to have been given HIVST kits were traced at 3 months and, following consent, interviewed about kit usage and linkage to prevention and treatment.

RESULTS: From November 2018 to July 2019, 516 ANC clients and 122 ART clients were recruited. Of ANC clients 509/516 (98.6%) took a HIVST kit for secondary distribution, 452 were re-interviewed after 1 month (88.8%) with 399/452 (88.3%) reporting having given the HIVST kit to their partner. Of ART clients 118/122(96.7%) took a HIVST kit for secondary distribution, 83 were re-interviewed after 1 month (70.3%) with 73/83 (88.0%) reporting having given the HIVST kit to their partner. On partner tracing 268 partners of ANC clients were interviewed (268/399; 67.2%) of whom 235 (87.7%) reported self-testing; 64/73 (87.7%) partners of ART clients were traced of whom 57 (89.1%) reported self-testing. A higher percentage of partners in the ART cohort (7.8%) reported a confirmed positive HIV test than ANC cohort partners (1.9%), and all had started ART at the time of follow-up. Among male HIV-negative partners, 51/196 (26.0%) in the ANC arm and 12/35 (34.3%) in the ART arm had previously undergone voluntary medical male and circumcision (VMMC). No additional HIV-negative men were linked to VMMC following HIVST.

CONCLUSIONS: Secondary distribution of the HIVST kits was highly acceptable to partners of those recruited through ANC and ART clinics. Although our conclusions are limited by cohort follow-up, untreated HIV-positive partners were identified and started on ART, but our data suggest the need to optimize referral routes for HIV prevention services to maximise the benefits of secondary distribution of HIVST.

PEC0680

LESSONS LEARNED FROM IMPLEMENTATION OF DETERMINED, RESILIENT, EMPOWERED, AIDS-FREE, MENTORED, AND SAFE (DREAMS) IN OSHIKOTO REGION OF NAMIBIA

B. Harases[1], F. Katuta[1], R. Indongo[1], N. Halweendo[1], C. Uakuramenua[1], S. Naholo[1], D. Kakupa[2], E. Derese[1], S. Neri[1], L. Shikongo[3], A. Omotayo[4], S. Mwetulundila[5], A.-M. Nitscke[6], T. Uukola[6], A. Eises[7], M. Manyando[8]
[1]Project HOPE, DREAMS Project, Windhoek, Namibia, [2]Star for Life, DREAMS Project, Windhoek, Namibia, [3]IntraHealth International, DREAMS Project, Windhoek, Namibia, [4]Namibia University of Science and Technology, DREAMS Project, Windhoek, Namibia, [5]Life Line Child Line, DREAMS Project, Windhoek, Namibia, [6]Ministry of Health and Social Services, Windhoek, Namibia, [7]Namibian Ministry of Education, Arts and Culture, Windhoek, Namibia, [8]United States Agency for International Development (USAID), Windhoek, Namibia

BACKGROUND: Adolescent girls and young women (AGYW) aged 15-24 years remain at high risk for HIV infection compared to their male counterparts, particularly in sub-Saharan Africa (Gourlay et al 2019). To address this urgent need, PEPFAR and partners launched DREAMS, a public-private partnership designed to reduce the rate of HIV among AGYW in 15 countries through a package of layered evidence-based interventions (Saul J. et al. 2018).

In June 2018, a consortium led by Project HOPE Namibia began to implement the PEPFAR-funded DREAMS project in Namibia's Oshikoto region.

DESCRIPTION: The DREAMS project delivered core package of age appropriate 'primary' interventions for all AGYW and 'secondary' interventions that are based on need to vulnerable AGYW 10 – 24 years old as per the PEPFAR Namibia guidance. Moreover, interventions to strengthen families and reduce risk among sexual partners of AGYW were provided. The core package is delivered in 448 safe spaces and youth-friendly clinics of 19 health facilities. AGYW vulnerability to HIV are determined based on established criteria.

LESSONS LEARNED: Client booklet and service registers were used to document the core package of interventions provided to DREAMS beneficiaries. Each beneficiary has unique identifier and individual level data was collected and layering of interventions was monitored using the REDCap database. Descriptive statistics are used to explore results.

From October 2018 through September 2019, 20,922 AGYW 10-24 years old were screened for enrolment into DREAMS and 14,886 (71%) were eligible based on the DREAMS HIV vulnerability criteria. There was no significant difference in vulnerability across age groups or districts. Of those eligible, 11,308 (10 – 14; 4,447; 15 – 19: 5,623; 20 – 24: 1,118) received at least one primary DREAMS interventions, including 73.3% who participated in the DREAMS project for ≤ 6 months. The proportion of AGYW who received less than full primary-package, full primary-package and full primary-package plus at least one secondary-package of interventions was 29.7%, 30.2%, and 40.1% respectively.

CONCLUSIONS/NEXT STEPS A significant proportion of AGYW were vulnerable to HIV which requires a relook at the vulnerability criteria. Moreover, layering with the full-range of intended interventions takes time; and efforts should be made to reach out-of-school AGYW 20-24 years old.

PEC0681

HIGH LEVELS OF BISEXUAL BEHAVIOURS AND ITS CORRELATES AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN MALAWI

L. Kapanda[1], A. Muula[2]
[1]University of Malawi, College of Medicine School of Public Health, Public Health, Blantyre, Malawi, [2]University of Malawi, College of Medicine School of Public Health and Family Medicine, Public Health, Blantyre, Malawi

BACKGROUND: Globally, men who have sex with men (MSM) have high HIV prevalence. Some MSM practice sexual intercourse with both men and women (bisexual behaviour). There is limited data on proportions of bisexual MSM and factors associated with such bisexual behaviour in order to inform Malawi's HIV prevention messages and programming.

METHODS: We enrolled MSM through respondent-driven sampling in a cross-sectional study in Lilongwe between May and November 2016. We collected data using interviewer-administered questionnaires and calculated RDS-adjusted population estimates for both descriptive and inferential statistics

RESULTS: Of the 462 men enrolled, 63.2% self-reported sexual debut with a male partner, 63% ever had sex with a female and 30% were currently in a male-female sexual relationship. Fifty-nine percent had unprotected vaginal sex during last intercourse and 31% had multiple female sexual partners. Forty eight percent had multiple male sexual partners and 20% had unprotected anal sex in the last intercourse. In bivariate analyses, bisexual behaviours were associated with being of age category 35 and above [(Odds Ratio (OR) 3.5 (95% CI:1.5 - 8.5)], divorced marital status [OR 5.9 (95% CI:1.4 - 30.4)], self-reported bisexual and transgender identity [OR 23.1 (95% CI:10.6 - 50.1)] and [OR 6.3 (95% CI:1.1 - 38.6)] respectively), preference for insertive partner [OR 2.4 (95% CI:1.4 - 4.3)], ever testing for HIV [OR 2.9 (95% CI:1.7 - 4.7)] and sexual debut with a female [OR 30.1 (95% CI:10.9 - 83.0)]. In multivariate analysis, being divorced [Adjusted Odds Ratio (AOR 13.0 95% CI: 1.3 -134.4)], self-reported bisexual identity [AOR 27.6 (95% CI: 9.9 – 76.6)], ever testing for HIV [AOR 2.3 (95% CI: 1.1- 5.1)] and sexual debut with a female [AOR 32.1 (95% CI: 8.2 - 126.2)] remained significant.

CONCLUSIONS: High levels of bisexual behaviours, multiple sexual partnerships and unprotected sex exist among Malawian MSM. Men who self-reported bisexual identity, divorced, ever tested for HIV and sexual debut with a female were more likely to report bisexual partnerships. While promotion of healthcare access for MSM focused HIV prevention programs is needed, current MSM interventions must include information on safe-sex with both male and female sex partners.

PEC0682

LABORATORY TESTING FOR SEXUALLY TRANSMITTED INFECTIONS AMONG SEX WORKERS IN SOUTHERN AFRICA – WHY WE NEED A STATUS NEUTRAL APPROACH

F. Cowan[1], S. Chabata[2], S. Magutshwa[2], S. Musemburi[2], J. Dirawo[2], F. Machingura,[2], T. Mharadze[2], J. Hargreaves[3], E. Fearon[3]
[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]CeSHHAR, Harare, Zimbabwe, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: As pre-exposure prophylaxis (PrEP) is scaled up, there have been calls to strengthen the management of bacterial sexually transmitted infections (STIs). Here we investigate the potential benefits of making laboratory screening a routine component of PrEP delivery among Zimbabwean female sex workers (FSW), where STIs are currently managed syndromically.

In addition we examine the implications of restricting laboratory testing to FSW who are HIV negative when >50% of FSW are already HIV infected.

METHODS: Data were collected in March-April 2017 from FSW from 3 sites in Zimbabwe using respondent driven sampling. All FSW had HIV / syphilis serology performed, and a random 1/3 had STI symptoms and signs recorded and were tested for bacterial STIs using GenXpert. Free treatment was provided for FSW with symptoms/signs or STI diagnosis. Analysis was conducted using the "RDS-II" approach and diagnostics did not suggest biased recruitment.

RESULTS: Overall 2507 FSW were recruited from Harare (n=1497), Bulawayo (n=808) and Shamva (n=202). HIV prevalence was 54.4%, 52.2% and 54.8% respectively. Between 10.9-19.7% had positive syphilis serology. Across settings, STI prevalence was high, irrespective of HIV status (see table).

	HIV negative FSW	HIV positive FSW VL <1000c/UL	HIV positive FSW VL ≥1000c/UL	All FSW regardless of status	Sensitivity	Specificity
	n/N, % (95%CI)	n/N, % (95%CI)	n/N, % (95%CI)	n/N, % (95%CI)	[n/N] %	[n/N] %
TPHA/RPR (n=2507)	136/1104, 13.7 (11.1-16.8)	243/871, 27.8 (23.9-32.0)	127/419, 32.7 (26.8-39.1)	506/2394, 21.8 (19.6-24.2)	N/A	N/A
Neiserria Gonorrhoea (n=715)	31/272, 11.9 (7.8-17.6)	29/260, 8.4 (5.2-13.4)	14/104, 11.4 (5.7-21.4)	74/636, 10.4 (7.8-13.7)	[8/31] 25.8	[230/249] 92.4
Chlamydia trachomatis (n=715)	38/271, 15.0 (10.2-21.5)	12/260, 3.1 (1.5-6.0)	10/104, 9.1 (4.0-19.2)	60/635, 9.2 (6.7-12.5)	[7/38] 18.4	[222/242] 91.7
Trichomonas vaginalis (n=715)	65/280, 23.7 (17.7-30.8)	80/266, 30.2 (22.8-38.7)	41/101, 34.8 (23.7-47.8)	186/647, 28.1 (23.6-33.0)	[6/65] 9.2	[210/215] 97.9

[Table]

Prevalence of Neisseria gonorrhoea among all FSW was 10.4% (95%CI:7.8-13.7%); of Chlamydia trachomatis was 9.2% (95%CI:6.7-12.5%); of Trichomonas vaginalis was 28.1% (95%CI:23.6-33.0%). STI prevalence was similar among HIV negative FSW (ie those eligible for PrEP) and HIV positive FSW including those with unsuppressed viral load. Symptoms and signs of all three infections were poorly predictive of laboratory diagnosed infection in both HIV negative and positive women.

CONCLUSIONS: STI rates were high among Zimbabwean FSW, independent of HIV status. Syndromic management had poor sensitivity and specificity for infection leading to under treatment of STI infected FSW and over treatment of uninfected FSW likely resulting in both poor STI control and increased likelihood of antimicrobial re-

sistance. Laboratory diagnosis would substantially improve STI management for all FSW and should not be restricted to PrEP recipients but be incorporated into routine status neutral care.

PEC0683

CORRELATES OF SELF-REPORTED SCREENING FOR SEXUALLY TRANSMITTED INFECTIONS AMONG MEN WHO HAVE SEX WITH MEN PARTICIPATING IN A CROSS-SECTIONAL STUDY IN, MALAWI

L. Kapanda[1], A. Muula[1]
[1]*University of Malawi, College of Medicine School of Public Health and Family Medicine, Public Health, Blantyre, Malawi*

BACKGROUND: Men who have sex with men (MSM) are at an increased risk for sexually transmitted infections (STIs) worldwide. Vulnerability to STIs increases with risky sexual practices. This study estimated the prevalence of self-reported STIs and identified correlates associated with screening for STIs among MSM in Malawi.

METHODS: We conducted a cross-sectional study between May and November 2016. We enrolled MSM 18 years and above using respondent driven sampling (RDS) and collected data through interviewer-administered questionnaires. We computed RDS adjusted population weights and proportion estimates, and used Odds Ratios obtained through logistic regression to identify correlates between self-reported screening for STIs and independent variables.

RESULTS: Out of 462 MSM, 130 self-reported to have screened for STIs 12 months preceding this study and 10.8% (14/130) were diagnosed with STIs through syndromic management approach. Twenty-seven MSM self-reported to have experienced STI symptoms and the majority (73%) sought treatment from health facilities. The remaining 27% either consulted herbalist, a friend, self-medicated or stayed without treatment.

In bivariate analysis screening for STIs was associated with ever testing for HIV [Odds Ratio (OR) 8.0, 95% Confidence Interval (CI) 4.0 – 17.1)], experiencing STI symptoms [OR 5.5 (95% CI: 2.1 – 14.6)], being diagnosed with an STI [OR 112.0 (95% CI: 14.0 – 895.9)] and ever having sex with a female [OR 3.7 (95% CI: 2.1 – 6.6)]. Participants cohabiting with a female had lower Odds of screening for STIs [OR 0.2 (95% CI: 0.07 – 0.59)] compared to those married. In the multivariable model, correlates of STIs screening included ever testing for HIV [adjusted Odds Ratio (aOR 7.7: 95% CI: 3.3 – 17.5)] and ever having sex with a female (aOR) 3.4, 95% CI: 1.6 - 6.9). Participants in a cohabitation relationship with a female were less likely to screen for STIs (aOR 0.14, 95% CI: 0.04 – 0.43) compared to those married to a female.

CONCLUSIONS: Men who ever tested for HIV, ever had sex with a female were more likely to screen for STIs. On the contrary, MSM cohabiting with a female were less likely to screen for STIs. Our study identified a need for effective interventions to control future STIs among MSM population.

PEC0684

FROM PREJUDICE TO PRIDE: STRENGTHENING COMMUNITY-LED RESPONSES TO MITIGATE VIOLENCE AND SUPPORT EMPOWERMENT AS A STRATEGY TO ENHANCE ACCESS TO SEXUAL HEALTH AMONG TGH POPULATION IN INDIA

F.R. Gulfam[1], S. Shaikh[1], V. Arumugam[1], A. Aher[1], R. Prasad[1]
[1]*India HIV/AIDS Alliance, Programs and Policy, New Delhi, India*

BACKGROUND: Supported by Amplify Change, Indian HIV/AIDS Alliance is implementing the programme 'Wajood' (meaning pride) which empowers Transgender and Hijras to access Sexual Health services. Documenting and addressing gender based violence, challenging stigma and discrimination and increased access to sexual health services are main thematic areas of Wajood.

DESCRIPTION: During last five years, 683 clients accessed violence mitigation services. Data on nature of violence, perpetrators, implication and redressal was collected from these clients through structured tool. In addition, focused group discussions were conducted with these clients, to carry out an in-depth analysis of the nature and implications of violence. While quantitative data was analyzed using univariate and bivariate analysis, qualitative data was analyzed after synthesizing themes emerging from the discussions.

LESSONS LEARNED: 53.4% clients reported Physical assault/harassment, 49.6% reported being subject to verbal abuse and 11% discrimination and/or denial of services. Of the almost 200 cases reported violence by their family members, majority (82%) reported the perpetrators to be father and brothers. Almost 15% reported physical injuries whereas only 33.7% reported seeking medical assistance. 12% (N=85) clients said that they were victims of forced sexual acts majority (36%) of which was committed by a local goon, intimate partner (16.7%) and family member (12.8%). Out of the 85 cases reported rape and sexual assault, only 35 taken any legal assistance and only 12 have filed an FIR. Lack of faith in the legal/judicial system due to gender identity was most common reason (82.2%) for not seeking legal assistance. TGH accessing violence mitigation services were twice more likely to return for follow-up of sexual health services including HIV, STI, TB and gender specific hygiene practices. Out of these clients more than 32% also accessed social welfare and social entitlement services which was accessed by only 18.2% clients registered in overall program.

CONCLUSIONS/NEXT STEPS It is important to remove structural barriers and stigma in various settings in order to TGH population to access HIV and other sexual health services. There is a need to collect data on psycho-social impact of violence on TGH population as well as a robust data collection and intervention mechanism needs to be introduced.

PEC0685

REACHING THE UNDERSERVED: DEVELOPING TOOLKITS TO SUPPORT EFFECTIVE COMMUNITY-BASED HIV TESTING IN ENGLAND

D. Gold[1], C. Douglas[1], K. Smithson[1]
[1]NAT (National AIDS Trust), London, United Kingdom

BACKGROUND: UK national guidelines recommend that HIV testing is offered in community-based settings to reach those not engaged by traditional health services. However, there is no guidance on good practice or standardised methods of evaluation. This makes is hard for providers to design services, demonstrate impact and for funders to commission effective services.

DESCRIPTION: NAT conducted desk-based research on community testing policy and practice. We established an Expert Advisory Group compromising of community providers and funders, Public Health England, HIV Prevention England and clinicians. 13 providers and 4 funders were interviewed. Analysis of these interviews and wider evidence enabled the development of two toolkits:

- A 'Community Testing: Intervention Design Toolkit' which highlights policy, evidence and good practice, and includes a range of case studies. Critically this toolkit looks at outreach settings and marketing and recruitment options relevant to the UK.
- A 'Community Testing: Evaluation Toolkit' proposing indicators that can be used to monitor success, support national data collection, and improve cross-sector learning.

Each resource was reviewed by the Expert Advisory Group and a wider group of current and prospective providers.

LESSONS LEARNED: There was not a clear definition of community testing in England or a consistent understanding of its value. Provision is patchy and dependent on the buy-in of local funders and clinicians. The toolkits position community testing as part of an HIV testing strategy, and their development has already helped to break down barriers and improve attitudes, with early versions supporting a workshop and action planning to improve community testing provision in Greater Manchester.

Though the toolkits will support better process and outcome evaluation, questions around value for money are more complex and could not be addressed easily. As the group of people living with undiagnosed HIV becomes smaller but more marginalised, returns on investment may be lower but will be vital.

CONCLUSIONS/NEXT STEPS Community testing has an important role to play in finding the 8% of people living with HIV in England who are still undiagnosed. These toolkits will help to ensure that interventions are effective in reaching people at increased risk of HIV and are both accessible and high quality.

PEC0686

PERCEIVED RISK OF HIV TRANSMISSION AMONG HIV SERODISCORDANT COUPLES USING PREP IN KENYA

D. Mangale[1], K. Ortblad[1], P. Mogere[2], C. Kiptinness[2], J. Baeten[1], K. Ngure[3,2]
[1]University of Washington, Global Health, Seattle, United States, [2]Partners in Prevention Research, Thika, Kenya, [3]Jomo Kenyatta University of Agriculture and Technology, Community Health, Nairobi, Kenya

BACKGROUND: HIV-negative individuals in serodiscordant couples have better adherence to pre-exposure prophylaxis (PrEP) for HIV prevention than individuals at HIV risk not in serodiscordant relationships. PrEP is nearly 100% effective at preventing HIV infection when used regularly. Perceptions of HIV risk transmission among individuals living with HIV in these couples may play an important role in decision making around sexual behaviors.

METHODS: 292 individuals (162 women, 130 men) living with HIV in Kenya were enrolled from May 2018 to December 2019. Eligible participants were ≥18 years of age, living with HIV (confirmed with rapid testing), and had a partner using PrEP for ≥1 month. Participants answered questions on sexual behaviors and perceived risk of HIV transmission within their relationship. We summarized survey responses using descriptive statistics.

RESULTS:

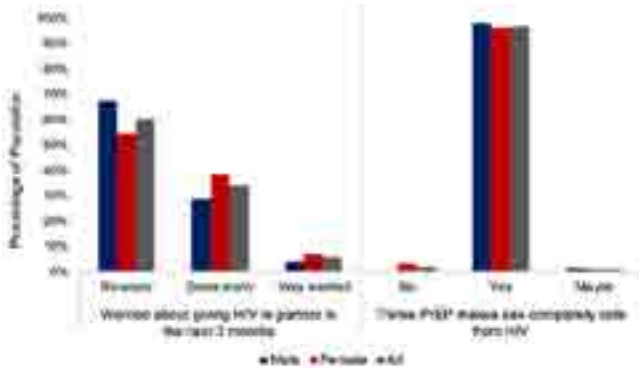

Figure 1. Perceptions of HIV risk transmission among individuals living with HIV.

The median age of participants and number of years in school were 33 (IQR 27-40) and 10 years (IQR 8-12), respectively. Participants reported a median of 8 sex acts (IQR 5-12) with their primary partner in the past month. Among all participants, 35% (n=103) reported any condomless sex in the past month; condomless sex was higher among men (40% , n=52) versus women (31%, n=51). Only 6% (n=16) of participants (7% [n=11] of men, 4% [n=5] of women) were very worried about transmitting HIV to their partners in the near term, Figure 1. The majority (97%, n=277) of participants were confident that PrEP use makes sex completely safe from HIV transmission.

CONCLUSIONS: Perceived risk of HIV transmission among individuals living with HIV in serodiscordant couples using PrEP was low (despite the common practice of condomless sex) and confidence in PrEP for HIV prevention was high. HIV prevention programs could leverage high confidence in PrEP among HIV serodiscordant couples to improve PrEP adherence among HIV-negative partners.

SEXUALITY, GENDER AND PREVENTION TECHNOLOGIES (INCLUDING CONDOMS, TREATMENT AS PREVENTION, MALE CIRCUMCISION, PRE-EXPOSURE PROPHYLAXIS)

PERSISTING BARRIERS FOR U=U IN FAMILY PLANNING AND ASSISTED REPRODUCTION OF PLHIV

V. Avelino-Silva[1], L. Yamakami[2], R. Tomioka[2], E. Miyadahira[2], O. Duarte[2], L. Matsumoto[2], C. Alvarenga[3]
[1]Faculdade de Medicina da Universidade de São Paulo, Infectious and Parasitic Diseases, Sao Paulo, Brazil, [2]Vida Bem-Vinda, Sao Paulo, Brazil, [3]Lab Medicina Masculina, Sao Paulo, Brazil

BACKGROUND: Despite its robust scientific evidence, the concept of U=U is inconsistently disseminated among healthcare providers, including specialists practicing in the context of family planning and assisted reproduction.

METHODS: A self-completion questionnaire was applied for participants of an assisted reproduction seminar in Sao Paulo, Brazil, on May-2019. The survey included demographics, training characteristics, and attitudes on family planning and assisted reproduction for people living with HIV (PLHIV). A case vignette describing a serodiscordant couple planning to conceive (a man living with HIV under antiretroviral treatment with good adherence and undetectable viral load for ≥1 year; an HIV-uninfected healthy female partner), was presented for illustration. We explored if age, time since graduation and care for serodiscordant couples in routine practice were associated with survey responses.

RESULTS: 110 participants were included in the study. Most (87%) were female, with a median age of 35 years (range 20-60), and median time since graduation of 11 years (IQR 7-15). Overall, 82% were obstetrician-gynecologists and 53% reported to routinely care for serodiscordant couples. Most participants (96%) declared to strongly agree/agree that they would encourage the vignette couple to attempt pregnancy. However, only 38% declared to strongly agree/agree they would recommend conceiving naturally. Seventy participants (64%) reported to strongly agree/agree they would refer the couple for assisted reproduction even without evidence of infertility. Finally, 56% of the participants declared to strongly agree/agree that, in case assisted reproduction is used, sperm-washing techniques would always be indicated (Table 1). We found no statistically significant associations between age, time since graduation and routine care for serodiscordant couples and recommendations for conceiving naturally or referral for assisted reproduction despite lack of infertility.

A serodiscordant couple is planning to have a baby. The man lives with HIV, is under antiretroviral treatment with good adherence; he has undetectable plasma HIV viral load for ≥1 year. His partner is an HIV-uninfected woman without any comorbidities.					
	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
Would you encourage the couple to conceive? (%)	46 (42)	60 (55)	2 (2)	2 (2	0 (0)
Would you recommend conceiving naturally? (%)	12 (11)	30 (27)	18 (16)	36 (33)	14 (13)
Would you refer the couple for assisted reproduction even without evidence of infertility? (%)	24 (22)	46 (42)	10 (9)	28 (25)	2 (2)
In case assisted reproduction, is sperm-washing always be indicated? (%)	22 (20)	40 (36)	40 (36)	6 (5)	2 (2)

[Table 1.]

CONCLUSIONS: Our findings show a critical gap between existing evidence for U=U and attitudes among specialists working with family planning and assisted reproduction. Additional training and education approaches on U=U should be implemented for these providers in order to improve care for serodiscordant couples planning to conceive.

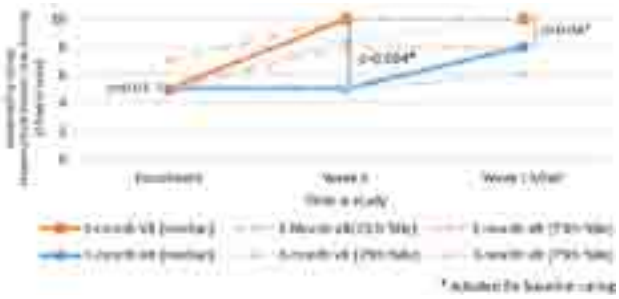
ACCEPTABILITY AND PREFERENCE FOR 3-MONTH VERSUS 1-MONTH VAGINAL RINGS FOR HIV-1 RISK REDUCTION AMONG PARTICIPANTS IN A PHASE 1 TRIAL: A MIXED METHODS ANALYSIS

S.T. Roberts[1], I. Hawley[1], E. Luecke[1], B. Mensch[2], T. Wagner[3], C.J. Hoesley[4], T. McClure[5], C.P. Dominguez Islas[6], J. Piper[7], A. Liu[3,8], A. van der Straten[1,8], on behalf of the MTN-036 protocol team
[1]RTI International, Women's Global Health Imperative, Berkeley, United States, [2]Population Council, New York, United States, [3]San Francisco Department of Public Health, San Francisco, United States, [4]University of Alabama at Birmingham, Birmingham, United States, [5]FHI 360, Durham, United States, [6]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division, Seattle, United States, [7]National Institute of Allergy and Infectious Diseases, Division of AIDS, Bethesda, United States, [8]University of California, Department of Medicine, San Francisco, United States

BACKGROUND: We examined acceptability and preference for 3-month versus 1-month vaginal rings (VRs) for HIV-1 risk reduction in a phase 1 clinical trial. A longer duration VR may reduce user burden and improve adherence.

METHODS: MTN-036 enrolled 49 participants from San Francisco, CA and Birmingham, AL who were healthy, HIV-negative, aged 18-45, and assigned female sex at birth. Participants were randomized to one of two 3-month VRs (100mg or 200mg dapivirine) or the 1-month VR (25mg dapivirine). Quantitative acceptability ratings were collected at enrollment, week 4, and study exit (week 13). At exit, preference for the 3-month VR (vs. 1-month or no preference) was assessed quantitatively among all participants and via in-depth interviews (IDIs) with 24 randomly selected participants. We compared acceptability by assigned duration and explored preferred duration using mixed methods.

RESULTS: Acceptability of each VR was initially moderate but increased during the trial (Figure).



[Figure. VR acceptability over time]

Ratings were lower in the 3-month VR arms than the 1-month arm throughout the trial, including at baseline. Nevertheless, 72% (34/47) of all participants reported preferring a 3-month VR at exit (95% CI 58%-83%). Participants from San Francisco and college graduates were more likely to prefer a 3-month VR, whereas those who were African American, disliked wearing the VR during menses, or never thought about the VR inside their body were less likely (all p<0.05). IDIs revealed reservations about hygiene, safety, or forget-

ting to replace the 3-month VR, but these were usually outweighed by its increased convenience, especially as participants using the 3-month VRs gained experience.

CONCLUSIONS: Both VR durations were highly acceptable at study exit. Although most participants preferred a 3-month VR, preference was more divided in certain subgroups, highlighting the benefit of offering different duration options. Providing additional support to address concerns about hygiene, safety, and replacement may improve acceptability of a 3-month VR.

PEC0689

ACCEPTABILITY OF A PEER-TO-PEER DELIVERY OF HIV SELF-TESTING AND SEXUAL HEALTH INFORMATION TO SUPPORT HIV PREVENTION AMONG YOUNG WOMEN IN RURAL KWAZULU-NATAL, SOUTH AFRICA

O. Adeagbo[1,2], D. Nondumiso[3], S. Xulu[3], D. Gumede[3], C. Herbst[3], J. Dreyer[3], N. Chimbindi[3,2], N. Okesola[4], G. Harling[1,5], L. Sherr[5], N. McGrath[6,7], F. Cowan[8,9], C. Johnson[10], K. Hatzold[11], H. Subedar[12], L. Corbett[13,14], J. Seeley[14,1], M. Shahmanesh[1,5]

[1]Africa Health Research Institute, Social Science and Research Ethics Unit, Mtubatuba, South Africa, [2]University College London, London, United Kingdom, [3]Africa Health Research Institute, Social Science and Research Ethics, Mtubatuba, South Africa, [4]Africa Health Research Institute, Clinical, Mtubatuba, South Africa, [5]University College London, Institute for Global Health, London, United Kingdom, [6]Africa Health Research Institute, Mtubatuba, South Africa, [7]University of Southampton, Medicine, Southampton, United Kingdom, [8]The Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [9]University of Liverpool, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [10]World Health Organization, Geneva, Switzerland, [11]Population Services International, Washington D.C, United States, [12]National Department of Health, Pretoria, South Africa, [13]Malawi-Liverpool-Wellcome Trust, Clinical Research Unit, Blantyre, Malawi, [14]London School of Hygiene & Tropical Medicine, London, United Kingdom

BACKGROUND: Suboptimal uptake of HIV testing and linkage to post-test services contribute to HIV transmission. We conducted a cluster randomised controlled trial to investigate whether different HIV self-testing (HIVST) peer-to-peer (PTP) distribution models, including social networks, could create demand for HIV treatment and Pre-Exposure Prophylaxis (PrEP) amongst adolescent girls and young women (AGYW) in rural KwaZulu-Natal (#NCT03751826). Here, we describe the acceptability of these PTP approaches.

METHODS: Between March and September 2019, 24 pairs of geographically separated peer-navigators were randomised to: (1) incentivised-peer-networks: Peer-navigators recruited AGYW (peer distributers) to distribute five HIVST packs (kit + HIV prevention information) to peer-age friends within their social network. Peer-distributers received US$1.5 per pack-recipient transitioning into peer-distribution by collecting 5 HIVST packs themselves; (2) direct distribution: Peer-navigators distributed HIVST packs directly; (3) standard-of-care: Peer-navigators distributed information. All arms distributed clinic referral slips. We conducted a process evaluation, by combining routine programme data and semi-structured interviews with purposively sampled peer-navigators (n=30) and beneficiaries aged 18-29 years (n=30) from each arm. Programme data were analysed descriptively. Qualitative data were transcribed, translated and thematically analysed using an interpretivist approach.

RESULTS: Peer-navigators approached 6,871 of the 16,473 resident 15-30-year-olds of whom 6,141 (89%) accepted health promotion; condoms (41,620) and HIVST kits (5,898). Of 4,162 referrals, 438 (11%) attended clinics. Overall, PTP approaches were acceptable. Peer-navigators and beneficiaries reported that AGYW were comfortable sharing sexual health issues they would not have shared with adults. Peer- distributers felt they were 'making a change' and appreciated the incentive. However, some AGYW were wary of receiving health information from friends perceived as non-professionals. Although HIVST motivated AGYW and their partners to test, it distracted them from other health and PrEP information provided. Referral slips, adolescent-friendly clinics with non-judgemental staff were facilitators to PrEP uptake. Social disapproval, daily pills and unpredictable nature of risk were barriers.

CONCLUSIONS: Both professional (peer-navigators) and social network PTP approaches were acceptable methods to receive HIVST and information with wide reach. Social and structural factors remain barriers which need to be addressed for HIVST to increase uptake of PrEP among AGYW.

PEC0690

PREP ELIGIBILITY, HIV RISK PERCEPTION, AND WILLINGNESS TO USE PREP AMONG MSM IN INDIA

V. Chakrapani[1], P.A. Newman[2], M. Shunmugam[1], R. Nelson[1], S. Rawat[3], D. Baruah[3]

[1]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [2]Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Canada, [3]The Humsafar Trust, Mumbai, India

BACKGROUND: In India, men who have sex with men (MSM) are at elevated risk for HIV. As pre-exposure prophylaxis (PrEP) has emerged as an important HIV prevention tool globally, and with PrEP demonstration projects underway in India, we assessed the associations between guideline-informed PrEP eligibility, HIV risk perception (a Health Belief Model construct), perceived benefits and costs (Rational Choice Theory constructs), and stated willingness to use PrEP (WTUP).

METHODS: From December 2016 to March 2017, MSM were recruited at „cruising" sites ('hotspots') by peer outreach workers from community-based organizations (CBOs) in Mumbai and Chennai. Interviewer-administered Tablet-Assisted Survey Interviews were conducted in private CBO offices. We used logistic regression to examine associations between PrEP eligibility, HIV risk perception, perceived benefits and costs of PrEP and WTUP (outcome) among HIV-negative MSM. PrEP eligibility criteria were adapted from CDC/WHO/European guidelines:

1) condomless anal sex (past-month),
2) STI diagnosis (past-year),
3) sex work (past-month), and
4) >1 male partner (past-month).

Perceived benefits and costs were assessed with Likert-type scales (Cronbach's alphas >.85). Additionally, we conducted logistic regression to identify factors associated with unwillingness to use PrEP among PrEP-eligible MSM.

RESULTS: Participants' (n=197) mean age was 26.6 (SD 6.6); one-third (34%) completed college-degree education, and half (49%) engaged in sex work; 93% met at least one PrEP-eligibility criterion. Three-fourths (77%) reported they would 'definitely use' PrEP; however, one-fifth (19%; 38/197) met PrEP-eligibility criteria but reported unwillingness to use PrEP. PrEP eligibility (aOR=3.89, p=.04), higher HIV risk perception (aOR=1.48, p=.01), and higher perceived benefits scores (aOR=1.12, p<.01) were associated with higher odds of WTUP. Among the 183 PrEP-eligible MSM, unwillingness to use PrEP was associated with lower HIV risk perception (aOR=.67, p=.02) and lower perceived benefits score (aOR=.87, p<.01).

CONCLUSIONS: MSM in India reported high willingness to use PrEP, with PrEP-eligibility criteria significantly predicting WTUP. However, a subgroup of PrEP-eligible MSM reported unwillingness to take PrEP due to low HIV risk perception and low perceived PrEP benefits. Interventions to facilitate accurate self-perceived HIV risk, and to promote awareness of PrEP benefits and eligibility criteria, may increase PrEP uptake among MSM in India who would most benefit.

PEC0691

LEARNING FROM THE ROLLOUT OF CURRENT HIV PREVENTION METHODS TO IMPROVE ACCESS TO AND UPTAKE OF NEW PREVENTION PRODUCTS FOR WOMEN AND ADOLESCENT GIRLS

A. Ismail[1], S. Chan[1], S. Magni[1], Z.B. Dube[1], L. Solai[2], N. Sutton[3], S. Tenn[2], C. Sadia[4], J. Wamoyi[5], M.M. Umlisa[6], S. Kusemererwa[7], N.M. Mgodi[8], S. Kokera[8], S. Johnson[1]
[1]Genesis Analytics, Johannesburg, South Africa, [2]International Partnership for Microbicides, Silver Spring, United States, [3]Johnson & Johnson, Global Public Health, New Brunswick, United States, [4]Kenya Medical Women's Association, Nairobi, Kenya, [5]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [6]Rinda Ubuzima, Kigali, Rwanda, [7]MRC/UVRI & LHSTM Uganda Research Unit, Entebbe, Uganda, [8]Zimbabwe College of Health Sciences Clinical Trials Research Centre, Harare, Zimbabwe

BACKGROUND: The monthly dapivirine (DPV) vaginal ring has been developed as a long-acting, female-initiated HIV prevention method. Pending regulatory approval, the International Partnership for Microbicides (IPM), the ring's developer, sought to understand the lessons from the introduction and rollout of oral pre-exposure prophylaxis (PrEP) and the female condom that could inform the prospective launch of the DPV ring.
METHODS: This qualitative study was conducted in Kenya, Malawi, Rwanda, South Africa, Tanzania, Uganda and Zimbabwe where the first regulatory submissions in Africa are planned. We conducted 12 key informant interviews (KIIs) with policymakers, 101 KIIs with healthcare providers (HCPs) (doctors, pharmacists and nurses) and 20 focus group discussions with community health workers (CHWs) (n=127). Data were analysed using thematic content analysis.
RESULTS: Several key themes emerged when participants reflected on the introduction of PrEP (available in five of the seven countries) and the female condom (available in all seven countries). These were: usability of the ring by end-users, HCP training, and health systems readiness.
Participants emphasised highlighting the usability of the ring to end users, as the female condom had low uptake due to low knowledge on its functional use and the discomfort experienced when using it. HCP training was insufficient prior to the introduction of PrEP and often extended to a few staff members and excluded CHWs. As a result, knowledge of PrEP was low and HCPs lacked the confidence to prescribe it. At the health system level, the importance of wide distribution and consistent availability of the ring was emphasised. In some countries, stock-outs of female condoms have made HCPs and CHWs reluctant to promote them.
CONCLUSIONS: If approved, ring introduction programs can build from the experiences of other female-oriented prevention methods. To do so, IPM and its partners should prioritise raising awareness among policymakers and HCPs through the use of clear communication and behavioural strategies such as framing and overcoming biases. Prior to ring implementation, a broad range of HCP cadres and CHWs should be trained to develop confidence to prescribe the ring and relay its usability to end-users. In addition, country-specific health system barriers should be addressed.

EARLY ENGAGEMENT ON PREP AMONG TRANSGENDER WOMEN IN LATIN AMERICA: THE IMPREP EXPERIENCE

J.V. Guanira[1], K.A. Konda[2], A. Ramos[3], R. Ismerio Moreira[3], I. Leite[3], B. Hoagland[3], M. Benedetti[3], G. Mariño[2], M. Vinicius Lacerda[4], B. Grinsztejn[3], E.H. Vega-Ramirez[5], C.F. Caceres[2], V. Veloso[3], ImPrEP Study Group
[1]Inmensa, Lima, Peru, [2]Universidad Peruana Cayetano Heredia, Centro de Investigaciones Interdisciplinaria en Salud, Sexualidad, y SIDA, Lima, Peru, [3]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [4]Fundacao de Medicina Tropical Dr Heitor Vieira Dourado, Manaus, Brazil, [5]National Institute of Psychiatry Ramon de la Fuente Muñiz, Mexico City, Mexico

BACKGROUND: Transgender Women (TGW) are a key population in the worldwide HIV epidemic. While Pre-exposure prophylaxis (PrEP) is recommended by the WHO to prevent HIV acquisition among individuals at substantial risk, including TGW, PrEP uptake among TGW globally has been low. ImPrEP is a PrEP demonstration study to assess the feasibility providing daily oral PrEP to MSM and TGW at risk for HIV in Brazil, Mexico and Peru. We explore baseline characteristics associated with early engagement of enrolled TGW
METHODS: This analysis includes all individuals who self-define as TGW enrolled in ImPrEP. Early engagement was defined as returning for the first follow-up visit within 15-60 days of enrollment. Data were collected on socio-demographics, factors associated with HIV acquisition (i.e. condomless anal sex), and past use of Pre or Post-exposure prophylaxis. Enrollees were tested for syphilis and anal STIs (Neisseria Gonorrhea and Chlamydia Trachomatis). In bivariate analysis, the effect of each covariate was estimated controlling by country, covariates significant at 10% were selected for the multivariate analysis.

		N (% with early engagement)	OR* (95% CI) adjusted by country	p-value	aOR (95% CI)	p-value

[Table]

RESULTS: Until December 1st, 2019, ImPrEP enrolled 480 TGW (235, 49.0% from Peru; 184, 38.3% from Brazil; and 61, 12.7% from Mexico), who were on average 29 years-old (IQR:24-37). The majority completed only secondary education (71.0%). In the past 6 months, their median number of sex partners was 20 (IQR: 5-100); 89.6% reported condomless anal sex; 4.6% reported sex with an HIV positive partner; and 68.5% reported sex work.

Baseline prevalence for syphilis, anal NG and anal CT were 18.1%(95%CI:14.4%-22.2%), 14.7%(95%CI:11.2%-18.9%) and 17.8%(95%CI:13.9%-22.2%), respectively. Early engagement was achieved by 71.1% of TGW. Having greater than secondary education was independently associated with a higher chance of early engagement among TGW (aOR2.42, 95%CI1.37-4.29).

CONCLUSIONS: Greater efforts to improve early retention to PrEP among TGW should be undertaken to improve their PrEP continuation, especially among TGW with lower education.

PEC0693

MEN'S SEXUAL EXPERIENCES WITH THE DAPIVIRINE VAGINAL RING IN MALAWI, SOUTH AFRICA, UGANDA AND ZIMBABWE

E.T. Montgomery[1], A. Katz[1], Z. Duby[1], L. Mansoor[2], N. Morar[3], K. Naidoo[2], M. Tsidya[4], M. Chitukuta[5], V. Guma[6], S. Tenza[7], J. Leslie[1], M. Garcia[8], S. Naidoo[3], MTN-032 AHA

[1]RTI International, Women's Global Health Imperative, San Francisco, United States, [2]CAPRISA, Durban, South Africa, [3]Medical Research Council, HPRU, Durban, South Africa, [4]University of North Carolina - Lilongwe Programme, Lilongwe, Malawi, [5]University of Zimbabwe - Community Health Sciences, Harare, Zimbabwe, [6]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [7]Wits Reproductive Health and HIV Research Institute, Johannesburg, South Africa, [8]FHI360, Durham, United States

BACKGROUND: The dapivirine vaginal ring has been well-tolerated and shown to prevent HIV in clinical trials. The ring is female-initiated yet endorsement for use is often sought from male partners (MPs). In clinical studies, participants have expressed worries about men detecting rings during sex, which introduces concerns about disclosure, sexual pleasure, penile harm, inter-partner dynamics, and ring removals. This study reports men's firsthand sexual experiences with the ring.

METHODS: Eleven focus group discussions with 53 random- and purposively-selected MPs of ring-users at six sites in Malawi, South Africa, Uganda and Zimbabwe were conducted. Following a semi-structured guide, and using demonstration rings, vulva and penis models, men were asked about the ring's impact on sex and views on male engagement and ring use. Interviews were facilitated by local, male, social scientists; audio-recorded, translated into English, and analyzed thematically.

RESULTS: MP's average age was 37.5 (range 21-61); 61.1% had not completed secondary school. Forty percent of MPs reported feeling the ring during sex, often attributed to perceived incorrect insertion. Many men described the ring as "scratching" the tip of their penises, and sensations of "prodding" something that "blocked" the vagina and prohibited "full entry". In most cases, physical feelings dissipated with ring experience or increased lubrication. Some men felt the vaginal texture, wetness and size was different, which increased pleasure for several, and decreased for others. Three-fifths never noticed the ring; some attempting and failing to feel it during intercourse. The majority of men reported that the ring did not change the positions, feelings, frequency or experience of sex, although some were initially afraid that the ring was a "magic snake" or "potion". MPs expressed strong opinions that ring use was a shared prevention responsibility and their engagement was important to relationship trust and open communication.

CONCLUSIONS: The ring was noticed by many MPs, particularly at study initiation, although this led to few sexual problems or changes. Nevertheless, results suggest that risk of ring discovery should be discussed with women to mitigate any potential negative reactions or social harm. Strategies to increase MP engagement will enhance support of this prevention method for women.

PEC0694

THE RELATION OF INTERNALIZED HOMONEGATIVITY WITH HIV PREVENTION STRATEGIES: RESULTS FROM LATIN-AMERICA MSM INTERNET SURVEY (LAMIS) IN BRAZIL

I. Prado Generoso[1], A. Borges Moreira da Rocha[1], A. J. Schmidt[2], L. Fasciolo Maschião[1], T. Félix Pinheiro[1], J.L. Gomez Gonzalez Júnior[1], J. Casabona[3], C. Cáceres[4], M. Edward Reyes-Diaz[4], V. Stuardo[5], M.A. Veras[1], NUDHES, RIGHT-PLUS

[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Collective Health Department, São Paulo, Brazil, [2]Sigma Research, London, United Kingdom, [3]Centre d'Estudis Epidemiològics Sobre les Infeccions de Transmissió Sexual i Sida de Catalunya, Barcelona, Spain, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Universidad de Chile, Santiago, Chile

BACKGROUND: Internalized homonegativity (IH) could be defined as negative thoughts towards homosexuality and its features in oneself. In Brazil, MSM are a key population for HIV care and policy making. Combination HIV prevention (condoms, PEP, PrEP, testing, treatment as prevention) is the most complete and effective way to approach HIV epidemic. This study aimed to analyze the relation of IH with adherence to different HIV prevention strategies.

METHODS: LAMIS was an online cross-sectional survey conducted between January-April 2018. The survey was promoted through dating apps, social network groups and websites with gay content. For this analysis, we considered 13.205 participants from Brazil (those who reported living with HIV and/or had discrepant answers were excluded). IH was categorized as "Low" (0-0.43); "Medium" (0.431-2.99); "High" (3-6) according to quartiles distribution using the Short Internalized Homonegativity Scale. Multiple logistic regression models were used to assess the relation between IH and HIV-prevention outcomes, adjusted by age, settlement size and education level. The reference category are always those who scored "Low IH".

RESULTS: Having high IH was associated with lower odds (aOR=0.75; CI95%0.68-0.83) of receiving free condoms in the last 12 months. Medium (aOR=0.79; CI95%0.70-0.89) and high IH (OR=0.52; CI95%0.46-0.59) were negatively associated with ever having an HIV test. Those with high IH had lower odds of being aware of PrEP (aOR=0.42; CI95% 0.38-0.47) and to be currently using daily PrEP (aOR=0.36; CI95%0.24-0.55). Having high IH was also negatively associated with PEP awareness (aOR=0.37; CI95%0.33-0.42) and PEP use (aOR=0.66; CI95%0.57-0.78). Those who had high internalized homonegativity also had lower odds of knowing about U=U (aOR=0.42; CI95%0.38-0.47).

CONCLUSIONS: These results suggest that negative attitudes and thoughts towards homosexuality (high internalized homonegativity) reduces access to several HIV-prevention strategies such as condoms, testing, PrEP, PEP and even knowledge about U=U. Determinants such as prejudice and stigma, especially those directed towards oneself, might be an important risk factor for HIV-infection.

In the context of combination prevention, addressing IH in health services, HIV counseling and even advancing in gay rights agenda might be important structural interventions to improve HIV prevention.

ACCESS TO HARM REDUCTION INTERVENTIONS

SHARED SYRINGE USE AND HIV PREVALENCE AMONG HIGH FREQUENCY DRUG USERS IN TAJIKISTAN IS ASSOCIATED WITH INADEQUATE PROVISION OF PREVENTION SERVICES AND LOW INCOME

A. Nabidzhonov[1], R. Nurov[2], V. Ivakin[3], M. Courey[4], A. Deryabina[3], W.P. Killam[5]
[1]Centers for Disease Control and Prevention, DGHT, Central Asia, Dushanbe, Tajikistan, [2]Republican AIDS Center of the Ministry of Health and Social Protection of the Population of the Republic of Tajikistan, Dushanbe, Tajikistan, [3]ICAP at Columbia University, Central Asia, Almaty, Kazakhstan, [4]Centers for Disease Control and Prevention, DGHT, Pretoria, South Africa, [5]Centers for Disease Control and Prevention, DGHT, Atlanta, United States

BACKGROUND: Sharing of needles, syringes and injecting equipment by people who inject drugs (PWID) primarily drives HIV transmission in Tajikistan. To inform improvement of the needle-syringe exchange programs (NSPs), the national HIV program conducted a bio-behavioral survey among PWID in eight districts in 2018 to estimate HIV prevalence, risk-behaviors, and program coverage.
METHODS: We used respondent-driven sampling to recruit adults who injected drugs at least once in the 6 months preceding enrollment. The sample size range was 250-500 across the sites. Participants completed an interview and provided blood samples for HIV, viral load, and syphilis testing. Data were analyzed for injection frequency, sharing of contaminated injection equipment, participation in NSP in the last 3 months, and monthly income. People injecting drugs more than once daily in the last 6 months were classified as high frequency injectors (HFI); those injecting once daily or less were considered low frequency injectors (LFI). Descriptive analysis and chi-square test of the crude estimates were conducted using Stata/SE.
RESULTS: 2,350 participants were recruited. Among NSP clients (n=1,067), 13.6% of HFI and 2.8% of LFI (p<0.0001) reported sharing of contaminated injecting equipment. HIV prevalence was higher among equipment sharing HFI (31%) than among non-sharing HFI (10.3%, p=0.0004), and was higher than among equipment sharing LFI (9.7%, p<0.0001). Median monthly income was lower for equipment sharing HFI versus non-sharing HFI (US$45.00 vs. US$78.00USD, p = 0.0071). HFI who did not receive free sterile equipment from NSPs and did not share injecting equipment had a much higher median monthly income (US$136.00) than HFI NSP clients who shared equipment (US$45.00USD, p < 0.0001).
CONCLUSIONS: Currently, the Global Fund HIV grant provides only one syringe per client per day. If provided an adequate supply of sterile needles and syringes through NSPs, low-income HFI are less likely to share needles and become HIV-positive. Harm reduction programs should consider targeting low-income HFI. A screening tool that assesses for median monthly income and frequency of drug use could help ensure that the highest risk PWID have access to adequate supplies of sterile needles, syringes and injecting equipment.

PEC0696

INCREASING ACCESS TO MEDICATION-ASSISTED TREATMENT (MAT) FOR HARD-TO-REACH PEOPLE WHO INJECT DRUGS (PWID) THROUGH SATELLITE SITES IN NORTH-EAST INDIA

P.K. Choudhury[1], P. Goswami[1], R.N. Singh[1], G. Shreenivas[1], B. George[1]
[1]FHI 360, Project Sunrise, Guwahati, India

BACKGROUND: HIV prevalence among PWID in North-East states is higher than the national PWID average of 6.2% (Mizoram 19.8%, Tripura 8.5%, Manipur 7.6%). To address the rising HIV infections, National AIDS Control Organization (NACO) has scaled up harm reduction services including MAT in facility and community settings. The distance and hilly terrain are barriers for PWID to access MAT in Northeast states. With funding from PEPFAR/CDC, Project Sunrise implemented by FHI 360 introduced Satellite sites to bring MAT to PWID in remote areas in Northeast India.
DESCRIPTION: Staff conducted a feasibility assessment related to location of satellite sites along with community consultation. The sites identified included a primary health centre, drop-in-centre, faith and community-based organization with no additional infrastructure cost. Each site was linked with the closest parent MAT centre approved by NACO. All clients who were on stable doses accessed their medication at the satellite site on a monthly basis. The sites also provided linkage to HIV screening, index testing, ART and psychosocial support.
LESSONS LEARNED: A total of 1,948 hard-to-reach PWID accessed MAT from 32 satellite sites through August 2019. Around 1,480 (75%) clients were retained on MAT in the last six months; 1,535 (78%) clients were tested for HIV of which 306 (20%) tested positive and 276 PWID were initiated on ART (90%). Needle/syringe exchange, abscess management and linkage to social protection schemes were also provided. MAT uptake increased by 40% in one year (7,022 to 9,883 clients). MAT coverage increased from 15% to 22% among active PWID. Capacity building of existing staff, travel compensation for doctor for MAT induction, and proper supply chain management contributed to improved access to MAT. A policy change to permit 'Take Home' dosing for stable clients will further increase OST adherence.
CONCLUSIONS/NEXT STEPS Hard-to-reach PWID who are not accessing MAT and other HIV services were efficiently reached through satellite sites. NACO has included satellite MAT as a new innovative approach within the revised national targeted intervention strategy for key populations and scale up this approach across the country. This is a cost-effective model that can be replicated in low resource settings.

PEC0697

MYANMAR-INDIA CROSS BORDER HARM REDUCTION A GOLDEN RECIPE TO REDUCE DRUG USE RELATED HARM

T. Lin[1]
[1]Asian Harm Reduction Network, Program Department, Yangon, Myanmar

BACKGROUND: According to 2014 national statistics there were 1641 people who inject drugs (PWID) in Tamu Township located at the Myanmar-India border; with 20% HIV prevalence rate amongst cross border PWID. No harm reduction, HIV prevention and treatment services were available and only 140 PWID were on Methadone Maintenance Therapy. Tamu, border township of Myanmar and India is

located in the north-west of Myanmar. The border region shows historically opium fields, heroin production and, drug and supplies and is a trafficking 'corridor' between India and Myanmar. People from both sides frequently cross the border (unofficially) for trading and drug consumption in this heroin and opium rich border area.

DESCRIPTION: With funding support of 3MDG, the Asian Harm Reduction Network opened comprehensive harm reduction services in February 2015 in Tamu. Recognizing the mobile and cross border realities, AHRN initiated cross-border outreach for PWID/PWUD from both India and Myanmar, providing NS, Condoms, foil paper, HE, HTS and HIV referral. Cross-border linkage and coordination was established with other NGOs in India such as DPU and MSF.

LESSONS LEARNED: Both PWID/PWUD from Myanmar and India received HIV prevention services and 1,800 received Harm Reduction services annually. From February 2015 to December 2017, 870,724 Low Dead Space Syringes were distributed (majority in India side); 150 HE sessions were conducted, 528 PWID received the HTS services; 689 PWID/PWUD received Hepatitis B vaccination. 34 HIV positive PWID received ART treatment from National AIDS Program and 9 HIV Positive PWID received ART from MSF in India. 216 PWID/PWUD were screened for TB and 8 received TB treatment, providing cross border harm reduction services significantly reduced drug use related harm among PWID/PWUD in said area.

CONCLUSIONS/NEXT STEPS It was found that HIV syndemic can be tackled more effectively when communities came together from the neighboring countries as HIV among drug users is never a problem of a single country. Thus, cross border coordination should be strengthening further in the region.

PEC0698

BREAKING BARRIER TO INCREASE SERVICE ACCESSIBILITY BY INTEGRATING COMMUNITY LED PREVENTION PROGRAM IN HARM REDUCTION AND HIV PREVENTION PROGRAM

L. Thu[1], T. Linn[1], H. Aye[1]
[1]*Asian Harm Reduction Network, Program, Yangon, Myanmar*

BACKGROUND: Myanmar is struggling with a concentrated HIV, viral hepatitis and drug use syndemic. Vicarious discrimination of People Who Inject Drug (PWID) is witnessed, hampering access to vital lifesaving services. Organizations providing harm reduction services face strong community opposition and believe that NSP and drop-in-centers increase numbers of PWID.Community also implemented the anit drug use campaign by targeting the PWID. This opposition and anti drug use campaign limits PWID to access HIV prevention and health care service.

DESCRIPTION: AHRN transforms its approach from working in community to working with community to overcome this resistance by integrating a community prevention program at Waimaw Township in January 2018 with focused advocacy and providing training workshops to local community members. With their community ownership, these community prevention workers, receiving a small stipend to cover expenses, conduct prevention training in the community and conduct health education sessions for PWID/PWUD, provide the referral (cards) to access the HTS in AHRN clinic or DIC and mobile team. They participate in neighborhood NS cleaning-up campaigns and advocate others to take part in this campaign. Within the two years, 9 ToTs training for community were conducted and trained community also conducted the 22 training for their fellow community member as well as 30 HE session also conducted for PWID. 9 NS cleaning-up campaigns were done

LESSONS LEARNED: After integration of community led prevention program, the perception of community on Harm reduction services has change positively and the significant increased of accessing Harm Reduction and HIV prevention services by PWID. During 2017 from 2019, NSP was increased from 700,000 to 1574800 (125%). PWID reach from 2269 to 3231(42%). Condom distribution from 38304 to 58912 (54%). HTS accessed from 355 to 656(85%). Overdose management from 7 to 18.(157%) MMT accessed from 313 to 679(117%).

CONCLUSIONS/NEXT STEPS Integration of the community led prevention program is a good advocacy which significantly create the sense of ownership on the public health intervention by community themselves, AHRN will further expand its integration of community led prevention program in existing Harm Reduction Service.

PEC0699

RESISTANCE AND RESILIENCE: ACCESS TO CLEAN NEEDLES AND SYRINGES IN REMOTE-RURAL AREAS IN MYANMAR

A. Yu Naing[1], T. Tun[2], T. Linn[2]
[1]*Asian Harm Reduction Network, Health, Yangon, Myanmar,* [2]*Asian Harm Reduction Network, Program, Yangon, Myanmar*

BACKGROUND: In Myanmar, HIV prevalence among PWID vary between 34.9% up to 64.1% mainly related to needles and syringes (NS) scarcity and unsafe injecting practice. Injecting is a rural phenomenon in hard to reach concentrated hotspots of Northern Myanmar. Illegal possession of hypodermic NS may face legal challenges and prosecution. AHRN initiated community-based NS Automatic Taking Machines (NSATMs) at grocery-shops to increase easy access to clean NS in remote areas. Nevertheless, it remains subject to community resistance by anti-drug faith-based groups and public criticism for low return rates and scattered NS is perceived as a public health risk.

DESCRIPTION: In 2017, AHRN scaled-up community-based NSATMs at grocery-shops and pharmacies across its projects in Northern Myanmar. NSATM owners are trained in harm reduction, HIV prevention and assist and navigate PWIDs in the whole HIV treatment and care cascade. Local communities are trained and empowered to have more understanding on complex nature of drug problems. Outreach, needle patrolling by peers and NSATM shops collect used NS. Peers and community members participate in neighborhood NS cleaning-up campaigns and advocate others to have better understanding on Needles Syringe Program (NSP). Hotlines for needle stick injuries, used needle collection and post-exposure-prophylaxis are provided.

LESSONS LEARNED: Routine data and FGDs analysis of this innovation conclude: NS distribution increased from 9,227,769 in 2016 to 12,619,444 in 2017 and 15,486,275 in 2018 and the return rates were 73%, 63% and 68% respectively. PWID can access clean NS at all times from NSATM without worry. FGDs with community health workers, peers and users confirm: no widespread disposal of used NS in public; various methods of used NS destruction practiced (burning, discarding in bio-bin/latrines...); no significant difference of discarded NS & needle-stick injuries in those projects.

CONCLUSIONS/NEXT STEPS NSP is a proven HIV prevention strategy among PWID; empower community to enhance community advocacy leads to acceptance; lower return rates do not automatically mean widespread NS disposal in the community; zero transmission

from NS injuries occurred. Increased access to NS has a proven to significantly lower HIV risks amongst PWID and community at large. Further qualitative study and analysis on low return rates is warranted.

PEC0700

NEEDLE SHARING PRACTICES AND ACCESS TO HARM REDUCTION SERVICES AMONG PEOPLE WHO INJECT DRUGS IN NIGERIA: FINDINGS FROM A 2018 PROGRAMMATIC MAPPING EXERCISE ACROSS 10 STATES

R. Aguolu[1], I. Ezirim[1], K. Green[2], G. Ashefor[1]
[1]National Agency for the Control of AIDS (NACA), Abuja, Nigeria, [2]Center for Global Public Health, University of Manitoba, Abuja, Nigeria

BACKGROUND: Information on needle sharing, and harm reduction services such as needle syringe programs and opioid substitution therapy are currently not readily available in Nigeria. This study provides recent information on the needle sharing practices and access to harm reduction services among PWIDs in 10 states in Nigeria.

METHODS: This study was conducted in 10 states (Abia, Anambra, Enugu, Gombe, Kano, Kaduna, Taraba, Oyo, Imo and Edo) in Nigeria in 2018, using a programmatic mapping approach. It involved a two-level (L1, L2) process: L1- systematic information gathering regarding the geographic locations and description of their hotspots through secondary key informants' interview and L2- Spots validation and in-depth profiling of spots identified in Level 1. Information regarding needle sharing practices and access to harm reduction services six months prior to this exercise were collected.

RESULTS: Total number of PWIDs estimated across the 10 states was 49,874, about 22% (11,031) were females. Approximately 40% (19,918) of the total estimated PWIDs share needles across the 10 states, with Oyo state having the highest estimate 41% (8,252). Rate of needle sharing per state was also highest in Oyo, about 56% of the total estimated PWIDs in the state share needles. High rates were also seen in Abia, Gombe, Kaduna and Anambra states. Across the 10 states, access to all types of HIV prevention services six months prior to the exercise was highest in Gombe state. HIV testing service was available in 30% of spots in Gombe. Needle replacement services and opioid substitution therapy were provided in less than 10% of spots in Gombe state while safe needle disposal services were not available across the 10 states.

CONCLUSIONS: A large proportion of PWIDs share needles and this varied in proportion across states. Access to harm reduction services was extremely poor across all 10 states. There is an urgent need to address this gap as PWIDs are at a very high risk of contracting and spreading HIV among themselves and to the general population. Information from this study can be used as a policy advocacy tool for the effective implementation of harm reduction services in Nigeria.

OPTIMIZING VERTICAL TRANSMISSION PREVENTION PROGRAMMES

PEC0701

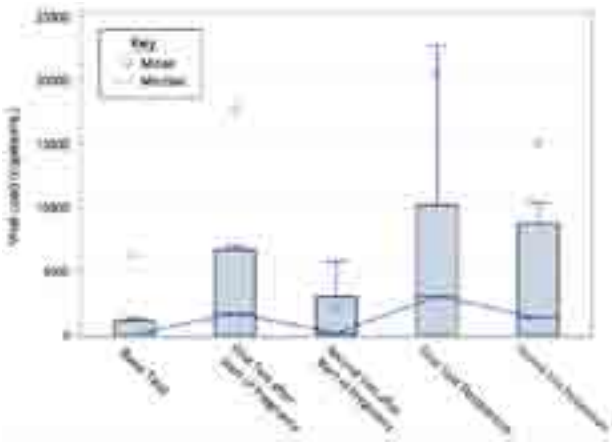
RISK FACTORS ASSOCIATED WITH VIROLOGIC FAILURE AMONG HIV-POSITIVE PREGNANT AND POSTPARTUM WOMEN RECEIVING ANTIRETROVIRAL THERAPY: A CASE-CONTROL STUDY IN KISUMU, KENYA

V. Poole[1], B. Samba[2], I. Ogolla[2], L. Otieno[2], F. Odhiambo[2], C. Cohen[3], E. Bukusi[2], L. Abuogi[4]
[1]Colorado School of Public Health, Aurora, United States, [2]Family AIDS Care and Education Services, Research Care and Training Program, Kenya Medical Research Institute, Nairobi, Kenya, [3]University of California, Department of Obstetrics, Gynecology and Reproductive Services, San Francisco, United States, [4]University of Colorado, Denver, Department of Pediatrics, Aurora, United States

BACKGROUND: Viral suppression is critical for pregnant and breastfeeding women living with HIV (PWHIV). This study aimed to identify risk factors for virologic failure [>1000 copies per mL (cpm)) among PWHIV on antiretroviral treatment (ART).

METHODS: We conducted a case-control study among 159 women on ART who were pregnant or <1-year postpartum January 2016–January 2018. Cases included women with at least one viral load >1000 cpm during pregnancy or postpartum (n=53). Women with viral loads <1000 cpm throughout pregnancy and postpartum were randomly selected as controls (n=106). Data on demographic characteristics and medical history were abstracted from medical charts at a large volume, urban facility in Kisumu, Kenya. Multiple logistic regression was used to test the significance of association between extracted variables and virologic failure. The final model was adjusted for age and time since HIV diagnosis (p>0.10).

RESULTS: Overall, mean age was 29 years (SD 5.2) and mean duration on ART was 46 months (SD 36). The majority of women were on first line ART (N=140; 88.1%) and were diagnosed with HIV prior to pregnancy (N=117; 74.0%). Logistic regression revealed that women who did not know their male partner's HIV status were significantly more likely to experience virologic failure during pregnancy or postpartum than those who did [adjusted odds ratio (aOR) 3.53, 95% Confidence Interval (CI) 1.08-11.48, p=0.04]. Women who started pregnancy on a second line ART regimen were significantly more likely to have virologic failure than those who were on first line ART [aOR 65.06, CI 7.65-553.01, p=0.0001]. Median viral load among cases appeared to peak in the early postpartum period (Figure 1).



[Figure 1. Mean and median viral load among women with virologic failure throughout pregnancy and postpartum]

CONCLUSIONS: This study identified important risk factors for viremia in pregnant and postpartum women with HIV. Efforts to address virologic failure in PWHIV should consider improving male partner engagement and disclosure, and management of pregnant patients on second-line ART.

PEC0702

ENGAGING COMMUNITY WOMEN AS PEER HEALTH EDUCATORS IN PROMOTING BETTER HEALTHCARE FOR TRIBAL PREGNANT WOMEN IN MYSORE DISTRICT, KARNATAKA, INDIA

P. Jayakrishna[1], N. Ningaiah[1], S. Chowdagudda[1], K. Krupp[1,2], P. Madhivanan[1,2,3,4]
[1]Public Health Research Institute of India, Public Health, Mysore, India, [2]Mel & Enid Zuckerman College of Public Health, University of Arizona, Public Health, Arizona, United States, [3]Division of Infectious Diseases, College of Medicine, University of Arizona, Arizona, United States, [4]University of Arizona, Department of Family & Community Medicine, College of Medicine, Arizona, United States

BACKGROUND: Involving women from the target community to promote health of indigenous tribal pregnant women is important in a country like India where there is an acute shortage of qualified health professionals and a large burden of maternal mortality and HIV transmission. These women can act as "change agents" and assist healthcare providers by providing education, and motivating women to seek prenatal care including HIV/STD testing.

METHODS: In May 2016, Public Health Research Institute of India(PHRII) a community-based organization working for Women's Health identified and trained 11 active tribal women from 22 tribal areas to serve as peer health advocates from Mysore District, Karnataka as part of a larger effort to empower local women to improve women's health in their community. Training was conducted in *Kannada* using didactic presentations, debate, role-play and panel discussions. Topics included maternal health, childcare, HIV and reproductive health. Knowledge was assessed before and after the training with pre- and post-tests. An equal emphasis was given in empowerment and leadership building among women in addition to focus on increasing the uptake of integrated prenatal care and HIV testing among tribal pregnant women with limited access to health care through the use of a mobile medical clinics.

RESULTS: The median age of community women was 28 and most of them had completed 11th grade education. The training program proved to be successful as 290 (97.6%) out of 297 pregnant women in the community were referred by community women to the mobile clinics conducted by PHRII. Of these women, 286 (98.6%) received prenatal care and all 290(100%) underwent HIV testing and counseling. Over the program period 2016-17, only one pregnant woman was diagnosed with HIV infection (0.35%) and was referred to the ART center for further treatment.

CONCLUSIONS: Empowering local community women through training can be effective in improving women's health in hard to reach communities in the context of providing prenatal care and HIV testing. This can be an important strategy for promoting and sustaining community health programs in under served communities.

PEC0703

HIV STIGMA LIMITS THE EFFECTIVENESS OF PMTCT IN GUINEA, THE ANRS 12344 DIAVINA TRIAL

G. Breton[1,2], O.H. Diallo[3], M. Cisse[4], O.H. Diallo[5], N.A. Diallo[5], S. Soumaoro[6], Y. Camara[6], A. Montoyo[7], C. Rouzioux[8], Y. Koita[9], G. Peytavin[10], R. Tubiana[2,1], P. Frange[11], ANRS 12344 DIAVINA study group
[1]SOLTHIS, Paris, France, [2]Pitié Salpêtrière Hospital, Infectious and Tropical Diseases, Paris, France, [3]SOLTHIS, Conakry, Guinea, [4]Donka Hospital, Conakry, Guinea, [5]Fondation Espoir Guinée, Conakry, Guinea, [6]Ignace Deen Hospital, Conakry, Guinea, [7]ANRS, Paris, France, [8]CHU Necker-Enfants Malades, Paris Descartes University, Virology, Paris, France, [9]PNLSH, Conakry, Guinea, [10]CHU Bichat-Claude Bernard, Paris, France, [11]CHU Necker-Enfants Malades, EHU 7327, University of Paris, Clinical Microbiology, Paris, France

BACKGROUND: Nearly half of HIV-infected children worldwide are born in West and Central Africa, where access to PMTCT programme is still limited. The 2016 WHO guidelines recommend reinforced ARV prophylaxis for infants at high risk of MTCT that needs to be further investigated in the field.

METHODS: The prospective ANRS 12344-DIAVINA trial evaluates at Ignace Deen Hospital, Conakry, Guinea, the feasibility of a strategy combining early infant diagnosis (EID) and reinforced ARV prophylaxis (AZT-3TC-NVP 12 weeks) in high-risk infants.

RESULTS: From Feb 2017 to Feb 2018, 6,493 women were admitted for delivery, 6,141 (96%) accepted HIV testing, 114 women were HIV-infected (1.9%). Among them, 51 high-risk women (newly diagnosed with HIV (n=38) or treated for <4 weeks (n=13)) and their 56 infants were included. At birth, blood sample for EID was collected and reinforced ARV prophylaxis was initiated in 48/56 children (86%, $IC_{95\%}$ 77-95%). No clinical adverse events was attributed to the prophylaxis. Iron supplementation was given to 35% of children for non-severe anaemia. Most (91%) infants were exclusively breastfed.

Retrospective measure of maternal HIV-RNA at delivery revealed than 49% of children were misclassified as high-risk infants (maternal HIV-RNA <400 cp/mL) due to undisclosed ARV use by mothers. Self-stigmatization was more frequent in falsely classified women than in others (85% vs. 44%, p=0.02). Compared to low-risk infants (maternal HIV-RNA <400 cp/mL), high-risk children (median maternal VL 4.9 log10cp/mL) were more frequently lost to follow-up (44% vs 8%, p<0.01), which was associated to the mother's self-stigmatization (69% vs 31%, p<0.01). HIV infection was documented in 4 high-risk children, 3 of whom at birth.

CONCLUSIONS: HIV testing in delivery room and EID at birth are widely acceptable, as well as reinforced ARV prophylaxis, whose safety profile was good. However HIV stigma seems to be a major obstacle to the effectiveness of PMTCT strategies in Guinea. Because the risk of MTCT could not been appropriately evaluated by interview of mothers, implementation of measurement of maternal VL near delivery seems crucial. More, the improvement of PMTCT requires, beyond medical strategies, a consideration of the social issues of stigmatization in order to limit loss of follow-up of high-risk infants.

PEC0704

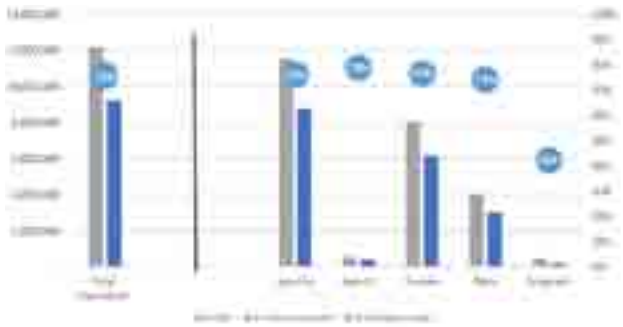
VIRAL LOAD TESTING COVERAGE AMONG PREGNANT WOMEN IN PEPFAR-SUPPORTED COUNTRIES, OCTOBER 2018 – SEPTEMBER 2019

L.J. Viens[1], A.L. Geller[1], N. Gaffga[1], K.A. Battey[1]
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States

BACKGROUND: Sustained HIV viral suppression reduces the risk of vertical transmission and eliminates the risk of sexual transmission. Viral load (VL) suppression is the most reliable measure of the effectiveness of antiretroviral therapy (ART). We evaluated the President's Emergency Plan for AIDS Relief (PEPFAR) VL program data to assess how well VL testing reached children, women, and pregnant women.

METHODS: We analyzed VL testing coverage among ART patients in 19 high-burden HIV countries. VL testing coverage proxy estimates were calculated as the number of patients with a VL test divided by the number on ART 6 months earlier. VL testing coverage for pregnant women was estimated as those with a VL test among those already on ART at their first antenatal visit.

RESULTS:



[Figure 1. Number of patients on ART at PEPFAR sites in 19 high-burden HIV countries with a viral load test result, October 2018 - September 2019*

Botswana, Burundi, Cameroon, Cote d'Ivoire, Democratic Republic of the Congo, Eswatini, Ethiopia, Haiti, Kenya, Lesotho, Mozambique, Nigeria, Rwanda, South Africa, South Sudan, Tanzania, Uganda, Zambia, Zimbabwe]

Between October 2018 and September 2019, over 9 million patients had a VL test documented in their medical or laboratory records (76%). (Figure 1) The majority of tests were conducted in ≥15 year old (95%) and female (67%) sub-populations; 2% of tests were in pregnant women. The majority of patients <15 years and women on ART had a VL test (77% and 79%, respectively), but VL testing coverage among pregnant women was low overall (42%), and <50% in all but 6 countries (median 25%, range 7%-86%).

CONCLUSIONS: Suboptimal VL testing coverage of pregnant women in PEPFAR-supported facilities limits the ability of programs to effectively intervene to lower HIV transmission risk and protect the health of pregnant women and their families. Given the wide gap between the high VL testing coverage for all women on ART and the very low coverage for pregnant women, programs must critically review both data quality and program implementation gaps among pregnant women, to enable a reliable assessment of progress towards the UNAIDS goal that 90% of people on ART are virally suppressed by 2020.

PEC0705

THE IMPACT OF CASE CARE WORKERS HOME VISITS ON ADHERENCE TO ART AMONG CAREGIVERS AND THEIR CHILDREN

H. Mushumbamwiza[1], V. Simms[1], D. Chandramohan[1]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: The PMTCT has been a success in controlling HIV/AIDS in children and caregivers but evidence indicates an increase in the risk of vertical transmission during breastfeeding period due to lower adherence to ART in the postpartum period, and this urges to extend support of adherence to ART and retention in care among caregivers and infants. Therefore, we assessed the impact of Case Care Workers (CCW) home visits on adherence to ART among HIV exposed or infected children below 2 years of age and their HIV positive caregivers in rural Zimbabwe.

METHODS: This was a secondary data analysis of a multicomponent intervention cluster trial in 1:1 allocation. The sample size was randomly selected using PMTCT registries in 30 clinics in two districts in Zimbabwe. The standard arm received national HIV guidelines standard of care and the intervention arm on top to standard care received three interventions including CCW home visits to support adherence to ART and retention in care. Study outcomes; adherence to ART that was measured using Medication Adherence Rating Scale, and infant HIV testing were both measured after 12 months from enrolment. The study was analysed per protocol and logics regression was used to measure the effect and to adjust for predictors.

RESULTS: In total 574 caregiver-child dyads were enrolled and about 89.5% (514) completed 12 months of follow-up. There was no evidence of intervention effect on adherence to ART among caregivers (98.0% of adherence in intervention arm vs 98.3% in control arm; (OR=0.81, 95%CI:0.21 – 3.18, p=0.768) or infant HIV testing (98.1% ever tested for HIV in intervention arm vs 98.8% in control arm; OR=1.03, 95%CI:0.06 – 16.58, p=0.982). Adherence to ART among children was not explored due to the small number (6 children in treatment arm vs 6 in control arm) who were HIV positive.

CONCLUSIONS: CCW home visits did not have an impact on adherence to ART compared to Option B+ as standard care among caregivers of children between 0-24 months old with 12 months follow-up in Zimbabwe. Further research is needed to understand other specific factors in Zimbabwe that may hinder achieving the new global HIV target of 95-95-95.

PEC0706

FACILITATING HIV RETESTING AMONG PREGNANT AND BREASTFEEDING WOMEN: A MULTI-COUNTRY ANALYSIS FROM 2016 TO 2018

K. Schmitz[1], C. Metekoua[2], T. Mhembere[2], K. Shumba[2], C. Mlandu[2], M. Mbule[1], A. Ronan[1], F. Burtt[1], F. Mpungu[1], A. Chivafa[2], V. Williams[2], E. Musenge[2], E. Scheepers[1], J. Igumbor[2]
[1]mothers2mothers, Cape Town, South Africa, [2]University of the Witwatersrand, Johannesburg, South Africa

BACKGROUND: Regular testing cascades to early treatment initiation, achieving timely viral suppression and preventing mother to child transmission. HIV programs often prioritize HIV positive women over HIV negative women, negating the value of primary prevention. This study investigated the impact of using lay health workers to promote the uptake of HIV retesting services amongst HIV negative women receiving antenatal and postnatal care.

METHODS: We conducted a secondary analysis of data collected from Eswatini, Lesotho and South Africa. The data included services provided by mothers2mothers' Mentor Mothers which was collected using a mobile health application between 2016 and 2018. We cross-linked this data with population level data from the national Demographic and Health Surveys. The sample consisted of HIV negative antenatal and postnatal women registered into mothers2mothers' Mentor Mothers program at health facility level. A total of 7,604 clients who had been enrolled for a minimum of 6 months and a maximum of 12 months were included in the analysis. A multilevel mixed-effects Poisson regression analysis was performed to identify factors associated with the frequency of retesting amongst HIV negative women in the program.

RESULTS: The median duration of participants in the program from enrollment was 8 months (IQR: 7-10 months) with the median number of HIV retests done being 2 (IQR: 1-2). The median number of contact sessions with a Mentor Mother was 5 (IQR: 3-5). Every additional Mentor Mother contact session increased retesting by 4% (p<0.001). An increase in the median number of contacts with HIV negative women at the health facility increased HIV retesting by 7% (p=0.009). With an additional month spent between contact sessions with a Mentor Mother, HIV retesting decreased by 11% (p<0.001). An increase in new pediatric HIV infections that occur during birth or an increase in the proportion of male-headed households in a community linked to a heath facility reduced HIV retesting by 1% (p<0.001).

CONCLUSIONS: The results showed how routine engagement with Mentor Mothers increased retesting in antenatal and postpartum women. This information could help in extending PMTCT service packages to HIV negative women in high HIV prevalence areas.

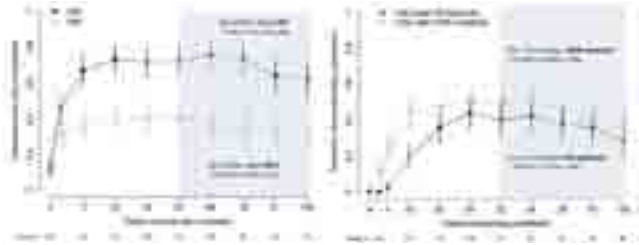
Burns[12], W.C. Miller[9], I.F. Hoffman[13], and the HPTN 074 Study Team

[1]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, United States, [2]Fred Hutchinson Cancer Research Center, Statistical Center for HIV/AIDS Research and Prevention (SCHARP), Seattle, United States, [3]UNC Vietnam, Hanoi, Vietnam, [4]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [5]University of Indonesia, Cipto Mangunkusumo Hospital, Jakarta, Indonesia, [6]FHI 360, Durham, United States, [7]Johns Hopkins University, Baltimore, United States, [8]University of Pennsylvania, Philadelphia, United States, [9]The Ohio State University, Columbus, United States, [10]The University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, United States, [11]Vietnam Administration of HIV/AIDS Control, Hanoi, Vietnam, [12]Division of AIDS, National Institute of Allergy and Infectious Diseases, Bethesda, United States, [13]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States

BACKGROUND: HIV+ people who inject drugs (PWID) experience inadequate access to antiretroviral treatment (ART) and medication-assisted treatment (MAT) and insufficient viral suppression (VS). HPTN 074 demonstrated that an integrated, systems navigation and psychosocial counseling intervention reduced mortality and increased ART and VS over 52 weeks. We present results from an additional 52 weeks of follow-up.

METHODS: HPTN 074 was conducted in Ukraine, Indonesia and Vietnam. Participants were randomly assigned 3:1 to standard-of-care (SOC) versus intervention. Eligibility criteria included: HIV positive; active injection drug use; 18-60 years of age; ≥1 HIV-uninfected injection partner; and viral load ≥1,000 copies/mL. Re-enrollment to extended follow-up was offered to all available participants. Outcome durability in the intervention arm was estimated over weeks 52 to 104 using longitudinal linear-binomial models. During the extension under-treated (off-ART or off-MAT) SOC arm participants were offered the integrated intervention and uptake was assessed.

RESULTS: Overall, 502 HIV+ PWID were enrolled: 85% were men, median age was 35 years (Q1-Q3: 31-38). In the extension, 327 participants re-enrolled (71% of the intervention arm, 63% of the SOC arm). Death, incarceration, and compulsory rehabilitation accounted for 74% (129/175) of those who did not re-enroll. In the intervention arm at weeks 52 to 104, respectively, 72% and 62% were on ART, 41% and 31% were on MAT, and 50% and 39% had VS <1000 copies/mL. From week 52 to 104, probability of ART decreased at an estimated rate of 7.1% (95% CI: -15.2%, +1.1%), MAT decreased 3.6% (-10.9%, +3.7%), and VS decreased 11.2% (-20.0%, -2.3%) per year (Figure). In the under-treated SOC group, only 49% (82/168) started the integrated intervention.



[Figure. ART, MAT, and viral suppression in the intervention arm]

CONCLUSIONS: Over 104 weeks of follow-up, many participants in the intervention arm reported continued ART and MAT. However, the decline in viral suppression suggests a need for maintenance support. Additional programs are needed for under-treated PWID.

PEC0708

CHARACTERIZING NEW HIV INFECTIONS WITHIN SEARCH, A UNIVERSAL TEST AND TREAT TRIAL IN RURAL EAST AFRICA

M. Nyabuti[1], D. Havlir[2], E.A. Bukusi[3], M.R. Kamya[4], M. Petersen[5], E. Charlebois[2], G. Chamie[2], J. Kabami[4], F. Mwangwa[4], J. Ayieko[1]

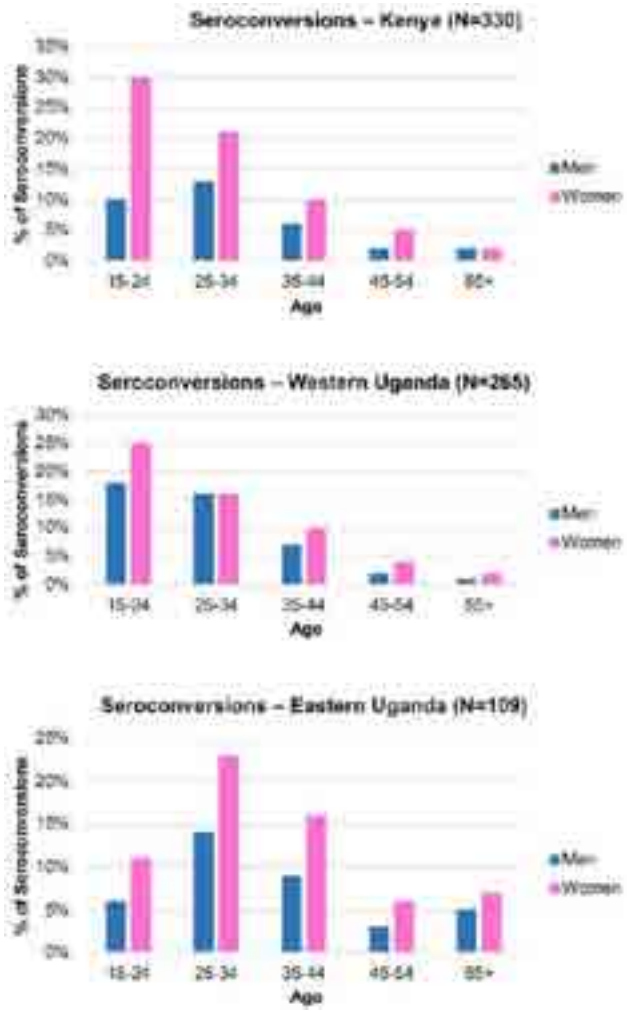
[1]Kenya Medical Research and Training Institute, Research Care and Treatment Programs, Kisumu, Kenya, [2]University of California, Division of Infectious Diseases, San Francisco, United States, [3]Kenya Medical Research Institute, Research Care and Treatment Programs, Nairobi, Kenya, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, [5]University of California, Division of Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: Additional progress towards HIV epidemic control requires understanding who remains at risk of HIV infection in the context of high uptake of universal testing and treatment (UTT). We characterized seroconverters in the SEARCH UTT Trial conducted in rural Uganda and Kenya.

METHODS: We evaluated seroconverter characteristics, potential infection sources, and risk factors with multi-variable adjustment using targeted maximum likelihood. As previously reported, at baseline

and in both study arms, HIV testing (health fairs and home-based testing) achieved 90% coverage in 32 communities of ~5000 adults (≥15 years) each. Viral suppression increased rapidly from 42% to 68% (control) and 79% (intervention) ; HIV incidence reduced by 32%; no difference between arms (0.25% intervention, 0.27% control). After 3 years, HIV retesting was done; seroconverters were surveyed about potential infection sources.

RESULTS:



[Figure.]

Of 704 seroconverters (no differences in characteristics by arm), 63% were women. Men aged ≤24 years made up a larger proportion of seroconverters (18%) in West-Uganda than East-Uganda (6%) or Kenya (10%)(Figure). After adjustment for other risk factors, men who were mobile [>1 month of prior year outside community] (aRR:1.68, 95%CI:1.09,2.60) and who HIV tested at home vs. health fair (aRR:2.50,95%CI:1.89,3.20) were more likely to seroconvert. Women aged ≤24 years (aRR:1.91; 95%CI:1.27,2.90), mobile (aRR:1.49;95%CI:1.04,2.11), and who reported a prior HIV test (aRR:1.34; 95%CI:1.06,1.70), or alcohol use (aRR:2.07; 95%CI:1.34,3.22) were more likely to seroconvert. Among survey responders (N=607, 86%), the suspected infection source was more likely for women than men to be >10 years older (22% vs 6%) or a spouse (44% vs. 26%) and less likely to be transactional sex (8% vs 14%).

CONCLUSIONS: In addition to universal testing and treatment, strategies that protect young women, alcohol users, mobile populations and those engaged in transactional sex from HIV infection, tailored to regional variability, may be necessary to further reduce HIV incidence rates.

INNOVATIVE BEHAVIOURAL INTERVENTIONS

PEC0709

FEASIBILITY AND ACCEPTABILITY OF "WE ARE FAMILY," AN HIV-RELATED HEALTH PROMOTION INTERVENTION FOR SAN FRANCISCO BAY AREA HOUSE BALL AND GAY FAMILY COMMUNITIES

E. Arnold[1], M. Benjamin[2], J. Wong[1], L. Pollack[1], P. Saberi[1], T. Neilands[1], G. Lockett[2], S. Kegeles[1]

[1]University of California, Center for AIDS Prevention Studies, Dept of Medicine, San Francisco, United States, [2]California Prostitutes Education Project (CAL-PEP), Oakland, United States

BACKGROUND: African American gay, bisexual, and transgender youth are disproportionately impacted by HIV in the United States (US) where incidence is high and continues to increase for these key populations. The House Ball and gay family communities, made up of gay, bisexual, and transgender youth of color who form chosen families, are ubiquitous across the US. Both communities are associated with protective HIV-related health behaviors, and are ripe for inclusion in HIV prevention efforts. The We Are Family intervention leverages these existing supportive social relationships to change community-level social norms.

METHODS: From September 2018-September 2019, we enrolled N=118 members of the House Ball and gay family communities and followed them for 6 months, conducting baseline and follow-up behavioral assessments. Eligible participants were 18 years or older, San Francisco Bay Area residents, members of a house or gay family or attendees at a ball in the past year, smart phone users, and sexually active. We Are Family intervention components included one 2-hour in-person group session, community-level events, a mobile health app, and a dedicated service provider at a local community-based organization.

RESULTS: Mean age was 31, 97% self-identified as being of color, 32% self-identified as transgender. We retained 94% of participants through follow-up with 73% attending a group session, 100% using the mobile health app, and 56% attending a community-level event sponsored by We Are Family. Modest changes in the expected direction were observed in HIV-related behavior from baseline to follow-up: among all participants any condomless anal intercourse past 3 months (74.6% to 66.7%, p=0.064); among HIV-negative participants (N=82) HIV testing past 6 months (80.7% to 87.2%, p=0.166); among HIV-positive participants (N=34) receiving HIV primary care past 6 months (64.5% to 78.8%, p=0.139) and adherent to ART past 30 days (22.6% to 28.1%, p=0.712). When asked if they would be willing to refer a friend to the We Are Family mobile health app 86% agreed, and 65% found the app relevant to them.

CONCLUSIONS: We Are Family, a culturally tailored multi-level HIV-related health intervention, reaches and retains its target population. We Are Family is feasible, acceptable and has promising trends to improve HIV-related health behavior.

PEC0710

BEHAVIORAL INTERVENTIONS ALONG THE PREP CARE CONTINUUM: A SYSTEMATIC REVIEW

J. Schexnayder[1], S.E. Moore[1], J. Chang[1], A. Soler-Carracedo[2], A.R. Webel[1]
[1]Case Western Reserve University, Frances Payne Bolton School of Nursing, Cleveland, United States, [2]Kings College London, London, United Kingdom

BACKGROUND: HIV pre-exposure prophylaxis (PrEP) remains underused in populations at highest risk for HIV infection. The PrEP care continuum provides a framework for evaluating critical outcomes towards effective PrEP use. This systematic review summarizes evidence on behavioral interventions to improve PrEP care continuum outcomes.

METHODS: We performed searches of six online databases for articles published between 1/1/10 and 4/15/19. Two conference archives underwent manual searches for presentations occurring between 1/1/14 and 4/15/19. We limited analysis to studies testing PrEP behavioral interventions in randomized controlled trials (RCTs), quasi-experimental studies, observational cohorts, and pilot studies and published protocols when consistent with the included study designs.

RESULTS: Our searches recovered 763 citations, and of these we retained 43 for analysis. Most interventions included education, counseling, navigation services, or eHealth support, and targeted individual, patient-level behavior change (n=30, 70%). PrEP adherence and PrEP prescription were the most frequently reported outcomes, followed by PrEP awareness/willingness (Table 1).

There were nine completed RCTs and of these four were pilot studies. RCTs tested only patient-level interventions (n=8) and system-level interventions (n=1). Of these, one study (11%) reported awareness/willingness to use PrEP outcomes, five (56%) reported access outcomes, three (33%) reported prescription outcomes, and four (50%) reported adherence outcomes. As measured, access consistently improved in trials for e-Health support, home-based PrEP, a home-based counseling intervention, and combined navigation/counseling services. Two RCTs of counseling and combined counseling/navigation interventions reported mixed PrEP prescription results. Mixed results were also observed in RCTs targeting adherence. Adherence interventions consisted of eHealth interventions (n=2) and combined counseling/education interventions (n=2).

Published protocols (n=11) suggest widening interests in multilevel interventions and diversified PrEP care continuum targets.

	Care Continuum Outcomes, No.(%)				
Level of Intervention (No. Studies)	Risk Recognition	Awareness/ Willingness	Access	Prescription	Adherence
Individual/Patient (n=30)	5(17)	10(33)	9(30)	11(37)	17(57)
Provider (n=5)	1(20)	3(60)	1(20)	2(40)	0(0)
System (n=5)	1(20)	1(20)	2(40)	3(60)	1(20)
Community (n=3)	0(0)	2(67)	1(33)	2(67)	0(0)
Total (n=43)	**7(16)**	**16(37)**	**12(30)**	**18(42)**	**18(42)**

[Table 1. Reported PrEP Care Continuum Outcomes by Level of Intervention]

CONCLUSIONS: Patient-level interventions predominated in the first generation of PrEP behavioral research. However, additional studies are needed to establish the efficacy of existing and new Prep behavior change techniques across the PrEP care continuum.

PEC0711

PRELIMINARY RESULTS FROM THE BET: A PEER-BASED DIGITAL SYSTEMS NAVIGATION INTERVENTION TO INCREASE HIV PREVENTION AND CARE BEHAVIORS OF YOUNG TRANSWOMEN IN RIO DE JANEIRO, BRAZIL

E. Jalil[1], B. Grinsztejn[1], C. Castro[1], C. Jalil[1], A.L. Ferreira[1], N. Fernandes[1], L. Kamel[1], I. Moura[1], C. Souza[1], N. Proenca[1], D. Bezerra[1], E. Carvalheira[1], L. Monteiro[1], V. Veloso[1], E. Wilson[2]
[1]FIOCRUZ, LAPCLIN-AIDS, Rio de Janeiro, Brazil, [2]UCSF/SFDPH, San Francisco, United States

BACKGROUND: Recent data show that almost one quarter of young transwomen aged less than 24 years old are living with HIV in Rio de Janeiro (RJ)-Brazil. HIV testing, care access, and PrEP use remain low despite availability in the public health system. We present early results from a peer-based Health intervention to increase HIV prevention and care behaviors among young transwomen in Brazil.

METHODS: We tailored an evidence-based systems navigation intervention for use with digital methods and peer-based delivery and a status neutral focus to increase HIV prevention and care behaviors among young transwomen in RJ-Brazil. Trans peers led the tailoring and pilot implementation. Inclusion criteria were: 1) self-identification as transwomen, 2) aged 18-24 years, and 3) living in RJ-Brazil. HIV prevention and care behaviors were assessed at 3-months after intervention initiation.

RESULTS: Twenty transwomen were enrolled (14 HIV-negative, 6 living with HIV). At enrollment, median age was 20.5 years old (IQR:18.8-23.0). Most were black/mixed race (15, 85%), 9 (45%) had less than 8 years of schooling, all earned less than US$1.00/day. All HIV-negative participants were PrEP naive and eligible for PrEP, of which 13 (92.9%) reported high willingness to use PrEP and 8 (57.1%) had a high-risk behavior score. Among participants living with HIV, 3 were not engaged in HIV care or on antiretroviral therapy (ART), 1 reported a missed visit in the last 6 months, and 5 had detectable viral load (VL). After the intervention, all HIV-negative participants were regularly tested for HIV, and 13 (92.9%) engaged in PrEP. All participants living with HIV were engaged in HIV care, on ART and achieved an undetectable VL.

CONCLUSIONS: Early results show increased HIV testing, PrEP uptake, and improvements in HIV care cascade indicators among young transwomen in Brazil after the digital intervention. Peer-based digital systems navigation may be an effective approach to mitigating barriers that hinder engagement in HIV prevention and care among young transwomen in a highly discriminatory setting such as Brazil.

STRUCTURAL INTERVENTIONS

PEC0712

ASSESSING HIV RISKS FOR PEOPLE WHO INJECT DRUGS (PWID) EXPOSED TO COMPULSORY DRUG ABSTINENCE PROGRAMS (CDAPS): A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Vo[1], C. Magana[1], L. Beletsky[2], A. Borquez[1], N. Martin[1], J. Cepeda[1]
[1]University of California, La Jolla, United States, [2]Northeastern University, Boston, United States

BACKGROUND: Compulsory drug abstinence programs (CDAP) are increasing in number and scope to address addiction in the US and many global settings. For people with opioid use disorder, CDAPs are often deployed in lieu of opioid agonist therapy (OAT), despite growing evidence of individual and community-level iatrogenic harms. We conducted a systematic review and meta-analysis to evaluate associations between CDAP exposure and HIV-related risk behaviors among people who inject drugs (PWID).

METHODS: From June-September 2019, we systematically searched PubMed, EBSCOhost and Sociological Abstracts bibliographic databases, with terms related to HIV-risk factors (e.g. injection equipment sharing, antiretroviral therapy access), without geographic, language, or date restrictions. Articles that reported associations between exposure to CDAP (defined as coerced or involuntary, abstinence-based treatment programs, either extrajudicial or state-mandated) and related HIV among PWUD and PWID were included in the systematic review. Meta-analytic methods were used to quantify the association between CDAP exposure and HIV-related outcomes. We conducted random-effects modeling for studies that reported the same timeframe for CDAP exposure and outcomes.

RESULTS: From a total of 863 abstracts screened, 46 studies were identified for full-text reviews. We included final results from six studies reporting on HIV risk factors, two conducted in China, two in Thailand, and one each in Malaysia and Mexico. Current or previous exposure to CDAP was associated with a 46% increase in HIV seroprevalence at time of survey, though with substantial uncertainty (95% CI: 0.1-21.14, n=3 studies) and heterogeneity (tau^2 =0.9). Five out of six studies indicated a positive association between CDAP exposure and injection risk behavior, with a borderline-significant 14% increased in the odds of receptive syringe sharing, ever or in the last 6 months (95% CI 0.9-1.6,n=3 studies,tau^2=0.0054).

CONCLUSIONS: While data are limited and results are heterogeneous due to differences in CDAP across settings, exposure to such programs was associated with increased risk of syringe sharing and a weak increase in HIV seroprevalence amongst PWID. This study adds to the body of evidence linking CDAP to overdose and other negative health outcomes. Programmatic and policy measures should favor evidence-based harm reduction and treatment services for PWID, including voluntary OAT, while minimizing CDAP exposure.

PEC0713

DREAMS INTERVENTIONS REDUCE HIV POSITIVITY AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN WESTERN KENYA

G. Kimondo[1], O. Madiang'[1], H. Alwang'a[1], R. Obanda[1], S. Bii[2], R. Mokaya[2], N. Diaz[3]
[1]PATH, Kisumu, Kenya, [2]United States Agency for International Development, Nairobi, Kenya, [3]PATH, Washington DC, United States

BACKGROUND: In 2017, five counties contributed 43 percent of all new HIV infections in Kenya with women aged 15-24 accounting for one third of new infections and five counties recording more than 1,000 infections each. PATH's PEPFAR-funded USAID DREAMS program for adolescent girls and young women (AGYW) focuses on three of these counties–Homa Bay, Kisumu, and Migori.

DESCRIPTION: The DREAMS core package of interventions addresses structural drivers that increase HIV vulnerability and aims to reduce HIV infections among AGYW (ages 9-24). The interventions target AGYW at highest risk of HIV, their male sexual partners, families, and communities. DREAMS provides services at girl-only safe spaces, each linked to a health facility. Enrolled AGYW receive a package of age-based primary interventions and an individualized package of secondary interventions.

Between 2017-2019, 98,937 AGYW were enrolled in DREAMS services. Of those enrolled, 91,589 were reached with evidence-based interventions (EBIs), 90,018 attended financial capability training, 56,054 were given education support, 12,725 were provided with economic strengthening services, 11,280 were supported with school fees, and 10,989 received cash transfers. By September 2019, 95 percent of active AGYW were fully layered, which requires completing the total DREAMS primary package of EBIs and at least one secondary service. HIV testing services are provided as a primary intervention for AGYW ages 15-24, they are encouraged to know their HIV status at enrollment and to be voluntarily retested annually. Between 2017-2019, 81,906 AGYW knew their HIV status.

LESSONS LEARNED: HIV testing data for AGYW during DREAMS enrollment in 2017 showed 0.93 percent HIV positivity, with the highest positivity among ages 20-24 at 1.43 percent. Repeat testing among seronegative girls enrolled in DREAMS showed lower positivity. Of enrolled AGYW with known HIV status, 133 (0.16 percent) tested HIV-positive. From 2017 to 2019, the positivity dropped from 0.19 percent to 0.05 percent. In 2019, the highest prevalence was among ages 9-14 with 0.08 percent, an improvement from initial enrollment.

CONCLUSIONS/NEXT STEPS A multi-pronged approach is necessary to address the multiple drivers of the HIV epidemic that is disproportionately affecting AGYW.

OTHER NEW PREVENTION TOOLS

PEC0714

HIV POST-EXPOSURE PROPHYLAXIS-IN-POCKET ("PIP"): A NOVEL APPROACH FOR INDIVIDUALS WITH A LOW-FREQUENCY OF HIGH-RISK HIV EXPOSURES

A. Alghamdi[1], A. Heendeniya[2], M. Clifford-Rashotte[3], D. Tan[1,4], I. Bogoch[1,5]
[1]University of Toronto, Toronto, Canada, [2]University of Manitoba, Medicine, Winnipeg, Canada, [3]University of British Columbia, Vancouver, Canada, [4]St. Michael's Hospital, Toronto, Canada, [5]Toronto General Hospital, Toronto, Canada

BACKGROUND: PEP-in-Pocket ("*PIP*") is a novel HIV prevention strategy where individuals who have 1-4 HIV exposures per year are *proactively* identified and provided with a full 28-day course of antiretroviral (ARV) medications for Post-Exposure Prophylaxis (PEP). Individuals may self-initiate PIP following an exposure, without having to first present to an emergency department or clinic. Those who initiate PIP are followed-up in a clinic within a week on a non-urgent bases.

METHODS: We report on prospective and retrospective cohorts of patients using a PIP strategy from two HIV-prevention clinics in Toronto, Canada. HIV-negative individuals at risk of infection were counseled on HIV prevention options (e.g. PrEP, PEP, or PIP) and initiated on a PIP strategy based on shared decision making between patients and healthcare providers, taking into account current and future HIV risk. Demographic and clinical data was recorded with standardized tools.

RESULTS: In the prospective cohort of 44 individuals using PIP, 42 (95%) identified as gay or bisexual men who have sex with men (gbMSM). ARVs were initiated 25 times by 8 (18%) individuals in 34 cumulative patient-years. During this study, 6 (14%) individuals were diagnosed with 10 bacterial sexually transmitted infections (STIs), and there are no HIV seroconversions documented to date. In the retrospective cohort of 79 patients, 74 (94%) identified as gbMSM. We recorded 137 cumulative patient-years of PIP with individual average PIP use of 17 months. PIP was initiated 40 times by 25 (32%) individuals. In this cohort, 23 (29%) individuals transitioned from PrEP to PIP, and 25 (32%) of the cohort transitioned from PIP to PrEP. Participants who initiated PIP more than once per year were significantly more likely to switch their HIV prevention modality from PIP to daily PrEP (P.0.02). No HIV seroconversions were recorded.

CONCLUSIONS: PIP may be a valuable HIV prevention modality for individuals with a low frequency of high-risk HIV exposures by facilitating timely access to HIV prevention care. Patients may transition between PIP and PrEP based on evolving HIV risk. PIP may be included with PEP and PrEP as a biomedical HIV prevention option for HIV-negative individuals at risk for infection.

PEC0715

MSM AT HIGH HIV RISK IN LATIN AMERICA PREFER LONG-ACTING PREP

T.S. Torres[1], L.E. Coelho[1], K.A. Konda[2], E.H. Vega-Ramirez[3], O.A. Elorreaga[2], D. Diaz-Sosa[3], B. Hoagland[1], J.V. Guanira[2], C. Pimenta[4], M. Benedetti[1], B. Grinsztejn[1], C. Caceres[2], V. Veloso[1], ImPrEP Study Team
[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]National Institute of Psychiatry Ramon de la Fuente Muñiz, Mexico City, Mexico, [4]Ministry of Health, Brasilia, Brazil

BACKGROUND: In Latin America, HIV incidence continues to grow, while some countries are slowly scaling-up daily oral PrEP (d-PrEP); event-driven PrEP (ED-PrEP) is not being promoted yet; and other PrEP modalities such as long-acting injectable PrEP (inj-PrEP) remain under development. This study aimed to assess preferences across those three PrEP modalities and associated factors among MSM from Brazil, Mexico and Peru.

METHODS: During March-May/2018, MSM were recruited to complete a web-based survey through advertisements on dating apps (Grindr and Hornet) and Facebook. Subjects were: cisgender MSM, ≥18 years, and HIV-negative (self-report). Preferences for PrEP modalities were assessed through the question: "If all these forms of PrEP were available, please rank from 1 (most preferred) to 3 (least preferred)" (i.e. d-PrEP, ED-PrEP and inj-PrEP)." Multivariable logistic regression models assessed factors associated with each modality.

RESULTS: A total of 19,457 MSM completed the questionnaire (58%, 31% and 11% from Brazil, Mexico and Peru; respectively); median age was 28 years (IQR:24-34) (Table).

		d-PrEP 6771 (34.8%)	ED-PrEP 4538 (23.3%)	Inj-PrEP 8148 (41.9%)	Total 19457	p-value

[Table]

Overall, inj-PrEP was the first option for 42% [95%CI:41-43] of the respondents, followed by d-PrEP (35%, 95%CI:34-35), and ED-PrEP (23%, 95%CI:23-24). In multivariable logistic regression, preference for d-PrEP was associated with age ≤25 years (aOR 1.18, 95%CI1.09-1.27), lower income (aOR1.18,95%CI:1.10-1.26), lower education (aOR1.10,95%CI:1.02-1.19) and never testing for HIV (aOR1.18,95%CI:1.08-1.29). Preference for inj-PrEP was associated with age >25 (aOR 1.12,95%CI:1.04-1.21), higher income (aOR1.21,95%CI:1.13-1.29), HIV ever testing (aOR 1.32,95%CI:1.22-1.44), PrEP awareness (aOR1.23,95%CI:1.15-1.32), having >5 male sexual partners (aOR1.05,95%CI:0.99-1.12) and binge drinking (aOR1.15,95%CI:1.07-1.23).

Preference for ED-PrEP was associated with lower sexual risk behavior (≤5 male sexual partners: aOR1.15,95%CI:1.06-1.24; binge drinking: aOR1.10,95%CI:1.02-1.19) and being unaware of PrEP (aOR1.25,95%CI:1.15-1.34).

CONCLUSIONS: Long-acting injectable PrEP was preferred by MSM at high HIV risk in Latin America, while individuals with fewer sexual partners and unaware of PrEP preferred ED-PrEP. Interventions to increase literacy about PrEP modalities in the region are necessary especially among young, lower income and less educated MSM.

PEC0716

USING A JUST-IN-TIME ADAPTIVE INTERVENTION (JITAI) TO PROMOTE HIV RISK REDUCTION BEHAVIORS AMONG YOUTH EXPERIENCING HOMELESSNESS (YEH)

D. Santa Maria[1], N. Padhye[1], M. Businelle[2], Y. Yang[1], J. Torres[1]
[1]University of Texas Health Science Center at Houston, Cizik School of Nursing, Center for Nursing Research, Houston, United States, [2]Oklahoma Tobacco Research Center, mHealth Shared Resource, Oklahoma City, United States

BACKGROUND: US studies show that YEH may be up to 6-12 times more likely to get HIV than their housed peers. Yet, HIV prevention interventions in this population have been only marginally effective. Ecological Momentary Assessment (EMA) is the most accurate way to measure real-time risk factors in natural settings allowing for risk detection that would facilitate a tailored intervention. The purpose of this study was to pilot test a JITAI that reacts to daily, modifiable predictors of HIV risk behaviors to drive delivery of HIV risk-reduction messages among YEH (18-25).

METHODS: YEH aged 18 and 25 years old were recruited in Houston, Texas in June 2019. We conducted an attention control trial of 6 week duration on youth randomized to control and JITAI groups (N=50 per group). All participants received a study-issued smartphone and daily EMAs, one random EMA every day, and could self-initiate EMAs. EMA items assessed sexual behaviors, cognitions, stress, affect, drug use, and environmental factors and circumstances. The JITAI group received tailored intervention messages based on reported HIV risk factors. The control group received general health messages. Generalized linear mixed effects models (GLMM) were used to test the intervention effect on sexual activity and substance use. The intervention effect was represented by the interaction term of group and time effects.

RESULTS: Participants (N=100) were predominantly male (59%), black (71%), and heterosexual (54%) with a mean age of 21 years. The median participation time was 5 weeks, while the response rate decreased substantially during the first week of the study and more steadily thereafter. Sharp declines were seen over 6 weeks for sexual activity (OR=0.10, p<.001), drug use (OR=0.12, p<.001), and alcohol use (OR=0.21, p=.004). Furthermore, the JITAI was effective in reducing drug use (OR=0.06, p<.001) compared to the control group.

CONCLUSIONS: JITAI is a feasible method to promote HIV risk reduction behaviors among YEH. Drug use, an HIV risk factor, decreased in the JITAI group, while sexual activity and alcohol use decreased in both groups. Future research should explore ways to improve EMA completion rates and test this JITAI in a larger sample.

PEC0717

THE EFFICACY OF INSTI IN EXPANDING HIV SCREENING IN COMMUNITY-BASED SETTINGS IN SOUTH AFRICA

J. Pienaar[1], L. Molobetsi[1], K. Chimelwane[1]
[1]Centre for HIV-AIDS Prevention Studies, Johannesburg, South Africa

BACKGROUND: South Africa has an estimated 7.7 million PLHIV. Significant strides have been made in identifying PLHIV and linking them to ART, however barriers to large-scale opt-in for testing remains at both facility and patient-level. These barriers comprise congestion at facilities, inconvenient operating times, stigma and patient-level barriers such as time taken for the test, especially for repeat testers. A documented impediment for repeat testers is that they have to undertake the entire pre-test counselling session and wait 10-15 minutes for the test result, when they have tested before and understand the pre-test counselling messages. Furthermore, current 1st line rapid testing require dedicated spaces for testing and the rate of HIV screening coverage is determined by the number of counselors/testers, not demand for testing. We assessed the ability of the HIV rapid test, INSTI that provides a rapid result within 60 seconds, in addressing these structural and patient-level barriers in community settings, as part of a rapid HIV screening campaign. We further compared result concordance between INSTI and the 1st line rapid test, Abon.

METHODS: Between October 2019 and December 2019, CHAPS conducted INSTI within our HTS programme in the Ekurhuleni District, South Africa. We compared the increase in reach between 2 teams (comprising 10 counselors each) by number of clients screened using INSTI compared to Abon. The team using INSTI collected an extra blood sample from the patient for use on Abon, as a measure of concordance.

RESULTS: The INSTI Team tested on average 52 clients per day, compared to the average reach of 15 clients per day for the Abon Team. This signified a 247% increase in productivity. The INSTI Team managed to conduct 10 326 tests compared to the total 5 607 tested by the Abon Team. Concordance was 100% between INSTI in Abon, demonstrating reliability of INSTI compared to the accepted 1st line rapid test, Abon.

CONCLUSIONS: INSTI has demonstrated potential to reach more clients and significantly enhance HIV screening coverage. Its ability in expanding coverage through addressing known barriers to current HIV uptake can substantially improve reaching the 1st 95 (People knowing their HIV status) of the 95-95-95 goals.

PEC0718

HIV PREVENTION PRODUCT PREFERENCES AMONG PARTICIPANTS WHO COMPLETED THE AMP HVTN 704/HPTN 085 CLINICAL TRIAL

R. Gonzalez[1], S. Houshangi[1], L. Oseso[2], H. Van Tieu[3], K. Mayer[4,5,6], S. Shoptaw[7,8], E. Okafor[9], M. Andrasik[2]
[1]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States, [2]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division (VIDD), Seattle, United States, [3]New York Blood Center, Laboratory of Infectious Disease Prevention, New York, United States, [4]The Fenway Institute, Boston, United States, [5]Harvard Medical School, Department of Medicine, Boston, United States, [6]Harvard T.H. Chan School of Public Health, Department of Global Health and Population, Boston, United States, [7]David Geffen School of Medicine, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States, [8]David Geffen School of Medicine, Department of Family Medicine, Los Angeles, United States, [9]Baylor University/Robbins College of Health and Human Sciences, Department of Public Health, Waco, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP) is an efficacious biomedical HIV prevention approach, but barriers to its effective use remain, including maintaining adherence, inaccurate self-perceived risk, and stigma. New long-acting prevention methods may reduce these barriers. HVTN 704/HPTN 085 (Antibody Mediated Prevention or AMP study) is one of the first efficacy trials of a monoclonal broadly neutralizing antibody (bnAb) for HIV prevention. The aim of this analysis was to assess preferences and acceptability of current and potential HIV prevention methods among a subset of American AMP participants.

METHODS: Recruitment for this mixed methods substudy took place at 6 U.S. sites from February 2018 through December 2019, and included interested, consenting AMP participants. Study enrollment targeted persons at-risk for HIV acquisition, specifically HIV-uninfected cisgender men and transgender persons who have sex with men, aged 18-50 years. HIV prevention product preferences were collected via quantitative surveys and in-depth individual interviews from participants who completed all scheduled AMP study visits.

RESULTS: Participants (n=131) had a median age of 33 years (IQR = 9), 53% were White, 27% were Latinx, and 18% were Black, and 94% had some college education or higher. Most (79%) reported current or previous experience with use of daily oral PrEP. When asked about their ideal HIV prevention method, 43.5% preferred an HIV vaccine, 18.3% preferred the U.S. FDA-approved regimen of daily oral Truvada for PrEP and 11.5% preferred an injectable form of PrEP every 2 months. A subset of other endorsed methods included the bnAb infusion studied in AMP (3.8%), on demand PrEP (3.8%), and a rectal microbicide gel/lubricant (0.8%). The main factors that participants considered when evaluating their top preference were convenience, ease, and familiarity.

CONCLUSIONS: An HIV vaccine was most frequently stated as the ideal HIV prevention method among this subset of AMP participants. Findings also support acceptability and feasibility for uptake of new methods and formulations for PrEP in at-risk individuals. Given the participants' experience with oral PrEP and a clinical trial assessing the HIV prevention efficacy of bnAbs, the range in the sample's opinions emphasizes a need to continue diversifying prevention options and offer more convenient and efficient prevention methods.

PEC0719

EXPANDING THE HIV PREVENTION WORKFORCE WITH HIV PREVENTION CERTIFIED PROVIDERS™

B. Hujdich[1], D. Cropper-Williams[1], A. Clayton[1]
[1]HealthHIV, Washington, United States

BACKGROUND: Despite an overall increase in pre-exposure prophylaxis (PrEP) uptake from 2014-2017, it is estimated that 1.1 million Americans could benefit from PrEP.1 In addition, in 2016, nearly six times as many white men and women (68.7%) were prescribed PrEP as were black men and women (11.2%).4 Primary care providers, in particular, are underutilized as members of the HIV prevention workforce. Barriers such as discomfort prescribing HIV medications and identifying candidates for PrEP preclude the provision of PrEP.3
In response to these disparities and service gaps, HealthHIV launched the HIV Prevention Certified Provider™ (HIV PCPTM) program, a free online CME curriculum, in October 2019 to prepare clinicians to deliver effective HIV prevention interventions, and expand the HIV prevention workforce beyond infectious disease specialists.

DESCRIPTION: The five modules of HIV PCP review the epidemiology and policy of HIV in the United States, HIV risk assessment and testing, U=U, PrEP, cultural humility and methods to address barriers to care. Clinicians who complete the curriculum receive the HIV Prevention Certified Provider national designation and certificate and are added to the HIV PCP National Directory for consumers to locate HIV prevention providers.

LESSONS LEARNED: As of January 2020, the HIV PCP has engaged more than 1800 providers nationwide and designated over 450 as HIV Prevention Certified Providers. Medical doctors and nurses value being able to bring HIV prevention services to their community and take part in efforts to end the epidemic.
The steady and vast engagement of primary care providers in this program demonstrate the continued need for HIV prevention education outside of the existing HIV prevention workforce. Additional tools have been added to help providers translate education to practice, including PrEP eligibility guidelines and fact sheets. Social workers, case managers, and others have also requested inclusion in the program via CE.

CONCLUSIONS/NEXT STEPS The HIV PCPTM expands the HIV prevention workforce to engage primary care physicians, nurses, and pharmacists in comprehensive HIV prevention activities, including PrEP. As the program expands it will include training on implementing a comprehensive PrEP program and counseling clients on PrEP adherence. The credit types will be expanded to include social workers and case managers.

MEASURING AND ENHANCING RETENTION AND ADHERENCE IN HIV PREVENTION PROGRAMMES

PEC0720

ROUTINE HIV CLINIC APPOINTMENT ADHERENCE IN THE AFRICAN COHORT STUDY

N. Dear[1,2], A. Esber[1,2], M. Iroezindu[1,3,4], E. Bahemana[1,5], F. Kiweewa[6], J. Owuoth[1,7,8], J. Maswai[1,7,9], T.A. Crowell[1,2], C.S. Polyak[1,2], J.A. Ake[1]
[1]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]U.S. Army Medical Research Directorate, Nairobi, Kenya, [4]Henry Jackson Foundation MRI (Nigeria), Abuja, Nigeria, [5]Henry Jackson Foundation MRI (Tanzania), Mbeya, Tanzania, United Republic of, [6]Makerere University Walter Reed Project, Kampala, Uganda, [7]Kenya Medical Research Institute, Nairobi, Kenya, [8]Henry Jackson Foundation MRI (Kericho), Kericho, Kenya, [9]Henry Jackson Foundation MRI (Kisumu), Kisumu, Kenya

BACKGROUND: Routine engagement in care is important for all people living with HIV (PLWH), whether feeling unwell or thriving with HIV managed as a chronic disease. Evidence suggests that missed clinic appointments contribute to poor outcomes including lower CD4 counts, virologic failure, and overlooked opportunistic and other coinfections. We identified factors associated with missed clinic follow-up appointments in the African Cohort Study (AFRICOS).

METHODS: Since 2013, AFRICOS has prospectively enrolled adults at risk for HIV and PLWH at 12 PEPFAR-supported clinics in Tanzania, Uganda, Kenya, and Nigeria. At each study visit, occurring twice per year, questionnaires are administered, and clinical outcomes assessed. For this analysis, missed clinic visits were defined as the self-reported number of clinic follow-up appointments missed in the past six months and dichotomized into 1) no missed visits; 2) one or more missed visits. Generalized estimating equations were used to estimate odds ratios (ORs) and 95% confidence intervals (95% CIs) for associations between potential risk factors and missed clinic visits among PLWH.

RESULTS: As of September 1, 2019, 2892 PLWH were enrolled, with 94.5% (n=2732) reporting no missed visits in the prior six months. Factors associated with increased odds of missed visits included age 18-29 years as compared to 50 years and older (OR: 2.82; 95% CI: 2.07-3.84), dissatisfaction with clinic waiting time (OR: 1.28; 95% CI: 1.00-1.63) and moderate or severe depression based on CESD score (OR: 1.40; 95% CI: 1.06-1.86 and OR: 2.76; 95% CI: 2.01-3.79). As compared to participants in Uganda, higher odds of missed visits were observed in Nigeria (OR: 1.81; 95% CI 1.38-2.37) with lower odds in Kericho and Kisumu, Kenya (OR: 0.67; 95% CI: 0.54-0.85 and OR: 0.57; 95% CI: 0.44-0.75) and Tanzania (OR: 0.34; 95% CI: 0.25-0.46).

CONCLUSIONS: Strategies are needed to improve engagement of young people and those with depression, and to reduce HIV clinic waiting times. Further research is needed to identify site-specific factors that may mitigate missed clinic visits.

PEC0721

A RANDOMIZED TRIAL TO ASSESS A COLLABORATIVE DATA-TO-CARE-MODEL: DID IT IMPROVE HIV CARE CONTINUUM OUTCOMES?

R. Neblett Fanfair[1], G. Khalil[1], T. Williams[2], K.A. Brady[3], A. DeMaria[4], M. Villanueva[5], L. Randall[4], H. Jenkins[6], N. Camp[2], C. Lucas[3], F. Altice[5], A. Gerard[3], N. Kishore[4], T. Samandari[1], P.J. Weidle[1]
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]ICF, Atlanta, United States, [3]Philadelphia Department of Public Health, Philadelphia, United States, [4]Massachusetts Department of Public Health, Boston, United States, [5]Yale School of Medicine, Division of Internal Medicine, New Haven, United States, [6]Connecticut Department of Public Health, New Haven, United States

BACKGROUND: The Cooperative Re-Engagement Controlled Trial (CoRECT) implemented a collaborative data-to-care (D2C) model using health departments and clinics to identify out-of-care (OOC) persons living with HIV with the objective of increasing the number of persons re-engaged, retained in medical care, and achieving viral suppression.

METHODS: OOC was determined by surveillance and clinic data from three jurisdictions: Connecticut (CT), Massachusetts (MA) and Philadelphia (PHL). Patients were included if they had no evidence of care > 6 months after being in care during a 12-month eligibility period. All patients were randomized to receive standard of care (SOC) clinic engagement services or SOC plus an intervention utilizing disease intervention specialists/field epidemiologists. Re-engagement in care was defined as linking to a clinic within 90 days of randomization. Retention was defined as two clinic visits > three months apart within 12 months of randomization. Viral load suppression was defined as a viral load <200 copies/ml ever within 12 months of randomization.

RESULTS:

Retention (YES)	Intervention	Standard of Care	p value
CT	176 (53.0%)	167 (51.9%)	0.769
MA	139 (43.9%)	144 (46.0%)	0.586
PHL	177 (57.3%)	129 (43.0%)	0.0004
Viral Suppression (YES)	Intervention	Standard of Care	p value
CT	225(68.0%)	198(61.5%)	0.093
MA	197(62.0%)	204(65.0%)	0.429
PHL	193(62.5%)	173(58.0%)	0.227

[Table]

Between August 2016 and July 2018, a total of 654 (CT), 630 (MA), and 609 (PHL) OOC patients were randomized. Among all sites 40%-66% were non-Hispanic black and 30%-45% identified as MSM. The intervention improved re-engagement in all three jurisdictions and improved retention in PHL (p=0.0004). The intervention did not improve viral suppression (VS) but among patients who achieved VS, median time (days) to VS was reduced in two jurisdictions; Massachusetts 76 (intervention) vs 95 (SOC), p=.02; Philadelphia 64 (intervention) vs 102 (SOC), p<.0001.

CONCLUSIONS: This trial showed that a collaborative D2C model and active field services intervention increased the proportion of persons re-engaged in HIV care within 90 days but had varying effects on retention and viral suppression over one year. Health department interventions that utilize a collaborative approach can improve re-engagement in care among HIV-infected persons and may decrease time to achieve viral suppression.

PEC0722

PREDICTORS OF MISSED APPOINTMENT AMONG HIV-INFECTED PATIENTS ON LIFELONG ANTIRETROVIRAL THERAPY IN TANZANIA

F. Mazuguni[1], G. Antelman[1], R. Van de Ven[1], B. Kilama[1], O. Jahanpour[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Strategic Information & Evaluation, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Data from most ART programmes indicate high rates of missed treatment management appointments among HIV-positive patients following ART initiation. Individuals who miss appointments are more likely to have poorer HIV health status. This study examined the predictors of missed appointments among HIV-infected patients in northern and central Tanzania.

METHODS: Data describing demographic and clinical characteristics (age, sex, region, duration on ART, number of days dispensed, viral load status) were extracted from electronic care and treatment clinic (CTC2) databases (n=416 health facilities; six regions). Patients classified as currently on ART by September 2019 were included in the analysis. A missed visit was defined as a 14+ day delay in returning to the clinic for treatment management, determined by the next appointment date or the number of ARV doses dispensed. Missed visits were classified from October 2016 to September 2019. Multivariate logistic regression models were fit to examine predictors of missed appointments.

RESULTS: Of 160,618 current ART patients (68% female; 32% male), the median (IQR) age of the participants was 41.8 (32.2-50.7) years; 9,530 (6%) were under age 15 years. The majority 120,969 (75%) had been on treatment for more than 12 months. In the past 3 years, 114,557 (71%) clients had at least one missed visit by 14+ days. Females (adjusted odds ratio [AOR] = 1.06; 95% CI [1.03-1.09]), patients <15 years (AOR = 1.53; 95% CI [1.45 -1.62]) and patients on treatment ≥12 months (AOR = 9.39; 95% CI [9.14-9.64]) had higher odds of missed appointments. Patients on multi-month dispensing (MMD) for ≥2 months had lower odds of missed appointments (AOR = 0.55; 95% CI [0.52-0.58]).

CONCLUSIONS: This analysis showed that a high proportion of clients who are classified as current on ART experience missed visits. Implementation of MMD is promising in improving retention on ART, although it is also possible that MMD-retention association is confounded by the fact that patients who are not adherent to ART or visit schedules are not MMD-eligible. Developing effective interventions that target groups of HIV clients who are at high-risk of missed appointments may help reduce long-term loss to follow-up from HIV care and improve treatment outcomes.

PEC0723

MORTALITY UNDER EARLY ACCESS TO ANTIRETROVIRAL THERAPY VERSUS ESWATINI'S NATIONAL STANDARD OF CARE: THE MAXART CLUSTERED RANDOMIZED STEPPED WEDGE TRIAL

D. Spiegelman[1], A. Chao[1], S. Khan[2], F. Walsh[3], S. Mazibuko[4], M. Pasipamire[4], B. Chai[5], R. Reis[6,7,8], K. Mlambo[2], W. Delva[9,10,11,12], G. Khumalo[13], M. Zwane[14], Y. Fleming[15], E. Mafara[2], A. Hettema[2], C. Lejeune[2], T. Barnighausen[16], V. Okello[17]
[1]Yale School of Public Health, Biostatistics, Center for Methods in Implementation Science (CMIPS), New Haven, United States, [2]Clinton Health Access Initiative (CHAI), Mbabane, Eswatini, [3]Clinton Health Access Initiative (CHAI), Boston, United States, [4]Ministry of Health, Eswatini National ART program (SNAP), Mbabane, Eswatini, [5]Harvard T.H. Chan School of Public Health, Nutrition, Boston, United States, [6]Leiden University, Leiden University Medical Center, Leiden, Netherlands, [7]University of Amsterdam, Amsterdam Institute for Social Science, Amsterdam, Netherlands, [8]University of Cape Town, Children's Institute, Cape Town, South Africa, [9]Stellenbosch University, The South African Department of Science and Technology- National Research Foundation (DST-NRF) Centre of Excellence in Epidemiological Modeling and Analysis (SACEMA), Stellenbosch, South Africa, [10]Hasselt University, Center for Statistics, Diepenbeek, Belgium, [11]Ghent University, International Centre for Reproductive Health, Gent, Belgium, [12]KU Leuven, Rega Institute for Medical Research, Leuven, Belgium, [13]Eswatini National Network of People Living with HIV (SWANNEPHA), Mbabane, Eswatini, [14]SAfAIDS, Manzini, Eswatini, [15]Aidsfonds, Amsterdam, Netherlands, [16]University of Heidelberg, Heidelberg Institute of Public Health, Heidelberg, Germany, [17]Ministry of Health, Directorate Office, Mbabane, Eswatini

BACKGROUND: Current WHO guidelines recommend "Early Access to ART for All" (EAAA) for HIV treatment because it has been shown that early ART initiation contributes to better survival and lower infectiousness. The MaxART trial investigated the impact of EAAA on retention in care and viral suppression compared to the then-national standard of care (SoC) in Eswatini, and found significant improvements for both endpoints. This secondary analysis examines the impact of EAAA on mortality, as a potential additional indicator of EAAA's benefits.

METHODS: The MaxART trial was conducted in 14 Eswatinian health clinics through a clinic-based stepped-wedge design, by transitioning clinics from SoC to EAAA intervention. All-cause, disease-related, and HIV-related mortality were analyzed using the Cox proportional hazard model, censoring SoC participants at clinic transition. Cumulative incidence rates were estimated by the Breslow estimator.

RESULTS: Between September 2014 and August 2017, 3405 participants were enrolled. In SoC and EAAA respectively, the multivariable-adjusted 12-month all-cause mortality rates were 1.42% (95% CI: 0.66-2.17) and 1.60% (95% CI: 0.78-2.40), disease-related mortality rates were 1.02% (95% CI: 0.40-1.64) and 1.10% (95% CI: 0.46-1.73), and HIV-related mortality rates were 1.03% (95% CI: 0.40-1.65) and 0.99% (95% CI: 0.40-1.58). EAAA had no significant impact on all-cause (HR: 1.12, 95% CI: 0.58-2.18, p=0.73), disease-related mortality (HR: 1.04, 95% CI: 0.52-2.11, p=0.90), or HIV-related mortality (HR: 0.93, 95% CI: 0.46-1.87, p=0.83).

CONCLUSIONS: There was no immediate beneficial effect of EAAA on mortality, and there may have been an initial adverse effect that crosses over to a longer term benefit among the survivors. Since a major purpose of EAAA is to decrease infectiousness to prevent new cases, it is important that there is no evidence of harm to the recipients of EAAA. Further follow-up of these participants is needed to better understand the long-term consequences of EAAA on recipients and the communities that surround them.

PEC0724

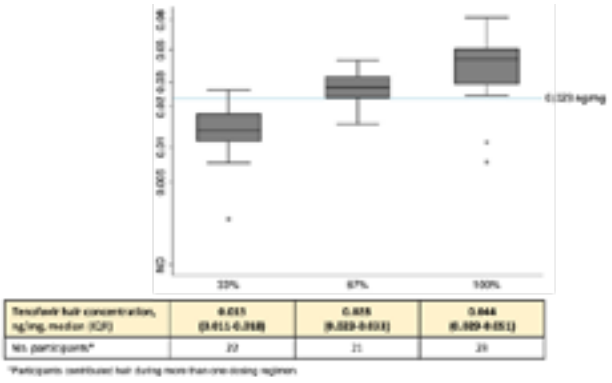
TENOFOVIR HAIR CONCENTRATIONS AFTER DIRECTLY OBSERVED DOSING OF F/TAF: A PROMISING METRIC FOR PREP ADHERENCE MONITORING

C.A. Koss[1], M. Gandhi[1], P. Bacchetti[1], J.R. Castillo-Mancilla[2], M.A. Spinelli[1], M. Morrow[2], J. Yager[2], C. McHugh[2], K.M. Brooks[2], R.M. Tallerico[1], K. Kuncze[1], H. Okochi[1], D.V. Glidden[1], S. MaWhinney[2], P.L. Anderson[2]
[1]University of California, San Francisco, United States, [2]University of Colorado Anschutz Medical Campus, Aurora, United States

BACKGROUND: Daily emtricitabine/tenofovir alafenamide (F/TAF) is approved for PrEP for non-vaginal exposures and is used in HIV treatment. Antiretroviral hair concentrations reflect cumulative drug exposure and predict treatment and prevention outcomes. Hair is easy to collect, store, and ship without cold-chain or biohazardous precautions. We sought to measure tenofovir hair concentrations to inform F/TAF adherence monitoring.

METHODS: The TAF-DBS study (NCT02962739) enrolled healthy volunteers without HIV in Denver, USA. Participants were assigned to two of three F/TAF regimens (33% [1 day on/2 off], 67% [2 days on/1 off], or 100% of daily dosing) with directly-observed dosing of each regimen for 12 weeks, separated by a 12-week washout. Tenofovir concentrations were measured in the proximal 1-centimeter of small hair samples collected at dosing weeks 12 and 36, reflecting ~30 days of drug exposure following drug accumulation. Hair concentrations were measured using validated liquid chromatography/tandem mass spectrometry (LC-MS/MS)-based methods at the UCSF Hair Analytical Laboratory (HAL).

RESULTS: Thirty-five participants (median age 29 years [IQR 23-32]; 49% female; 83% white, 14% black/African American; 17% Hispanic; median baseline weight 72 kg [IQR 62-81]) contributed 69 hair samples for this analysis. Median (IQR) tenofovir hair concentrations were 0.013 ng/mg (0.011-0.018), 0.028 (0.023-0.033), 0.044 (0.029-0.051) for 33%, 67%, and 100% of daily dosing, respectively (Figure).



[Figure. Tenofovir hair concentration by percentage of daily dosing]

Hair concentrations were similar by sex (women vs. men -7%;95%CI -28%,+18%, p=0.53). Of observations with tenofovir hair concentrations ≤0.023 ng/mg, 94% had taken F/TAF less than daily in the last 30 days (specificity 91%).

CONCLUSIONS: Tenofovir concentrations were quantifiable in hair following directly-observed F/TAF dosing, increased linearly with dose, and did not differ substantially by sex. A tenofovir hair level of ≤0.023 ng/mg excluded daily dosing with high specificity. As F/TAF is increasingly used for prevention and is investigated for PrEP among ciswomen, tenofovir hair concentrations are a promising tool for monitoring and supporting adherence.

PEC0725

FACTORS ASSOCIATED WITH HIV AND STI TESTING PRACTICE NOT COMPLIANT WITH GUIDELINES AMONG USERS OF HIV PRE-EXPOSURE PROPHYLAXIS (PREP) IN A SETTING OF SELF-PAID PREP

J. Seifried[1], U. Marcus[1], S. Albrecht[2], K. Jansen[1], H. Jessen[3], B. Gunsenheimer-Bartmeyer[1], V. Bremer[1], U. Koppe[1]
[1]Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany, [2]Robert Koch Institute, Department of Epidemiology and Health Monitoring, Berlin, Germany, [3]Praxis Jessen[2] + Kollegen, Berlin, Germany

BACKGROUND: Testing for HIV (every 3 months) and sexually transmitted infections (STI) (every 3-6 months) is recommended by the German PrEP guidelines during use of HIV pre-exposure prophylaxis (PrEP). While PrEP and the tests are covered by statutory health insurances in Germany since September 2019, both had to be self-paid before. We investigated the testing behavior among PrEP users in routine medical care in the setting of self-paid PrEP.

METHODS: Between July - November 2018 and April – June 2019, we recruited PrEP users in Germany on MSM geolocation dating apps, community-based HIV testing sites and a community website for an anonymous online survey. The outcome was a testing interval incompliance with guidelines, defined as >3 months for HIV and >6 months for STI. Associated factors were assessed with multivariable logistic regression adjusting for age and gender.

RESULTS: We recruited 4,848 unique PrEP users; 52.4% used PrEP for >6 months. The median age was 37 years (IQR 30-45) and 88.8% identified as male (missing 9.9%). Testing frequencies were reported by 3,892 participants for HIV and 3,735 for STI. Of those, 26.3% and 20.9% reported incompliant testing frequencies for HIV and STI, respectively.

Common factors associated with incompliant testing frequencies were on-demand/intermittent PrEP use (HIV: OR = 7.3, 95% CI 6.2 – 8.6; STI: OR = 5.1, 95% CI 4.3 – 6.0), no tests prior to PrEP start (HIV: OR = 16.5, 95% CI = 10.5 – 26.1, STI: OR = 24.2, 95% CI 15.2 – 38.6), ≤10 anal sex partners within the last 6 months (HIV: OR = 2.0, 95% CI 1.7 – 2.3, STI: OR = 1.6, 95% CI 1.4 – 1.9), and use of PrEP from informal sources (HIV: OR = 5.4, 95% CI = 4.5 – 6.5, STI: OR = 4.0, 95% CI 3.4 – 4.9). Self-payment for tests was only associated with incompliant STI testing (OR = 1.4, 95% CI = 1.1 – 1.7).

CONCLUSIONS: Incompliant testing frequency was common in PrEP users in a setting of self-payment for PrEP and testing. Health insurance coverage will probably reduce barriers for accessing testing and improve safe PrEP use. Future changes in testing behavior will be monitored.

PEC0726

FACTORS ASSOCIATED WITH RETENTION AT FIVE YEAR AMONG PEOPLE LIVING WITH HIV ON TREATMENT IN NATIONAL HIV PROGRAM, NIGERIA

B. Onifade[1], G. Eluwa[2], C. Nzelu[1], F. Oluwasina[3], D. Odoh[1], O. Ilesanmi[4], A. Davies[5]
[1]National HIV/AIDS Control Program, Federal Ministry of Health, Public Health, Abuja, Nigeria, [2]Population Council, Reserach, Abuja, Nigeria, [3]AIDS Healthcare Foundation, Abuja, Nigeria, [4]World Health Organization, Abuja, Nigeria, [5]The United Nations Children's Fund, Abuja, Nigeria

BACKGROUND: The 2nd 90 of the UNAIDS target aims to ensure that 90% of identified persons living with HIV (PLHIV) are on treatment and retained to ensure viral suppression and thus reduce risk of transmission of HIV infection thus preventing new infection. We evaluated factors associated with retention in treatment at 5-year (RiT 5-year) in Nigeria.

METHODS: A retrospective cohort study was conducted to assess retention at five-years among PLHIV initiated on ART between January and December 2013 across all the states in Nigeria. RiT 5-year was assessed by estimating the proportion of clients who were active on treatment five year after initiating treatment. Chi-Square test was used to assess differences between categorical variables. Multiple logistic regression was used to determine factors associated with RiT at 5-year and Kaplan-Meier was used to estimate survival at 5-year.

RESULTS: Of the 4,083 folders abstracted, retention was highest at 1 year (77.1%) after initiating treatment and consistently dropped over the 5-year period; 75.1%, 73.8%, 73.2% and 58.1% at 2, 3, 4 and 5-year respectively. RiT at 5-year was higher among females (59%) than males (55.7%) (p<0.05) and among those with secondary school education as compared to those with none (p<0.05). When controlled for predictor variables, those who were single (AOR 0.73; 95% CI:0.59 – 0.92), those resident in North-East (AOR 0.63; CI:0.46 – 0.87) and North-West (AOR 0.52; CI:0.46 – 0.83) were less likely to be RiT 5-year while those with no history of tuberculosis were more likely to be retrained (AOR 1.29; CI:1.04 – 1.60). The five-year survival for clients on treatment showed that the probability of being on treatment at the end of 5-years was 0.86, 0.79, 0.74, 0.69 and 0.64 at 12, 24, 36,48 at 60 months respectively.

CONCLUSIONS: There is a sustained decline in the proportion of clients retained in treatment over time. This calls for evidenced based interventions to urgently reverse this trend to improve viral suppression and thus mitigate propagation of transmission. Furthermore, efforts should be made to increase adolescent participation in HIV program to promote the design of effective strategies for them.

PEC0727

PRE-EXPOSURE PROPHYLAXIS PERSISTENCE AMONG GREEK MEN WHO HAVE SEX WITH MEN: RESULTS FROM THE PREP FOR GREECE (P4G) STUDY

M. Waetjen[1,2], J. Schneider[1,2], D. Paraskevis[3], A. Hatzakis[3], V. Sypsa[3], M. Papadopoulou[3], S. Chanos[4], C. Liao[1,2], M. Psichogiou[3]
[1]University of Chicago, Chicago, United States, [2]Chicago Center for HIV Elimination, Chicago, United States, [3]National and Kapodistrian University of Athens, Athens, Greece, [4]Athens Checkpoint, Athens, Greece

BACKGROUND: Nearly half the new HIV infections in Greece occur in men who have sex with men (MSM), yet pre-exposure prophylaxis (PrEP) is currently unavailable for public use. No data therefore exist on PrEP care in Greece. In advance of national access to PrEP, we examined baseline factors associated with PrEP persistence among MSM in PrEP for Greece (P4G), the first Greek PrEP study.

METHODS: P4G participants were recruited between 2016-2018 from the SOPHOCLES study, a representative sample of MSM in Athens, Greece generated by respondent-driven sampling (RDS). Candidates for PrEP were identified based on HIV-negative serostatus, HIV risk factors, and network connection to people who inject drugs (PWID) or people living with HIV/AIDS (PLWHA) (n=100). Participants received daily PrEP at regular visits over one year, and PrEP persistence was defined as attendance at all visits. Models examined associations between PrEP persistence and baseline data collected on demographics, sex practices, substance use and HIV stigma.

RESULTS: 100 Greek MSM participated: mean age was 33.6, 72% were employed and 85% had health insurance. PrEP persistence among Greek MSM was 74%. Higher alcohol risk scores (OR, 1.27; p=0.004) and adherence to HIV testing guidelines (OR, 1.23; p=0.05) were associated with PrEP persistence. PrEP discontinuation was associated with housing instability (OR, 0.14; p=0.002) and serostatus disclosure concerns, a measure of HIV stigma (OR, 0.77; p=0.03). We found no relationship between PrEP persistence and age or condomless anal intercourse.

CONCLUSIONS: PrEP persistence among Greek MSM is high, and may speak to a desire for access to a known prevention resource currently unavailable outside the context of research. However, were PrEP to be implemented in Greece, socioeconomic factors and societal attitudes may challenge prevention efforts. More research will be needed to determine and intervene on drivers of PrEP discontinuation to promote success.

PEC0728

ANTIRETROVIRAL MEDICATION COVERAGE ALONG THE PMTCT CASCADE OF CARE IN THE ERA OF TREATMENT FOR ALL IN KENYA: RESULTS FROM A PRAGMATIC, CLUSTER RANDOMIZED TRIAL (THE EMMA STUDY)

B. Larson[1], N. Halim[1], I. Tsikhutsu[2,3,4], M. Bii[4,2,3], J. Muli[4,2,3], P. Agaba[5], F. Sawe[4,2,3]
[1]Boston University School of Public Health, Boston, United States, [2]Kenya Medical Research Institute/US Army Medical Research Directorate-Africa, Kericho, Kenya, [3]US Military HIV Research Program, WRAIR, Silver Spring, United States, [4]Henry Jackson Foundation, MRI, Kericho, Kenya, [5]Henry Jackson Foundation, Bethesda, United States

BACKGROUND: Initiation of antiretroviral therapy (ART) during (or before) pregnancy, and adherence to ART throughout the antenatal and postnatal periods, is crucial for the prevention of mother-to-child transmission (PMTCT) of HIV and is also associated with lower

mortality among HIV-exposed but uninfected infants. Measuring adherence along the PMTCT cascade of care in sub-Saharan Africa, however, has relied on unvalidated, self-reporting measures of adherence. As part of an evaluation of a PMTCT service delivery study in Kenya (the EMMA Study), we estimated the proportion of days covered (PDC) with ART, a standard for measuring adherence to chronic medications.

This analysis reports on two primary outcomes for the EMMA study, PDC during the final 24 weeks of pregnancy (PO1) and the first 24 weeks after delivery (PO2), among two cohorts of HIV-infected mothers enrolled in study in western Kenya.

METHODS: The EMMA study was a pragmatic cluster-randomized trial to examine the effect of targeting health worker efforts (specifically Mentor Mothers) on retention along the PMTCT cascade. Study subjects were adult, HIV-infected pregnant women presenting for antenatal care (ANC) at the 12 study clinics (6 per arm, target 30 per clinic). PDC of at least 85% during each period is considered an 'uninterrupted supply'. Risk differences (RD) in these primary outcomes between study groups are estimated with 95% confidence intervals (CIs) adjusted for the small number of clusters.

RESULTS: 363 subjects were enrolled (181/182: comparison/intervention arm) during 2017/2018. After excluding known transfers and subjects with incomplete data collection due to the unplanned, early stoppage of study funding, data were analyzed for 309 subjects (151/158 by arm), with the majority on ART when presenting for ANC. For PO1, 39%/32% respectively achieved 85% coverage (RD: -7%; 95% CI: -20%, 5%). For PO2, 44%/39% achieved 85% coverage (RD: -5%; 95% CI: -24%, 13%).

CONCLUSIONS: The proportion of days covered with ART during two key periods in PMTCT cascade of care were low for both study groups, with some important variation across the 12 study sites. Future, clinic-specific, qualitative research may serve to identify key service-delivery factors that support higher rates of coverage for treatment experienced patients.

PEC0729

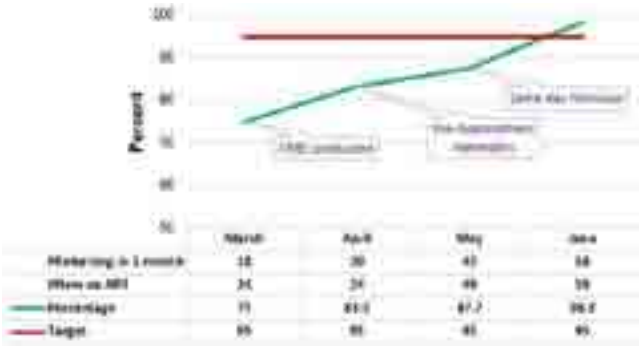
TARGETED CQI IMPROVES EARLY RETENTION OF HIV+ CLIENTS NEWLY INITIATED ON ANTIRETROVIRAL THERAPY: LESSONS FROM THE PAEDIATRIC INFECTIOUS DISEASES CLINIC-MULAGO, UGANDA

L. Engurat[1], O. Angela[1], N. Mukiza[1], I. Kassozi[1], P. Nahirya-Ntege[1], A. Katawera[1], A. Kekitiinwa[1]
[1]*Baylor College of Medicine Children's Foundation, Clinic, Kampala, Uganda*

BACKGROUND: The UNAIDS goals of achieving 90-90-90 targets by 2020 requires retention of clients in care and on treatment for HIV epidemic control to be possible. In March 2019 at the Paediatric Infectious Diseases Clinic (PIDC)-Mulago, only 75% of PLHIV returned within one month of initiating ART against MOH target of at least 95%. This presented a risk of increased HIV transmission, drug resistance, drug adverse events, and a failed ART program. We set out to improve early retention (proportion of HIV+ clients returning for their second visit within 1 month of initiation on ART) to 95% by June 2019.

DESCRIPTION: A Work Improvement Team (WIT) comprising clinic staff and community volunteers conducted brainstorming sessions using affinity diagrams and Fishbone techniques to identify barriers to early retention. We used an Interventions Prioritization Matrix to address inadequate counsellor skills, work load, forgetting appointments and lack of monitoring system for newly initiated clients. Interventions included conducting a Continues Medical Education (CME) on the Early Retention Care Bundle, registering and updating all new client appointments, designating a focal person for newly enrolled clients, using peers to fast-track new clients, phone call and SMS pre-appointment reminders, same-day follow-up of missed appointments and immediate referral of clients who are unable to return. Progress was monitored using a Quality Improvement Journal and weekly performance review meetings.

LESSONS LEARNED: 156 patients were rapidly initiated on ART between March and June 2019. 17% of the patients came from upcountry and 93% were women. Early retention increased from 75% in March 2019 to 98% by June 2019 which was above the targets. See figure 1.



[Figure 1. Showing pecentage of clients returning within one month after ART initiation]

CONCLUSIONS/NEXT STEPS A combined quality improvement initiative has shown to improve early retention and some of them can be used on patients who are already in care.

PEC0730

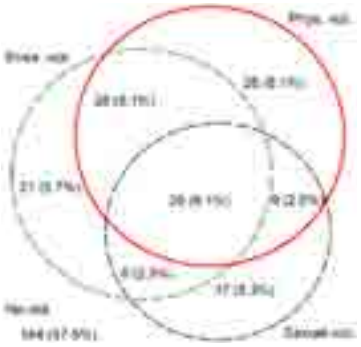
EXPERIENCES OF INTIMATE PARTNER VIOLENCE AMONG HIV-POSITIVE PREGNANT WOMEN IN A RANDOMIZED TRIAL IN KENYA: ANALYSIS OF THEIR EFFECTS ON ATTRITION FROM HIV CARE

J. Njah[1], M.A. Chiasson[2], R. Fayorsey[1], W. Reidy[1]
[1]*Columbia University, ICAP at Columbia, New York, United States,* [2]*Columbia University, Department of Epidemiology, New York, United States*

BACKGROUND: Intimate partner violence (IPV) among HIV-positive pregnant women may be associated with attrition from the prevention of mother-to-child transmission of HIV (PMTCT) services, however, there is limited data to support this hypothesis. We evaluated the prevalence of IPV and its effect on attrition among HIV-positive pregnant women in PMTCT care.

METHODS: From September 2013 through June 2014, HIV-positive pregnant women initiating PMTCT services in 10 health facilities in western Kenya were randomized to receive standard of care (SOC) or an intervention provided by lay counselors (health education, appointment reminders, tracking of missed visits, adherence and retention support). A 13-item WHO Violence Against Women questionnaire was administered during antenatal care (ANC) visits. We assessed relationships between emotional, physical, and sexual violence; individually, in dual and triple combinations, with attrition by 6 months postpartum to estimate prevalence ratios (PR) using modified Poisson regression with robust variance, adjusting for confounders.

RESULTS:



[Figure 1. Proportionate Venn diagram with number (%) of women expoeriencing IPV types and overlaps]

Overall, 43% (n= 136) of the 320 women initiating ANC had experienced some act of IPV in the past 12 months. The proportions of physical, emotional and sexual violence were 28% (n= 90), 26% (n= 84) and 20% (n= 63), respectively (Figure 1).

In the intervention group, experiencing emotional violence only was significantly associated with higher attrition compared to women with no violence (PR 2.00, 95% CI: 1.07-3.72); this association remained after adjusting for age, level of education, marital status and partner disclosure of HIV+ status (aPR 1.88, 95% CI: 1.04-3.39). The prevalence of attrition in the SOC group was lower among women experiencing only emotional violence (PR 0.39, 95% CI: 0.15-1.02). This association was not significant in either the bivariate or multivariable analyses.

CONCLUSIONS: The high prevalence of IPV and increased risk of attrition among women experiencing emotional violence highlights the importance of screening and treating IPV in routine PMTCT services.

PEC0731

REENGAGING PATIENTS LOST TO FOLLOW-UP THROUGH COMMUNITY LIAISONS IN UNSECURE LOW-BURDEN SETTINGS: EXPERIENCE FROM EL SALVADORD

R. Mendizabal-Burastero[1], G. Martinez-Pavon[2], S. Argueta[3], Y. Villaseñor[1]
[1]IntraHealth International, Guatemala, Guatemala, [2]Ministerio de Salud, Programa Nacional ITS/VIH/SIDA, San Salvador, El Salvador, [3]IntraHealth International, San Salvador, El Salvador

BACKGROUND: El Salvador is considered one of the most insecure countries in the Americas because of gang- and drug-related violence. El Salvador has relatively low HIV burden and has consistently improved its HIV continuum of care. However, key gaps persist that prevent the country from reaching the UN 90-90-90 goals. One of the main gaps is retention of patients on ART.

DESCRIPTION: To address retention, the national health information system, SUMEVE, provides alerts to HIV clinics about patients lost to follow-up. Contact by phone is attempted to try to reschedule appointments. If patients cannot be contacted, a home or near-home visit is scheduled. Through support from the USAID-funded HIV care and treatment program led by IntraHealth International, HIV clinics provide a list of lost to follow-up patients to community liaisons weekly. When patients live in gang-controlled zones, community liaisons coordinate with municipal authorities to ensure their safety. Reengaged patients receive rapid re-initiation of ART and clinical examination to screen for and diagnose comorbidities.

LESSONS LEARNED: We implemented the community liaison strategy in 7 ART clinics from November 2018-November 2019, in pursuit of 1,277 lost to follow-up patients. Of those, 646 (50.5%) were reengaged to ART, 161(12.6%) were found to be deceased, and 66 (5.2%) had been transferred to other ART clinics. Median age of reengaged patients was 39; 58.8% were male and 24.7% self-identify as men who have sex with men. The main reasons for loss to follow-up were personal or family reasons (32%) and job-related issues such as lack of time off to attend appointments (29.9%). Reengagement increased from 29% in November 2018 to 76.3% in November 2019 due to strong supervision of community liaisons, effective communication between HIV clinics and liaisons, and goal-setting with patients.

CONCLUSIONS/NEXT STEPS Strong supervision and close coordination between community and facility health workers can provide a good basis for improving reengagement to care. Differentiated care models, especially for patients reengaged to care, are needed to increase retention. This model shows promise for expansion to countries with similar security and HIV epidemic characteristics.

PEC0732

PRE-EXPOSURE PROPHYLAXIS (PREP) ADHERENCE AMONG HIGH RISK WOMEN BY MEASURING INTRACELLULAR TENOFOVIR-DIPHOSPHATE (TFV-DP) CONCENTRATION IN A PILOT STUDY IN ESWATINI

A. Aung[1], N. Ntshalintshali[1], C. Mamba[1], Q. Mpala[1], R. Nesbitt[1], M.L. Tombo[1], S. Matse[2], A. Telnov[3], B. Rusch[3], A. Gonzalez[3], I. Ciglenecki[3], B. Kerschberger[1]
[1]Médecins Sans Frontières, Operational Center of Geneva (OCG), Nhlangano, Eswatini, [2]Eswatini National AIDS programme, Ministry of Health, Mbabane, Eswatini, [3]Médecins Sans Frontières, Geneva, Switzerland

BACKGROUND: Pre-exposure Prophylaxis (PrEP) has proven effective in HIV prevention, but variable medication adherence may lead to suboptimal response. Tenofovir disoproxil fumarate (TDF) is an active component of a drug used in PrEP together with lamivudine (3TC). By quantifying intracellular tenofovir-diphosphate (TFV-DP) concentration in blood, we identified adherence level of PrEP users in the public sector of Eswatini (formerly Swaziland).

METHODS: From September 2017 to January 2019, PrEP (TDF+3TC) was offered to young (16-25 years) and pregnant/ lactating women who were at risk of HIV acquisition in the Shiselweni region. Venous blood was drawn to prepare dried blood spot (DBS) cards at 3 and 6 months after PrEP initiation, and every 6 months thereafter. The DBS samples were stored at –20°C. At the end of the study, 10% of these participants were randomly selected to perform blood TFV-DP testing. The TFV-DP levels were classified into <132, 132–384, and >384 fmol/punch, representing low (<2 doses/week), moderate (2-4 doses/week) and good adherence (>4 doses/week). A level of >504 fmol/punch suggested perfect adherence (7 doses/week).

RESULTS: Of 283 PrEP users, 131 (46%) were pregnant, 64 (23%) lactating and 88 (31%) were young women. Half of them (n=141) perceived themselves at high and very high risk of HIV acquisition. Of 34 participants with blood TDF level results, the median TFV-DP level was 516 fmol/punch (IQR 346 – 725) at 3 months after PrEP. Half of them (n=17) had perfect adherence (>504 fmol/punch). Five (15%) had TFV-DP concentration <132 fmol/punch, 7 (20%) between 132–384, and 22 (65%) >384 fmol/punch suggesting low, moderate and good adherence. Of 15 patients with available TFV-DP level at 6 months, the

median concentration was 532 fmol/punch (IQR 409 – 767), and of 5 patients with 12 months TFV-DP level, the median concentration was 753 fmol/punch (IQR 675 – 807).

CONCLUSIONS: The average adherence of PrEP users remained high throughout the study, although a few PrEP users had very low and moderate drug level. While there is no practical way to measure adherence, this indicates the need to enforce adherence for better drug efficacy.

PEC0733

SUBOPTIMAL RATES OF PREP RETENTION AND ADHERENCE AMONG PWID WITH OUD RECEIVING HCV TREATMENT

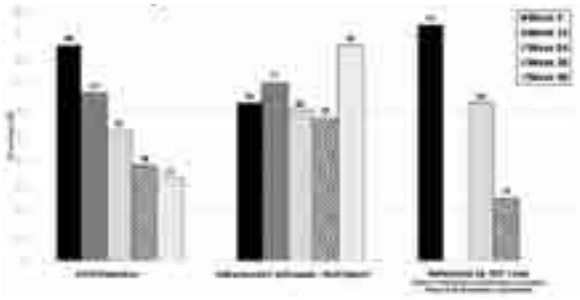
C. Brokus[1], L. Nussdorf[1], R. Silk[2], J. Mount[1], J. Stevens[1], R. Eyasu[2], A. Davis[2], A. Cover[2], E. Ebah[2], P. Bijole[3], M. Jones[3], R. Kier[3], D. Sternberg[3], H. Masur[1], S. Kottilil[2], S. Kattakuzhy[2], E. Rosenthal[2]
[1]National Institutes of Health, Critical Care Medicine Department, Bethesda, United States, [2]Institute of Human Virology at University of Maryland School of Medicine, Division of Clinical Care and Research, Baltimore, United States, [3]HIPS, org, Washington, United States

BACKGROUND: Pre-Exposure Prophylaxis(PrEP) with tenofovir(TDF) is an evidence-based method to prevent HIV among those at risk, including people who inject drugs(PWID). Despite outbreaks of HIV among PWID, uptake remains low, with limited research on adherence and retention in this key population.

METHODS: ANCHOR is a single-center study in Washington, D.C. evaluating a model of care collocating hepatitis C(HCV) treatment, buprenorphine, and PrEP in PWID with chronic HCV, opioid use disorder(OUD), and IDU within 3 months. PrEP was offered at each study visit from Day 0 through Week 24 of HCV treatment. Patients who initiated PrEP were followed for 48 weeks and assessed for adherence by self-report and by dried blood spot analysis of plasma TDF-levels.

RESULTS: The 100 enrolled patients were predominantly black (93,93%), male (76,76%), and median age 58 (IQR 53, 62). Of 97 HIV-negative individuals, 21 (22%) initiated PrEP. Median time on medication was 127.5 days (IQR 24, 269). Seven patients (33%) were retained on PrEP until Week 48 (figure 1). The most common reason for discontinuation was side effects, experienced by 5 patients (36%) of the 14 who discontinued.

While adherence to ≥ 4 pills/week was reported by the majority of patients (figure 1), perfect adherence ranged from 12%-64% by self-report, and 25%-45% by TDF-level. In addition, no detectable TDF-level was found in 6% of Week 4, 18% of Week 24, and 38% of Week 36 patients. No seroconversions occurred on the study.



[Figure 1. PrEP retention and adherence]

CONCLUSIONS: In this cohort of PWID with OUD and HCV, 22% of patients initiated PrEP with high rates of discontinuation. Medication adherence was variable, and per TDF-level data, declined over the course of treatment. These findings highlight the challenges of a daily pill-based HIV-prevention strategy in PWID, and emphasize the need for interventions that promote adherence and retention in order to effectively implement PrEP in this vulnerable population.

PEC0734

INTERRUPTION PATTERNS IN HIV CLINIC VISITS AND TREATMENT FAILURE AMONG PREGNANT AND POSTPARTUM WOMEN IN THE KABEHO STUDY IN KIGALI, RWANDA

E. Nawar[1], K. Andrinopoulos[2], T. Carton[3], E. Bobrow[4], A. Asiimwe[5], P. Mugwaneza[6]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Washington DC, United States, [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, United States, [3]Louisiana Public Health Institute, New Orleans, United States, [4]Mathematica, Washington DC, United States, [5]National Early Childhood Development Program, Kigali, Rwanda, [6]Rwanda Ministry of Health, Kigali, Rwanda

BACKGROUND: ART for HIV-positive pregnant women is recommended for life, yet most studies describe retention as a binary outcome rather than patterns of intermittent attendance – a more likely description of the true nature of lifelong engagement in care and treatment. The absence of ART is strongly associated with high viral load, an indicator of treatment failure and an increased likelihood of vertical transmission of HIV. Pregnancy and postpartum are challenging periods where interruptions are common.

METHODS: The Kigali Antiretroviral and Breastfeeding Assessment for the Elimination of HIV (Kabeho) study was an observational prospective cohort of 608 HIV-positive women enrolled in their third trimester of pregnancy or within two weeks post-delivery, between April 2013 and May 2014. Interviews conducted at enrollment included questions focused on demographics, history of HIV and ART, and health and nutrition behaviors. Maternal viral load was assessed at the 24-month visit. Attendance at clinic visits were used to construct an interruption variable defined as a missed visit followed by a return to care. We examined the number and length of interruptions as predictors of treatment failure in multivariate analyses adjusting for age, months on ART, CD4 count, and ART regimen.

RESULTS: 80% of the study population had at least one interruption, and the mean number of interruptions was 1.8 per woman (SD=1.5). For women who had an interruption, the length ranged from 1-16 months with a mean of 2 months (SD=1.9). As compared to women with no interruptions, the odds of treatment failure (>1000 copies/ml) were 7 times higher among women who had an interruption of >2 months (OR=7.05, 95%CI=2.13, 23.29), and nearly 5 times higher among women with >3 interruptions throughout the study period (OR=4.95, 95%CI=1.40, 17.49). Even just one interruption (and each additional interruption) increased the odds of treatment failure by nearly 40% (OR=1.38, 95%CI=1.10, 1.73).

CONCLUSIONS: Interruptions in HIV care visits are common. Numerous and long interruptions are detrimental to viral suppression. Measuring patterns of interruption, rather than using a binary measure at one point in time, more accurately captures the fluid nature of life-time, health-seeking behavior, and can be assessed using clinic attendance data.

PEC0735

AGE *DOES* MATTER: OLDER MALES STAY LONGER ON PREP ACROSS DIFFERENT SUB-POPULATIONS OF MEN IN ZAMBIA

M. Njelesani[1], M. Nyumbu[1], L. Cicciò[1], P. Chungulo[1], C. Madevu-Matson[2], A. Fullem[2], M. Chikuba-McLeod[1]
[1]JSI Research & Training Institute, Inc., Lusaka, Zambia, [2]John Snow, Inc., Boston, United States

BACKGROUND: The USAID DISCOVER-Health Project (DISCOVER), implemented by JSI Research and Training Institute Inc (JSI), supports the Ministry of Health to improve access to and utilization of quality HIV services in Zambia. DISCOVER is among the first MOH-partners to rollout PrEP, both in the pilot phase and after May 2018 scale-up approval. In Zambia PrEP is provided only to individuals found to be at substantial risk of HIV using a national eligibility screening tool. Studies in Africa show continuation rates of around 40% and 25% at 1 and 3 months post-initiation, respectively. We present PrEP continuation rates for males under the Project.

METHODS: In a relatively young PrEP program, but with a growing number of male clients ever-enrolled (5,121 by September 30, 2019), DISCOVER developed/established a PrEP management information system, in order to strengthen the Project ability to provide PrEP, track clients, and analyse data to inform program implementation. We analysed program data from the DISCOVER PrEP info-system and present the results.

RESULTS: We analysed PrEP continuation rates for 1,791 males enrolled between October 2018 and June 2019.

	MSM		Males in discordant relationships		Other Males	
	One month	Three months	One month	Three months	One month	Three months
15-24 (n=433)	19 (58%)	11 (33%)	08 (42%)	04 (21%)	73 (19%)	28 (7%)
25-34 (n=726)	17 (71%)	12 (50%)	78 (55%)	35 (24%)	203 (36%)	96 (17%)
35+ (n=632)	10 (59%)	09 (53%)	96 (56%)	53 (31%)	191 (43%)	81 (18%)
All (n=1,791)	**46 (62%)**	**32 (43%)**	**182 (55%)**	**92 (28%)**	**467 (34%)**	**205 (15%)**

[Table. Sub-population and continuation of PrEP beyond months 1 and 3 / Age (Years)]

Across all sub-populations, older men have higher PrEP continuation rates than younger men. Although most PrEP messaging in Zambia targets men 20-34, older men access PrEP at almost the same rates as younger men, and stay on. MSM and men in discordant relationships (MiDR) have higher PrEP continuation rates than Other Males (primarily heterosexual men). MSM, MiDR and older males, are perhaps more HIV risk-aware and thus persist on PrEP longer. Younger males (across sub-populations) may cycle out of risk more frequently, with shorter 'on-PrEP' periods.

CONCLUSIONS: Age matters across all sub-populations for PrEP continuation. DISCOVER is engaging younger men and heterosexual men to understand factors that inform their persistence or non-persistence on PrEP in order to inform more effective PrEP programming.

PEC0736

DETERMINANTS OF RETENTION IN HIV ANTIRETROVIRAL THERAPY PROGRAMS IN THE CONTEXT OF TREAT ALL STRATEGY IN CAMEROON

A. Rogers[1], A. Adedimeji[2], E. Halle[1], E. Thomas[1], A. Jules[1]
[1]University of Buea, Buea, Cameroon, [2]Albert Einstein College of Medicine, New York City, United States

BACKGROUND: Retaining HIV positive patients in antiretroviral treatment (ART) is essential for successful ART outcomes. However, suboptimal ART retention continues to be reported in Cameroon and other sub-Sahara African countries. This study aimed at identifying the determinants ART retention in three HIV clinics in Cameroon within the HIV test and treat context.

METHODS: A 24-month retrospective chart review was conducted on 423 subjects who initiated ART between July and September 2016 in the Limbe (Soutwest region), Bamenda (Northwest region) and Jamot (Central region) Hospitals. Patients' sociodemographic and clinical characteristics and ART retention data were abstracted using standardized paper forms. Chi square test was used to test for bivariate associations and logistic regression used to adjust for confounders. P-value was set at <0.05 at 95% confidence interval.

RESULTS: The mean age was 39±11 years, and 65.08% were females. At the end of the 24 months following ART initiation, 30/423 (7.1%) were transferred out,11/423(2.6%) were reported dead, 73/423(17.3%) were lost to follow-up and 309/432(73.0%) remained in care. ART retention rate was 309/392(78.83%). Widowed (AOR 5.98, 95% CI 1.25-28.54, P=0.02) and non-disclosure of HIV status (AOR 0.18 95% CI 0.06-0.53, p=0.00) were associated with higher retention while being unemployed (AOR 0.48, 95% CI 0.14-0.166, P=0.01) was associated with lower retention. Jamot Hospital (AOR0.32 95%CI 0.12-0.88, P=0.00) was reported the lowest retention.

CONCLUSIONS: About a quarter of the patients were not retained after 24 months, suggesting a need to address barriers to ART retention. Associated patient and HIV clinic level factors should be considered when designing ART retention strategies. More research aimed at improving ART retention are needed.

ACCEPTABILITY AND ADHERENCE TO PRE-EXPOSURE PROPHYLAXIS AMONG HIGH-RISK POPULATIONS OF HIV INFECTION IN BEIRA CORRIDOR, MANICA PROVINCE, MOZAMBIQUE

M. Napua[1], D. Jacobson[2], X. McCollum[2], J. Reis[1], F. Faife[1], A. Lucas[1], A. Ouenzar[1], A. Chauca[1], J. Pacca[1]
[1]ECHO Project, Manica, Mozambique, [2]Abt Associates, Rockville, United States

BACKGROUND: Mozambique has an HIV prevalence of 13.2%; 15.4% among women and 10.1% among men (IMASIDA, 2015). In Manica, HIV prevalence is 13.5% (IMASIDA, 2015). The Beira Corridor connects Mozambique to interland countries and is one of the corridors with the highest rates of HIV infection (William M Miller, 2017). Pre-exposure oral prophylaxis (PrEP) with tenofovir disoproxil fumarate and emtricitabina has shown to be effective in preventing HIV in serodiscordant (SD) couples, female sex workers (FSW), men who have sex with men (MSM) and adolescents at risk (AR). Since May 2019 Mozambique's Ministry of Health introduced PrEP in Manica Province

with support from the Efficiencies for Clinical HIV Outcomes (ECHO) project. The objective of this study is to analyze the acceptability of PrEP in seven health facilities in the Beira corridor in Manica: four urban health centers (Eduardo Mondlane, 7 de Abril, Nhamaonha, and 1o de Maio) and three suburban facilities (Manica District Hospital, Gondola District Hospital, and Vanduzi Health Center).

METHODS: Data from patients' records from PrEP patients enrolled between October and November 2019 in the seven study facilities were analyzed using Excel.

RESULTS: From October to November 2019, 306 patients were counseled and tested negative for HIV in the study facilities, of which 289 (94.4%) accepted PrEP. Of those, 171 (60%) were women, and 171 (60%) were 25-49 years old. PrEP acceptability rates were 95.1% in urban areas (156/164) and 93.7% in suburban areas (133/142). Manica District Hospital had the highest acceptability rate (99%, 79/78), while Vanduzi Health Center had the lowest (87%, 26/30). FSW, MSM, and AR had the highest acceptability rates at 100%, while the rate for SD couples was 84% (243/289). Of the 95 patients who were due to return for their next dose within the period under analysis, 33 (35%) returned at 30 days.

CONCLUSIONS: Overall there was high acceptability of PrEP, with greatest acceptability rates among FSW, MSM and AR. Retention remains a major challenge for PrEP. ECHO will continue to monitor and analyze PrEP acceptability and retention rates to inform improvement strategies. More research is needed to understand factors affecting PrEP acceptability and retention.

PEC0738

PREP ROLL-OUT IN LATIN AMERICA SHOULD AIM TO INCREASE AWARENESS AMONG ELIGIBLE INDIVIDUALS TO PREVENT REFUSAL, AND PROVIDE SUPPORT TO NEW USERS TO PREVENT EARLY DISCONTINUATION

C.F. Caceres[1], K. Konda[1], G. Calvo[1], J.V. Guanira[1], H. Vega[2], B. Huaman[3], C. Benites[3], V. Veloso[4], ImPrEP Study Group
[1]Universidad Peruana Cayetano Heredia, Center for Studies in Sexuality, AIDS and Society, Lima, Peru, [2]Instituto Nacional de Psiquiatria Ramon de la Fuente Muñiz, Mexico City, Mexico, [3]Ministry of Health, Prevention and Control of HIV/STI/Hepatitis, Lima, Peru, [4]Fundacao Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

BACKGROUND: Despite the high efficacy of HIV PrEP, its roll-out has been slow globally. While free PrEP programs In Latin America are finally being set-up, uptake and/or continuation may be sub-optimal, implying a loss of prevention opportunities. We assessed the occurrence and reasons of PrEP refusal in the Peru component of ImPrEP, a PrEP implementation project. We also explored the phenomenon of early discontinuation among acceptors.

METHODS: Since 2018 ImPrEP has been enrolling eligible, adult MSM and transwomen (MSM/TW) for daily oral PrEP use in public STI clinics. Eligible subjects (i.e. HIV-, reporting either condomless anal sex with unknown partners, or sex work, or STIs, or HIV+ partners) came either for HIV testing or to ask about PrEP. They were offered PrEP; those who refused (Refusers) responded a short survey about reasons for refusal; those who accepted (Acceptors) were enrolled and asked to return in 30 days. Qualitative interviews were conducted with refusers, ongoing users and early discontinuers (defined as those who missed their 30-day visit within a 60-day window). Here we describe the frequency and reasons stated for PrEP refusal; as well as qualitative findings from refusers and early discontinuers.

RESULTS: Until 31 December 2019, 2554 eligible MSM/TW were invited to enroll in ImPrEP, of whom 2038 (80%) enrolled, and 516 (20%) refused participation. Main reasons for refusal were: Lack of time (39%); need more information on PrEP (20%); concerns about side effects (14%), do not want to take pills (9%) or to make quarterly visits (3%); and perceive their risk as low (6%). In qualitative interviews, reasons for early discontinuation were similar to those for refusal, i.e: lack of time; disbelief in PrEP effectiveness, low self-perceived risk; side effects; and concerns about PrEP/ART stigma. While early discontinuation is common, frequency data will be presented subsequently.

CONCLUSIONS: Of 5 eligible MSM/TW who are offered PrEP, one refuses. Both refusal and early discontinuation (also observed among many acceptors) may reflect natural reactions to PrEP roll-out in contexts of low awareness. Emerging PrEP programs should actively provide PrEP information to refusers to help them reconsider PrEP use, and support acceptors to prevent early discontinuation.

PEC0739

SEX DISPARITIES IN PATTERNS OF HIV INCIDENT CASES BETWEEN 2010 AND 2019 IN HIGH-INCOME COUNTRIES AND SUB-SAHARAN AFRICA: RESULTS FROM THE GLOBAL BURDEN OF DISEASE STUDY 2019

M.W. Walters[1], D. Jahagirdir[1], C. Lin[1], H. Kyu[1]
[1]University of Washington, Institute of Health Metrics and Evaluation, Seattle, United States

BACKGROUND: Though prevention of HIV transmission has become both more effective and available, social and geographic inequalities in access are prevalent. In particular, women and those in low-resource settings have lower access to preventive methods such as PreP. To assess the evolution of the HIV epidemic in these vulnerable groups, we compare the incidence of HIV between sexes in high-income countries and Sub-Saharan Africa over the last ten years.

METHODS: For Sub-Saharan Africa we estimated incidence using 87 population-based seroprevalence surveys and 14,746 site-years of antenatal care clinics data in UNAIDS-developed Estimation and Projection Packages. For high income countries, we used a modified version of Avenir Health's Spectrum incorporating vital registration data to estimate incidence. Our analysis was based on the 2019 Global Burden of Disease estimates.

RESULTS: Globally, estimated HIV incidence decreased from 1,169,732 (95% uncertainty interval 1,034,039 – 1,360,646) to 910,660 (95% UI 767,539 – 1,067,133) for women between 2010 and 2019. In this same period, women's share of incident cases decreased from 52.4% (95% UI 50.2% - 54.1%) to 49.4% (95% UI 46.5% - 51.6%).

The estimated number of incident cases for women in high-income countries increased from 28,744 (95% UI 18,436 – 40,411) to 37,450 (95% UI 21,705 – 54,728) however the share of incident cases between men and women remained stable, with men and women accounting for 72% (95% UI 69.1% - 74.5%) and 28% (95% UI 25.5% - 30.9%), respectively.

In sub-Saharan Africa, the number of incident cases for women decreased from 970,900 (95% UI 842,430 – 1,141,105) to 682,931 (95% UI 566,889 – 833,381) between 2010 and 2019. Women accounted for 59.8% (95% UI 56.2% - 60.1%) of all incident cases, an increase of 1.4% (95% UI 1.2% - 1.8%) between 2010 and 2019.

CONCLUSIONS: Trends in incident HIV cases among women vary regionally. In high-income countries, women's share of incident cases was stable, while the number of incident cases has decreased. In

sub-Saharan Africa the number of incident cases has decreased, yet the share has increased. These estimates suggest the need for prevention methods that are efficacious for and accessible to women in resource-rich and resource-poor settings.

PEC0757

TIME TO FOCUS ON RISK PERCEPTION AND PREP SERVICE AVAILABILITY TO ADDRESS PREP DISCONTINUATION AMONG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN IN THAILAND

R. Ramautarsing[1], T. Chinbuchorn[1], T. Sungsin[1], T. Sangprasert[2], O. Fungfoosri[2], P. Meekru[3], S. Sumalu[3], T. Pasansai[4], W. Bunainso[4], T. Wongsri[5], N. Mainoy[5], M. Avery[6], S. Mills[6], R. Vannakit[7], P. Phanuphak[1], N. Phanuphak[1]

[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]Service Workers in Group Foundation, Bangkok, Thailand, [4]Mplus Foundation, Chiang Mai, Thailand, [5]Caremat Foundation, Chiang Mai, Thailand, [6]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [7]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

BACKGROUND: HIV pre-exposure prophylaxis (PrEP) needs to be taken consistently during periods of risk to be effective as HIV prevention. Among men who have sex with men (MSM) and transgender women (TGW) at risk for HIV in Thailand, continuation on PrEP is low. We explored reasons for discontinuing PrEP, and risk behavior after discontinuation among MSM and TGW.

METHODS: Princess PrEP under the LINKAGES-project, which serves more clients than any other PrEP program in uses trained key population (KP) lay providers provide free PrEP to KPs at 8 community-based organizations in 6 provinces. In August 2019, clients not returning to Princess PrEP services for at least 6 months were invited to participate in an anonymous online survey about PrEP discontinuation.

RESULTS: 1291 clients (15.9% of clients in the program) not returning for at least 6 months were invited 120 (9.3%) responded and completed the questionnaire. Median age was 30 years, 105 (93.8%) were MSM, 5 (4.5%) were TGW. Of these 120 clients, 28 (23.3%) reported currently using PrEP from another source. Among 92 (76.7%) clients who had discontinued PrEP, reasons for discontinuation were: not at risk anymore (45 (49.0%), of whom 13 (28.9%) reported inconsistent condom use), moved away and PrEP not available (20, 21.7%), concerns about side effects (16, 17.4%) or drug interactions (12, 13.0%), and lack of time (11, 12.0%). After discontinuation, 36 (39.1%) reported inconsistent condom use, 7 (7.6%) reported chem-sex, and 48 (52.2%) did not have an HIV-test after stopping PrEP. Clients who had discontinued PrEP were then asked when they would restart PrEP: 64 (69.6%) clients indicated they would restart when their HIV risk increased, of whom 27 (42.2%) reported current inconsistent condom use, and 5 (7.8%) reported chem-sex.

CONCLUSIONS: A significant proportion of clients discontinued PrEP while still at risk for HIV and did not perceive themselves to be at risk. Given this lack of risk perception, gain-framed HIV prevention messages and PrEP educational campaigns are urgently needed to facilitate and support PrEP continuation during risk. Furthermore, PrEP services need to be scaled up across Thailand to ensure continuity of access throughout the country.

KEY POPULATION-LED PREVENTION PROGRAMMES (FROM REACH, RECRUIT, TEST, TREAT, PREVENT AND RETAIN)

PEC0740

TRENDS IN HIV RISK BEHAVIOR AND CARE OUTCOMES AMONG HISPANIC/LATINO MSM IN THE UNITED STATES: A SYSTEMATIC REVIEW OF NATIONAL SURVEILLANCE DATA

N. Crepaz[1], M. Mullins[1], D. Higa[1], J. Gunn[1], Y. Salabarria-Pena[1]

[1]Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: In the United States, Hispanic/Latino (H/L) men who have sex with men (MSM) are the only racial/ethnic group with increasing HIV incidence in recent years. We conducted a systematic review to examine trends in HIV risk behaviors among HIV-negative H/L MSM and care outcomes among H/L MSM with HIV diagnosis for informing ending HIV epidemic (EHE) efforts.

METHODS: We searched MEDLINE, EMBASE, PsycINFO, CINAHL, Sociological Abstracts for reports published between January 2008 and May 2019. Additional searches in CDC's HIV Resource Library, HRSA's Ryan White Data Reports, and Atlas Plus were conducted in December 2019. Reports from national surveillance that provided data from multiple years on relevant outcomes (see Table) for H/L and white MSM were included.

RESULTS: Seventeen reports from National HIV Behavioral Surveillance (NHBS), National HIV Surveillance System (NHSS), Medical Monitoring Project (MMP), and Ryan White Programs provided relevant data from 2011 to 2017. High-risk sex among HIV-negative persons decreased for both H/L and white MSM; however, a higher percentage of H/L MSM reported not taking PrEP and engaging in condomless sex. Although knowledge of HIV serostatus increased for both groups, a lower percentage of H/L MSM were aware of HIV-positive status. Having prescribed ART among those in HIV care was comparable between groups. Among patients receiving Ryan White programs, viral suppression increased for both groups and H/L MSM were close to the 90% target.

Outcome	% reported high-risk sex among HIV-negative persons[a]		% had knowledge of HIV-positive status		% had ART prescription among persons in HIV care		% had viral suppression (VL <200)	
Data Source	NHBS – MSM cycle		NHSS		MMP		Ryan White	
	H/L	White	H/L	White	H/L	White	H/L	White
2011	15.3%	10.8%	76.5%	86.4%	92%	93%	76.0%	79.0%
2012	-	-	77.3%	86.9%	91%	92%	77.9%	81.4%
2013	-	-	77.8%	87.4%	94%	95%	81.4%	84.3%
2014	15.3%	10.8%	78.5%	87.8%	-	-	84.0%	86.6%
2015	-	-	79.1%	88.2%	-	-	85.7%	88.3%
2016	-	-	79.8%	88.6%	-	-	87.2%	89.4%
2017	12.4%	8.7%	-	-	-	-	87.9%	90.1%

[a] % of HIV-negative gay and bisexual men who report not taking PrEP in the past 12 months and who report condomless sex with a HIV-positive partner or partner of unknown HIV status at last sex

[Table]

CONCLUSIONS: National surveillance data indicate that strengthening efforts to address barriers to HIV testing and use of PrEP among H/L MSM are needed. H/L MSM who are in HIV care can benefit from ART prescription and be virally suppressed. Caution is warranted as outcomes were assessed based on different national surveillance data. Identifying individual, social and structural factors contributing to high-risk sex, serostatus unawareness, and unsuppressed viral load may further inform effective EHE efforts.

PEC0741

A SYSTEMATIC REVIEW OF HIV CASCADE OF CARE INTERVENTIONS AMONG MEN WHO HAVE SEX WITH MEN IN SUB-SAHARAN AFRICA

P.-j. Coulaud[1,2], A. Eubanks[3,4], C. Mniszak[1,2], B. Spire[3,4], R. Becquet[5], R. Knight[1,2]
[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, Department of Medicine, Vancouver, Canada, [3]UMR1252 - Sciences Economiques et Sociales de la Santé et Traitement de l'Information Médicale (SESSTIM), Aix-Marseille University (AMU), Marseille, France, [4]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [5]U1219 - Bordeaux Population Health, University of Bordeaux, Bordeaux, France

BACKGROUND: HIV disproportionally affects men who have sex with men (MSM) and transgender (TG) communities across Sub-Saharan Africa (SSA). Preliminary estimates of the HIV care cascade outcomes among MSM and TG in SSA are far below the UNAIDS 90-90-90 targets, reflecting suboptimal access to HIV testing, treatment and care. Therefore, we conducted a systematic review to identify interventions that aim to optimize the HIV care cascade among MSM and TG in SSA.

METHODS: We searched MEDLINE, Embase, and Web of Science databases for peer-reviewed articles (from January 2010 to July 2019) reporting HIV interventions among MSM/TG living in SSA, following PRISMA guidelines. Qualitative and quantitative research articles were included if an intervention was performed to improve at least one of the HIV care cascade outcomes: uptake of HIV testing, access to treatment, and retention including adherence as well as viral load suppression. Records were screened independently by two reviewers using Covidence.

RESULTS: Of 1336 potentially relevant titles, 156 full-text studies were screened. From this, 14 studies were included (9 in East and Southern Africa, 5 in Western and Central Africa). HIV interventions targeted MSM only (8/14), key populations including MSM (5/14), specific subgroups such as male sex workers (1/14) and MSM who use drugs (1/14), while none targeted TG. None of the interventions providing PrEP evaluated its impact on the HIV care cascade outcomes. Most interventions (11/14) improved access to HIV testing through outreach counselling activities (3/11), social networks of peer educators (4/11), distribution of HIV self-testing kits (1/11) and developing MSM-friendly clinics (2/11). Interventions providing quarterly medical follow-up including regular contact with peers and counsellors improved access to treatment (2/14) and retention in HIV care (1/14).

CONCLUSIONS: Most of the interventions that have been evaluated and reported in the peer-reviewed literature involving MSM in SSA are focused on access to HIV testing. Future intervention and research efforts should focus on developing strategies to optimize access to treatment and retention in HIV care. Furthermore, significant efforts are still needed to better integrate MSM sub-groups (e.g., TG, MSM who use drugs) in HIV interventional research.

PEC0742

EFFECTIVENESS OF PEER-DELIVERED HARM REDUCTION INTERVENTIONS FOR PEOPLE WHO INJECT DRUGS IN YANGON AND NAY PYI TAW, MYANMAR

S. Kham[1], F. Farozar[2], G. Cazorla[2]
[1]Youth Empowerment Team, Yangon, Myanmar, [2]UNAIDS, Yangon, Myanmar

BACKGROUND: Myanmar has a concentrated HIV epidemic with an estimated 240,000 people living with HIV in 2018.The highest HIV prevalence is observed in people who inject drugs (PWID) at 34.9%. The Youth Empowerment Team (YET) was formed in June 2003 as a community-based organization, and a member of the National Drug Users Network in Myanmar. YET aims to educate young people about the harms associated with drug use and to implement harm reduction programs for PWID. Currently, YET is implementing a pilot project supported by the Open Society Myanmar in Yangon and Nay Pyi Taw in 2019, where limited services are provided for drug users.

DESCRIPTION: The pilot project uses a peer-to-peer approach to provide a comprehensive package of services to PWID, including the distribution of needles, syringes, and condoms; referral to methadone maintenance treatment, HIV testing, ART and STI treatment; hepatitis B screening and immunization; screening and treatment of tuberculosis (TB); as well as education and distribution of IEC materials. Between January and December 2019, over 10,000 needles and syringes (N/S) were distributed to 200 PWID in Yangon and Nay Pyi Taw. In Yangon only, a total of 275 PWID were tested for HIV; 25 referred to ART; 40 referred to MMT; 25 screened for HBs, and 5 for TB.

LESSONS LEARNED: Despite law enforcement activities (including police crackdowns and arrests), peers were able to successfully distribute syringe and needles. Through their experiential knowledge and relational skills, they were able to map where PWID gather and educate their peers to dispose of N/S safely, contributing to increasing acceptance of harm reduction in the community at large, while indirectly reducing stigma and discrimination.

CONCLUSIONS/NEXT STEPS The peer-led approach has demonstrated its effectiveness in raising awareness of the benefits of harm reduction among police, local communities, family members and PWID themselves. It has also increased awareness of/access to vital prevention, care and treatment services among PWID in challenging settings. Peer-delivered harm reduction can be powerful tools for fast-tracking the response to HIV in Myanmar.

PEC0743

ESTIMATING NATIONAL AND SUB-NATIONAL POPULATION SIZE AND HIV BURDEN AMONG KEY POPULATIONS IN MOZAMBIQUE

I. Sathane[1], N. Chicuecue[1], A. Couto[1], G. Amane[1], J. Seleme[1], M. Boothe[2], H. F Raymond[3]
[1]Ministry of Health, National Program for the Control of STI and HIV/AIDS, Maputo, Mozambique, [2]The Joint United Nations Programme on HIV/AIDS (UNAIDS), Maputo, Mozambique, [3]Rutgers University, School of Public Health, New Jersey, United States

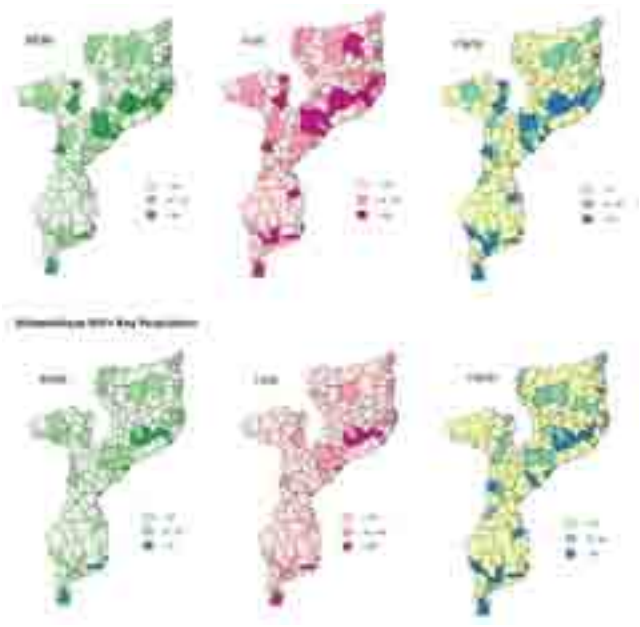
BACKGROUND: Population size estimates (PSE) of key populations (KP) living with HIV is imperative to estimate the burden of HIV among men who have sex with men (MSM), female sex workers (FSW) and people who inject drugs (PWID) and to allocate resources appropriately for targeted prevention and treatment services.

METHODS: Given the lack of a gold standard, we combined data from multiple sources to produce district-level PSE for PWID, MSM and FSW in Mozambique and the number of KP with HIV. Our analysis included data from the Census, Biological Behavioral Surveillance (BBS), AIDS Indicator Survey (AIS) and regional literature.

First, to estimate the PSE for each KP group in the 161 districts, we multiplied the literature-based KP PSE by district-level census data. In BBS cities, the PSE was the median of the literature estimate and the BBS-based PSE.

Second, we calculated the number of KP with HIV in urban areas by applying the BBS-based HIV prevalence estimates to the PSE of urban districts. To estimate number of KP with HIV in rural areas, we applied the regional AIS rural/urban HIV prevalence ratio. Stakeholders working with KP nationwide validated results.

RESULTS: We estimate that in Mozambique there are approximately 41,393 MSM (0.55% of adult male population), 93,412 FSW (1.1% of the adult female population) and 13,514 PWID (0.08% of adult population). Of which, 2,800 MSM, 21,631 FSW and 5,193 PWID have HIV. These estimates have been disaggregated by region, province, urban/rural areas, and district (Figure 1).



[Figure 1. Mozambique key population size estimates]

CONCLUSIONS: Given limited data and high prevalence of HIV among KP in Mozambique, these results provide important baseline for programmatic target setting, optimal resource allocation, and epidemic monitoring. Mapping and enumeration are necessary to provide additional data points, especially in high-burden districts. This should be an iterative process updated annually to produce robust estimates longitudinally.

PEC0744

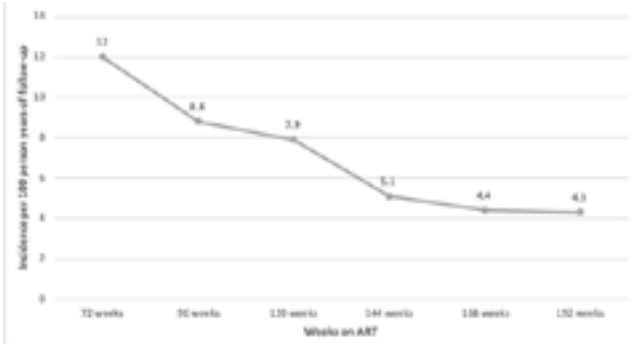
REBOUND VIREMIA IN KEY POPULATIONS ON ART IN ZIMBABWE: THE CASE FOR FURTHER INVESTIGATION

S. Gudukeya[1], M. Munjoma[1], B. Mutede[1], N. Madidi[1], N. Taruberekera[1]
[1]*Population Services International, Harare, Zimbabwe*

BACKGROUND: PSI Zimbabwe has offered specialized ART, including yearly viral load testing, to key populations (KP) since 2013. We were curious to determine the extent of possible viral rebound among clients with an initially suppressed viral load (VL)by reviewing successive VL test results within our cohort of MSM and SW key populations (KP) clients on annual virological monitoring.

METHODS: A retrospective cohort study was conducted on a secondary program dataset of 7,405 KP ART records created between 2013 and 2019 in 3 urban PSI clinics. To be eligible, a record had to include at least two VL tests conducted 12 months apart, with the antecedent VL result <50 copies/ml. Rebound viraemia was defined as a pair in which a VL result with ≥50 copies/ml followed an initial test with <50 copies/ml. Stata 13.0® was used to calculate one-time and cumulative incidence of rebound viraemia and test for its variation against covariates of age, sex, key population type and duration on ART.

RESULTS: The mean duration on ART for the 4,423 records analyzed was 2.6 years. 89% of records were from female KP. One-time incidence of rebound viraemia was 7.5% (331/4,423), whilst the 6-year cumulative incidence fell to 5.5% (CI: 4.9 –6.1) and did not vary by age, sex or key population type. The incidence of rebound viraemia reduced significantly with increasing weeks on ART (Figure 1).



[Figure 1. Incidence of rebound viraemia by weeks on ART]

CONCLUSIONS: Our results show that viraemia is a real risk for KP, even after initial suppression. The decline in detectable viraemia with increasing time on ART suggest that most high-risk clients can achieve an undetectable status. This suggests that annual monitoring may be insufficient for monitoring a subset of our population. Further analysis to find common factors among patients who rebound may enable us to proactively provide more frequent VL monitoring to those likely to rebound.

PEC0745

ALIGNING CIVIL SOCIETY BUDGET TO ADDRESS BARRIERS TO 'TEST- AND- TREAT POLICY' AND IMPROVE OUTCOMES OF THE 2ND AND 3RD 90 AMONG MEN WHO HAVE SEX WITH MEN IN GHANA

G. Vidda[1]
[1]*Maritime Life Precious Foundation, Finance, Takoradi, Ghana*

BACKGROUND: The HIV Prevalence rate amongst Men who have sex with men (MSM) in Ghana is 18.1% (Ghana Men study II, 2018) as compared to the general population of 1.3% (Ghana Demographic Health Survey, 2017). Despite the enrolment of the "test and treat" policy, some health facilities still demand baseline testing to be done before HIV positive clients are initiated on treatment. The cost of some of the baseline laboratory tests is not covered by the National Health Insurance (NHIS). MSM's are not able to afford the cost of these labs and with no budget line on these activities for CSO's, this results in delay in enrolment or no initiation on ART at all.

DESCRIPTION: Maritime Life Precious foundation(MLPF) is a Non-Governmental Organisation with vast experience in Key population implementation in the western region of Ghana. MLPF implemented the life support strategy to help improve ART initiation among MSM. It also revised its approach to budgeting to ensure that limited resource for programme implementation is allocated in a manner that address all financial barriers in achieving the 2nd and 3rd 90. The life support strategy ensured that newly diagnosed MSM PLHIV who needed financial assistance to complete baseline labs were provided with funds.

LESSONS LEARNED: The life support strategy and the realignment of the project budget was effective in improving the ART initiation among MSM. Between October 2017- September 2018 MLPF diagnosed 365 MSM HIV positive with 329 (90%) initiated on treatment. Out of the total initiated on ART 215(65%) were supported through budgetary allocations support transport cost to the facilities; 67(20.3%) were provided with life support and 47(14.2%) could afford to start and maintain treatment on their own. These findings imply that majority of MSM HIV positive require financial support to start and maintain ART.

CONCLUSIONS/NEXT STEPS In other to effectively achieve the 90-90-90 targets, budget should be allocated to address the financial needs of the MSM with regards to starting and maintain treatment on ART.

PUBLIC-PRIVATE PARTNERSHIPS

PEC0746

DETAILED PROFILE OPTIONS ON DATING APPS INCREASE AWARENESS ABOUT SEXUAL HEALTH

J. Hecht[1], D. Wohlfeiler[2]
[1]San Francisco AIDS Foundation/BHOC, San Francisco, United States, [2]Building Healthy Online Communities, Berkeley, United States

BACKGROUND: Hook-up apps, where an increasing percentage of MSM meet their sexual partners, play an important role in communication about sexual health strategies to mitigate behavioral risk. Most hook-up apps now give users the opportunity to disclose aspects of their sexual health and preferences (condom use, PrEP, undetectable viral load, HIV status) so that users can convey this information comfortably and easily prior to meeting in person.

Building Healthy Online Communities (BHOC) is a consortium of public health organizations working with dating apps to improve sexual health outcomes among app users.

DESCRIPTION: In 2011, BHOC conducted formative research with website owners, public health professionals, and hook-up website/app users. Nearly 80% of website users wanted to include safer sex information in website profile options and 58% wanted HIV testing reminders.

BHOC worked with five dating websites and apps (Grindr, SCRUFF, Adam4Adam, GROWLr, and Daddyhunt) to change default profile options to increase information shared among app users about sexual health strategies. BHOC also supported Grindr, Daddyhunt and Adam4Adam to send testing reminders to users who opt-in to that feature.

LESSONS LEARNED: In 2018, BHOC partnered with American Men's Internet Survey (AMIS) through Emory University to measure uptake. Among 10,129 AMIS participants, 66% reported using a dating app in the past year (n=6724). 74% of app users reported knowing that they could include sexual health strategy preferences on dating apps and 59% of those aware reported using sexual health profile options. Among the 26% (1,748 users) who didn't know about the options, more than half (56%) of users (n=979) reported that they would like to use these features in the future. Among individuals who reported recent unprotected sex and no recent HIV test (n=1791), a lower percentage reported knowing of the sexual health feature (69%) and opting into the feature (47%).

CONCLUSIONS/NEXT STEPS In order to reduce HIV/STI transmission, BHOC continues to work with app owners to encourage users to update their sexual health profiles, to increase awareness and uptake of existing sexual health profile options, and to advocate that websites and apps include condoms as a sexual health strategy option.

COMMUNITY INVOLVEMENT AND GOOD PARTICIPATORY PRACTICE IN EPIDEMIOLOGICAL AND PREVENTION RESEARCH

PEC0747

WALK THE TALK: ENGAGING COMMUNITY IN THE HIV RESEARCH AGENDA

B. Green-Ajufo[1], D. Mangosing[1], G. Rebchook[1], J. Hamiga[2], M. Lightfoot[1]
[1]University of California, Department of Medicine, Division of Prevention Science, Center for AIDS Prevention Studies and Prevention Research Center, San Francisco, United States, [2]University of California San Francisco, Department of Medicine, Division of Prevention Science, Center for AIDS Prevention Studies and Prevention Research Center, San Francisco, United States

BACKGROUND: National and international organizations share the vision that people determine what research is conducted in their communities and have opportunities to participate in community engaged research (CER). The benefits of CER are documented. Our community needs assessment (CNA) was conducted to understand the research interests and needs of our local community, and to assess its usefulness in forging an equitable process that identifies and addresses CER facilitators and barriers.

DESCRIPTION: From August-December 2017, we conducted a CNA in California's San Francisco Bay Area among organizations and advocacy groups that serve key populations – primarily PLWH, MSM, people who use drugs, sex workers, transgender and non-binary people, and young people (ages 15-24). The follow-up "Meet and Greet", held September 2019, drew 30 individuals from academia and the community, allowing participants to share their thoughts, reactions, reflect on CNA findings, and to identify potential CER opportunities.

LESSONS LEARNED: We used a semi-structured, IRB exempted qualitative guide and interviewed 22 individuals from 11 organizations/advocacy groups. We conducted a content analysis of verbatim transcripts from the recorded CNA interviews and took detailed notes of the meet and greet discussion, which we shared with participants. Participants expressed an interest in their organization having greater, improved, or continued access to/involvement in research, ranging from access to research publications, opportunities to attend our research symposiums, opportunities to interact with funders and understand funding mechanisms, and participation in CER projects focusing on key populations. Participants were invited to participate in a NIH listening session and have been included on our listserv, providing access to research findings. Leading with hu-

mility, flexibility, and equity of researcher and community expertise facilitates positive, transparent, and sometimes difficult conversations that are necessary to advance CER. When the interview process allows participants to veer off topic, respect of community voice and trust are created, garnering community pearls of wisdom that otherwise would remain unstated.

CONCLUSIONS/NEXT STEPS CNAs potentially serve as a helpful method to engage community members as equitable partners and advance CER endeavors. We are following up with other community recommendations, including supporting community identified/led forums and exploring potential new CER partnerships.

PEC0748

NOTHING ABOUT US, WITHOUT US! LESSONS LEARNT FROM ADOLESCENT ADVISORY GROUPS WITH YOUNG PEOPLE LIVING WITH AND CLOSELY AFFECTED BY HIV

L. Gittings[1], L. Nosiphiwo[1], S. Medley[1], E. Toska[1], N. Ralayo[1], N. Peterson[2], M. Thabeng[1], L. Cluver[3], T. Adolescent Advisory Group[1], T. Accelerate Hub Team[1]
[1]University of Cape Town, Accelerate Adolescent Hub, Cape Town, South Africa, [2]INTERFER, Cape Town, South Africa, [3]University of Oxford, Oxford, United Kingdom

BACKGROUND: Despite a commendable increasing policy and programmatic focus, AIDS-related deaths and new HIV infections among adolescents and young people continue. There is a clear imperative to better understand their needs, find tools that facilitate young people's participation, and to co-develop responses that are generated by young people themselves.

METHODS: Building on 10-years of work with an advisory group of young people (n=18, ages 16-23) living with, or closely affected by HIV in South Africa, this project expanded adolescent advisory group activities. Located in the Western Cape (n=18) and Eastern Cape (n=19) Provinces, a total of seven group engagements over twelve days were held throughout 2019. Activities aimed to foster reciprocal participation between advisory groups of young people, engagement practitioners and researchers. Activities drew on participatory, participatory action research, and more traditional qualitative methods and included theatre, group discussions, drawing, young people led-focus group discussions, singing and story-telling. Methods were participant-generated or selected.

RESULTS: Advisory group members demonstrated comprehensive age-appropriate engagement about the research process and interest and ability to co-create activities and co-generate rich evidence on a variety of topics. Methodological findings include: the importance of taking time to clarify and co-determine advisory group purpose; delivering age-appropriate capacity-building activities on the research process to facilitate understanding and participation; encouraging participant-generated methods and ensuring adequate referral support.

Participants never discussed HIV as a stand-alone concern, but consistently identified it as a cross-cutting issue across challenges facing young people in South Africa. The most prominently discussed challenges included:

(1) 'Blessers' (transactional, age disparate sex);
(2) Substance abuse;
(3) Medicine-taking and health;
(4) Bullying;
(5) Pregnancy; and,
(6) Careers and unemployment.

CONCLUSIONS: Adolescent advisory groups require time and resource investments, but are feasible and can generated rich methodological and empirical evidence to inform research, policy and practice – even with the most vulnerable adolescents. HIV was not an issue that was discussed on its own, but was rather understood as a complicating factor in many important life areas. This finding has relevance in the design of research, policy and programmatic responses and affirms HIV-sensitive (rather than specific), and combination approaches to adolescent health and development.

PEC0749

BEYOND BUILDING MORE BRIDGES: DECOLONIZING RESEARCH STRUCTURES THROUGH CO-CREATING RESPECTFUL AND EQUITABLE INDIGENOUS-SETTLER PLHIV PARTNERSHIPS IN A MULTI-SITE CANADIAN COHORT

C. Hui[1], M.R. Parsons[2], S. Young[3], S. Hillier[4], T.G. Stratton[5], A.D. Miller[6], M. Amirault[7]
[1]Ryerson University/Canadian HIV National Observational Cohort, School of Social Work/Community Invesitgator, Dish with One Spoon Territory/Toronto, Canada, [2]Canadian Aboriginal AIDS Network, Indigenous PHA Caucus, Traditional lands of Coast Salish Peoples, the Squamish, Tsleil-Waututh & Musqueam Nations, Canada, [3]Ryerson University, School of Social Work, Dish with One Spoon Territory/Toronto, Canada, [4]York University, School of Health Policy and Management, Dish with One Spoon Territory/Toronto, Canada, [5]Canadian Aboriginal AIDS Network, International Indigenous Working Group on HIV/AIDS, Traditional lands of Coast Salish peoples, the Squamish, Tsleil-Waututh & Musqueam Nations, Canada, [6]Healing Our Nations, Atlantic Peer Mentor and Community Health Educator, New Brunswick and PEI, Canada, [7]Canadian Aboriginal AIDS Network, AHA Centre, Traditional Lands of the Mi'kmaq and Wabanaki Confederacy/ Dartmouth, Canada

BACKGROUND: The creation of equitable Indigenous-settler research partnerships in settler-ally research can be challenging despite good-intentions. Efforts to bridge differences between Indigenous-settler research approaches are complicated by neo-colonial practices within research structures. This abstract describes an intentional co-creation of partnership in response to challenges that arose in a national HIV cohort study.

DESCRIPTION:

The study (analytic N = 4,151) utilized multivariable logistic and cox regression on treatment-naïve HIV+ MSM age 18+ who initiated combination antiretroviral therapy (cART) after January 1, 2000, had at least 6 months of follow-up,1 viral load test in the first 6 months after cART initiation, and 2 viral load tests in first year. A community advisory group guided the study. After settler researchers attempted to enforce neo-colonial work that contradicted GIPA/MIWA/MEPA, two community researchers living with HIV utilized a decolonizing, positive-people centered framework to engage in a culturally-safe, bilateral and reflexive knowledge exchange (KE) on Indigenous and anti-oppressive settler research approaches. The KE took place outside of a mainstream institutionalized research space and led to a respectful, equitable co-development of recommendations for researchers.

LESSONS LEARNED: Respectful, equitable Indigenous-settler research partnerships require researchers to:

1) recognize that Indigenous Peoples and settlers have different world views, ways of knowing and doing;
2) understand pan-Indigeneity does not exist across reserves on Turtle Island or globally due to ongoing displacement and genocide of cultures and communities, yet Indigenous solidarity work is vital;

3) don't speak for, or on behalf of communities and respect all consulted views;
4) understand that research has personal spiritual significance for some members of community; and,
5) know when to step back and support community in making decisions autonomously.

CONCLUSIONS/NEXT STEPS Decolonizing research within neo-colonial research structures requires researchers to implement ethical research guidelines in culturally safe manners. Having an understanding that Indigenous worldviews are not static and they change from a colonized to a traditional spiritual perspective while "one crosses the half moon" is critical in Indigenous-settler partnerships. As communities of people living with HIV are diverse, the co-creation of equitable, decolonizing HIV research must be GIPA/MIWA/MEPA centered and requires continuous and proactive engagement and critical reflexivity for implementation.

PEC0750

AWARENESS OF HUMAN IMMUNODEFICIENCY VIRUS AND ACQUIRED IMMUNE DEFICIENCY SYNDROME (HIV/AIDS) AMONG INFORMAL HEALTH CARE PROVIDERS IN URBAN SLUMS OF KARACHI

W. Mehraj[1], S. Guriro[2], J. Mehraj[3]
[1]Expanded Program on Immunization (EPI), Health Department Government of Sindh, Karachi, Pakistan, [2]Sindh Madressatul Islam (SMI) University, Karachi, Pakistan, [3]Shaheed Zulfikar Ali Bhutto Institute of Science and Technology (SZABIST), Karachi, Pakistan

BACKGROUND: A recent surge in HIV/AIDs cases due to an outbreak in which 80% of the cases are young children reported in Sindh province of Pakistan. Medical malpractices such as reuse of needles, unsafe blood transfusion, male circumcision with unhygienic blades, etc. by the unregistered and unqualified health care providers are reported as the main reasons for this outbreak among children. Therefore, this study is conducted to determine the awareness and attitudes of health care providers regarding HIV/AIDs in slum areas of Karachi, Pakistan.

METHODS: A cross-sectional survey was conducted among health care providers in different slum areas of Karachi. The questionnaire was administered by interviewers at different small clinics/ hospitals. Statistical significance of associations between predictors of knowledge about HIV/AIDS among qualified and unqualified health care providers were determined through the chi-square test.

RESULTS: A total of 160 health care providers were recruited in the study. The mean age of participant was 42.11 years with a standard deviation (SD) of 10.464 years. About 97 (60.6%) were male and 137 (85.6%) were qualified medical practitioners. From participants 133 (83.1%) heard of HIV/AIDS, 141 (88.1%) were aware of the sign and symptoms of HIV/AIDs and 127 (79.4%) knew that HIV infection can be asymptomatic. Around 87 (54.4%) were aware of blood tests for diagnosis of HIV infection and 112 (70.0%) correctly reported about all modes of transmission. Blood transfusion was identified by 142 (88.8%), re-used blades 147 (91.9%), re-used syringes 148 (92.5%) and unprotected sex 147 (91.9%) were correctly identified by the participants. About 130 (81.3%) considered HIV/AIDS as a serious health problem for Pakistan. More qualified medical practitioners as compared to un-qualified health care providers were aware of asymptomatic HIV patients (P-value; <0.000), the blood test for HIV diagnosis (P-value; 0.042) and nearby facility for AIDS treatment (P-value; 0.003).

CONCLUSIONS: Informal or unqualified health care providers have a very low level of knowledge about HIV/AIDS as compared to qualified medical practitioners. In order to prevent transmission and further outbreak, the Government needs to take initiatives to enhance knowledge of the general public including informal health care providers regard HIV/AIDS disease.

PEC0751

COMMUNITY ADVISORY BOARDS AS A MODEL FOR EFFECTIVE COMMUNITY ENGAGEMENT IN THE COLLABORATIVE AFRICAN GENOMICS NETWORK IN BOTSWANA

T. Regonamanye[1], K. Mathuba[1], K. Mokete[1], S. Kyobe[2], B. Mathuba[1], M. Matshaba[1,3]
[1]Baylor Children's Clinical Centre of Excellence, Gaborone, Botswana, [2]Makerere University, Kampala, Uganda, [3]Baylor College of Medicine, Houston, United States

BACKGROUND: Collaborative African Genomics Network (CAfGEN) is a Human Heredity & Health in Africa (H3Africa) affiliate and National Institutes of Health (NIH) funded study with the aim of integrating genetics and genomics technologies in Africa and probe host genetic factors that are important to the progression of HIV and HIV-TB co-infection in sub-Saharan African children from Botswana, Eswatini and Uganda. Collaborative genomics studies of this nature require effective community mobilization and engagement to encourage community participation. Community Advisory Boards (CABs) is an effective method to engage both the researcher and the community.

DESCRIPTION: The CAfGEN CAB in Botswana was established in 2015, it comprises of twelve key stakeholders with expertise and interest in welfare of children. The main role of the CAB is to be a guardian of CAfGEN study participants. CAB meetings are held monthly to be updated and provide feedback on study progress. The highlight of the CAB engagement with the community was the development of genome adventure comics translated into English, Setswana, Luganda, Swahili, Arabic, Hausa, French and Portuguese. The target for these comic books was school going children, youth and adults. During the CAB monthly meetings, useful feedbacks and suggestions were provided on graphics, method of distribution, and monitoring and evaluation. Once completed, the books were distributed and launched in Botswana, Tanzania and Uganda. The books are also freely accessible online.

LESSONS LEARNED: The CAB has provided useful guidance and feedback to CAfGEN study and is thus a suitable model for resource limited settings. Early engagement with community leads to a well accepted conduct of study as there is buy-in from the community. The CAB recommended the development of a scientific comic genome adventures book as part of engaging the public which has been well received the world over.

CONCLUSIONS/NEXT STEPS The model will continue to be used in the next funding phase of the CAfGEN study. The CAB will help with further development of 2 more books to deal with other research issues. We hope to publish this experience so that other communities can benefit from the model.

HARNESSING BIG DATA FOR EPIDEMIOLOGICAL RESEARCH/DIGITAL EPIDEMIOLOGY

PEC0752

KIDNEY FUNCTION AND RISK FOR CHRONIC KIDNEY DISEASE AMONG HIV-INFECTED INITIATING CARE IN ZAMBIA

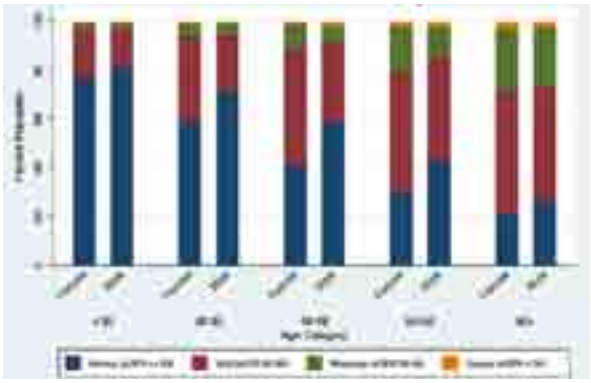
J. Pry[1,2], B. Pollock[3], I. Sikazwe[4], J. Mutale[4], A. Mody[5], C. Bolton-Moore[4,6], M. Herce[4,7]

[1]Washington University School of Medicine, Infectious Disease, St. Louis, United States, [2]Centre for Infectious Disease Research Zambia, Implementation Science, Lusaka, Zambia, [3]University of California, Davis, United States, [4]Centre for Infectious Disease Research Zambia, Lusaka, Zambia, [5]Washington University, St. Louis, United States, [6]University of Alabama, Birmingham, United States, [7]University of North Carolina, Chapel Hill, United States

BACKGROUND: As the global response to the HIV epidemic progresses, the risk for co-morbid non-communicable diseases (NCDs) like chronic kidney disease (CKD) and hypertension increases with an aging population living with HIV (PLHIV) on anti-retroviral therapy (ART). In Zambia, ART initiation includes a routine serum creatinine measurement to assess ART regimen safety and suitability. Here we assess potential to leverage the routinely measuring serum creatinine at ART initiation to describe risk for CKD and hypertension among those in HIV care in Zambia.

METHODS: For our analysis, we included all PLHIV recorded between January 1, 2011—December 31, 2017 in the national electronic medical record >17 years of age with ≥1 documented creatinine measure(s). We described kidney function using the CKD-Epi estimated glomerular filtration rate (eGFR) categorized by the Renal Association without modification for race/ethnicity. Logistic regression was used to describe the associations between covariates available in the HIV record. Blood pressure categories identified according to current WHO guidelines.

RESULTS: A total of 79,912 observations among 68,646 PLHIV in HIV care of which 61.0% identified as female and a median age 34 years (IQR: 28-40 in the study period. Of these, 2,853 (5.93%) had a moderately reduced eGFR, while 627 (1.3%) had a severely reduced eGFR. In addition, we observed a statistically significant increase in risk corresponding to increased age (figure), stage two hypertension (OR 1.46; 95% CI 1.30, 1.64), being male (OR 0.81; 95% CI 0.74, 0.88), and obesity (OR 1.26; 95% CI 1.05, 1.51).



[Figure. Estimated glomerular filtration rate by age and sex]

CONCLUSIONS: Using routinely collected data at antiretroviral therapy (ART) start can help identify individuals that may have underlying kidney disease and hypertension. As the PLHIV population in HIV care ages, it is increasingly important to evaluate non-communicable disease risk through HIV clinical care access points.

PEC0753

CREATING A BROADLY IMPLEMENTABLE AND OPEN ACCESS DATA COLLECTION AND MANAGEMENT PLATFORM TO SUPPORT MEASUREMENT OF ADOLESCENT HIV CARE TRANSITION PROCESSES AND OUTCOMES WITHIN LOW- AND MIDDLE-INCOME COUNTRIES

P.R. Tsondai[1], M.-A. Davies[1], T. Singtoroj[2], N. Maxwell[1], K.-G. Technau[3], S. Phiri[4], K. Chokephaibulkit[5], R. Hansudewechakul[6], P. Lumbiganon[7], A.H. Sohn[2], ; for the Global fRAmework of Data collection Used for Adolescent HIV Transition Evaluation (GRADUATE) project

[1]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Medicine, Cape Town, South Africa, [2]TREAT Asia/amfAR - The Foundation for AIDS Research, Bangkok, Thailand, [3]University of the Witwatersrand, Empilweni Services and Research Unit, Department of Paediatrics & Child Health, Rahima Moosa Mother and Child Hospital, Johannesburg, South Africa, [4]Lighthouse Trust Clinic, Kamuzu Central Hospital, Lilongwe, Malawi, [5]Mahidol University, Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand, [6]Khon Kaen University, Department of Pediatrics, Faculty of Medicine, Khon Kaen, Thailand, [7]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand

BACKGROUND: Few national programs and research cohorts within low- and middle-income countries (LMICs) document transition-related processes and outcomes for adolescents living with HIV transitioning to adulthood. The Global fRAmework of Data collection Used for Adolescent HIV Transition Evaluation (GRADUATE) project was established to create a broadly implementable and open access data collection and management platform that would support measurement of adolescent HIV care transition processes and outcomes within LMICs.

METHODS: During this collaborative effort (2017-2019), key data variables and definitions capturing the process, predictors, and outcomes across the transition period were identified by a global advisory group composed of HIV expert clinicians, researchers, and implementers. Thereafter, data tables were created and formatted into a GRADUATE Data Exchange Standard (DES), which were then added to and harmonized with the existing International epidemiology Databases to Evaluate AIDS (IeDEA) DES. Variables were categorized into three tiers; tier one (core basic) included variables most likely to be available within routine records, and tier two (core advanced) and three (research) included those likely to be unavailable within routine care but could be collected by longitudinal cohorts or during targeted research. These include variables capturing transition preparation, disclosure, caregiver status, housing, education, mental health, alcohol and substance use, and sexual activity.

RESULTS: Eight "GRADUATE tables" containing 104 variables identified as essential to capturing transition-related information were added to the existing IeDEA DES: 2 relating to socio-demographic characteristics and life experiences (e.g., disclosure, education, employment, housing, substance use, sexual behaviour); 3 relating to hospitalization and fracture events, and mental health management; 1 relating to HIV care responsibilities; and 2 relating to transfers and transition experiences.

CONCLUSIONS: Optimally measuring transition preparation, implementation, and outcomes is central to assessing and comparing transition outcomes. The GRADUATE DES is the first harmonized set of data tools designed to guide clinical programs and research cohorts as to the data variables, and their definitions, that can be collected to characterize adolescent-specific HIV outcomes. Integration of this DES across regional settings will facilitate comparisons and identify data gaps that need to be addressed in order to better characterize the health of this expanding population.

HARNESSING NEW TECHNOLOGY FOR UNDERSTANDING EPIDEMIC DYNAMICS

PEC0754

ENABLING REAL-TIME MONITORING OF ADHERENCE TO ANTIRETROVIRAL THERAPY AMONG PEOPLE LIVING WITH HIV USING THE 99DOTS MOBILE PHONE TECHNOLOGY SOLUTION: A FEASIBILITY ASSESSMENT IN NORTH INDIA

A.K. Paulraj[1], M.R. Parthasarathy[2], M. Bamrotiya[3], B. George[4], G.S. Shreenivas[1], A.R. Marak[5], M.K. Manihani[2], K. Krishnan[1], J. Baishya[6], M. Aguvaveedi[7], S. Subramanyan[7]
[1]FHI 360, LINKAGES, New York, India, [2]Formerly FHI 360, LINKAGES, New Delhi, India, [3]Formerly National AIDS Control Organization, New Delhi, India, [4]FHI 360, New Delhi, India, [5]National AIDS Control Organization, New Delhi, India, [6]USAID/India, New Delhi, India, [7]Everwell Health Solutions Pvt. Ltd., Bengaluru, India

BACKGROUND: Adherence monitoring and support are essential to maximize the benefits of antiretroviral therapy (ART) among people living with HIV (PLHIV). India's National AIDS Control Program (NACP) reports that 40% of PLHIV newly initiated on ART drop out within six months. Adherence normally gets assessed during their monthly follow-up visits. Under the PEPFAR/USAID-supported and FHI 360-led LINKAGES project, FHI 360 partnered with NACP to adapt the mobile phone-enabled 99DOTS from India's tuberculosis program to support ART adherence. Participating PLHIV self-verify adherence by calling a toll-free number (TFN) after consuming daily ART. A secure web dashboard and automated messages to providers' phones provide real-time cues to execute support actions (phone calls or house visits) when patients do not call the TFN. We conducted a feasibility assessment for adherence using 99DOTS at two ART centers in North India.

DESCRIPTION: From March 12 to April 13, 2019, 57 PLHIV newly initiated on once-daily tenofovir/lamivudine/efavirenz regimen, weighing >35 kg, age >10 years, with access to a mobile phone consented to voluntarily report their daily ART adherence through 99DOTS. Patients who were pregnant, had HIV/TB co-infection, or resided beyond the center's catchment area were excluded. Hands-on training and virtual WhatsApp-based support were offered to providers. Patient adherence data were captured digitally and analyzed for descriptive statistics and chi-square values to compare proportions between support actions and adherence.

LESSONS LEARNED: Participating PLHIV had a median age of 30.0 years (IQR=25.5-39.5), and 67% were male. Of the 906 expected calls during the assessment period, real-time self-verified adherence reported through the TFN was 80% (n=724), and the remainder of the time real-time cues were sent to providers for support actions. Support actions were conducted, and adherence changed accordingly for individual patients 96% of the time, increasing adherence to 99%. Adherence of >95% increased from 40% to 93% after support actions, which had a strong association (p=0.0002).

CONCLUSIONS/NEXT STEPS Successfully implementing a mobile-phone-enabled adherence monitoring system among PLHIV, adapting 99DOTS technology and engaging the PLHIV and providers on a real-time basis, is feasible. We recommend scale-up of this technology to further inform NACP and optimize its benefit for the PLHIV community.

ETHICAL AND HUMAN RIGHTS ISSUES IN RESEARCH AND DEVELOPMENT

PEC0755

ADVOCATES' PERSPECTIVES ON NEXT-GENERATION HIV PREVENTION TRIAL DESIGN

S. Hannah[1], D. Campbell[2,3], R. Coleman[4], N. Dedes[5], D. Evans[6], P. Goicochea[6], J. Johnson[7], G. Kumwenda[8], D. Nhamo[9], D. Ouya[10], J. Patterson[11], M. Warren[1], N. Yola[12,13]
[1]AVAC, New York, United States, [2]AVAC PxROAR, Los Angeles, United States, [3]Charles R. Drew University of Medicine Science, Los Angeles, United States, [4]UNAIDS, Geneva, Switzerland, [5]European AIDS Treatment Group, Brussels, Belgium, [6]Independent Consultant, Los Angeles, United States, [7]Treatment Action Group, New York, United States, [8]Pakachere Institute for Health and Development Communication, Blantyre, Malawi, [9]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe, [10]AVAC, Nairobi, Kenya, [11]Case/UHC ACTU CAB, Cleveland, United States, [12]Advocacy for Prevention of HIV and AIDS, Cape Town, South Africa, [13]Desmond Tutu HIV Foundation, Cape Town, South Africa

BACKGROUND: HIV incidence is declining globally, but not nearly at the pace or scale required to reach the UNAIDS Fast Track targets. Many populations and geographies remain underserved, and there is urgency to deliver existing treatment and prevention methods and simultaneously develop additional effective options. Researchers developing new biomedical prevention modalities, such as vaccines, antibodies and long-acting pre-exposure prophylaxis (PrEP), must design efficacy trials in this context of declining incidence and expanded access to daily oral PrEP, which have implications on sample size, statistical analysis, trial duration and cost. As various novel trial designs are discussed and deliberated, research stakeholders have called for meaningful community and advocacy engagement.

DESCRIPTION: In September 2019, AVAC convened a group of global advocates to advance understanding of novel trial design for HIV prevention research and forge initial engagement between advocates and key research stakeholders, including statisticians, trialists, ethicists, and regulators, around emerging questions and challenges. Workshop objectives included:

- Establishing a cadre of advocates skilled to engage in discussions and decisions with researchers, regulators, and funders;
- Identifying opportunities for further engagement on protocol-specific and broader product development issues;
- Developing mechanisms and tools for ongoing capacity building and engagement.

LESSONS LEARNED: Workshop participants developed a statement outlining their perspectives, asserting that:

- Efficacy trials will require a new level of cohesion between the trial context and evolving prevention standards.
- The gold standard of randomized, placebo-controlled trials should continue to be used where possible. Rationale for alternative, innovative designs need to be clearly articulated and carefully navigated with communities and advocates.
- Negotiated post-trial access plans should be in place in advance of trial launch.
- There is urgency for better congruence between ethics guidance at normative, national, and institutional levels to align around the practical conduct of next-generation HIV prevention trials.
- Robust Good Participatory Practice as a part of innovative trials will help safeguard research and accelerate translation of results into real world outcomes and public health impact.

CONCLUSIONS/NEXT STEPS A cadre of well-versed, committed advocates stands ready to partner with product developers, researchers, ethicists, regulators and funders to navigate discussions and necessary solutions for the success of next-generation prevention trial designs.

TRACK D

COMMUNITY ENGAGEMENT IN RESEARCH AND RESEARCH DISSEMINATION

PED0755

"I NEVER TEACH MY PUPILS. I ONLY PROVIDE THE CONDITIONS IN WHICH THEY CAN LEARN" ADVOCACY FOR HIV – STUDENT EXPERIENCES

H. Myezwa[1], J. Potterton[1], A. Ajidahun[1], N. Comley-White[1], N. Benjamin-Damons[1], K. Sekome[1], S. Pilusa[1], R. Roos[1], S. Nixon[2]
[1]*University of the Witwatersrand, Physiotherapy, Johannesburg, South Africa,* [2]*University of Toronto, Physical Therapy, Toronto, Canada*

BACKGROUND: As a result of intensive efforts in ART, HIV has transitioned into a chronic illness globally presenting new challenges of increased morbidity and care gaps. Gaps include an increased need for rehabilitation to address disability and wellness challenges. One of the responses has been to mainstream HIV management into all health workers education. Students receive input on HIV pathology, aetiology and management from a rehabilitation perspective. Once students are exposed to patients, they become aware of gaps in access to rehabilitation at patient, family, community and system level. The student needs to advocate where required. This project sought to establish the level and extent of advocacy for HIV rehabilitation undertaken by students as part of their HIV curriculum.
METHODS: Third and fourth-year physiotherapy students undertaking clinical rotations at the University of the Witwatersrand participated in an advocacy and rehabilitation session for people living with HIV. Consenting students participated in the study. Four of the six rotations required the students to identify a patient who was infected with HIV and includes advocacy in their management plan. The cases, including advocacy plans, were qualitatively analysed using MAXQDA.
RESULTS: A total of 31 verbal case presentations were analysed. These included cases from paediatrics, public health, adult neurology and cardiopulmonary. Four themes emerged, namely the goal, role, level at which advocacy was undertaken and concrete examples of how students undertook advocacy. The goal and role in advocacy included explicit and implicit advocacy for the individual patient and at structural level in the areas of improving education about the condition in general and person knowledge, importance of exercise, obtaining aids and appliances, improving facilities such as basic hygiene, referral to services such as psychologists and involvement of family. The level of advocacy was undertaken predominantly at an individual level with the aim of empowerment and protection.
CONCLUSIONS: Students were involved in patient advocacy at an individual level. Much of the advocacy resulted in the empowerment of the patient in managing HIV, and students play a facilitatory role in creating an enabling environment for effective outcomes in the patient management care continuum and successful functional outcomes.

PED0756

NARRATIVE MEDICINE, STORYTELLING AND UNDERSTANDING HIV & AIDS AMONG RURAL AND REMOTE CITIZENS OF MALAWI

C. Kalinga[1]
[1]*University of Edinburgh, Social Anthropology, Edinburgh, United Kingdom*

BACKGROUND: More than 80% of Malawain citizens live in rural or remote areas. This transdisciplinary study funded by the Wellcome Trust sought to establish the correlation between narrative, storytelling and beliefs about HIV in a localized context as they are shared amongst communities living in rural and remote areas. The project centres the aesthetics and socio-cultural constructions of traditional storytelling (including various styles, genres, & themes) and indigenous ways of knowing, teaching and communicating to identify the factors that influence access to HIV/AIDS testing, treatment, and social acceptance following seropositivity.
DESCRIPTION: The study took place between November 2018 and January 2020 in Malawi in the four geographical regions: north, central, east and southern Malawi. The qualitative project implemented participatory action research and indigenous reception theories which drew upon decolonizing methodologies in health care research in rural and remote communities. The study explored and framed challenges faced by ordinary citizens as they sought information about HIV/AIDS and other diseases in their localized context by understanding the framework for their traditional way of knowing. The study population was uniquely tailored to match traditional storytelling transmission incorporating factors such as disparate languages, ethnicities, ages, identities, sexual orientations and economic status within communities and families.
LESSONS LEARNED: Preliminary findings indicate that traditional narrative plays a significant role in shaping localized understandings of disease including origins, transmission, treatment and cure. Furthermore, that the study indicates that there are lacking structures within the government, the NGO, and individuals to address structures of complex understanding of disease burdens.
CONCLUSIONS/NEXT STEPS: Neglecting social and power hierarchies within groups is detrimental to the study of HIV/AIDS as the stories which emerge and are believed are contingent upon deeply rooted social hierarchies and figures of authorities depending on the 1) individual, 2) social setting and 3) age group. The study suggest that a different set of empirical questions must be raised in contemporary approaches to understanding collective formations of narratives about AIDS including metaphors, stories, myths, rumours, folklores and even recounting of dreams.The implementation of indigenous knowledge systems and audience reception methods would provide invaluable insight into the formation of beliefs, stigmas and conceptualisations about HIV/AIDS.

KNOWLEDGE TRANSLATION AND DISSEMINATION OF RESEARCH AND PROGRAMME OUTCOMES

PED0757

MESSAGING TRANSMISSION: A QUALITATIVE ANALYSIS OF FACTORS IN THE UPTAKE OF U=U IN CANADIAN PUBLIC HEALTH MESSAGING

A. Brett[1,2]
[1]Canadian AIDS Treatment Information Exchange, Communications, Toronto, Canada, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: A scientific consensus has emerged that a person living with HIV who has an undetectable viral load does not transmit the virus sexually, commonly known as "undetectable equals untransmittable" (U=U). However, the uptake of this science in Canadian public health messaging has been inconsistent. This study identified factors that may facilitate or delay knowledge transfer and exchange for public health messaging.

METHODS: Public endorsements and communications of the U=U message by 61 Canadian HIV and public health organizations between 2016 and July 2019 were compiled and analyzed. Organizations were grouped into discrete categories: national HIV organizations, local and regional HIV organizations by region, and public health authorities. U=U adoption within each category was charted over time. Qualitative one-on-one interviews were held with nine participants from organizations purposively sampled across multiple time periods of adoption. Interview transcripts were analyzed using framework analysis.

RESULTS: The pattern of U=U adoption varied based on the region and type of organization, with national HIV organizations being the first category of organizations to reach 50% adoption, followed by local and regional HIV organizations in the province of Ontario. Public health authorities were later to adopt the message than HIV organizations. Factors that played a role in the timing of adoption included the perceived relevance of the message to target audiences of the organization, congruence with pre-existing organizational values, institutional agility and risk tolerance, and the influence of funders, policy-makers and thought leaders.

CONCLUSIONS: The findings point to strategies that can leveraged by researchers, knowledge brokers and public health practitioners to expedite the uptake of new research in public health messaging. These include knowledge translation to reframe research in alignment with the interests and values of organizations and their audiences, identifying and altering characteristics of an institution's culture and decision-making processes that may hinder adoption of new research, and leveraging the influence of thought leaders.

PED0758

UNDERVALUED RESOURCE: WHY IMPLEMENTATION OF THE EDUCATIONAL ACTIVITIES FOR NURSES RESPONSIBLE FOR DISPENSING ART DRUGS IS A VITAL NECESSITY IN UKRAINE. PRESENTATION RESULTS OF THE TRAINING PROGRAM EFFECTIVENESS

V. Li[1], K. Pandeli[1]
[1]100 Percent Life, Kyiv, Ukraine

BACKGROUND: Since the beginning of 2017, PLHIV in Ukraine have gained expanded access to ART treatment: generic drugs entered the market. More than 30% of patients were transferred from multi-component to single-tablet regimens. ART became appealing to patients. In order to make dispensing ART faster, nurses were obligated to deliver ART. However, they were not educated to dispense medicines and working with PLHIV. In addition, feedback from the fields demonstrated that nurses have low-level proficiency in consulting in ART adherence, no knowledge in HIV and high level of stigma, which was influenced on the patients.

In order to fill the gap in the knowledge of nurses, Charitable organization "100 PERCENT LIFE" in cooperation with I-TECH Ukraine implement the project "Building clinical and managerial capacity of HIV / AIDS Service in Ukraine", aimed at raising the awareness of nurses in the context of building a adherence to ART, to reduce stigma and discrimination and destroy myths about generic and branded drugs.

DESCRIPTION: The project has been implemented from October 2018 to October 2019, active phase (training activities) were held for providers from the 12 most urgent regions for HIV. Were provided 1 ToT for 22 nurses and 8 trainings which attended by 176 nurses.

Each training intro and final assessment of knowledge was carried out in order to optimize the training course and obtain information on the progress of the project.

LESSONS LEARNED: Assessment results demonstrated low entrance level of nurses' knowledge and high response from participants (more participated than been announced). The average level of knowledge improvement is 36%, the highest level of increased knowledge is myths and truth about generic and branded ART (83%), stigma and discrimination related to HIV (77%).

CONCLUSIONS/NEXT STEPS: Conducting education with a detailed analysis of results significantly increased the level of professional knowledge of nurses, which improve the quality of the support of PLHIV. Non-priority regions demonstrate lower rates in attracting PLHIV to ART, continuing on outdated approaches and regulatory guidelines. This confirmes that the scaling of projects throughout the whole country will make it possible to align the situation, according to the standards of providing care for PLHIV.

PED0759

OVERCOMING THE DICHOTOMY OF DAILY AND EVENT DRIVEN PREP REGIMENS FOR MSM: LESSONS LEARNED FROM COMMUNITY SUPPORT PROGRAMS IN FRANCE

S. Morel[1], D. Rojas Castro[2,3], R.M. Delabre[2], B. Spire[3], J.-M. Molina[4,5], D. Michels[1,2]

[1]AIDES, Community-Based Research Unit, Pantin, France, [2]Coalition PLUS, Community-Based Research Laboratory, Pantin, France, [3]Université d'Aix Marseille, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, INSERM 1252, Marseille, France, [4]Assistance Publique Hôpitaux de Paris, Hôpital Saint-Louis, Maladies Infectieuse, Paris, France, [5]Université de Paris Diderot, Sorbonne Paris Cité, INSERM UMR 941, Paris, France

BACKGROUND: Regarding oral pre-exposure prophylaxis for HIV (PrEP) for MSM, two intake regimens have demonstrated their effectiveness through biomedical trials: the daily and the event-driven regimens. Since 2009 in France, community-based organization AIDES mobilized the MSM community around PrEP use as a new HIV prevention tool. AIDES has offered constant community support to new PrEP users since the early stages of the ANRS IPERGAY trial (2012-2016) and then with PrEP rollout from 2016 with French guidelines allowing both regimens for MSM. As from May 2017 this also includes the 17 hospitals units and free STI clinics of the ANRS PREVENIR study.

DESCRIPTION: Trained community workers and volunteers were available after each medical appointment and during 6 months after PrEP initiation. They offered repeated counseling sessions to users, focusing on HIV, STIs and drugs risk reduction, PrEP adherence and global sexual health.

LESSONS LEARNED: The community worker teams, benefiting from bimensal professional practice analysis and supervision sessions, identified three crucial situations for PrEP users, generating most of the questions during follow-up, either during counselling sessions or on social media support groups: how to start and stop PrEP, how to adjust PrEP to their evolving sex life and how to react when a dose is missed or not taken on time. These questions suggest that the guidelines are not clear, or adapted to the evolving needs of PrEP users, particularly for those who switch between the regimens. To simplify, community workers chose to promote notions around starting and stopping PrEP use that is independent of the chosen regimen.

CONCLUSIONS/NEXT STEPS: The research concepts of daily and event-driven PrEP for MSM have been inserted into worldwide guidelines without having been translated into real life situations. They could be merged into a "start and stop" concept that has recently been introduced in 2019 WHO guidelines. This concept would be much easier to explain by PrEP providers and would make PrEP autonomously adjustable. Further exploration and understanding of how individuals use PrEP and the feasibility and acceptability of concepts such as "stop and start" for users (and providers) are necessary to empower users.

PED0760

THE KNOW-DO GAP IN ADHERENCE TO TB-HIV SCREENING GUIDELINES IN URBAN NIGERIA: A STUDY OF TB-CARE QUALITY AMONG PRIVATE CLINICAL PROVIDERS IN TWO STATES

S. Faye[1], L. Rosapep[1]

[1]Abt Associates, International Development, Rockville, United States

BACKGROUND: The WHO classifies Nigeria as high burden country for TB, multidrug resistant TB (MDR-TB), and TB-HIV. Currently, little is known about the quality of screening, diagnosis and treatment of TB in the country, especially in the private sector. The USAID-funded Sustaining Health Outcomes through the Private Sector Plus (SHOPS Plus) project implemented a study to evaluate the extent to which private clinical facilities it trained to provide TB services adhere to national standards for management of presumptive and confirmed TB. These standards specify that providers should inquire about a presumptive and confirmed patients' HIV status, provide HIV counseling and testing if appropriate, and test PLHIV with TB symptoms for MDR-TB.

METHODS: The study used a standardized patient (SP) survey, which is considered the "gold standard" for examining provider behavior, and a medical vignette survey to assess provider knowledge gaps. The sample included 398 clinical facilities in urban areas of Lagos and Kano states. Two different patient scenarios were examined – a "textbook" case of presumptive TB and a treatment initiation case in which the SP presents with a confirmed TB diagnosis. The survey instrument included elements on PITC – whether providers asked if patients had been previously tested for HIV, and whether providers recommended HIV testing.

RESULTS: The study found that among presumptive and treatment initiation cases, few providers engaged in questioning on HIV testing status (respectively 13.4% and 27.1%) or made recommendations for HIV testing (respectively 10.3% and 13.4%). The vignette survey revealed a knowledge gap among providers about testing PLHIV for MDR-TB (only 0.9% said they would). By comparing results from both surveys a "know-do" gap is evident: although 34.3% recommended HIV testing for TB-presumptives on the vignette survey, only 10.3% made this recommendation in the SP survey.

CONCLUSIONS: Results indicate an adaptive management opportunity for SHOPS Plus. Going forward the project should implement supportive supervision or training remediation to better sensitize private clinical providers to TB-HIV protocols. A planned follow-up survey before the end of the project will assess effectiveness of such support to improve the quality of TB care provided by SHOPS Plus-affiliated providers.

MIXED METHODS, INTEGRATED APPROACHES AND SYNERGIES IN HIV RESEARCH AND INTERVENTION

PED0761

WILLINGNESS TO PARTICIPATE IN SHORT AND EXTENDED ANALYTIC TREATMENT INTERRUPTION (ATI) DURING HIV REMISSION TRIALS

G.E. Henderson[1], T. Jupimai[2], N. Ormsby[1], S. Rennie[1], R.J. Cadigan[1], K. Kuczynski[1], S.C. Isaacson[1], N. Phanuphak[3], E. Kroon[3], J. Ananworanich[4], D. Colby[3], C. Sacdalan[3], S. Vasan[5], P. Prueksakaew[3], K. Benjapornpong[3], H.L. Peay[6]
[1]University of North Carolina, Department of Social Medicine, Chapel Hill, United States, [2]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [3]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [4]University of Amsterdam, Amsterdam, Netherlands, [5]US Military HIV Research Program, Bethesda, United States, [6]RTI International, Early Education, Disability, and Health Program, Durham, United States

BACKGROUND: Short analytic treatment interruption (ATI) in HIV remission trials is employed to facilitate evaluation of an experimental agent. Investigators are currently exploring whether ATI and associated viremia time was too short to demonstrate benefits. Extended ATI implies a longer exposure to the potential risks of ATI for participants and partners. Several studies have explored participant attitudes toward ATI, but do not compare duration of ATI or include people with ATI experience.
We present quantitative data from a large cohort of acutely diagnosed individuals in Bangkok (SEARCH010) on attitudes toward short and extended ATI; and qualitative data on extended ATI from SEARCH010 members with ATI experience.
METHODS: Vignettes in an online survey for SEARCH010 participants described the rationale for short and extended ATI, potential benefits and harms, and criteria for restarting ART, followed by attitude questions about acceptability of conducting the trial and willingness to participate (WtP) (1-strongly disagree to 4-strongly agree). The extended ATI vignette was included in interviews conducted after 4 SEARCH010 remission trials (with short ATI). Descriptive analyses and T-tests were conducted on quantitative data. Coding and thematic analysis of qualitative data included "willing to participate", "unwilling", or "undecided".
RESULTS: Survey responses (n=408) are presented in Tables. Mean scores for acceptability and WtP were significantly higher for short versus extended ATI (p<.0001). Of participants (n=33) interviewed after experiencing short ATI, 45% (n=15) were willing, 21% (n=7) unwilling, and 33% (n=11) undecided about extended ATI. Willingness was higher in trials evaluating the efficacy of an intervention (15 of 28 willing) versus with ATI only (0 of 5 willing).

Short ATI	Disagree/strongly disagree	Agree	Strongly Agree	Mean
Acceptability	10%	42%	48%	3.4
Willing to participate	22%	43%	35%	3.1

[Table 1.]

Extended ATI	Disagree/strongly disagree	Agree	Strongly Agree	Mean
Acceptability	15%	51%	24%	3.2
Willing to participate	31%	45%	24%	2.9

[Table 2.]

CONCLUSIONS: We found higher WtP and acceptability of short vs extended ATI, though most were positive about both. About half with short ATI experience, even after viral rebound, remained willing to participate in extended ATI studies. Research interest and endorsement, while varied in response to these scenarios, is expected to be high among participants in an existing cohort like SEARCH010.

PED0762

"INTERSECTING VULNERABILITIES": HOUSING INSTABILITY AND LOW-INCOME WOMEN'S HIV-RISK

A. Dawson[1], K. Blankenship[2], A. Rosenberg[3], A. Groves[4], P. Schlesinger[3]
[1]Howard University, Sociology, Washington, United States, [2]American University, Sociology, Washington, United States, [3]Yale University, School of Public Health, New Haven, United States, [4]Drexel University, Community Health and Prevention, Philadelphia, United States

BACKGROUND: Much research explores the intersections of housing stability and HIV-risk. Increasingly, it recognizes stable housing as a social determinant of HIV. This research focuses primarily on the impacts of housing for those living with HIV. It rarely examines the specific experiences of women. We address these limitations by considering how housing and other factors associated with life in low-income, predominantly minority neighborhoods in a mid-sized city in the northeast US intersect to shape women's HIV-related vulnerability.
METHODS: Data are from surveys and semi-structured interviews collected as a part of the Justice, Housing, and Health Study (JustHouHS), a mixed methods study that explores the intersecting impacts of mass incarceration, housing stability, and sexual health. We analyze data from the 126 low-income women survey participants using bivariate analytical techniques to compare the HIV-related risks of "unstably vs. stably" housed women. We further explore these intersections were qualitatively. Thematic analysis was performed on 67 interviews with 17 low-income women interview participants.
RESULTS: 44% of women in the quantitative sample experienced unstable housing at baseline. Unstable housing was significantly related to several HIV-risk factors (i.e. criminal justice involvement, substance use, and riskier sex practices). 59% of women in the qualitative sample experienced unstable housing during JustHouHS. Qualitative interviews reveal several different forms of unstable housing (i.e., homelessness, doubling-up, and marginal housing). They also provided insight into how unstable housing intersects with and shape HIV-risk.
CONCLUSIONS: Our findings indicate that housing instability is an important issue in the lives of low-income women. Moreover, the results suggest that access to stable housing has implications for low-income women's HIV-related vulnerability. Policies and programs that seek to address these impacts will need to attend to the different forms that housing instability can take and the different ways that it intersects with HIV. Our findings suggest that women may have a unique experience with unstable housing. Thus, future work should compare women's and men's experiences to understand how gender may also shape the relationship between housing instability and HIV-risk.

QUALITATIVE AND ETHNOGRAPHIC METHODS IN HIV RESEARCH

PED0763

ADHERENCE TO ANTIRETROVIRAL TREATMENTS IN A NATIONAL NETWORK OF YOUNG ACTIVISTS LIVING WITH HIV

T. Kierszenowicz[1]
[1]National Council of Scientific and Technical Research (Argentina) - Buenos Aires University, Anthropology of Health, Buenos Aires City, Argentina

BACKGROUND: Since the mid-1990s, the development of highly active antiretroviral therapy (HAART) improved the prognosis of HIV infection of affected people. "Adherence" to treatments became a central issue of medical-institutional approaches. In this context, civil society organizations have played a significant role in articulation with international cooperation agencies and agencies.
In this study, I seek to understand how members of a national network of young people living with HIV articulate their activism practices with the experience of being young and living with HIV. Thus, I propose to analyze the meanings expressed by some activists around these long-term treatments and I will present how the category of "adherence" is discussed in different events and institutional activities in which medical infectologists also participated.
METHODS: For this study I implemented an ethnographic approach through observation with participation in the activities of the network, complementing with interviews to activists and analysis of secondary sources. I carried out the field work between August 2015 and June 2016 within the institutional framework of the network, which was formed in 2011 and is considered a space for participation nad support organized exclusively by young people who ive with HIV in Argentina.
RESULTS: In the testimonies of young people, other meanings of "good adhesions" are highlighted. Young people show how a "good adherence" can include an adequate intake of medication with the development of a full youth life. Here, "good adherence" is not translated into the effectiveness of the treatment, but rather that the youth life is not affected by the treatment. A "good adherence" is translated in the recognition of the efficacy of the treatment, but accepting that the medication intake may be interrupted. However, the network is valued by young people as an emotional space that allows treatment to be resumed.
CONCLUSIONS: This study shows how the medical category "adherence" circulates within a network of young people with HIV. The notion of "adherence" is appropriate for young people and given new meanings in the different instances of participation. Medical knowledge is molded from the knowledge produced by young people in their lives, which expose other dimensions of treatments obstacles.

PED0764

SEXUAL PRACTICES OF YOUTH AND ADOLESCENTS - MEN WHO HAVE SEX WITH MEN (MSM) AND TRANSGENDER WOMEN (TGW) - USING PRE-EXPOSURE PROPHYLAXIS (PREP) TO HIV: LESSONS FROM BRAZIL

L. Pedrana[1], L.A. Vasconcelos da Silva[2], M. Castellanos[3], S. Assis Brasil[4], L. Silva[3], R. Oliveira[3], L. Magno[4], I. Dourado[3]
[1]Instituto de Saúde Coletiva (ISC), Universidade Federal da Bahia (UFBA), Social Sciences, Salvador, Brazil, [2]HIAC/UFBA, Salvador, Brazil, [3]ISC/UFBA, Salvador, Brazil, [4]UNEB, Salvador, Brazil

BACKGROUND: Studies on PrEP uptake and sex behaviour in "real-world" settings remain largely unknown for adolescents and young MSM and TGW (AYKP). Our goal is to explore narratives of sexual behaviour among AYKP using PrEP in Northeast Brazil, to understand changes in aspects of their health, youth, and sexuality.
METHODS: Thirty semi-structured interviews were conducted with selected participants of the first PrEP demonstration cohort study ongoing in 3 Brazilian cities among AYKP aged 15-19 (PrEP1519 study), during June-November 2019 in Salvador site (25 MSM, 5 TGW). Our sample is made of adolescent in a follow-up from 1 to 5 months, all belonging to the medium-low class of the black population of AYKP.
RESULTS: Even though most of the participants say they have been using condoms since their first sexual relationship, they also reported unprotected sex at least one time. The participants who have a steady relationship are generally less interested in prevention practices, unless they fear that their partner has been unfaithful - in this case, some of them have been tested for HIV. After PrEP enrolment, they mentioned a feeling of being safe and more protected in their sex life and referred less frequent sexual intercourse, specifically occasional encounters. In fact, some participants highlighted the need to improve their self-care in their sexual practices. Furthermore, even those in a steady partnership mentioned that they became more conscious of using the condoms more frequently.
CONCLUSIONS: PrEP1519 is not only enrolling AYKP in PrEP but raising awareness on STI/HIV combination prevention, and providing counselling for a healthy and more protected sex life. Despite these new possibilities in the field of HIV prevention, the challenge is to consider aspects of the vulnerability of different groups and ages as well as the way they live their sexuality.

ROLE OF SOCIAL AND BEHAVIOURAL SCIENCE IN BIOMEDICAL RESPONSES

PED0765

OPTIMIZING UPTAKE OF INDEX TESTING SERVICES AND PARTNER ELICITATION BY INDEX CLIENTS IN 7 STATES IN NIGERIA: EFFECT OF INTEGRATED HEALTH MESSAGING STRATEGY

O.E. Amoo[1], S. Adamu[1], O. Iyaji-Paul[1], I. Onwuatuelo[1]
[1]APIN Public Health Initiatives, Prevention and Community Services, Abuja, Nigeria

BACKGROUND: Index Testing (IT) is known to be an effective strategy for HIV case finding and assurance of an Index client's anonymity is fundamental to the success of IT services. Despite efforts made in scaling up IT in Nigeria, acceptance and sub-optimal elicitation

remains a challenge. The objective of this study was to assess the outcome of using an integrated health message approach to improve service uptake and partner elicitation during Index testing services offered to Index clients in a CDC funded HIV program in Nigeria.

DESCRIPTION: IT service providers were trained on the use of integrated health message script (IHMS) for contacting sexual partners elicited by index clients. The script encouraged partners of index clients to take up free health checks supported by the government which included vital signs check, Hepatitis B, syphilis, malaria and HIV. Providers discussed this approach with index clients during IT initiation to encourage acceptance. An analysis of IT program data before and after the deployment of the IHMS was conducted to determine the rates of acceptance of Index testing services and partner elicitation rates using data from 165 health facilities across 7 states in Nigeria

LESSONS LEARNED: Prior to the application of the IHMS 15,941 (5,970 Male and 9,971 Female) HIV positive persons were offered index testing; 14,234(5407 Male and 8,827 Female) (89%) accepted the service; and elicited 24637 (14,231 Males, 10,406 Females) partners -1:1.7 partner elicitation ratio.

After the application of IHMS, 14,460(5,428 Males; 9,032 Females) were offered IT; 14,144 (5,329 Males; 8,815 Females) accepted the service and they elicited 36,119(21,360 Males and 14,759 Females) - 1:2.6 elicitation ratio.

The acceptance rate before the application of IHMS was 89% (14,234/15,941) and 98% (14,144/14,460) after.

CONCLUSIONS/NEXT STEPS: The use of an integrated health messaging and services approach for index testing services improves acceptance of the service by index clients and improves elicitation of more partners. This strategy eliminates the fear of intimate partner violence and stigma associated with disclosure and should be scaled up.

SOCIAL AND BEHAVIOURAL CONCEPTS AND THEORIES

PED0766

FACTORS INFLUENCING WOMEN'S PERCEIVED SEXUAL SELF-EFFICACY IN BOTSWANA: AN IMPLICATION FOR HIV INTERVENTION PROGRAMS

O. Lesotlho[1]
[1]University of Botswana, Population Studies Department, Gaborone, Botswana

BACKGROUND: Most sexual and reproductive health policies have focused too narrowly on the spread of HIV thus psycho-social factors like perceived sexual self-efficacy are relatively under researched in many African countries. In investigating the disproportion of HIV/AIDS skewed towards women in the region, there is need to examine the factors affecting sexual self-efficacy of women in order to influence and direct policy related interventions as well as to achieve goal 3 of the SDG's. For Botswana this is especially pivotal if the country is to simultaneously reduce HIV prevalence as well as rectifying this disproportion.

METHODS: Data from the most recent 2013 Botswana Aids Impact Survey was used which focused on women aged 15-35 years. Perceived sexual self-efficacy is a dichotomous variable with outcomes being high or low. Descriptive, bi-variate and binary logistic analysis was used to examine the factors associated with perceived sexual self-efficacy. A total of 6 independent variables was considered in the analysis.

RESULTS: At bi-variate level, marital status, religion, occupation, age, type place of residence and education were associated with sexual self-efficacy. Overall, the proportion of women with low sexual efficacy was 56.5%. Odds of low sexual self-efficacy were higher for older women aged 20-24 (OR, 3.733), 25-29 (OR, 1.027) and 30-35 (OR, 1.173). They were also higher for women with secondary (OR, 2.038) and higher education (OR, 1.641). Sexual efficacy was higher for non-religious people, those cohabiting, those living in rural areas as well as non-working students.

CONCLUSIONS: Conclusion: There is an association of women's perceived sexual self-efficacy with all the independent variables. From our results, we can deduce that as age and educational attainments increase, women's sexual self-efficacy is seen to be low; the same applies for people in urban areas and those who have never been married. Apart from having targeted policies and campaigns for these vulnerable populations, alternative models must be formulated in order to rectify the gender-double standards. Such psycho-social factors must be considered in any HIV intervention program for the melioration of their overall effectiveness and to empower women to take up a more mindful position as sexual agents.

PED0767

MEASURING SEXUAL RELATIONSHIP POWER AMONG WOMEN LIVING WITH HIV IN CANADA: POWER, RESILIENCE AND VIOLENCE

K. Closson[1,2], M. Lee[3], A. Gibbs[4], V. Nicholson[3,1], R. Gormley[3,1], E. Ding[1], J. Li[1], N. Pick[5], M. Loutfy[6,7], A. de Pokomandy[8], S. Greene[9], C. Logie[6,7], A. Kaida[3]
[1]British Columbia Centre for Excellence in HIV/AIDS, Epidemiology and Population Health, Vancouver, Canada, [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [4]South African Medical Research Council, Cape Town, South Africa, [5]Women's Hospital, Oak Tree Clinic, Vancouver, Canada, [6]University of Toronto, Dalla Lana School of Population Health, Toronto, Canada, [7]Women's College Hospital, Toronto, Canada, [8]McGill Univeristy, Montreal, Canada, [9]McMaster University, School of Social Work, Hamilton, Canada

BACKGROUND: Low sexual relationship power (SRP), including controlling behaviours within intimate relationships, has been linked with increased HIV-risk, low condom use, and experiences of violence. Among women living with HIV (WLWH), few studies have examined associations between SRP and condom use, violence, and resilience. We examined the psychometric properties, prevalence, and relative associations of the relationship control (RC) SRP sub-scale.

METHODS: This study includes baseline data from sexually active WLWH (≥16 years) enrolled in the Canadian HIV Women's Sexual and Reproductive Health Cohort Study (CHIWOS). Pulerwitz's RC sub-scale was trichotomized and low/medium scores were compared to high scores (higher scores=more SRP equity [SRPE]). Exploratory factor analysis and Cronbach's alpha assessed scale reliability. Crude and adjusted logistic regression examined associations between education and resilience (RS-14) and RC, as well as RC and condom use and violence (any violence [sexual, physical and/or emotional] and emotional violence). All models were adjusted for education, age, ethnicity, income, housing stability, and gender discrimination [measured using the Everyday Discrimination Scale]).

RESULTS: Of 1422 WLWH in CHIWOS, 473 (33%) reported being sexually active in the last 6 months and completed the RC sub-scale: 80% had high SRPE. The RC sub-scale demonstrated good reliability (Cronbach alpha= 0.92) loading onto one factor. Bivariably, compared to those with low SRPE, WLWH with high SRPE were more likely (p<0.05) to have higher education and incomes, to be married or in a common-law relationship, have no children and not currently using injection drugs.

In multivariate models, higher resilience scores were associated with high SRPE (aOR=1.03, 95%CI=1.00-1.06/per 1-score increase). WLWH with high SRPE were more likely to be consistent condom users (vs. never users) (aOR=5.38, 2.05-14.1), and less likely to have experienced any violence (aOR=0.09, 0.03-0.28) and emotional violence (aOR=0.13, 0.06-0.28) in the last 3 months (vs. never).

CONCLUSIONS: We found good reliability and validity for the RC sub-scale among WLWH in Canada. Aligned with previous studies, SRPE was associated with reduced experiences of recent violence and increased consistent condom use. Findings highlight fostering resilience may improve SRPE, and in turn reduce experiences of violence, supporting improved HIV-outcomes and wellbeing among WLWH.

PED0768

PREDICTING INTENTION TO USE PRE-EXPOSURE PROPHYLAXIS (PREP) USING THE THEORY OF PLANNED BEHAVIOR AMONG KENYAN ADOLESCENT GIRLS AND YOUNG WOMEN

S. Ngere[1], P. Oduor[1], M. Nyanjom[2], G. Otieno[2], H. Awuoche[2], D. Aduda[3]
[1]Maseno University, Kisumu, Kenya, [2]KEMRI/CGHR, Kisumu, Kenya, [3]Jaramogi Oginga Odinga School of Science and Technology, Kisumu, Kenya

BACKGROUND: Pre-exposure Prophylaxis (PrEP) remains the most viable Human Immunodeficiency Virus (HIV) prevention method among Adolescent Girls and Young Women (AGYW) given their disproportionate risk and gives promise for HIV epidemiological control. However, PrEP uptake, a function of one's intent, remains low among the AGYW in Kenya.

Understanding the importance of attitude, perceived norms and perceived behavioral control as predictors of intention to use PrEP is important in tailoring messages to non-intenders. We sought to identify predictors of intention to use PrEP among AGYW using Theory of Planned Behavior (TPB).

METHODS: A mixed method study was employed to enroll 418 AGYW aged 15-24 years in Kisumu County, Western Kenya. Data was collected using structured questionnaires and Focused Group Discussions (FGDs). Intention to use PrEP was measured using a 5 point continuous rating scale and categorized to either low or high intention to use PrEP. Intention to use PrEP was predicted using constructs of TPB. Qualitative data was transcribed and analyzed thematically while Chi-square test of independence was used to measure associations.

RESULTS: Quantitative: High intention to use PrEP was reported in 30% (100/335) of the participants. Intention to use PrEP was higher among AGYW in rural areas (p-value= 0.001), more educated (p-value= 0.048) and married (p-value=0.001). Qualitative: Participants provided several reasons for their intention to use PrEP or lack of it thereof. They reported difficulty in taking a pill everyday although access was easy. Fear of being perceived as HIV positive or promiscuous if taking PrEP was unfavorable. They were pessimistic that their parents/guardians would approve of them taking PrEP and positive feedback from PrEP users was encouraging although they report fear of side effects. The promise of protection against HIV was a major motivator in the AGYW intention to use PrEP.

CONCLUSIONS: Low intention to use PrEP was reported among AGYW. Intention to use PrEP was particularly higher among the married and rural populace a fact that requires further investigation. PrEP messaging should be tailored around modifying attitudes, perceived norms and perceived behavioral control and creating innovative programs to target sub-populations with low intentions thus increasing intentions and ultimately uptake of PrEP.

PED0769

DEVELOPMENT OF A MODEL TO UNDERSTAND AND ADDRESS PREP STIGMA AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN SUB-SAHARAN AFRICA

S.T. Roberts[1], M. Hartmann[1], L. Nyblade[2]
[1]RTI International, Women's Global Health Imperative, Berkeley, United States, [2]RTI International, Global Health Division, Washington, DC, United States

BACKGROUND: Stigma is a well-known barrier to HIV testing and treatment, and is emerging as a barrier to PrEP use. To guide future research, measurement, and interventions, we developed a conceptual framework for PrEP stigma among adolescent girls and young women (AGYW) in sub-Saharan Africa, who are a target population for PrEP.

METHODS: A literature review and expert consultations were conducted to adapt the Health Stigma and Discrimination Framework, which describes the stigmatization process nested within the socio-ecological framework. We reviewed all articles on PrEP stigma and those addressing HIV, contraceptive, or sexuality stigma among AGYW. Expert consultations were conducted with 10 stigma or PrEP researchers and 2 Kenyan youth advisory boards to review and revise the framework.

RESULTS: The conceptual framework identifies potential drivers, facilitators, and manifestations of PrEP stigma; its direct outcomes and ultimate health impacts; and relevant intersecting stigmas (Figure 1). Main findings include:

1) PrEP stigma is primarily driven by established HIV, gender, and sexuality stigmas, and by low PrEP awareness within communities.

2) Stigma is facilitated by factors at the policy (e.g. targeting of PrEP to high-risk populations), health systems (e.g. youth-friendly service availability), community (e.g. social capital), and individual (e.g. developmental stage) levels.

3) Similar to other types of stigma, manifestations include labelling, violence, and shame.

4) PrEP stigma results in decreased availability and acceptability of PrEP, lack of social support, and community resistance, which can ultimately decrease PrEP uptake and adherence.

5) Stigma may also engender resilience by motivating AGYW to think of PrEP as an exercise in personal agency.

CONCLUSIONS: Our PrEP stigma conceptual framework highlights potential intervention targets at multiple levels of influence and points in the stigmatization process. Its adoption would enable researchers to develop standardized measures and compare the burden of stigma across timepoints and populations as well as evaluate intervention outcomes.

[Figure 1. Conceptual framework of PrEP stigma among AGYW in sub-Saharan Africa]

participants. Responses included hope for cure during the trial; optimism for future cure; and cure is not possible in the foreseeable future (Table 1). Data suggest that trial design and/or experimental agent impacted participants' hopes. After trials ended, equal proportions of participants and decliners endorsed cure as important to normalcy and health. A substantial minority reported cure as not very important due to living normally on ART (Table 2). Most participants were disappointed by their failure to suppress virus for a longer time during ATI. Yet most retained their baseline hopes, and a few reported higher hopes due to scientific progress.

	Hope for cure in trial	Hope for cure in future	Cure not possible
Participants: RV397 n=15	5	8	2
Participants: RV405 n=19	10	5	3
Decliners RV397/405 n=14	3	6	5

[Table 1 Optimism statements]

	Important to normalcy/health	Not important	Not interpretable
Participants (RV397/RV405)	23	10	1
Decliners (RV397/RV405)	8	5	1

[Table 2 Importance of cure]

CONCLUSIONS: Respondents understood the nature of early-phase "cure" research, but similar to other studies, participants displayed optimism regarding personal and scientific benefit. They differed regarding anticipated importance of cure for their own lives. Longitudinal data indicate that for most, a personal experience of rapid viral rebound did not alter optimism regarding future HIV cure.

PED0770

WHAT DOES "HIV CURE" MEAN TO ACUTELY DIAGNOSED THAI INDIVIDUALS INVITED TO REMISSION TRIALS WITH ANALYTIC TREATMENT INTERRUPTION?

H.L. Peay[1], T. Jupimai[2], N. Ormsby[3], S. Rennie[3], R.J. Cadigan[3], K. Kuczynski[3], S.C. Isaacson[3], E. Kroon[4], N. Phanuphak[4], J. Ananworanich[5], D. Colby[4], C. Sacdalan[4], P. Prueksakaew[4], S. Tipsuk[4], G.E. Henderson[3]
[1]RTI International, Early Education, Disability, and Health Program, Durham, United States, [2]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [3]University of North Carolina, Department of Social Medicine, Chapel Hill, United States, [4]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [5]University of Amsterdam, Amsterdam, Netherlands

BACKGROUND: HIV remission ("cure") research comprises early-phase trials seeking to eradicate HIV, often employing ATI to assess time to viral rebound as a measure of efficacy. Despite careful attention by investigators to informed consent, many studies find that people entering early-phase clinical trials are optimistic about personal benefit. In HIV trials with ATI, participants' hope for "cure" focuses on maintaining viral suppression without ART.

METHODS: We present longitudinal interview data from participants (n=34) and decliners (n=14) to two remission trials with ATI in Thailand (SEARCH010 RV397, trial of VRC01; and RV405, vaccine trial). Interviews queried motives and hopes for trial participation; meaning of HIV cure; and importance of cure to their lives. All but one participant experienced viral rebound during ATI.

RESULTS: 48 respondents were male/MSM and one was female. Most were familiar with biomedical concepts of HIV cure (sterilizing and functional) and demonstrated good understanding of the trials. Anticipated trial outcomes varied within interviews and across

TRANSLATION AND VALIDATION OF THE HIV STIGMA SCALE TO MOSHI, TANZANIA

S. Sao[1], L. Minja[2], M. Watt[3], B. Mmbaga[2], J. Vissoci[4]
[1]Duke University, Duke Global Health Institute, Durham, United States, [2]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [3]University of Utah, Population Health Sciences, Salt Lake City, United States, [4]Duke Global Health Institute, Durham, United States

BACKGROUND: Enacted, anticipated and internalized HIV stigma are informed by individual and community-level stigmatizing attitudes that impede all steps of the HIV care continuum. While much research has been conducted to understand HIV stigmatizing attitudes from the perspective of people living with HIV, little psychometric evidence exists on scales that evaluate stigmatizing attitudes in the general population. Furthermore, HIV stigma has been shown to vary by cultural context, pointing to the need for measures validation in various regions and across languages.

METHODS: A scale to measure HIV stigmatizing attitudes in Tanzania was developed from a modification of the HIV stigma scale (HSS) by Visser et al. Items were added to the original scale based on the team's formative qualitative research and other stigma instruments. The resulting 18-item scale was translated into Swahili and back

translated into English by the team's native Swahili speakers. The scale was pilot tested and further modified for cultural context and ease of understanding. From April to November 2019, 1008 women and 489 male partners were enrolled in an HIV stigma reduction study at two antenatal care clinics in Moshi, Tanzania. The validity and reliability of the HSS scale were analyzed using rigorous statistical methods for scale validation.

RESULTS: The translated version of the HSS scale was found to have acceptable domain coherence. Reliability was strong (Cronbach's alpha = 0.92). Exploratory and confirmatory factor analysis of one, two, and three factor models were conducted, and the two-factor model showed ample results, pointing to subscales of blame/moral judgement and isolation/social distancing. HSS scores were externally validated with the anticipated HIV stigma scale scores and were moderately positively correlated (r = 0.43, n = 1497, p < 0.001).

CONCLUSIONS: Given the role that HIV stigma plays as a barrier to HIV care engagement, the development of tools to adequately evaluate HIV stigmatizing attitudes is critical for public health research. This study presents one of the only Swahili adaptations and validations of the HSS instrument. The tool had acceptable psychometric properties, suggesting it can be used to measure stigma in a Tanzanian setting and is adaptable to other locales.

UTILIZING PARTICIPATORY MAPPING TO CONTEXTUALIZE PERCEIVED HIV RISK ACROSS GEOGRAPHY AMONG YOUNG BLACK MSM IN THE DEEP SOUTH

T. Arnold[1], T. Stopka[2], K. Johnson[3], P.A. Chan[4], C.E. Gomillia[5], J.H. Soler[6], M.L. Monger[5], E. Jacque[2], C.S. Coats[7], T.C. Willie[7], A. Ogunbajo[7], M. Murphy[7], L. Mena[8], A. Nunn[7]
[1]Brown University, Department of Psychiatry, Providence, United States, [2]Tufts University School of Medicine, Department of Public Health & Community Medicine, Boston, United States, [3]Mississippi State Department of Health, Jackson, United States, [4]Brown University, Department of Medicine, Providence, United States, [5]University of Mississippi Medical Center, Department of Medicine, Jackson, United States, [6]Columbia University, New York City, United States, [7]Brown University, School of Public Health, Providence, United States, [8]University of Mississippi Medical Center, John D. Bower School of Population Health, Jackson, United States

BACKGROUND: HIV incidence among young Black men who have sex with men (YBMSM) has remained stable. HIV spreads at increased rates in dense sexual networks. Identifying the location of HIV clusters and risk behaviors that occur within them could inform geographically-focused HIV prevention interventions.

METHODS: Five semi-structured focus groups were conducted with 27 YBMSM between the ages of 18 and 34 years who met criteria to receive a PrEP prescription. Using a modified social mapping technique based on Singer et al.'s approach, the focus groups explored how and where HIV risk behaviors occur in Jackson, Mississippi. Outcome measures included: 1) meeting places for sexual encounters; 2) distance traveled to meet sexual partners; 3) location of sex encounters; 4) locations where HIV risk behaviors occurred and 5) knowledge of the geographic distribution of HIV.

RESULTS: A commonality was that participants believed that most individuals living with HIV resided in the Southern area of Jackson and reported feeling safer when attending sexual encounters in the Northern areas. Many of the participants identified similar locations for meeting places for sexual encounters (i.e. colleges and universities, gay clubs, or nearby convenient areas) and reported they would not travel outside of the city to meet for hookups. However, many have had partners travel into Jackson from outlying areas. Many of the participants reported attending or being invited to sex parties. Participants noted that sex parties take place in North Jackson rather than in South Jackson where most individuals living with HIV reside. Participants discussed being more comfortable having sexual encounters when outside of the Jackson area. Many participants noted that they were more likely to have condomless anal sex or concurrent anonymous partners while traveling. People generally knew that HIV was more commonplace in South Jackson, but understood little about geographic hotspots.

CONCLUSIONS: HIV transmission may be occurring outside identified HIV hot spots. Utilizing mixed geospatial and qualitative methods offered a comprehensive assessment of where HIV transmission occurs, and suggests that geographically circumscribed interventions may need to focus on where YBMSM reside and in specific geographic locations where they engage in HIV risk behaviors.

PED0773

A TALE OF TWO "U" S AND THEIR USE BY HEALTHCARE PROVIDERS: A CROSS-COUNTRY ANALYSIS OF INFORMATION-SHARING ABOUT 'UNDETECTABLE = UNTRANSMITTABLE' (U=U)

C. Okoli[1], P. de los Rios[2], B. Richman[3], B. Allen[4], G. Brough[5], D. Hardy[6], M. Mcbritton[7], M. Muchenje[2], G.M. Corbelli[8], E. Castellanos[9], B. Young[10]
[1]ViiV Healthcare, Middlesex, United Kingdom, [2]ViiV Healthcare, Quebec, Canada, [3]Prevention Access Campaign, New York City, United States, [4]ICASO, Toronto,, Canada, [5]Positively UK, London, United Kingdom, [6]Johns Hopkins University School of Medicine, Baltimore, United States, [7]Barong Cultural Institute, São Paulo, Brazil, [8]EATG - European AIDS Treatment Group, Brussels, Belgium, [9]Global Action for Trans Equality GATE, New York, United States, [10]ViiV Healthcare, RTP, North Carolina, United States

BACKGROUND: The remarkable scale-up of ART globally, has seen 20.7 million people living with HIV (PLHIV) on treatment, thus accelerating the UNAIDS target to end AIDS as a public health threat by 2030. However, PLHIV's incentive to remain on ART needs to be prioritized. U=U is an empowering discussion that may help with that incentive to reach and maintain undetectability. We investigated the percentage of PLHIV informed of "U=U" by their healthcare provider (HCP), and measured associations with health-related outcomes.

METHODS: Data was from the 24-country 2019 Positive Perspectives Survey of PLHIV on treatment (n=2112). HIV-related knowledge, attitudes, and behaviors, including health-related outcomes were compared between those informed vs. not informed of "U=U" ($p<0.05$).

RESULTS: Overall, 67% were informed of "U=U" by their HCP. Those informed (n=1413) were significantly more likely than those not informed (n=699) of reporting: awareness that antiretrovirals prevent transmission (78% vs. 62%); treatment satisfaction (76% vs. 57%); optimal adherence (79% vs. 69%); self-reported virologic control (75% vs. 68%); and optimal overall (60% vs. 48%), mental (62% vs. 45%), and sexual health (50% vs. 41%). The percentage informed of "U=U" was significantly higher among ≥50-year-olds (71%) than <50-year-olds (65%, $p=0.014$), those in metropolitan (69%) than non-metropolitan areas (64%, $p=0.015$), and those with high-school or lower, than with higher than high-school education (75% vs. 64%, $p<0.001$). Overall, prevalence was 71.7%, 65.7%, and 55.2% among men who have sex with men (MSM), women, and heterosexual males respectively

(p<0.001); country-specific prevalence was highest among women in the U.S. (90%), but highest among MSM in Germany (84%), Portugal (83%), and Taiwan (77%).

CONCLUSIONS: Those that reported they were informed of U=U by their HCP had more favorable health outcomes than those not informed. Missed opportunities exist, given that one-third were not told about U=U by their HCPs, and in particular, heterosexual males were by far the least likely to be given this information. As gatekeepers of essential information, intensified efforts by HCPs to better engage patients can benefit public health. Patient-HCP U=U discussions should be considered in care guidelines to help improve PLHIV's quality of life.

ADAPTATION TO LIVING WITH HIV FOR INDIVIDUALS, FAMILIES AND COMMUNITIES

PED0774

THE IMPACT OF PARENTAL HIV-POSITIVE STATUS ON THE LIVES OF CHILDREN WITHIN THE FAMILY CONTEXT IN BANGLADESH

M.S. Islam[1]
[1]University of New England, School of Health, Faculty of Medicine and Health, Armidale, Australia

BACKGROUND: HIV is particularly challenging for children in a family with HIV-positive members. Studies suggest that children in HIV-affected families are extremely vulnerable. However, little is known about the vulnerabilities faced by the children in HIV-affected families in Bangladesh. In order to address this gap in knowledge, this study examined the impact of parental HIV status on the lives of children within family context in Bangladesh.

METHODS: A qualitative research design using aspects of grounded theory approach was adopted and data were collected using in-depth interviews with nineteen HIV-positive parents who were living with their children in Khulna and Dhaka, Bangladesh.

RESULTS: The results indicate that parental HIV-positive status had a significantly negative impact on children ranging from disrupted socialization to reduced academic achievement. The results further indicate that parents' HIV-positive status negatively influenced the parent–child interpersonal relationships within the family. Parents described how their children's socialization and education were hampered by HIV as they could no longer provide an environment conducive to social and academic success. Factors which had a negative effect on children's academic achievement included: an unsupportive environment, economic hardship, gender roles, increased household responsibility, social stigma and discrimination, and negative psychological thoughts and feelings.

CONCLUSIONS: The results of this study demonstrate the effect of and need for appropriate programs for the betterment and welfare of children living with HIV-positive parents in Bangladesh.

PED0775

MEDIATING IMMEDIATE LINKAGE TO CARE IN THE ERA OF 'TREAT ALL': QUESTIONING THE (CHRONO) LOGICS OF HIV TREATMENT INITIATION IN SHINYANGA, TANZANIA

L. Reynolds[1,2], J. de Klerk[3], J. Meta[3], E. Moyer[3]
[1]Pivot Collective, Cape Town, South Africa, [2]Stellenbosch University, Department of Sociology and Social Anthropology, Stellenbosch, South Africa, [3]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands

BACKGROUND: Immediate initiation of antiretroviral treatment is considered a cornerstone of the current HIV 'universal test and treat' approach. Delayed linkage to care is often framed as a major stumbling block in HIV epidemic control. Here we examine the linkage to care and treatment initiation trajectories of people diagnosed with HIV in Shinyanga Region, Tanzania. We provide a critical interrogation of public health definitions of immediate linkage to care by exploring when and how linkage to care occurs for different clients, and the social dynamics that shape this process.

METHODS: The data are drawn from a broader social science study on the uptake of a treat all model in Shinyanga Region, Tanzania. Between April 2018 and December 2019, 30 participants who tested HIV-positive in community-based testing campaigns were interviewed in-depth on their HIV testing and (non-)linkage to care process. In addition, structured observations (24) were conducted during HIV testing campaigns and treatment literacy classes. Thematic analysis based on inductive coding was completed using NVivo software.

RESULTS: Many participants followed non-linear pathways to (eventually) link to HIV care and initiate treatment. These pathways often involved movements back and forth along the HIV care continuum or repetitions of particular steps. This included re-testing multiple times at different locations, sometimes involving intimate partners or others in subsequent testing encounters, before formally linking to care and initiating treatment. In some cases, this meant that what was reported as an 'immediate initiation' was in fact part of a longer process — unfolding over the course of several months or years — of coming to terms with a diagnosis and mediating its potential social fallouts.

CONCLUSIONS: Linkage to care must be understood as a socially embedded process, not a once-off event in a unidirectional cascade or continuum. Public health models built on the assumption that people diagnosed with HIV follow a (chrono-)logical series of steps from diagnosis to effective viral suppression lose too many people along the way. The development of responsive approaches that help people navigate the health system and the social dynamics that shape their engagements with it could more effectively support people along their diverse trajectories to treatment initiation.

HEALTH EDUCATION TALKS DURING WAITING TIME FOR POSITIVE LIVING AMONG CLIENTS ATTENDING ART CLINICS OF BUKOMANSIMBI DISTRICT IN CENTRAL UGANDA

E. Nambozo[1,2], J. Iule[3], L. Alupo[2], S. Kentutsi[4]
[1]National Forum for People Living with HIV/AIDS Networks in Uganda (Nafophanu), Programs, Kampala, Uganda, [2]National Forum for PLHIV/AIDS Networks in Uganda, Programs, Kampala, Uganda, [3]National Forum for PLHIV/AIDS Networks in Uganda, Kampala, Uganda, [4]National Forum for PLHIV Networks in Uganda, Programs, Kampala, Uganda

BACKGROUND: Background: Health Education Talks (HETs) have been recognized as a powerful vehicle through which health literacy is achieved thus contributing to improvement in numerous patient outcomes, delay disease and improved adherence on Antiretroviral Therapy. The study examined the use of health education talks during waiting time and healthy living practices among clients attending ART clinics

METHODS: The study was conducted between August 2018 and April 2019 targeting 162 respondents in 07 health facilities in Bukomansimbi District. It was a cross sectional study using both qualitative and quantitative methods. Sampling size was determined using Kish Leslie's 1965 formula at 5% precision and data obtained through random and purposive sampling techniques. Quantitative data was analyzed using SPSS version 20 while qualitative data was organized in ATLAS Ti for analysis.

RESULTS: The respondents' mean age was 40 years, (F-84, M-78). About 58% PLHIV reported waiting time for over 3 hours of which 37.5 % spent that time doing nothing. The average waiting time was 181 minutes with averagely 30 minutes spent on HETs. Majority (90.1%) of the respondents reported having received HET with 67.9% of them taking up healthy living practices such as improved adherence, quitting smoking and alcohol consumption and avoidance of multiple sexual partners among others. However, inadequate time for the talks due heavy workload among health workers, missed talks by late arriving clients, monotony of talks, lack of practical talks, non-involvement of PLHIV in selection of topics for discussion were cited as challenges affecting HET at health facilities.

CONCLUSIONS: Given the chronic nature of HIV, there is need for continuous patient education to prepare PLHIV for any complications they might encounter including non-communicable diseases and opportunistic infections. ART clinics should therefore purposefully use every contact time with PLHIV for education programs including the unutilized waiting time not only to address some of the challenges affecting HETs such as inadequate time allocated to talks but also promote quality of life and enhance Positive living through equipping them with other skills like entrepreneurship necessary for survival beyond only HIV related information.

PED0777

THE ASSOCIATION BETWEEN BEING A PARENT AND VIRAL SUPPRESSION IN PEOPLE LIVING WITH HIV AT A REFERENCE HOSPITAL IN LIMA

V. Navarro[1,2], J. Robledo[2], F. Mejía[1,2,3], E. Gotuzzo[1,2,3], E. González-Lagos[1,2]
[1]Universidad Peruana Cayetano Heredia, Facultad de Medicina Alberto Hurtado, Lima, Peru, [2]Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Hospital Cayetano Heredia, Division of Infectious Diseases, Lima, Peru

BACKGROUND: Whereas having children is a well-known motivator for patients' health care, it also implies responsibilities that may limit attendance to health services. We determined the association between having infant and adolescent children (ages up to 19 years-old) with viral suppression of people living with HIV health (PLWH).

METHODS: Retrospective cohort study based on secondary data of PLWH enrolled at the largest HIV program in Lima from 2012 up to 2017. The main exposure was the presence of infant and adolescent children at admission; in addition, we identified cases with a child born during the first year after enrolment.

The main outcome was viral suppression (<400 copies/ml) until end of follow up (December 2018). We conducted Cox regression analysis for repeated events, with censoring by time of death or end of follow-up; the final model, selected by log likelihood ratios, was built by backward stepwise starting with all variables theoretically important or with p-value ≤ 0.20 in bivariate analyses. We present hazard ratios (HR) with 95% confidence intervals (CIs).

RESULTS: In 3170 PLWH, mean age was 31.6 years (SD: 10.9), 79.8% were men and 862 (27.2%) reported infant and adolescent children, with a median number of two children. At the end of the follow up (8766.6 person-years), 534 (62.0%) were in viral suppression. In a final model that included age, sex, level of education, sexual orientation, having a partner, baseline CD4, time for ART start, interactions of having children with age and having partners; having infant and/or adolescent children (HR 3.53; [95% CI] 1.88 - 6.62) and the birth of a child during the first year after enrolment in the HIV program (HR 1.81; [95% CI] 1.30 – 2.50) were independently and significantly associated with no viral suppression by the end of follow up.

CONCLUSIONS: The presence of infant and adolescent children was associated with negative effects for viral suppression, probably due to parental responsibilities that may affect own health care. Family supporting services may benefit HIV care.

PED0778

WHAT SHAPES RESILIENCE AMONG PEOPLE LIVING WITH HIV? A MULTI-COUNTRY ANALYSIS OF DATA FROM THE PLHIV STIGMA INDEX 2.0

A. Gottert[1], T. McClair[1], B. Friedland[2], S. Sothearidh[3], A. Bajracharya[4], D. Almonte[5], F. García[6], A. Del Valle[7], E. Yam[1], S. Kentusi[8], J. Pulerwitz[1]
[1]Population Council Washington DC, HIV and AIDS Program, Washington, United States, [2]Population Council New York, HIV and AIDS Program, New York, United States, [3]Cambodia PLHIV Network (CPN+), Boeung Ka, Cambodia, [4]Population Council Cambodia, HIV and AIDS Program, Phnom Penh, Cambodia, [5]Red Dominicana de Personas de Personas que Viven con VIH/SIDA (REDOVIH), Santo Domingo, Dominican Republic, [6]Alianza Solidaria para la Lucha Contra el VIH y SIDA (ASOLSIDA), Santo Domingo, Dominican Republic, [7]Population Council Guatemala, HIV and AIDS Program, Guatemala City, Guatemala, [8]National Forum of PLHIV Networks in Uganda (NAFOPHANU), Kampala, Uganda

BACKGROUND: Understanding factors that lead to resilience among people living with HIV (PLHIV) is critical for informing programming. We examined the influence of multi-level factors on resilience in three countries, using the PLHIV Stigma Index 2.0 survey.

METHODS: The Stigma Index was implemented in Cambodia (n=1,207), the Dominican Republic (DR, n=891), and Uganda (n=391), since 2017. We measured resilience with a newly developed PLHIV Resilience Scale (range -10 to +10), which asks about the effect of HIV status (negative, neutral, or positive) on attainment of needs, such as ability to cope with stress, find love, or contribute to one's community. We used hierarchical multiple regression to assess associations between individual, interpersonal and structural/policy-level factors and resilience, controlling for potential confounders.

RESULTS: About 60% of respondents were female. Mean time since HIV diagnosis was 11 years in Cambodia, seven in the DR/Uganda; ≥95% were on antiretroviral therapy. Mean resilience scores were 1.50 (Cambodia), 0.25 (DR), and 0.69 (Uganda), and varied substantially by the six provinces/districts within each country (all p<0.001). In multivariable analyses, at the individual-level, higher resilience was associated with lower internalized stigma (all countries; p<0.05 to <0.001) and no experience of human rights abuses (DR/Uganda; p<0.05). At the interpersonal-level, higher resilience was associated with less HIV-related stigma from family (DR, p<0.05). At the structural/policy-level, higher resilience was associated with greater awareness of legal protections for PLHIV (Cambodia/DR; p<0.01, p<0.05) and experience of HIV-related stigma (lower in Cambodia, higher in DR; both p<0.01). The set of structural/policy-level factors in Cambodia and the DR, and individual-level in Uganda, explained the most variance in resilience.

CONCLUSIONS: Factors at multiple levels, especially internalized stigma and human rights abuses, affect whether PLHIV in Cambodia, the DR, and Uganda report resilience. To promote resilience among PLHIV, multilevel interventions addressing individual factors, interpersonal dynamics, and the structural/policy environment are required.

IMPLEMENTATION OF COMMUNITY ART REFILL GROUPS (CARGS) IN THE HIV CARE AND TREATMENT (ZHCT) PROJECT TO STRENGTHEN RETENTION IN ART CARE IN ZIMBABWE

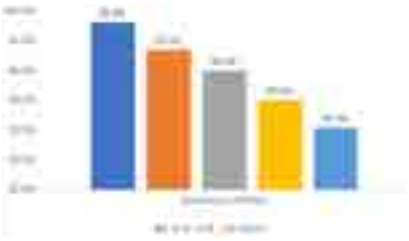
T.A. Tafuma[1], A. Muchedzi[2], R. Dhliwayo[2], T. Nyagura-Madziro[3], C. Gwanzura[4], T. Zulu[1], T. Mavimba[2], T. Samushonga[1], D. Harbick[5], F.H. Mudzengerere[1]

[1]FHI360, Monitoring and Evaluation, Harare, Zimbabwe, [2]FHI360, ZHCT, Harare, Zimbabwe, [3]United States Agency for International Development, Harare, Zimbabwe, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]FHI360, Harare, Zimbabwe

BACKGROUND: Zimbabwe's general antiretroviral (ART) retention rate is estimated to be 91% at 6 months, decreasing to 64% by 24 months post ART initiation. As the number of clients has increased, there is need to maintain adequate support for adherence to treatment while also decongesting health facilities. Community ART Refill Group (CARG) is one differentiated service delivery model designed to facilitate access to regular ARV drug refills and to reduce the workload at health facilities. We present retention rates and viral suppression from the CARGs model implemented by FHI 360's Zimbabwe HIV Care and Treatment (ZHCT) project.

METHODS: The ZHCT staff worked closely with health facility nurses to support formation of CARGs. CARG eligibility was based on: 6 months CD4 count>400, been on ART >6 months, weight above 30kg, aged ≥ 15years, and no signs of opportunistic infection. Due to limited availability of viral load (VL) machines, this was not part of the eligibility criteria. However, client enrolled in CARGs were prioritised for annual VL tests. Groups of 4-12 stable people living with HIV (PLHIV) on ART would take turns to: pick up ARVs at the health-facility; and distribute ARVs to group members in the community. A retrospective assessment of CARG outcomes (retention in care, VL suppression) were tracked from October 2016-July 2019 in the eight districts.

RESULTS: A total of 2397 CARGs were formed from October 2016 to July 2019 in the 8 ZHCT supported districts with 16,450 (16,262 adults and 188 adolescents) members. As intended with this model, the retention rates were very high (Figure 1).



[Figure 1.]

CONCLUSIONS: Scaling up CARGs to all districts could improve the overall ART program retention rate in Zimbabwe and CARG retention rates could serve as a proxy indicator for viral suppression, due to its limited availability as shown by the ZHCT results.

AGEING WITH HIV: EVOLVING AND ADDITIONAL NEEDS AND RESPONSES

EXAMINING THE RESILIENCE OF RACIALLY DIVERSE, HIV-POSITIVE, MIDDLE-AGED AND OLDER MEN WHO HAVE SEX WITH MEN TO HIV/AIDS: RESOURCES, PROTECTIVE FACTORS, AND PERSONAL STRENGTHS

R. Liboro[1,2], T.C. Yates[3], C. Fehr[2], G. Da Silva[2], F. Ibañez-Carrasco[4,5], A. Eaton[6], D. Pugh[5,7], L.E. Ross[2,8], P.A. Shuper[2,8]

[1]University of Nevada, Psychology, Las Vegas, United States, [2]Centre for Addiction and Mental Health, Institute for Mental Health Policy Research, Toronto, Canada, [3]Realize, Toronto, Canada, [4]St. Michael's Hospital, Centre for Urban Health Solutions, Li Ka Shing Knowledge Institute, Toronto, Canada, [5]Universities Without Walls, Toronto, Canada, [6]University of Toronto, Social Work, Toronto, Canada, [7]Sherbourne Health, LGBTQ Health Team, Toronto, Canada, [8]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada

BACKGROUND: Despite being at increased risk for acquiring HIV, many men who have sex with men (MSM) aged 40 years and older (≥40y/o) have remained HIV-negative since the 1980s. Among HIV-positive ≥40y/o MSM, many have exhibited resilience to HIV/AIDS not only by surviving its clinical/social impacts, but also by thriving, living full lives, and advocating for their rights and needs. Jurisdictional and international policymakers have identified research involving older MSM, and strengths-based studies, as priority areas for further research.

METHODS: From January to June 2019, we conducted semistructured, two-on-one interviews with HIV-positive ≥40y/o MSM (*n = 41;* Table 1) from Ontario, Canada to obtain their perspectives on their resilience to HIV/AIDS. We employed Thematic Analysis (Braun & Clarke, 2006) on our data to generate our results.

Identifies As	Gay = 31	Bisexual = 7	Men Who have Sex with Men = 1		Two-Spirit = 2	Cis = 40	Trans = 1
Age Range	40-44 y/o = 7	45-49 y/o = 8	50-54 y/o = 10	55-59y/o = 7	60-64y/o = 5	65-69 y/o = 1	>70 = 3
Race/ Ethnicity	White = 17	Black = 8	Latino = 4	S/SE/E Asian = 7	W Asian/M Eastern = 3		Aboriginal = 2
Region	Downtown Toronto = 30		Greater Toronto Area = 8		Southwest Ontario = 3		

RESULTS: We generated three superordinate themes:
(1) resources,
(2) protective factors, and
(3) personal strengths ≥40y/o MSM have relied on to stay resilient to HIV/AIDS.
Resources included LGBTQ not-for-profit agencies, AIDS service organizations, healthcare/service providers, community health centers/clinics, and the larger LGBTQ and HIV-positive communities. *Protective factors* included support from family members/life-long friends; the impact of losing so many during the epidemic; meaningful sexual relationships; volunteering; controlled/managed substance use; compartmentalization; information/education; religion/spirituality; serosorting; and activism/advocacy. *Personal strengths* included being proactive and/or persevering; having the right attitude; remaining self-aware; and learning to age well. Participants also discussed their views on the younger generation of MSM, racism in the LGBTQ community, and barriers to remaining resilient to HIV/AIDS.

CONCLUSIONS: The findings of our study will prove extremely beneficial to establishing strengths-based programs that could promote resilience to HIV/AIDS among both racially-diverse, HIV-positive ≥40y/o MSM, and their younger counterparts.

PED0781

HIV DISEASE BURDEN AMONG OLDER ADULTS (50+ YEARS) IN ESWATINI: SUCCESS IN MITIGATING THE CONSEQUENCES OF A SUSTAINED SEVERE HIV EPIDEMIC

N. Ginidza[1], C. Ngcamphalala[2], N. Gwebu[2], M. Ndlangamandla[2], M. Mabuyabala[3], R. Sahabo[2], R. Nkambule[4], Z. Mnisi[4], Y. Wu[5], H. Nuwagaba-Biribonwoha[5]
[1]Health Research Training Program (HRTP) Fellow, ICAP in Eswatini, Mbabane, Eswatini, [2]ICAP at Columbia University, Mailman School of Public Health, Mailman School of Public Health, Mbabane, Eswatini, [3]Health Research Training Program (HRTP) Mentor, ICAP in Eswatini, Mbabane, Eswatini, [4]Ministry of Health, Mbabane, Eswatini, [5]Columbia University, Department of Epidemiology, Mailman School of Public Health, Department of Epidemiology, Mailman School of Public Health, New York, United States

BACKGROUND: Eswatini's severe HIV epidemic has been ongoing for over 3 decades. Scale-up of antiretroviral therapy(ART) has increased life expectancy among people living with HIV(PLHIV), but previous national HIV indicator surveys have only included adults up to 49 years. We described the sociodemographic and clinical characteristics of older PLHIV in Eswatini, and determined correlates of HIV prevalence in this population.

METHODS: We utilised data from the second Swaziland/Eswatini HIV Incidence Measurement Survey(SHIMS2), a Population-based HIV Impact Assessment(PHIA) cross-sectional survey of a nationally representative sample of households with structured questionnaires, and biomarker testing for HIV, ART, CD4 count and viral load. Our analysis was restricted to adults 50 years(y) and older (50+y, older adults). We estimated HIV prevalence and described demographic and clinical characteristics of older PLHIV. We used logistic regression to determine correlates of HIV infection among older adults.

RESULTS: Of 1988 adults 50+y, 43%(n=702) were male.HIV prevalence was 26%(95% Confidence Interval, 95% CI, 24-28, n=489) overall; 28%(95% CI 26-33, n=199) among males and 23%(95% CI 22-27, n=290) among females. HIV prevalence was 37%(n=186/495) among those 50-54y, 32%(n=131/414) among those 55-59y, 27%(n=105/401) among those 60-64y, and 11%(n=67/678) among those 65+y. Most older PLHIV reported ART use 94%(n=462): 42%(n=197) for 0-4y, 40%(n=183) for 5-10y and 16%(n=76) for 10+y.Most older PLHIV (91%, n=441) had detectable antriretroviral drugs in blood collected during the survey, of whom 99%(n=438) were virally suppressed.Most (74%, n=362) had CD4 count >350 cells/μL.

In adjusted analyses, HIV prevalence was associated with younger agegroups (ref: 65+y): 50-54y (adjusted odds ratio [AOR]=5.0, 95% confidence interval [95% CI]: 3.4-7.2), 55-59y (AOR=5.1, 95% CI 3.2-7.9), and 60-64y (AOR=3.1, 95% CI 2.1-4.7). HIV prevalence was also associated the lowest (AOR 2.0, 95% CI:1.3-2.9) and second lowest wealth index (AOR 1.7, 95% CI: 1.1-2.6). ref: highest wealth index.

CONCLUSIONS: This first description of the HIV epidemic among older adults in Eswatini demonstrates substantial disease burden, especially in the 50's. Older PLHIV had optimal ART access, viral suppression and CD4 status.HIV programs in Eswatini must be strategically designed to accommodate this aging HIV population with long-term ART use.

PED0782

THE EFFECTS OF EXERCISE ON PHYSICAL AND MENTAL HEALTH IN OLDER PEOPLE LIVING WITH HIV: A SCOPING REVIEW

L. Chetty[1], S.E. Cobbing[1], V. Chetty[1]
[1]University of KwaZulu-Natal, Physiotherapy, Durban, South Africa

BACKGROUND: Older people living with HIV (OPLWH) are expected to live longer in the era of antiretroviral treatment. However, they are at risk for developing various health complications as a consequence of life with infection, exposure to medications that carry their own toxicity and side effects, and natural effects of aging on the immune system. Because senescence is an inherent process that can be accelerated by HIV, it is important to identify strategies that can modify this phenomenon. Emerging data suggests that while exercise may not have a positive impact on viral replication and immune system of people living with HIV, it can elicit improvements in physical and mental health, and overall quality of life.

METHODS: A scoping review methodology was employed, based on the Preferred Reporting Items for Systematic Reviews and Meta-analyses extension for Scoping Reviews (PRISMAScR) methodology. Peer-reviewed primary studies were extracted from relevant electronic databases, and the search strings on each electronic database were conducted using Boolean logic. A thorough title, abstract and full article screening, prior to extraction of relevant studies was conducted, while the quality of the studies was assessed using an appraisal tool prior to final inclusion.

RESULTS: Following a comprehensive systematic search process and quality appraisal of appropriate evidence, six articles were included and analysed in this study. None of the articles included in the review indicated any adverse effects of exercise on physical health in OPLWH. The findings demonstrated that irrespective of the association between HIV and declining physical functioning, exercise is an effective strategy to improve physical health and quality of life in OPLWH. The simultaneous use of aerobic, resistance and strength exercise encouraged greater independence in this population. However, the scoping review revealed a dearth of literature regarding exercise intervention on mental health outcomes and exercise prescription guidelines for OPLWH.

CONCLUSIONS: Findings thus far have demonstrated the holistic benefits that rehabilitation can provide for OPLWH, namely, the improvement of physical health and quality of life using exercise and physical activity. However, exercise interventions for mental health outcomes together with specific and well-formulated exercise programmes that ensure successful implementation and adherence requires further exploration.

PED0783

COMMUNITY PERSPECTIVES ON FUNCTION AND QUALITY OF LIFE IN PEOPLE LIVING WITH HIV IN MALAYSIA: ARE WE MEASURING IT RIGHT?

M.L. Chong[1], P.L. Wong[2], C.Y. Chang[3], A. Kukreja[2], M. Neelamegam[4], R. Rajasuriar[2]
[1]University Malaya Medical Centre, Department of Medicine, Kuala Lumpur, Malaysia, [2]University Malaya, Department of Medicine, Kuala Lumpur, Malaysia, [3]Hospital Sungai Buloh, Department of Medicine, Sungai Buloh, Malaysia, [4]Yale School of Public Health, Department of Epidemiology of Microbial Diseases, New Haven, United States

BACKGROUND: As life expectancy increases and people living with HIV (PLHIV) grow older, appreciating the definition of function and quality of life from the communities perspective is important to ensure the right tools are used to accurately measure these characteristics.

METHODS: We sought to address the above through a Patient and Public Involvement (PPI) session with PLHIV from a community-based organization based in Kuala Lumpur, Malaysia. Four groups with five to seven participants each were convened. Discussions were initially carried out by age groups (old >40 years and young <40 years), then collectively to clarify meaning and prioritise measures. Participants were asked:

1) "What would be a good measure of how old you are, apart from your age?" and directed to think about function; and

2) "What would be a good measure of happiness in life?"

RESULTS: All participants (n=24) were male, with an age range of 24 to 59 years and living with HIV for a mean of 7 years. The most important measure of function to both groups was not being incontinent and maintaining mobility to perform daily living activities. Using living aids such as wheelchair, walking stick, reading glasses were considered signs of aging. In the senior group, loss of physical fitness, decreased libido, memory loss and difficulty concentrating were important measures of decreased functionality as they aged whereas the younger age group were focused on maintaining creativity and problem-solving skills.

In both groups, remaining socially engaged with community and family was the most important source of happiness. Among the seniors, the ability to remain in control and enjoy meals/food/hobbies as well as contribute to society, especially their peers, was important, whereas career achievements and body image were among the elements of happiness for the younger group. Both groups eluded to living in a stigmatized society as a source of unhappiness which impacts their quality of life.

CONCLUSIONS: Tools incorporating activities of daily living and domains of locomotion/mobility, physical activity, cognition and sensory were important to define function; while characteristics associated with control, pleasure and self-realisation were identified as important measures influencing quality of life of PLWH in our setting.

PED0784

REDUCING SOCIAL ISOLATION AMONG HIV LONG-TERM SURVIVORS BY BUILDING FRIENDSHIPS AND TIES TO COMMUNITY

V. Crisostomo[1], D. Araujo[1], J. Lifshay[2]
[1]San Francisco AIDS Foundation, Department of Housing, Ageing & Retention in Care, San Francisco, United States, [2]Vincent Crisostomo, Department of Housing, Ageing & Retention in Care, San Francisco, United States

BACKGROUND: People with HIV are living longer and the proportion of HIV-positive people over age 50 continues to grow. In San Francisco, there are more than 10,500 HIV-positive adults over age 50--representing 67% of all people living with HIV. In addition to physical challenges related to aging with HIV, these individuals are confronting unique social and emotional challenges with health care systems ill-equipped to respond. In a survey of HIV-positive San Franciscans over age 50 (ROAH 2.0 survey), 38% indicated moderate to severe depression; 43% reported being "lonely" or "very lonely"; and, three-quarters said their emotional support needs were not fully met. People living with HIV who are struggling with depression or other mental health concerns are less likely to remain adherent to ARVs.

DESCRIPTION: To address unmet health needs of HIV-positive seniors, San Francisco AIDS Foundation (SFAF) established a social support network serving MSM over age 50. The Elizabeth Taylor 50-Plus Network offers weekly social and wellness activities. With input from geriatricians, HIV providers and clients, in recent years, activities were adapted to meet the needs of people aging with HIV who may be on limited incomes. Staff host activities in venues with elevators and ADA access, prepare materials with large font sizes, provide balanced and nutritional meals at events with take-home containers, and encourage activity participation at the right level for each individual. The group is popular in the community and regularly brings in >200 members for events that range from coffee meetups, to HIV activism, to salsa on Sunday afternoons. With two full-time staff members, the group engages >400 members who actively participate in weekly activities.

LESSONS LEARNED: Many individuals losing friends and loved ones over the years to HIV experience social isolation. Social support programs--by and for long-term survivors--combining social and health services can lead people out of isolation and can be adapted to meet the needs of people aging with HIV.

CONCLUSIONS/NEXT STEPS: Organizations must include long-term survivors as they shape policies and programs serving people aging with HIV. SFAF will continue to collaborate with HIV providers and geriatricians to build effective, evidence-based programs and services.

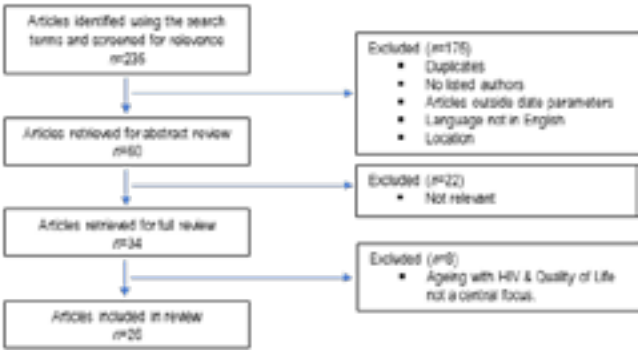
PED0785

A REVIEW OF THE PHYSICAL, MENTAL, AND SOCIAL FACTORS OF AGEING WITH HIV

J. Hirono[1], N. Sparling[1]
[1]HIV Scotland, Edinburgh, United Kingdom

BACKGROUND: More people are growing older with HIV and living into older age. 43% of Scotland's cohort of PLWHIV are over the age of 50. Evidence suggests that with complex health concerns, mixed with other societal factors, many PLHIV face major life challenges in ageing. This 'greying' of the HIV population has prompted a need to understand the health and societal considerations of ageing among PLHIV.

METHODS:
Relevant peer-reviewed literature was collated from reputable sources, and compiled using specific search terms and the results checked to verify the validity of the search parameters: (HIV OR AIDS) AND (Ageing OR Older People OR People living with HIV) AND (Quality of Life). Articles were then scrutinised to ensure relevance.



[Figure.]

RESULTS: 26 studies that met the reviews eligibility criteria were identified and analysed, and represented within seven thematic areas (Comorbidities, Mental Health, Utilisation of Health Services, Access to Social Services, Social Isolation, Age– and HIV–related stigma, and Financial Distress) that can impact on the quality of life for older adults living with HIV. The review highlighted the following a wide variety of issues that impact on the healthy ageing of people living with HIV. For example, a common theme was that improving access to employment, benefits, and financial products is seen as a critical element in addressing financial insecurity among older adults living with HIV.
CONCLUSIONS: A diversity of factors that contribute to quality of life for older people living with HIV are evident in literature. Whilst government stakeholders typically have the most prominent role in setting health system change, relevant cross-sector and community actors play a critical role in ensuring quality and effective implementation of initiatives aimed at improving the quality of life for people living and ageing with HIV.

PED0786

"I DRINK VODKA OR BRANDY, I AM NOT A GIRL ANYMORE": ALCOHOL USE IN OLDER (50+ YEARS) HIV-POSITIVE MALE AND FEMALE PATIENTS IN UKRAINE

T. Kiriazova[1], I. Zaviriukha[1], O. Zeziulin[1], S. Shenoi[2], A. Allen[3], V. Yaryy[4], F. Altice[2], J. Rozanova[2]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Yale University, School of Medicine, New Haven, United States, [3]State University of New York, Brooklyn, United States, [4]Kyiv Narcology Hospital "Sociotherapy", Kyiv, Ukraine

BACKGROUND: While the proportion of older (50yo+) people living with HIV (OPWH) among newly HIV diagnoses in Ukraine is increasing, this population delays ART initiation compared to younger adults. Heavy alcohol drinking is associated with lower ART uptake and adherence and suboptimal viral suppression; however, drinking patterns in male and female OPWH in Ukraine are unknown. We aimed to explore collective accounts of alcohol use reported by HIV patients and their health providers, to develop potential intervention strategies.
METHODS: In October-November 2019, we conducted five focus-groups with OPWH and one focus-group with their health providers at Kyiv City HIV Clinic. We audio-recorded and transcribed focus-groups verbatim, and performed data thematic analysis.
RESULTS: Thirty-four OPWH (13 women, median age 52 [49-60 years], and 21 men, median age 52 [50-75 years]) and seven health providers (four females; 2 infectious disease (ID) physicians, 2 narcologists, 2 psychologists, and 1 social worker; aged 31-55) participated in focus-group discussions.
Across all focus-groups, participants reported that both men and women continued drinking alcohol after their HIV diagnosis, that contributed to delaying ART initiation. However, while women maintained or increased their pre-diagnosis alcohol use to cope with their diagnosis, men might temporarily or permanently quit drinking alcohol after learning their HIV status. Men's accounts described recreational, "moderate" drinking of beer or wine socially, as a way to relax, while women's accounts included regularly (2-7 days per week) consuming hard liquor to forget problems.
OPWH shared that ID physicians asked primarily men about their drinking at the beginning of HIV treatment, using no instruments. Providers' accounts confirmed they may ask new patients "whether they abuse alcohol", not following up if the answer is "no", since "a patient's appearance reveals their alcohol abuse". In providers' accounts, OPWH may not disclose their alcohol use due to shame, especially women fearful of stigma against traditional cultural perceptions – "a mother, a grandmother, a hearth keeper".
CONCLUSIONS: To identify and address OPWH' unhealthy alcohol consumption as a barrier to ART, providers need training in screening and brief interventions for alcohol use and in trust-building and non-judgmental attitudes towards male and female OPWH.

PED0787

UNDERSTANDING THE CHANGING TREATMENT CONCERNS OF OLDER PEOPLE LIVING WITH HIV AND DIFFICULTIES WITH PATIENT-PROVIDER COMMUNICATION

D. Short[1], F. Spinelli[2], C. Okoli[3], P. De Los Rios[4]
[1]ViiV Healthcare, Innovation and Implementation Science, London, United Kingdom, [2]ViiV Healthcare, Medical Affairs North America, Research Triangle Park, United States, [3]ViiV Healthcare, Global Medical Team, London, United Kingdom, [4]ViiV Healthcare, Global Medical Sciences, Research Triangle Park, United States

BACKGROUND: Treatment priorities and needs of people living with HIV (PLHIV) evolve as they age. To continue to identify and address these for older PLHIV, providers need to understand such changes and ensure that there is ongoing open dialogue. We compared perspectives on treatment-related concerns and on patient-provider communication in older PLHIV and explored differences based on level of treatment experience.
METHODS: Data of 648 PLHIV aged ≥50 years from the 24-country 2019 Positive Perspectives Survey were analyzed. We compared older newly diagnosed PLHIV (n=61, median duration=2 years) vs older treatment experienced PLHIV (n=587, median duration=20 years). Comparisons were with chi-square tests ($p<0.05$).
RESULTS: Current treatment issues reported as most important to older treatment-experienced PLHIV included medicine related concerns such as 'Keeping HIV medicines at a minimum' (57.8% [339/587]), 'Ensuring minimal side effects' (77.0% [452/587]) and 'Minimizing long-term treatment impact' (69.8% [410/587]). Older treat-

ment-experienced PLHIV were less likely than newly diagnosed older PLHIV to be asked by their providers about their treatment concerns 65.1% [382/587]) vs (75.4% [46/61]), side effects (61.2% [359/587]) vs (82.0% [50/61]), or to have new treatment options discussed (63.9% [375/587] vs 80.3% [49/61]) (all p<0.05). Barriers to raising concerns to HCPs were reported between older PLHIV and their provider in 52.6% (309/587) of treatment experienced and 86.9% (53/61) of newly diagnosed individuals.

For salient medicine related issues, more than one in four older PLHIV (25.5%, 165/648) self-reported as being uncomfortable to discuss side effects of HIV medications, while approximately one third (32.6%, 211/648) were uncomfortable discussing concerns about drug-drug interactions.

Expressed fears among all older PLHIV who experienced a barrier (both treatment experienced and newly diagnosed combined) included: fear of being labelled "difficult" (34.3%, 124/362), perception nothing could be done (32.6%, 118/362), perception HCP's priorities were different (30.1%, 109/362), and that the HCP knows best (30.9%, 112/362).

CONCLUSIONS: Providers must acknowledge the evolving and unique needs of PLHIV as they age. Patient-provider communication issues can hinder optimization of care by preventing some needs being broached. Providers must also recognize that some patients find it difficult to raise issues including medicine-related concerns with their current treatments.

PED0788

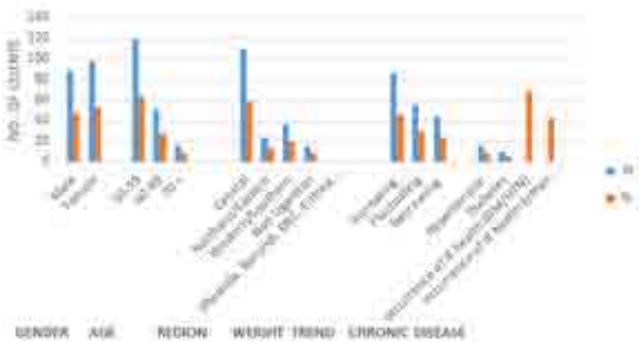
AN INTEGRATED HEALTH CARE PACKAGE TO IMPROVE THE WELL BEING OF ELDERLY CLIENTS WITH HYPERTENSION AND DIABETES RECEIVING ANTI RETRO VIRAL THERAPY AT AIDS INFORMATION CENTRE(AIC) KAMPALA, UGANDA

N. Elizabeth[1], N. Rehema[1]
[1]*Aid Information Centre, Medical, Kampala, Uganda*

BACKGROUND: The increasing risk of diabetes, hypertension and other NCDs among the aging population is becoming a major challenge in Uganda most especially among HIV/AIDS clients.

An integrated healthcare package was implemented at AIC Kampala to address the increasing morbidity trends due to either hypertension/diabetes among elderly clients stable on ART. It involved screening, monitoring and management of hypertension/Diabetes alongside Anti-retroviral therapy

The main objective of this package was to increase early diagnosis and monitoring of diabetes and hypertension among elderly clients receiving ART treatment at AIC.



[Figure. A clustered graph showing the demographics, weight trend and chronic diseases among the elderly clients on ART]

DESCRIPTION: Based on results of a data analysis conducted in January 2019 below, A Friday clinic that screened clients with 50years and above using BP measurement, Fasting/Random blood sugar, weight measurement and risk factor history and those diagnosed were managed and monitored Health education talks were held for all elderly receiving ART at the clinic. Bi-monthly weekly reports on client weight trends, new diagnoses, stable vitals for Diabetes and hypertension clients were continuously reviewed and monitored from February to December 2019.

LESSONS LEARNED: The morbidity occurrences due to diabetes and hypertension among the elderly ART clients reduced to 30%. The percentage of Clients diagnosed increased to 13% and 8% for hypertension and diabetes respectively. The percentage of clients with increasing weight who attended health talks reduced by 20%

CONCLUSIONS/NEXT STEPS: To offer an integrated care package on screening and management of Diabetes, Hypertension and other non-communicable diseases associated with aging to improve the wellbeing of elderly clients living with HIV

PED0790

PHYSICIANS AND HIV+ PEOPLE ON LONG-TERM HEALTH ISSUES

J. Deemer[1], K. Mach[1], N. Melinis[1], S. Brown[1]
[1]*Ipsos, Healthcare, New York, United States*

BACKGROUND: Previous research has found the life expectancy gap between people with and without HIV has decreased from 44 years in 1996-1997 to 12 years in 2011*. With a longer life expectancy, people with HIV are becoming more concerned about long-term health issues, such as renal and bone issues. The objective of this research is to compare physicians and patients' long-term health considerations of taking antiretrovirals (ARV) medication.

METHODS: The Ipsos HIV syndicated Patient Community gathered qualitative patient perceptions via an online community platform; collected via a patient's PC, tablet or via an app in the US in August 2019. 42 patients were recruited from a specific HIV patient panel and were diverse in age, time since diagnosis, and ethnicity.

The Ipsos HIV US Therapy Monitor, a syndicated retrospective patient chart audit running since 1994, was used for this analysis. 193 physicians from across the US provide demographic, disease and treatment data on 3853 HIV+ patients seen in consultation between October to December 2019.

RESULTS: From the patient community, the top safety issue most mentioned was organ damage involving kidneys, liver, and bones followed by problems with weight/fat distribution and cardiovascular complications. The top safety issues were primarily driven by patients diagnosed over 5+ years ago. When asked "what does long-term health mean to you?', top mentions were to live a normal life, age normally, control HIV symptoms, and maintain overall health. Patients diagnosed for less than 5 years were primarily concerned about controlling HIV symptoms and living a normal life. From the therapy monitor, when physicians were asked about their primary reason for prescribing the current regimen, the top reasons were Convenient dosing (12%), To support patient long-term health (9%), Low renal risk (9%), Durability of efficacy (8%), Good tolerability profile (7%).

CONCLUSIONS: Renal issues were a top concern among patients regarding long-term health and it was a top priority for doctors when prescribing ARV medication. Patients want to live normal lives without interference from HIV, which was complimented by doctors prescribing treatments with convenient

PED0791

CHARACTERIZING INTIMATE PARTNER VIOLENCE REPORTED BY HIGH-RISK WOMEN IN KENYA WHEN OFFERING HIV SELF-TESTS OR CLINIC BASED HIV TESTING REFERRAL CARDS TO THEIR PARTNERS

C. Obiero[1], P. Ochwal[1], N. Marcus[2], H. Thirumurthy[2], R. Bosire[1], S. Napierala[3], S. Maman[4], K. Agot[1]
[1]Impact Research and Development Organization, Kisumu, Kenya, [2]University of Pennsylvania, Philadelphia, United States, [3]RTI International, North Carolina, United States, [4]University of North Carolina at Chapel Hill, North Carolina, United States

BACKGROUND: In sub-Saharan Africa, men are less likely to know their HIV status than women. Secondary distribution of HIV self-tests, an approach in which a person is provided multiple self-tests to offer to individuals in their sexual networks, has shown promise in reaching male sexual partners of women. However, there are concerns over possible intimate partner violence (IPV). We report IPV cases in a large ongoing study among high-risk women in Kenya.
METHODS: We analysed data from an ongoing cluster randomized-controlled trial of an HIV self-testing intervention (NCT03135067). HIV-negative women aged ≥18 years with ≥2 sexual partners in the past 4 weeks were eligible. Women in intervention clusters received multiple HIV self-tests on an ongoing basis for distribution to sexual partners while women in control clusters received referral vouchers for clinic-based testing. All women were counselled on how to avoid IPV. Information on IPV (physical, psychological and sexual) is collected during six-monthly and phone-based quarterly follow-up visits. Participants are urged to call the help-line to report any IPV.
RESULTS: 2,091 women were enrolled from 66 clusters. Participants' mean age was 27.1 years, 64.4% were married, and average monthly income was US$47.1. Baseline IPV was 50.5% (29% physical, 44.9% psychological, and 12.2% sexual). Over a 16-month follow-up, 41 IPV cases (21 intervention and 20 control) were reported; 39% related, a rate of 1.3%pa, implying that counselling on IPV effectively reduced incident cases almost 40-fold. Psychological violence was reported by 29.3%, physical by 48.8%, sexual by 7.3%, and multiple by 12.2%. Most IPVs (56%; n=41) were perpetrated by non-primary partners (NPP) both in the intervention and control clusters (57%; n=21 vs 55%; n=20, respectively). Violence was triggered mainly from suggesting testing (24.4%) and partner testing positive (12.2%); 53% of the relationships were terminated following IPV.
CONCLUSIONS: Among high-risk women participating in partner and couples testing intervention study, overall IPV rates were low. Non-primary partners were the main perpetrators of IPV and introducing HIV testing or receiving an HIV-positive test result were the main triggers of IPV. Adequate counselling to women on how to negotiate HIV testing with partners is crucial.

PED0792

HIV-ELDERS: REDUCING SOCIAL ISOLATION AMONG HIV-POSITIVE GAY AND BISEXUAL MEN 50 YEARS OF AGE AND OLDER IN LOS ANGELES, CA

J. Bailey[1]
[1]APLA Health & Wellness, HIV Access, Los Angeles, United States

BACKGROUND: Los Angeles County, California, is home to an estimated 61,000 people living with HIV (PLWH). Of this number, 45% are over the age of 50, which is poised to increase to 72% by 2025. In 2016, APLA Health conducted the Healthy Living Project (HLP), an in-depth qualitative research project designed to identify the needs of various sub-populations of aging PLWH in Los Angeles County, resulting in the formation of HIVE (HIVelders), a program for HIV-positive gay and bisexual men 50 years of age and older.
DESCRIPTION: The Healthy Living Project conducted focus groups with four sub-populations of older adults living with HIV: gay and bisexual men, heterosexual men, transgender women, and cis-gender women. Staff hosted an additional focus group in Spanish, comprised of gay and bisexual men. Findings led to the creation of HIVE, focused on HIV-positive gay and bisexual men 50 years of age and older. Launched at APLA Health in July 2018, HIVE includes the following intervention modalities: Shared Interest Groups, Life Skills Support, Health Education, and Community Building/Social Networking strategies.
LESSONS LEARNED: Among the gay and bisexual men, more than half reported Disability or Social Security as their primary source of income, and relying on financial assistance to pay for their housing. Only a quarter reported having someone they considered a primary partner. The program elements of HIVE, derived from these findings, reached 610 older gay and bisexual men from July 1, 2018 to June 30, 2019. Initial findings revealed that 85% reported men felt less isolated because of participating in a HIVE social activity; 82% reported an increase in self-care and self-efficacy skills, and 75% reported an increase in health literacy.
CONCLUSIONS/NEXT STEPS: The medicalization of HIV has created a significant gap in supportive services for an expanding population of older adults living with HIV; in particular, gay and bisexual men who remain disproportionately impacted by HIV in Los Angeles County. A paradigm shift in programmatic emphasis for older gay and bisexual men is needed to reduce social isolation, promote financial security, and housing stability to promote long-term health outcomes. Next steps include provider competency training specific to aging and HIV.

CONFRONTING STIGMA: LESSONS LEARNED

PED0793

USING MOVEMENT AND CREATIVE PERFORMANCE TO SUPPORT WELL BEING IN WOMEN LIVING WITH HIV: MOVING WITH POWER, A CATWALK4POWER PROGRAMME

M. Rattue[1], I. Routledge[2], L. Griffith[1], N. Moepi[1]
[1]Positively UK, Womens Services, Islington, United Kingdom, [2]University of California, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States

BACKGROUND: Women make up one-third of people living with HIV in the UK, but our voices and visibility are not prominent in discourses surrounding HIV. Stigma continues to form a major barrier and has real consequences on the health and wellbeing of women living with HIV in the UK; over half have experienced violence as a result of their HIV status and 31% have avoided or delayed healthcare attendance in the past year due to fear of discrimination. Creative, physical performance gives women a platform to take up space, express individuality and collective strength. Close physical contact also challenges stigma in relation to intimacy and connection.
DESCRIPTION: A series of workshops were developed collaboratively between Women living with HIV, a public health researcher and a movement director. 30 women participated, as part of the Catwalk-

4power project, using movement to explore trust, connection, self-expression and visibility. This culminated in a performance with 22 women living with HIV owning the stage at a major academic conference.

LESSONS LEARNED: Feedback from participants suggested that the workshops built confidence, sense of connectedness and trust. The success was dependent upon open communication and a flexible response to the diverse needs of participants, from the facilitators and allies. Simple community-building activities, shared meals after workshops and a Whatsapp group were also key to sharing information and ensuring the direction was peer led.

[Delegates at #AIDSImpact brought cheering to their feet by the brilliant women of #Catwalk4Power.]

CONCLUSIONS/NEXT STEPS: This project demonstrated the power of performance in highlighting women's voices and shifting internalised stigma. Our experiences provide a pathway for developing future creative performance programmes and collaborations.

PED0794

PEER-LED PROJECT: CATWALK4POWER, WOMEN LIVING WITH HIV USING CREATIVITY, EMBODIMENT AND PERFORMANCE TO OVERCOME INTERNALIZED STIGMA, DEVELOP CAPACITIES AND STRENGTHEN INDIVIDUAL AND COMMUNITY EMPOWERMENT

S. Petretti[1], P. Moepi[1], M. Rattue[1], D. Riddington[2], M. Tralla[2], L. Kwardem[3], S. Fraser[1]
[1]Positively UK, Community Based Organisation, London, United Kingdom, [2]Act Up London, Community Based Organisation, London, United Kingdom, [3]4M CIC, Community Based Organisation, London, United Kingdom

BACKGROUND: Over 30,700 women are living with HIV in the UK - a third of all HIV diagnoses (PHE,2019). Women with HIV continue to experience HIV-related stigma from society and within their communities, often including intersectional stigma from the convergence of their gender, ethnicity and migrant status.

Women with HIV in the UK face significant psycho-social challenges: 45% live below the poverty line (PHE,2019); over half have experienced violence as a result of their HIV status (Sophia Forum/THT,2017); one in three have been diagnosed with a mental health condition (PHE,2017).

Within this context, women lack voice, visibility and meaningful involvement in HIV healthcare and support services.

We created the Catwalk4Power as a peer-led empowerment project, engaging creativity, performance, spoken word, to empower ourselves, to overcome stigma, amplify our voices as women, and improve our well-being.

DESCRIPTION: Throughout 2018-2020, Catwalk4Power produced five performances: three in London, one in Manchester and one in Brighton. A set of five workshops were used to develop each performance with a total of 123 participants.

Workshops covered:

- 'Leadership Skills'
- 'Our Amazing Bodies'
- 'Making Artifacts, Framing Key Messages'
- 'Collective Poetry & Telling Our Stories'
- 'Embodying Positive Affirmations & Strutting Class'

The team produced a toolkit so that communities of women, based in other locations, can engage with the process, tailoring it to suit their specific needs.

LESSONS LEARNED:

- Participants' feedback and interviews reported a rapid decrease in internalised stigma, increased confidence and new connections made to other women with HIV and allies.
- Joined-up collaborative approach among women with HIV, activists/artists, HIV organisations and academic institutions was core to Catwalk4Power's success.
- Catwalk4Power generated broad media interest and provided platforms for women with HIV to be heard.
- Women outside London have less access to support but need this intensely, beyond workshops, highlighting a greater need for peer support specifically for women.
- Catwalk4Power's multifaceted approach, using words, movement, informal discussion, and a focus on action and performance, is accessible and offers something for everyone.

CONCLUSIONS/NEXT STEPS:

- Toolkit dissemination: working with other women's groups and adapting the model to their needs.
- Secure more funding to work collaboratively with national/international women's groups.

PED0795

THE LIVED EXPERIENCE OF MULTIPLE STIGMAS AMONG HIV-POSITIVE GAY AND BISEXUAL MEN IN AUSTRALIA

N. Lucas[1], S. Buzwell[1]
[1]Swinburne University of Technology, Centre for Mental Health, Hawthorn, Australia

BACKGROUND: For many gay and bisexual men (GBM) living with HIV, discrimination for living with a chronic health condition can negatively impact on psychological well being. Although we have seen an advancement in pre/post antiretrovirals, U=U campaigns and greater acceptance of societal views towards non-heterosexual sexual orientations, it might be considered that for many GBM living with HIV, internalized stigma is still prevalent and negatively impacts on everyday functioning.

The aim of this study was to examine the lived experience of HIV-positive GBM in Australia and better understand how both sexual orientation and HIV-related stigma impair mental health. Additionally, feasibility of a stigma reduction program based on the lived experiences and recommendations from study participants was assessed.

METHODS: 21 GBM were recruited through HIV organisations in Melbourne, Australia in 2019. Each participant completed series of stigma measures followed by a one-to-one qualitative interview of approximately 80 minutes. Participants were asked to describe their experiences of discrimination and stigma in relation to sexual orientation and HIV. Participants were also asked what they would like to see in a stigma reduction program as well as what would retain their attendance. Thematic analysis was used to generate themes.

RESULTS: Both sexual orientation and HIV -related stigma impacted negatively on all participants. Among older participants, residual sexual orientation stigma impacted on decision to disclose HIV status. For all participants, rejection from family and friends was common and daily discrimination was experienced across several life domains.

All participants reported 'resilience' as something that helped reduce the impact of multiple stigmas. Participants suggested ways in which resilience can be used to reduce the impact of stigma for newly diagnosed individuals and incorporated into future interventions/programs. The themes and implication of findings will be discussed.

CONCLUSIONS: Both sexual orientation and HIV-related stigma is still experienced among GBM in 2019. Both in-group (LGBTQIA+) and out-group (hetero-normative population) discrimination was reported that resulted in internalized-stigma. However, resilience was found to be fundamental in reducing the impact of such stressors and was reported to be increased through social and peer support.

PED0796

BREAK THROUGH THE HIV STRATOSPHERE AND TOWARD A GREATER INVOLVEMENT OF PLWHA IN TAIWAN – THE EXPERIMENT OF "POSITIVE FACE TO FACE" PLATFORM

C.M. Lin[1], C.L. Chen[1], K.S. Sun[1], Y.H. Lan[1], Y.C. Chuang[1], R.P. He[1], P. Hsu[1]
[1]Taiwan Lourdes Association, Taipei, Taiwan, Province of China

BACKGROUND: In its effort to reduce stigma and discrimination toward PLWHA and to implement GIPA, Taiwan Lourdes Association initiated in February 2019, with PLWHA opinion leaders, the "Positive Face to Face" social dialogue platform. This innovative platform provides the public a direct interaction space with PLWHA, with the aim to expand the positive impact of PLHWA.

DESCRIPTION: The website-based platform provides a safe space of dialogue that surmounts the limit of time and space, on which PLWHA volunteers could directly interact with the public: PLWHA volunteers post their own stories online and give feedback to the public's comments and questions via voice recording, giving PLWHA's narrative particular warmth of humanity. A pre-enrollment meeting and regular meetings for PLWHA volunteers were organized as part of the empowering process.

LESSONS LEARNED: As of the end of 2019, 17 PLWHA volunteers have participated. In total, 106 voice-recording feedbacks were published. The feedbacks covered a wide variety of topics such as: how a teacher living HIV could adopt himself to his career; a computer engineer worried about HIV infection; service providers curious about HIV/AIDS medical care and related policies; HIV/AIDS treatment; private insurance eligibility; the coming-out issue; PLWHA seeking support; magnetic-status couple relationship issue, etc.

CONCLUSIONS/NEXT STEPS: The platform has played a facilitating role, provided a safe space for dialogue and advocacy, and empowered PLWHA to have a constructive interaction with the community, the public, and service providers, etc. PLWHA volunteers enhanced their identity due to their HIV status and gained a sense of self-worth through the narration and interaction process. The public has benefitted from the open dialogue space and been able to get closer to PLWHA, with their voice. As of the current stage, most of the volunteers are MSM PLWHA. We look forward to female, middle-aged, and substance-user volunteers to join the project in order to present the diversity of the community. We are also going to bring on-line interaction in to off-line face-to-face meeting to make the "Face-to-Face" aspect of the project come true. We will further innovate the platform as well in order to expand its impact.

PED0797

DO HIGHER LEVELS OF INTERNALIZED HOMOPHOBIA AND HIV STIGMA LOWER YOUR CHANCES FOR VIRAL SUPPRESSION?: RESULTS FROM HPTN 078

J. Malone[1], K. Mayer[2], Z. Wang[3], J.P. Hughes[3], J. Farley[4], C. Del Rio[5], D.S. Batey[6], R. Remien[7], C. Beyrer[8]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]The Fenway Institute, Boston, United States, [3]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division, Seattle, United States, [4]Johns Hopkins School of Nursing, Baltimore, United States, [5]Emory University, Department of Global Health & Emory Center for AIDS Research, Atlanta, United States, [6]University of Alabama at Birmingham, Social Work, Birmingham, United States, [7]Columbia University, HIV Center for Clinical and Behavioral Studies, New York, United States, [8]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Center for Public Health and Human Rights, Baltimore, United States

BACKGROUND: "Ending the HIV Epidemic" in the U.S. requires identifying factors that influence viral suppression among men who have sex with men (MSM). Growing attention is being focused on how stigma contributes to the U.S. HIV epidemic; though, quantitative assessments for the association between HIV stigma or internalized homophobia with viral suppression have been understudied.

METHODS: We used cross-sectional data from 864 MSM living with HIV with available viral load measurements screened for the HPTN 078 trial. Recruitment occurred via direct and respondent driven sampling across four U.S. cities. High internalized homophobia was defined as answering 'Agree' or 'Strongly Agree' on at least one question out of nine items. HIV stigma was measured by a 5-point ordinal score from averaging responses across eleven items on a 5-point Likert scale. We estimated prevalence ratios for the associations between high internalized homophobia and high HIV stigma score with viral suppression using Poisson regression with robust variance adjusting for older age (>=35 years), race, education, and study site. We then stratified analyses by race (Black vs. non-Black).

RESULTS: In these 864 MSM, 76% were virally suppressed (<200 copies/mL). Thirty-six percent reported high internalized homophobia and 61% had an HIV stigma score > 2.5. Black race was consistently significantly associated with lower viral suppression prevalence in all non-stratified analyses. After adjusting for covariates, there was no association between high internalized homophobia and viral suppression prevalence, [PR: 0.97, p=0.39]. Additionally, there was no association between higher scores for HIV stigma and viral suppression prevalence, [PR: 0.96, p=0.06]. After stratifying by race, HIV stigma was significantly associated with lower viral suppression prevalence among non-Blacks [PR: 0.92, p=0.04], but there was no association among Blacks.

CONCLUSIONS: Overall, higher internalized homophobia or HIV stigma was not associated with viral suppression; however, higher HIV stigma was associated with lower viral suppression among non-Blacks. Thus, given that Black participants had lower viral suppression, other social factors (e.g. structural racism, socioeconomics, etc.) may influence their health engagement more so than HIV stigma. Given prior, qualitative literature concerning stigma's influence on healthcare engagement, this research deserves further exploration with more robust data.

PED0798

DEVELOPMENT AND PRELIMINARY TESTING OF AN INTERVENTION DESIGNED TO ADDRESS INTERNALIZED HIV STIGMA IN THE US SOUTH

S. Reif[1], H. Cooper[1], E. Wilson[1], D. Rao[2], D. Ward[3,3]
[1]Duke University, Center for Health Policy and Inequalities Research, Durham, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Southern AIDS Coalition, Birmingham, United States

BACKGROUND: The US Deep South has been disproportionately affected by HIV, in part due to the pervasive intersectional stigmas in the region and the stigmas' negative impact on health outcomes. With funding from Gilead Sciences' COMPASS Initiative and the Southern AIDS Coalition, we adapted the UNITY Workshop, now called the YOUnity Workshop, to address stigmas among predominantly African American populations of men and women living with HIV in the Deep South.

DESCRIPTION: The YOUnity Workshop was adapted using qualitative and quantitative methods and piloted at five sites in the Deep South to examine feasibility, acceptability, and preliminary outcomes. The peer-led and interactive day-long workshop was designed to strengthen stigma coping skills. Participants completed surveys pre- and post-intervention and participated in focus groups to assess outcomes (3 sites).

Skill(s) Learned from Participating in the YOUnity Workshop	% of Survey Respondents who Strongly Agreed or Agreed they had Learned a New Skill(s)	% of Survey Respondents who Tried a New Skill(s) in their Personal Life
Coping with Stigma	85.4%	65.00%
Disclosure	85.0%	68.30%
Assertiveness	83.0%	82.10%

[Table. YOUnity Workshop findings]

[Figure 1. The YOUNITY Workshop adoption cycle]

LESSONS LEARNED: A majority of YOUnity Workshop pilot participants were African American, male, had lived with HIV for over five years, and reported less baseline stigma than documented in previous research in the region. Most participants reported high workshop satisfaction, 85% gained new skills for coping with stigma, and two-thirds reported using a new stigma coping skill post-intervention. Common themes from the focus group included significant benefit from sharing experiences with other participants and the importance of learning tools for assertiveness and disclosure. Participants described a need for ongoing opportunities for support and building stigma coping skills.

CONCLUSIONS/NEXT STEPS: Study findings demonstrated the acceptability and utility of the YOUnity Workshop. However, more testing is needed, including testing to determine the effectiveness of the workshop among individuals with high levels of baseline stigma. Based on recommendations from this pilot, the YOUnity Workshop was further adapted and additional testing of the intervention is underway in the Deep South.

PED0799

PSYCHOLOGICAL FACTORS MEDIATE THE NEGATIVE IMPACTS OF LAYERED STIGMA ON QUALITY OF LIFE AMONG PEOPLE LIVING WITH HIV

S. Qiao[1], C. Zen[1], X. Li[1]
[1]University of South Carolina, Health Promotion, Education, and Behavior, Columbia, United States

BACKGROUND: People living with HIV(PLWH) are often stigmatized due to their multiple identities and social conditions such as same-sex sexual behaviors, HIV infection, gender and sexual minority identity, and poor socioeconomic status. Layered stigma could affect health seeking behaviors and mental health, but there is a dearth of empirical studies that explore the paths through which stigma affects quality of life (QoL) among PLWH. The current study aims to examine if depression, anxiety, and resilience can mediate the impact of layered stigma on quality of life (QoL) among PLWH.

METHODS: A cross-sectional survey was conducted among 402 PLWH from a large immunology clinic in South Carolina, United States in 2018. Participants were asked about sociodemographic background, depression, anxiety, resilience, perceived layered stigma, and QoL. Perceived layered stigma was measured by accumulating perceived stigma due to gender, HIV infection, same-sex sexual behaviors, migration status, and poverty. Quality of life was assessed by four domains including physical health, mental health, social relationship, and social function. Descriptive analysis and path analysis were conducted with controlling age, income, and employment status.

RESULTS: The final path model fits the data well: $\chi 2 = 34.3$, $p < .001$; CFI = .98; SRMR = .05; RMSEA = .08. Layered stigma significantly and negatively affected social function. Layered stigma was significantly associated with anxiety and depression but not with resilience. Both anxiety and resilience were significantly associated with all domains of QoL while depression was only associated with physical and psychological well-being. Mediation analysis revealed that anxiety could mediate the paths between layered stigma and all domains of QoL while depression could only mediate the paths between layered stigma and physical and psychological well-being. Resilience could not mediate the relationship between layered stigma and QoL.

CONCLUSIONS: Our findings suggest anxiety and depression could play mediating roles between layered stigma and QoL among PLWH. Although resilience could not mediate this relationship, it

is still an important psychological factor which could promote QoL of PLWH. Interventions with aims to reduce anxiety and depression and promote resilience should be integrated into the efforts to improve health outcomes and quality of life for PLWH.

PED0800

UNPACKING IMPACT OF HEALTH RISK AND PROTECTIVE FACTORS ON DIMENSIONS OF STIGMA AND OVERALL HEALTH IN PEOPLE LIVING WITH HIV: INSIGHTS FROM THE ONTARIO HIV STIGMA INDEX

S.B. Rourke[1,2,3], J. Watson[1], J. Lo Hog Tian[1,2], A.J. Odhiambo[4], A. Mcgee[1], A. Boni[1], A. Fraleigh[1], F. Ibanez-Carrasco[1], G. Da Silva[1], J. Gough[1], J. Cotnam[5], J. Lindsay[1], K. Showers[1,6], L. Cioppa[1], M. Mwalwanda[1], M. Murphy[1,7], M. Sumner-Williams[1], M. Ajiboye[1,8], M. Hodge[1], S. Leblanc[9], S. Smith[1], W. Bristow[1], Ontario HIV Stigma Index Team
[1]Unity Health Toronto, Centre for Urban Health Solutions, Toronto, Canada, [2]University of Toronto, Institute of Medical Science, Toronto, Canada, [3]University of Toronto, Department of Psychiatry, Toronto, Canada, [4]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [5]Canadian Aboriginal AIDS Network, Vancouver, Canada, [6]Toronto People with AIDS Foundation, Toronto, Canada, [7]AIDS Committee of Windsor, Windsor, Canada, [8]International Community of Women Living with HIV, London, United Kingdom, [9]Drug User Advocacy League, Ottawa, Canada

BACKGROUND: While the negative effect of stigma on health and well-being is well established, there is less known about the dimensions of stigma and their differential impacts on health outcomes of people living with HIV. Understanding the relationships between health risks and protective factors that impact dimensions of stigma may allow for development of targeted intervention strategies aimed at overcoming HIV stigma and potentially improving overall health and wellbeing of people living with HIV.

METHODS: Peer research associates recruited 724 people living with HIV from across Ontario (mean age=47.8 years, % male=67%) to complete the HIV Stigma Index – a global survey tool developed by and for people with HIV to measure nuanced changes in different forms of stigma (e.g., internalized stigma, enacted stigma, and anticipated stigma). Health risks (alcohol and drug misuse, depression, low income, lack of basic needs, and unemployment) and protective factors (social support, self-efficacy, and resiliency) were assessed and risk scores were established for each person. Relationships between health risks and dimensions of stigma were examined as well as the potential for protective factors to mitigate the negative impact of stigma.

RESULTS: Rates of enacted and internalized stigma were high (50-60%) in our sample across priority populations and were significantly associated with self-ratings of overall health ($p<0.0001$), while rates of anticipated stigma were even higher (80-90%) but were not associated with overall health. With each additional health risk, rates increased significantly and in a stepwise fashion for enacted (47% to 72%, $p<0.0001$) and internalized stigma (31% to 63%, $p<0.0001$). Protective factors had the opposite effect, with the addition of each factor seeing a stepwise decrease in enacted (73% to 54%, $p<0.01$) and internalized stigma (69% to 38%, $p<0.0001$). Similar relationships were not observed for anticipated stigma.

CONCLUSIONS: There is a high burden of HIV stigma in people living with HIV in Ontario. Findings suggest focusing in on interventions to increase external support systems and internal resources (e.g. self-efficacy and resiliency) may buffer against the negative impact of experiencing stigma, reduce the internalization of stigmatizing attitudes, and lead to improvements in health and wellbeing for people living with HIV.

PED0801

LESSONS LEARNED FROM AN INNOVATIVE COUNSELLING INTERVENTION EMBEDDED IN ROUTINE ANTENATAL CARE TO REDUCE HIV RELATED STIGMA IN TANZANIA

H. Osaki[1], J. Renju[2,3], B.A. Knettel[4], L. Minja[1], R.N. Mwamba[4], S.S. Sao[4], J.S. Ngocho[2], G. Kisigo[4], B.T. Mmbaga[1], M.H. Watt[5]
[1]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [2]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Duke Global Health Institute, Durham, United States, [5]University of Utah, Salt Lake City, United States

BACKGROUND: Internalized and anticipated HIV stigma negatively impact care engagement among pregnant women living with HIV (WLHIV). Antenatal care (ANC) offers an opportunity to directly address HIV stigma during pre- and post-test HIV counselling. We examined the feasibility of a brief stigma-focused counselling intervention, delivered by lay counselors and embedded within routine HIV testing during ANC in Tanzania.

DESCRIPTION: We enrolled women (n=1041) and their partners (n=494) in the study between April and December 2019. Women were equally randomized to intervention or standard of care. Two lay counsellors delivered the intervention before standard of care, guided by semi-structured counselling manuals. Counsellors received a two-week training on counselling skills and HIV-related stigma. The intervention consisted of a short video about a couple's journey after their HIV diagnosis during first ANC, followed by a brief counselling session. WLHIV were invited to attend two additional sessions, one after standard of care and another two weeks later. Content addressed concerns related to stigma, plans for engaging in care, and strategies for bolstering social support. Sessions were audio-recorded and counsellors recorded counseling notes. Four clinical supervisors conducted weekly supervision sessions to audit quality and help counsellors develop skills.

LESSONS LEARNED: Counsellors practiced reflexive listening and were mindful to mirror clients' attitude to not further heighten the anticipation of HIV testing and/or a new diagnosis. They developed skills to balance the semi-structured session guides with flexibility and adaptability, to reflect each client's unique needs and experiences. They learned how to convey the importance of social support in care engagement without needing to push for disclosure and gave clients space to process and express emotion. Supervision sessions were an important forum for counsellors to receive guidance and reflect on their journey, and provided a source of relief and support.

CONCLUSIONS/NEXT STEPS: Lay counsellors were able to implement a stigma-based counselling intervention during routine ANC in a low-resource setting. Effective implementation of counseling interventions to reduce stigma can be achieved if counsellors practice reflexivity and acknowledge each client's unique experience. Regular supervision of counselors is useful for reflection and discussing challenges during the process.

PED0802

SENSITIZATION OF HIV, STIGMA AND DISCRIMINATION ISSUES AMONG RELIGIOUS LEADERS IN 6 REGIONS OF MYANMAR

K. Taung[1], M.K. Lwin[2]
[1]Myanmar Interfaith Network on AIDS, Yangon, Myanmar, [2]UNAIDS, Yangon, Myanmar

BACKGROUND: Myanmar has the second-highest HIV prevalence in the Asia Pacific region at 0.8% among adults (15-49 years), after Thailand. In 2018, Myanmar reported 11,000 new infections. HIV-related stigma and discrimination remain a barrier to ending AIDS in many townships in the country. Stigma index studies (2015) shows that 53% of people surveyed report they were the subject of stigmatizing gossip, and 27% experienced verbal insults, harassments, and threats.
DESCRIPTION: In collaboration with UNAIDS, Myanmar Interfaith Network on AIDS (MINA) implemented a project aimed to increase awareness on HIV AIDS to religious leaders of Christianity, Hindu, Buddhist, and Muslim in six regions in 2017. A total of 708 participants received the half-day training, which included MINA's mission, basic awareness of HIV services availability, effects of stigma and discrimination on social and health-seeking behaviors of PLHIV, sharing experiences from PLHIV and KPs, and discussion on roles of religious leaders in the HIV response. KPs explained religious leaders their experiences related to stigma and discrimination faced such as restriction of entering the religious compound as they were being immoral, limited participation in donations and reluctance to eat together. They discussed with religious leaders to solve these issues out together and get a better environment for them. After the awareness program, religious leaders from four religions visited 5 hospitals and provided emotional support to PLHIV, 158 clients received nutrition support, 40 clients referred to hospital, 20 clients received financial support while admitted hospital, and 2 clients received shelter and financial support.
LESSONS LEARNED: The faith-based and interfaith approach in HIV response resulted in the sustainability of some HIV responses, for instance, religious leaders and faith-based organizations in Kalay coordinated through monthly meetings, supported orphanage, provided nutrition for PLHIV, and organized World AIDS Day event with their trust fund.
CONCLUSIONS/NEXT STEPS: The HIV awareness workshop resulted in increased awareness among the religious leaders on HIV and issues faced by PLHIV and KPs. Additionally, as the leaders have a strong influence in the local communities, they helped reduce stigma towards affected population.

PED0803

NOTHING FOR US, WITHOUT US, BELONGS TO US; HOW TO TACKLE THE STIGMA OF THOSE LIVING WITH HIV THROUGH COMMUNITY PEER EDUCATION LED BY YOUNG PEOPLE LIVING WITH HIV

K. Bavor[1,2], E.R. Adjordor[1,2,3], D. Vos[1,2], J. Adjordor- van de Beek[1,2,3]
[1]The STARS, Kpando, Ghana, [2]HardtHaven Children's Home, Kpando, Ghana, [3]UNiTED Projects, Kpando, Ghana

BACKGROUND: The STARS (Support, Train and Advocate in Response to Stigma) is a youth driven organization made up of teenagers living with HIV in the Volta Region of Ghana. Their aim is to reduce the stigma on HIV in reality, as they face stigma when they disclose their HIV status. The STARS found various ways to open the discussion in the community of their peers to change the perception of their community towards people living with HIV.
DESCRIPTION: In 2017 The STARS started with a program to break the silence on HIV/AIDS among their peers in 12 various schools in the municipality for World AIDS Day. This program included a speech on the basic facts of HIV as well as highlighting the negative effects of stigma towards those living with HIV. In 2018 a drama play was added based on community feedback from the 2017 event and the speech and play was conducted at 8 schools, 2 churches and a mosque, to reach a bigger audience. In 2019 The STARS added PhotoVoice, a tool that provides visual representation of key aspects related to stigma. The members of the STARS tell their personal stories through the pictures they made, based on a designed research question the group created. In total we have reached an approximate population of 10,000 people.
LESSONS LEARNED: An indigenous message that has been developed by people in the same age group as the target audience is effective. The message on the basic of HIV and stigma is more effective when reinforces with visual aids that are also created in and by the community.
CONCLUSIONS/NEXT STEPS: In 2020 we plan to introduce a knowledge attitudes and practices questionnaire before and after the program is presented to the audience to determine whether the program with the interactive aspects of PhotoVoice has a measurable impact in changing community perception towards people living with HIV. We mainly focus on Junior and Senior High school students now, because of the neglect towards gay and lesbian people we have to include aspects of the program addressing this population too, as it is likely that they carry HIV with them.

PED0804

POSITIVE AFFIRMATION DAY, 2ND DECEMBER, A CREATIVE RESPONSE TO SHIFTING INTERNALISED STIGMA AND CELEBRATING PEOPLE LIVING WITH HIV

M. Rattue[1]
[1]Positively Mindful CIC, Watford, United Kingdom

BACKGROUND: Established in 2013 as a grass roots initiative, Positive Affirmation Day is now a global platform for people living with HIV to share our status in a supportive and celebratory way. The objective is to connect creatively, to identify the unique qualities we all have, and to share a "positive" message. The process shifts internalised stigma, by identifying our atributes and qualities beyond HIV and challenges societal stigma by sharing these messages and images on social media. #PADHIV
DESCRIPTION: The project is always evolving and adapting, following feed back from participants:
In 2017, 672 participants were assisted to share a photo or art work and find words containing the letters H I and V that are positively affirming and a collection of 452 individual's images were shared either personally or as part of a large collage. This process redefined the acronym, however was very labour intensive, and not all who wanted to participate could be supported in time.
In 2018 the process was simplified and a series of frames were produced which could be selected rather than uniquely made. The affirmation of "I am ..." was used and participants invited to share any uplifting and inspiring affirmation in any language.

In 2019 a creative workshop was arranged in London to support the social media campaign, so participants could make their own frames and have quality photographs taken. Supporting creative expression, and combating isolation by strengthening a sense of community and belonging.

LESSONS LEARNED: Reviews indicate that joining the online event significantly increased a sense of well-being, a total of 11 participants have used this event to share their diagnosis publicly for the first time.

The workshops boosted self esteem, a sense of self worth and awareness of artistic talent.

CONCLUSIONS/NEXT STEPS: Exploring identity in a safe space, either with online peer support or in participatory creative workshops, allows perceptions to change and people living with HIV to live well and stigma free.

The workshop format of discovering our unique affirmations and creative abilities can be used throughout the year to facilitate this empowerment and awareness.

Any day can be Positive Affirmation Day.

PED0805

"I LOVE MY LIFE, I DON'T WANT TO MISS A THING": MOTIVATORS AND BARRIERS TO ART ADHERENCE AMONG WOMEN LIVING WITH HIV/AIDS IN IRAN

N. Amiri Sani[1], O. Zamani[2], A. Azimi[1]
[1]Society for Protection of Socially Disadvantaged Individuals, Tehran, Iran, Islamic Republic of, [2]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Kerman, Iran, Islamic Republic of

BACKGROUND: Adherence to ART plays a vital role in HIV/AIDS prevention and treatment. Iran has embarked on the fast-track strategy to end the AIDS epidemic by 2030, so it is necessary to fully understand the motivators and barriers to optimal adherence.

METHODS: Participants were recruited between June and November 2018 .Using semi-structured interviews, we explored the motivators and barriers to ART adherence in 42 women (aged 27-63) who were taking medication for at least 6 months. Medication adherence was assessed by self-report of how many times they have missed their pills in the past 7 days. If it was <90%, they were considered non-adherent. These women were participating in weekly social support sessions. Interviews were audio-recorded and transcribed. Data were inductively analyzed, using thematic analysis.

RESULTS: Only 6 women were nonadherent. The will to live was the major motivator for adherence. The sense of belonging to family and playing the role of caretaker gave the women a reason to stay healthy and strong. For most women, their children were their first and most important priority. On the other hand, family and friends were effective facilitators because they constantly reminded them to take the pills and provided psychological support in times of distress. A close relationship with doctors and counselors and believing in the efficacy of ART also enhanced the adherence. Interacting with other HIV-positive women and sharing their experiences motivated them to keep using the prescribed medications. In addition, most women admitted that if their treatment was not free, they could not afford it. Exploring the barriers of adherence, some themes emerged: side-effects, lack of social support, stigma and playing the role of care-taker.

CONCLUSIONS: Adherence is a multifaceted concept. We should never forget that the patient is part of several social networks and should always include family members, friends, peers, health-care providers and the society that surrounds him/her in programs for enhancing adherence. With the support of social system, the patient can overcome the barriers that stand in the way of optimal adherence.

EXPERIENCES AND IMPACTS OF ANTIRETROVIRAL THERAPY

PED0806

LIVING WITH HIV, MARKET, AND PUBLIC HEALTH: THE UNREGULATED AND INFORMAL DISTRIBUTION OF ANTIRETROVIRAL DRUGS AND SELF-MEDICATION IN CHINA

P. Wang[1], H. Raymond[1], C. Wei[2]
[1]Rutgers School of Public Health, Department of Biostatistics and Epidemiology, Piscataway, United States, [2]Rutgers School of Public Health, Department of Health Behavior, Society, and Policy, Piscataway, United States

BACKGROUND: While antiretroviral drugs (ARVs) are provided for free to people living with HIV (PLWH) in China, limited research suggested that some PLWH are skeptical of the quality of the ARVs available from the government. Anecdotes from affected communities also suggest that some PLWH are purchasing ARVs from other countries for self-medication and selling them to other PLWH. The objectives of this study was to describe patterns of unregulated and informal distribution of ARVs among mostly men who have sex with men (MSM) in China and to explore how and why these men self-medicate and trade medication.

METHODS: From Dec 2017 to Mar 2019, online participatory observation was conducted on social media platforms where PLWH/MSM gather to exchange treatment information and buy and sell ARVs from foreign countries. In-depth interviews were also conducted with select individuals from these platforms.

RESULTS: Unregulated ARVs are mainly from India, Thailand, and South Africa through "sellers" on the Internet. India's ARVs are most common and popular due to their regimens and affordability among middle-income "buyers." At the individual level, men believe that these ARVs are of higher quality with less side effects so that they could return to their normal lives sooner and not be ashamed of living with HIV. Their perceptions and experiences are reinforced by "sellers" within the communities who establish themselves as trustworthy medical advisors and continuously promote the most up-to-date regimens. As a result, some men switch their regimens on an arbitrary basis with little or no consultation from their physicians in fear that they may lose the benefits of free CD4 and viral load testing available in China. Furthermore, discriminatory practices within the healthcare environment drive men to seek informal medical advice online. Finally, several interviewees also reported selling or purchasing ARVs for PEP and PrEP use.

CONCLUSIONS: Our study observed and documented patterns of unregulated and informal distribution of ARVs among Chinese PLWH/MSM and their experiences with self-medication. This phenomenon could have implications for potential drug resistance and abuse due to lack of monitoring. Quantitative research is warranted to determine the extent of this phenomenon.

ASSESSING THE FINANCIAL AND NON-FINANCIAL BURDEN FOR HIV PATIENTS IN NIGERIA. HOW MUCH ARE THEY REALLY SPENDING?

J. Ugaz[1], D.S. Dauda[2], D. Silfverberg[1], A. Ogundipe[3], A. Dutta[1]
[1]Health Policy Plus, Palladium, Washington DC, United States, [2]Health Policy Plus, Palladium, Abuja, Nigeria, [3]National Agency for the Control of AIDS, Abuja, Nigeria

BACKGROUND: Evidence suggest health facilities in Nigeria charge allowable and unallowable user fees for HIV services. Direct user fees add to the burden of travel costs and time spent traveling to a facility. User fees pose a financial barrier which can reduce treatment adherence and lead to reduced viral suppression. We assessed the prevalence and magnitude of user fees and quantified all indirect costs to estimate the current financial burden faced by people living with HIV.

METHODS: We surveyed 640 patients seeking HIV services in 31 healthcare facilities across Akwa-Ibom, Kano, Lagos, and Rivers states. Patients were approached at point-of-care and interviewed either before or after they had received services. Data were collected on costs incurred during the most recent visit for HIV services, along with transportation costs, travel time, time spent, and sociodemographic information. Our study is unique as we also interviewed practitioners in the 31 facilities to find conflicting responses.

RESULTS: During their last visit for HIV services, 25% of patients paid at least one user fee. User fees were more common in states with higher HIV prevalence. The average amount per episode was US$3.4, about 92% of the average daily income and 170% for poor patients. Charges were more common for hospital registration costs, ARV prescriptions, CD4, and viral load tests. Transportation costs amounted to an average of US$1.7 per visit; with an average time spent of about 4 hours per visit, the sum of indirect costs was 89% of average daily income. Across direct and indirect costs, the average total financial burden per visit was US$6.9, 187% of average estimated daily income. We also found conflicting responses from patients and practitioners around what user fees were being charged at facilities.

CONCLUSIONS: The overall burden from user fees and other costs for people seeking HIV services is high in Nigeria. We explore and propose several policy options to eliminate user fees charged for HIV services and reimburse providers from existing state-level health insurance schemes, and to reduce need to travel and visit providers with scaled-up differentiated service delivery. Civil society organizations should track user fee elimination policies as they are introduced.

PED0808

PUTTING THE HEART BACK INTO HAART: GREATER HCP-PATIENT ENGAGEMENT IS ASSOCIATED WITH BETTER HEALTH OUTCOMES AMONG PERSONS LIVING WITH HIV (PLHIV) ON TREATMENT

C. Okoli[1], P. de Los Rios[2], G. Brough[3], G.M. Corbelli[4], B. Allan[5], M. Muchenje[2], E. Castellanos[6], A. Eremin[7], M. Mc Britton[8], B. Young[9]
[1]ViiV Healthcare, Middlesex, United Kingdom, [2]ViiV Healthcare, Quebec, Canada, [3]Positively UK, London, United Kingdom, [4]EATG - European AIDS Treatment Group, Brussels, Belgium, [5]ICASO, Toronto, Canada, [6]Global Action for Trans Equality GATE, New York, United States, [7]spid.center, Moscow, Russian Federation, [8]Barong Cultural Institute, São Paulo, Brazil, [9]ViiV Healthcare, RTP, North Carolina, United States

BACKGROUND: High quality healthcare provider (HCP)-patient engagement is critical for patient-centered care. We investigated HCP-patient discussions and explored associations with health outcomes.

METHODS: Data were from a 24-country survey of HIV+ adults on anti-retrovirals during 2019 ("Positive Perspectives", n=2112). HCP-patient engagement (low, moderate, high), was modified from the Observing Patient Involvement scale. Descriptive/multivariable analyses were performed.

RESULTS: With their HIV providers, 85% reported ≥one issue they felt uncomfortable discussing. Of those virally suppressed (n=1536), non-suppressed (n=482), and with unknown viral status (n=94), respectively, reasons for discomfort in discussing were: not confident (13.6%, 33.0%, 24.5%); difficulty broaching topic (16.3%, 28.4%, 24.5%); apprehensive of wasting doctor's time (13.4%, 24.9%, 31.9%), perception of issue as "not important" (12.3%, 16.8%, 21.3%); fear of being labelled "difficult" (23.2%, 37.3%, 34.0%); and perception HCP's priorities differed from theirs (17.6%, 27.8%, 26.6%) (all p<0.05). While 61.5% were updated on new treatment options, 65% reported their HCP asked their views before new treatments, and 72% reported they understood about their HIV treatment, However 64% still wanted more involvement. The top issues considered treatment priorities among those diagnosed for ≥2 years (n=1624) were concerns regarding ART side-effects (67%) and long-term impacts (60%); yet, among those rating these issues as important, ~one-third were uncomfortable discussing with their HCP. Additionally, 16.3% had not shared their HIV status with their current non-HIV-care doctor. PLHIV had higher odds of perceiving their treatment needs as being met if they reported HCPs provided enough information (AOR=4.13), sought their views (AOR=4.14), inquired about their concerns (AOR=3.31), asked about side-effects (AOR=4.12), discussed new treatment options (AOR=2.42), and had told them about "Undetectable=Untransmittable"/"U=U" (AOR=2.78). Odds of full adherence (0 missed dose/past 30d) were 1.33 (95%CI=1.01-1.74) and 3.10 (95%CI=2.40-4.01) higher among those with moderate and high vs low HCP engagement.

CONCLUSIONS: High HCP-patient engagement was associated with better health-related outcomes. A substantial proportion of PLHIV did not have high engagement and reported reduced health-related quality of life endpoints. Improving quality of communication between patients and HCPs may better support 4th 90 goals of improving health-related quality of life.

PED0809

"WHY START LATER IF I CAN START TODAY?" PATIENT PERSPECTIVES ON THE EXPERIENCE OF RAPID/SAME-DAY LINKAGE AND ANTIRETROVIRAL THERAPY AFTER HIV DIAGNOSIS

K.A. Christopoulos[1], X. Erguera[1], L. VanderZanden[2], M. Green[2], S. Coffey[1], J. Schneider[2], M. Gandhi[1], K. Koester[1]
[1]University of California, San Francisco, United States, [2]Howard Brown Health, Chicago, United States

BACKGROUND: Clinical outcomes following rapid linkage and antiretroviral therapy (ART) are promising. The U.S. Department of Health and Human Services and WHO have endorsed rapid ART, however, little is known about the patient experience of this treatment strategy.

METHODS: Between May 2018—August 2019, we conducted 37 in-depth interviews in English or Spanish with individuals referred for rapid ART at a safety-net HIV clinic in San Francisco (Ward 86) and a clinic network focused on LGBTQ health in Chicago (Howard Brown Health). Data were coded and analyzed using thematic analysis.

RESULTS: Median age was 27 (range 19-49) and 27% were cis/transgender women, 27% heterosexual, 35% Black, 41% Latino, and 49% homeless/unstably housed. ART initiation occurred within 7 days of diagnosis for 80% (40% same-day starts). Three interrelated themes emerged:

1) participants felt highly supported by providers/staff at linkage sites;

2) to delay ART start would be nonsensical;

3) ART initiation meant participants could take charge of their well-being, thereby alleviating anxiety about living with HIV. No participant described feeling pressured to start ART.

Rather, ART initiation was perceived as life-affirming and a logical next step. "It didn't even really seem like a decision. It was more just the obvious course of action."

Participants saw ART as being proactive in preserving health "you're not just sitting and waiting while your body gets destroyed by the virus" and maintaining normalcy "I felt like if I didn't take the pill I couldn't do anything...if I took the pill, I would be okay." ART initiation was experienced as grounding during intense emotional turmoil because it provided a trajectory with an end-goal (viral suppression). It also facilitated disclosure in certain situations – "I walked out of there with a treatment plan...that's what really gave me the courage to go home and tell my family."

Participants were incredulous at the idea of providers waiting to offer ART to individuals newly diagnosed with HIV – "I see it as a human right."

CONCLUSIONS: In two U.S. cities, rapid linkage and ART initiation, a treatment strategy endorsed globally, was highly acceptable to individuals with newly diagnosed HIV.

GROWING UP WITH HIV: SPECIFIC NEEDS AND INTERVENTIONS FOR CHILDREN AND ADOLESCENTS

PED0810

COMMUNICATION BETWEEN CAREGIVERS AND CHILDREN PERINATALLY INFECTED WITH HIV ABOUT THE DISEASE AND MEDICATION WITHOUT DISCLOSURE: QUALITATIVE DATA FROM NYANGABGWE HOSPITAL, BOTSWANA

P. Manye[1,2], D.S. Madiba[3]
[1]University of Limpopo, Public Health, Pretoria, South Africa, [2]North West University, Health, Mahikeng, South Africa, [3]Health Sciences University, Public Health, Pretoria, South Africa

BACKGROUND: The increased survival of children to older age and adolescence has focused attention to disclosure of HIV diagnosis to infected children. While the positive effects of HIV disclosure have been documented, health care providers providing HIV treatment and care services to children in Botswana, report that most primary caregivers delay disclosure to HIV-infected children. The study explored primary caregivers' perceptions about disclosure to HIV infected children and examined ways that could make disclosure easy. Aim: To explore primary caregivers' perception about disclosure of HIV diagnosis to infected children and examine ways that could make disclosure easy.

METHODS: Explorative descriptive qualitative study was conducted using focus group discussions with 41 caregivers of HIV infected children between 5-18 years of age receiving ART from the pediatric clinic of Nyangabgwe Hospital Infectious Disease Control Clinic in Botswana. Thematic data analysis using NVivo10, software for data analysis and coding, revealed 10 themes.

RESULTS: Primary caregivers had positive perceptions about disclosure to HIV infected children. They believed that HIV infected children have the right to know their illness. In the absence of disclosure, primary caregivers made the child understand the disease, the importance of good adherence to medication, and prevent the child from getting sick without mentioning HIV. They further reported feelings of guilt for not disclosing and expressed that keeping the diagnosis secret is emotional and hurting. Disclosure could be made easy if it is done by health workers, and caregiver who are trained and counselled on how to approach disclosure to HIV infected children.

CONCLUSIONS: HIV pediatric programs should have disclosure guidelines in place and provide disclosure material that could facilitate disclosure to HIV infected children.

PED0811

FRIENDS' FORUM, AN APPROACH FOR CREATING RESILIENCE AMONG CHILDREN LIVING WITH HIV/AIDS: EXPERIENCE FROM CENTRAL UGANDA

M.P. Buwembo Luyera[1], E. Sendaula[2], S. Nassolo[1]
[1]Reach Out Mbuya HIV/AIDS Initiative, Community Social Support, Kampala, Uganda, [2]Reach Out Mbuya HIV/AIDS Initiative, Research, Kampala, Uganda

BACKGROUND: Children living with HIV/AIDS(CLWA) aged 14-18 years experience challenges relating to stigma, stress and non-disclosure which lead to poor health and education outcomes resulting to school dropout. They are also more likely to be non-suppressed compared to other age groups in Uganda. This increases their risk for increased malnutrition and severe illness. Friends' Forum plat-

form was set up with the aim of developing a coping mechanism for them to support each other to achieve viral load suppression.The ultimate goal is to build resilience among CLWA through positive living and preventing further spread of HIV.

DESCRIPTION: Reach Out Mbuya (ROM) is a faith based organisation located in central Uganda. It has 3 static clinics serving a total of 220(64.1%)children aged 14-18years.ROM rolled out the Friends' Forum approach in 2016.The key pointers monitored in this forum include viral load suppression,adherence,social capital,nutritional status and school attendance.Teenage and Adolescent Supporters (TAS) have been trained to monitor and write reports on a weekly basis. A viral load monitoring is done by a child psychotherapist every 6 months and annually for those that are stable. Those children with viral load results greater than 1000copies/mL are supported at household level by finding out their challenges and identifying solutions. Through the TAS,school peer clubs have been established .These clubs organise life skill seminars, debates, dialogues and exhibitions at the community level to enable the CLWA cope and lead a dignified positive life. They share information and experiences on HIV,drug adherence and life skills with their peers.

LESSONS LEARNED: The suppression rate among children aged 14-18 years has increased from 67.8% in 2016 among 133 children of which 66 females and 67 males to 86% among 220 children of which 132 females and 88 males by September 2019. Through peers, these children are able to acquire leadership skills, share experience and sensitize others on HIV/AIDS prevention.It promotes supportive school environments, young people's friendship and social networks which enable them become resilient.

CONCLUSIONS/NEXT STEPS: This approach provides a protective and nurturing environment for peer relationships which fulfills a critical psycho-social and developmental needs of CLWA.

PED0812

DEVELOPMENT OF A YOUTH PLHIV NETWORK "LITTLE STARS" IN RURAL TAMIL NADU, INDIA: CHALLENGES AND OPPORTUNITIES

J.E.M. Antony Joseph[1], S. Durai[1], M. Tamilarasan[1], S. Pandian[1], B. Shacklett[2], K. Van Rompay[3,4]
[1]Rural Education and Action Development (READ), HIV Program, Andimadam, India, [2]University of California, Microbiology and immunology, School of Medicine, Davis, United States, [3]University of California, Pathology, Microbiology and Immunology, School of Veterinary Medicine, Davis, United States, [4]Sahaya International Inc., Davis, United States

BACKGROUND: In rural India such as Ariyalur District (Tamil Nadu), problems of low literacy, poor HIV awareness and HIV stigma persist. We previously developed an HIV peer education model using cartoon-based educational materials that was effective in increasing awareness, reducing stigma, and led to formation of a PLHIV support network. The network meets monthly and provides additional moral, medical and economic support to ~ 200 PLHIV of all ages (https://human-resources-health.biomedcentral.com/articles/10.1186/1478-4491-6-6). Since 2003 this network has included children/youth living with HIV, but they are generally silent at meetings, and their concerns and voices are not heard. While the program has not lost any children/youth due to AIDS in 13 years, as the children grow up, the formation of a club was considered important to better address their needs.

DESCRIPTION: In 2017, a children/youth HIV club called "Little Stars" was started, with currently 30 members (ages 9 to 29). The network meets monthly under supervision of 3 counselors (2 of them young PLHIV women). In addition, the trained counselors visit the children at home as needed. The children also receive nutritional supplements and financial support for their education.

LESSONS LEARNED: Discussions with Little Stars members and their caretakers revealed many challenges, including delayed HIV disclosure, poor adherence, doubts on the basic facts of HIV, depression, fear, lack of hope and stigma from community members. The problems are age-related and show high variability between individuals and families. The reasons are multifactorial, complex, and often interlinked to challenges of caretaking (including low literacy, high poverty and limited time and resources of caretakers). Overall, the youth expressed that they enjoy attending the meetings and sharing feelings, and requested additional activities including games, creative activities, field trips, and more information on general health and HIV-related topics. Additional printed materials are being developed in the local language to aid with counseling, education and disclosure.

CONCLUSIONS/NEXT STEPS: Because children/youth infected by HIV face unique challenges, there is a need for dedicated funding and resources for this age group. A comprehensive approach including counseling, educational, nutritional and medical support, is important.

PED0813

LOW KNOWLEDGE ABOUT SEXUAL TRANSMISSIBILITY OF HIV AND HIGH VIRAL DETECTABILITY AMONG ADOLESCENTS LIVING WITH HIV IN PUNE, INDIA: A PRESSING CONCERN

S. Nimkar[1], S. Sangle[2,1], A. Kinikar[2,1], A. Chavan[1], A. Pawar[1], S. Surawase[1], K. Zarekar[1], N. Suryavanshi[1], V. Mave[1,3], I. Marbaniang[1,4]
[1]Byramjee Jeejeebhoy Government Medical College – Johns Hopkins University Clinical Research Site, Pune, India, [2]B J Govt Medical College & Sassoon General Hospitals, Pune, India, [3]Johns Hopkins School of Medicine, Baltimore, United States, [4]McGill University, Montreal, Canada

BACKGROUND: India has the second highest number of adolescents living with HIV (ALWH) outside sub-Saharan Africa. A predominant Africa-centric focus on adolescent HIV, has limited our understanding of HIV-associated health knowledge (HAHK) among Indian ALWH. Little is also known about the interaction of these adolescents with the healthcare system. Both factors are important in HIV-transmission. We aimed to describe HAHK and the relationship with healthcare providers, among Asian Indian ALWH.

DESCRIPTION: We used data from 62 ALWH receiving ART aged 15-19 years, randomly recruited between August 2018 and September 2019, from the ART clinic of Byramjee Jeejeebhoy Government Medical College (BJGMC), Pune, India. Eligibility criteria included: self-awareness of HIV status; ability to provide consent (≥18years) or assent (<18 years); parental consent (<18 years) and non-institutionalization. Data on socio-demographic and clinical characteristics, rudimentary HAHK, and healthcare provider interaction were collected using an electronic counsellor-administered questionnaire. HAHK questions included enlisting ARV regimen, the utility of CD4 monitoring and modes of transmission.

LESSONS LEARNED: Of 150 ALWH approached, 43% were unaware of their HIV-status and ineligible. Of 62 enrolees, 77% had been vertically infected; 46% were male; median age was 18 years(IQR:17–18); 61% had≥11 years of education. Median duration on ART was 5 years(IQR:2-8); median CD4 count 516 cells/mm3(IQR:322-698); 37% were virologically undetectable. Only 9% knew their ARV regimen

and 70% were unable to articulate the utility of CD4 monitoring. Twenty-three percent were unaware that HIV was sexually transmitted. Unawareness about sexual transmission wasn't limited to any gender, educational attainment or viral undetectability (p>0.1). Although these ALWH are regular attendees of the ART clinic; 81% reported not being sensitized to the course of disease, treatment options, or preventive measures by healthcare providers.

CONCLUSIONS/NEXT STEPS: In a cohort of ALWH self-aware of their HIV-status, a fourth were unaware of the sexual transmissibility of HIV, and four-fifths had never discussed preventive measures with healthcare providers. The combination of low serostatus self-awareness, low sexual-transmissibility awareness, infrequent preventive measures communication and high viral detectability among AWLH could have calamitous consequences on future HIV-risk for young adult Asian Indians. Larger studies to corroborate our findings and mitigating strategies are mandated.

PED0814

"THERE'S NOT EVEN A POTENTIAL RULE BOOK FOR ANY OF THIS": A QUALITATIVE STUDY OF CHALLENGES AND COPING MECHANISMS AMONG US PARENTS WHO INTERNATIONALLY ADOPT CHILDREN LIVING WITH HIV

S. Alger[1], R. Olivero[2], C. Crowell[3], A. Bingaman[4], C. Fair[4]
[1]George Washington University, Milken Institute School of Public Health, Washington DC, United States, [2]Helen DeVos Children's Hospital, Grand Rapids, United States, [3]Seattle Children's Hospital, Seattle, United States, [4]Elon University, Public Health Studies, Elon, United States

BACKGROUND: An increasing number of US families seek to adopt children living with HIV from other countries. Caring for internationally adopted children living with HIV (IACH) requires comprehensive understanding of HIV and pre/post-adoption support. However, few resources exist for adoptive parents. This study explores the experiences of current parents to offer support to families interested in pursuing IACH.

METHODS: Hour-long, semi-structured, audio-recorded interviews were conducted with a purposive snowball sample of 38 parents of IACH from 18 states, mainly recruited at two pediatric infectious disease clinics. Parents were asked about motivations to adopt, medical and psychosocial needs, challenges associated with adoption, and advice to prospective parents. Interview transcripts were coded for emerging themes using standard qualitative methods.

RESULTS: A total of 38 participants completed interviews, with a mean age of 37 years. All identified as Caucasian, most as female (n=37), Christian (n=34), and married (n=37). Participants adopted a total of 40 IACH, primarily one per family (range 1-2). Mean age of IACH at time of interview was 8 years (range 3-19, 28 females, 25 from African countries, 40 currently on ART, 38 virally suppressed). Many parents had minimal knowledge about HIV prior to adoption. Faith and altruism motivated most parents' decisions to pursue adoption. Initially, parents expressed medical concerns primarily around HIV care and noted that adoption agencies did not typically have up-to-date HIV-related information. However, once educated by healthcare providers and informed of support networks, fears were eased. Parents noted that immediate adoption-related issues, such as pre-adoption trauma, loss, and behavioral issues, often took priority over HIV-related concerns. Many parents called HIV a "non-issue" and became advocates for their children, aiming to reduce HIV-related stigma to protect their children. Key strategies in overcoming challenges associated with raising IACH included using open communication with their child related to their adoption, culture, and HIV status; finding supportive medical, social, and legal resources; understanding disclosure rights; and normalizing HIV in the household.

CONCLUSIONS: Pre-adoption HIV education and post-adoption support for immediate adoption-related issues are crucial for comprehensive care of IACH. Longitudinal research on adoptive families is needed to examine needs across the life course.

PED0815

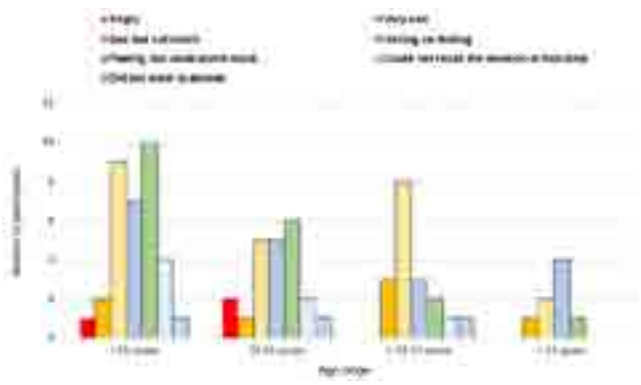
HIV DISCLOSURE EXPERIENCE OF ADOLESCENTS LIVING WITH PERINATAL HIV INFECTION IN NORTHERN THAILAND

L. Aurpibul[1], T. Sudjaritruk[2], S. Sarachai[1], N. Wongnum[2]
[1]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [2]Department of Pediatrics, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

BACKGROUND: Conveying a child's HIV status to the child is a critical process in pediatric HIV care, which both providers and parents always hesitate to perform due to many reasons. In this study we asked adolescents living with perinatal HIV (APHIV) to recall their own experience in order to inform health care providers what to anticipate during disclosure approaches.

METHODS: The cross-sectional study was conducted at Chiang Mai University in February 2018. APHIV were recruited from HIV clinics. Inclusion criteria were: 1) aged between 15-<25 years, 2) having perinatal HIV infection, and 3) willing to join the study. Data collection was performed by computer-assisted self-interviewing.

RESULTS: 110 APHIV were included; 51(46%) were female. Their mean age and duration on antiretroviral treatment were 20.2 (SD2.6) and 12.7 (SD3.1) years, respectively. Thirty-four (31%) were disclosed to their HIV status before the age of ten, while HIV disclosure was done between the age of 10-12, >12-15, and >15 years in 22(20%), 18(16%), and 8(7%), respectively. The emotional reactions were shown in Figure 1. The person who disclosed to the child were parents/caregivers in 42(38%), and health care providers in 48(44%); no significant difference in emotional reaction between the two groups (p=0.848). Currently 89% had their HIV status known to family members; 37%, 16%, and 13% disclosed to relatives, friends/school teachers, and others in community, respectively. Very few (2%) disclosed to employers/coworkers. The appropriate HIV disclosure ages were < 10 years, and between 10-12 years as proposed by 40% and 30% of APHIV, respectively.



[Figure 1. Emotional reactions to HIV disclosure at different age ranges: Experience recalled by adolescents living with perinatal HIV infection]

CONCLUSIONS: We documented HIV disclosure experience as recalled by APHIV who attended HIV clinics. While adults tend to postpone HIV disclosure to avoid unfavorable consequences, most APHIV proposed conveying by anyone before the age of twelve. Rate of social disclosure was low and required further exploration whether it was related to self-stigma.

PED0816

THE THIRD GENERATION: A LONGITUDINAL MIXED METHOD STUDY EXPLORING THE CLINICAL AND SOCIAL CONTEXT OF HIV-PERINATALLY INFECTED YOUNG MOTHERS IN HARARE, ZIMBABWE

Z. Mupambireyi[1], V. Simms[2], C. Mutasa[1], E. Matsikire[1], B. Senzanje[3], C. Pierotti[3], A. Mushavi[4], N. Willis[5], F. Cowan[6,7]
[1]CeSHHAR, Children and Adolescent, Harare, Zimbabwe, [2]London School of Hygiene and Tropical Medicine, London, Zimbabwe, [3]UNICEF, HIV, Harare, Zimbabwe, [4]Ministry of Health and Child Care, AIDS and TB, Harare, Zimbabwe, [5]Africaid, Harare, Zimbabwe, [6]CeSHHAR, Harare, Zimbabwe, [7]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

BACKGROUND: Lives of HIV-infected adolescents are typically dominated by numerous complex physical, psychological and social stressors including orphaning and multiple often sequential care giving environments. This longitudinal mixed-method study describes the clinical and psycho-social challenges being faced by HIV perinatally-infected young mothers in Harare, Zimbabwe.

METHODS: HIV-perinatally infected mothers were recruited in 2013 and followed up in 2019. In 2013, mothers completed a structured interview, had a clinical examination, a psychological assessment and provided blood samples for viral load and drug resistance testing. Additionally, a sub set of mothers took part in in-depth interviews (n=10), audio diaries (n=5). In 2019, 11 of the original sample were re-interviewed. Quantitative data were analysed using STATA 15.0. Descriptive summaries and frequencies of social, clinical and demographic characteristics were carried out. Qualitative data were analysed using thematic analysis.

RESULTS: Nineteen mothers aged 17-24 years were recruited in 2013 and 11 were retained in 2019. Between 2013 and 2019, 3 mothers died, 2 moved to South Africa and 3 were LTFU. In 2013, all 19 mothers were taking ART; the median duration of treatment was 8 years (range 2-11 years) and median CD4 count of 524 (IQR 272). Seven mothers (47%) had a viral load >1000 copies/ml, and had evidence drug resistant virus. In 2019 the prevalence of virological failure had significantly reduced to 2/11 (18.1%). Six mothers (54.5%) were on second line while 5/11 (45.5%) were still on first line. Switching to second line and learning about the limited treatment options was a major turning point for some mothers as their adherence improved. At follow up, six mothers were at risk of depression (54.5%) with 27.2% being at risk of severe depression (measured using the Shona Symptom Questionnaire-14). Onward disclosure of HIV status to partners remained limited.

CONCLUSIONS: HIV perinatally infected young women confront a number of a challenges which affects their health as evidenced by high levels psychological distress. Given the high risk of depression, and the impact of this on general well-being, targeted mental health interventions for mothers need to be scaled up.

PED0817

POPULATION CHARACTERISTICS AND IMPLICATIONS FOR ADHERENCE AND RETENTION INTERVENTIONS AMONG PREGNANT ADOLESCENT GIRLS LIVING WITH HIV IN MOZAMBIQUE

J. Falcao[1], K. Brittain[2], A. Zerbe[1], N. Chakhtoura[3], E. Pimentel De Gusmao[1], R. Sutton[1], M. Vitale[1], E.J. Abrams[1,4]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [2]School of Public Health & Family Medicine, University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [3]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States, [4]Vagelos College of Physicians & Surgeons, Columbia University, New York, United States

BACKGROUND: Adolescents living with HIV (ALHIV) are at disproportionate risk for poor health outcomes across the HIV care continuum. The CombinADO study aims to develop and test an adolescent-focused intervention to improve 90-90-90 targets among ALHIV in Mozambique. Formative work was conducted to characterize this population and found a high proportion of adolescent girls reporting current/previous pregnancies.

METHODS: A cross-sectional survey of 208 ALHIV (15-19 years) attending HIV services at three health facilities was conducted in Nampula, Mozambique, between June-December 2019. Information on demographic and medical history, relationship characteristics, HIV, and sexual and reproductive health (SRH) was collected using standardized measures. Recent viral load (VL) results were abstracted from clinical records. Of those surveyed, 70% (n=146) were girls of which 57% (n=83) reported a current or previous pregnancy.

RESULTS: Of the 83 girls who reported ever being pregnant, median age was 18 years [inter-quartile range (IQR), 18-19], and 72% (n=60) were not currently attending school. Of girls who were married (65%, n=54), median age at marriage was 17 years (IQR, 16-18), with median age of husband 25 years [IQR, 23-28]. At the time of the survey, 70% (n=58) reported that they had previously given birth; 27% (n=22) were currently pregnant; and 45% (n=37) currently breastfeeding. Median age at last pregnancy was 17 years [IQR, 16-18]; 70% reported their last pregnancy was planned. Pregnancy/having a child was cited as the primary reason (42%) for not attending school. History of an STI was reported by 27% of girls with 68% having an STI in the last 6 months. Median age at ART initiation was 18 years (IQR, 16-18) with 40% reporting a missed dose in the last 30 days. Of the 41 girls with a VL within 6 months of the survey, 51% had VL<50. Of 58 girls who had previously given birth, 8 (14%) reported that at least one of their children tested HIV-positive.

CONCLUSIONS: Given the young age at which girls become pregnant and the suboptimal ART outcomes in this group, there is an urgent need for tailored SRH programs and prevention of mother-to-child transmission interventions for young women living with HIV in Mozambique.

PED0818

WHAT MATTERS MOST TO ADOLESCENTS LIVING WITH HIV IN SOUTH AFRICA? ANALYSIS OF ASPIRATIONS AND SELF-PERCEPTIONS FROM A LARGE COHORT STUDY

J. Chen[1,2], W.E. Rudgard[1], A.M. Doyle[2], E. Toska[3,1], L. Cluver[1,4]
[1]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [2]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [3]University of Cape Town, Department of Sociology, Cape Town, South Africa, [4]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa

BACKGROUND: Adolescence is a crucial stage when life aspirations emerge. Having aspirations and positive self-perceptions have been linked with better health outcomes in adolescents. The aspirations and self-perceptions of adolescents living with HIV (ALHIV) could be limited due to stigma they encounter. The overall aim of the study is to describe and compare aspirations and self-perceptions of ALHIV and adolescents not infected with HIV in South Africa.

METHODS: A cross-sectional study interviewed adolescents in South Africa in 2014-2015. Study participants were aged 10-19, 55% female, and included ALHIV n = 1064 and uninfected peers n = 455. Qualitative and quantitative descriptive analysis was conducted on three open-ended questions which asked

(1) what would they do as president

(2) their job aspirations, and

(3) what they are most proud of about themselves.

Associations between major themes identified from qualitative analysis and HIV status were evaluated using bivariable and multivariable logistic regression adjusting for sociodemographic factors.

RESULTS: In qualitative findings, adolescents reported a strong desire to change their social circumstances, especially related to housing (41%) relative to 9 other themes identified in question (1) (all mentioned by <15% adolescents). A high percentage of adolescents reported aspirations for careers requiring tertiary education (68%), including Health Care Professionals. However, over 55% of the participants reported delayed grade progression – being at least one grade behind their expected grade-for-age. Nonetheless, adolescents were most proud of their educational achievements (22%) relative to 9 other major themes identified from question (3). In quantitative multivariable analysis, HIV status was not found to be a significant predictor of aspirations and self-perceptions identified in the qualitative analysis.

CONCLUSIONS: Future policies should focus on closing the gap between adolescents' perceived value of education and future aspirations, and the current reality of social and economic inequalities in South Africa. Furthermore, the absence of differences in self-perceptions and aspirations by HIV status supports youth-friendly HIV-sensitive programming of these policies. Including ALHIV in programmes alongside other equally underserved and underprivileged adolescents also helps to avoid stigma. Future interventions can help adolescents achieve their aspirations and positively influence their self-perceptions to improve their psychosocial well-being.

PED0819

IMPROVED ART KNOWLEDGE AND ADHERENCE SKILLS IN YOUTH LIVING WITH HIV PARTICIPATING IN A WHATSAPP SUPPORT GROUP IN NAIROBI, KENYA: THE VIJANA-SMART PILOT STUDY

K. Ronen[1], A. Kaggiah[2], C. Mugo[2], D. Seeh[2], M. Kumar[3], B. Guthrie[1], M. Moreno[4], G. John-Stewart[1], I. Inwani[2]
[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]University of Nairobi, Nairobi, Kenya, [4]University of Wisconsin, Madison, United States

BACKGROUND: Youth living with HIV (YLWH) experience poor treatment outcomes. Mobile health strategies show promise to improve ART adherence, but studies in youth are limited. We developed a facilitated WhatsApp support group intervention for YLWH, and evaluated change in mental health and HIV outcomes following 6-month intervention participation.

METHODS: We recruited 55 YLWH who were age 14-24, aware of their HIV status, and had weekly access to WhatsApp. Participants were recruited in person, through healthcare workers, and by snowball recruitment from a district hospital serving an informal settlement in Nairobi. Youth were given the Vijana-SMART intervention (a facilitated WhatsApp group with ~25 YLWH) for 6 months. WhatsApp groups were age-segregated (<18 vs. ³18 years) and gender-mixed. A study counselor facilitated groups by sending weekly scheduled messages, answering questions, and encouraging discussion. Youth could message the group at any time; the facilitator responded within 24 hours. At enrollment and 6 months, self-report questionnaires were administered assessing ART information, motivation, and behavioral skills (by Lifewindows IMB tool), depression (by PHQ-9), social support (by SS-B), stigma (by ALHIV-SS), and ART adherence (by Wilson 3-item scale). Changes from baseline to follow-up were evaluated by generalized estimating equations clustered by participant.

RESULTS: Of 55 participants enrolled, 37 (67%) were female, median age was 18 (interquartile range, IQR, 16-22), and 29 (53%) were currently in school. Nineteen (35%) reported acquiring HIV perinatally and median time on ART was 4 years (IQR 1-8). At enrollment, median ART information, motivation and behavioral skill scores were 3.7 (3.3-4.0), 2.8 (2.2-3.4) and 3.5 (3.0-3.7) respectively (score range 1-5). Median ART adherence was 88.9% (77.8-94.4) and 14 participants (25.5%) reported ³mild depressive symptoms (PHQ-9 score ³5). Forty-six participants (84%) completed follow-up visits. At 6-month follow-up, ART information and behavior skills scores were significantly higher than baseline: 4.2 (3.7-4.3, p<0.001) and 4.0 (3.4-4.4, p<0.001) respectively. We found no significant difference between baseline and follow-up in ART motivation score (2.7 [2.2-3.4], p=0.33), ART adherence (92.2% [77.8-97.8], p=0.50) or depressive symptoms (15, 32.6%, p=0.38).

CONCLUSIONS: The Vijana-SMART intervention is a promising mobile health intervention to improve youth knowledge and skills for ART adherence. Larger-scale randomized evaluation is warranted.

PED0820

ART ADHERENCE SUPPORT INTERVENTIONS TARGETING ADOLESCENTS AND YOUNG ADULTS LIVING WITH HIV IN SUB-SAHARAN AFRICA (SSA): A SYSTEMATIC REVIEW

T. Nyoni[1], W. Auslander[2], D. Gerke[3], S. Fowler[2]
[1]Washington University in St. Louis, Brown School of Social Work, St. Louis, United States, [2]Washington University in Saint Louis, Brown School of Social Work, St. Louis, United States, [3]University of Denver, Graduate School of Social Work, Denver, United States

BACKGROUND: This systematic review aimed to 1) identify the types of ART adherence support interventions for adolescents/young adults living with HIV in SSA, 2) describe the ART assessment methods used, 3) assess the methodological strengths and weaknesses of the intervention studies, and 4) compare the effectiveness of facility-based interventions versus those delivered in community settings and in combined settings.

METHODS: A systematic search of 9 databases identified peer-reviewed articles and gray literature. Included studies were: 1) published between 2003 and 2019, 2) conducted in SSA, 3) quantitatively evaluated ART adherence support interventions, 4) included adolescents/young adults ages 10-24, and 5) reported ART adherence outcomes. Study methodological rigor was evaluated using the 14-item Methodological Quality Rating Scale (MQRS). A median split of MQRS scores was used to determine high versus low-rigor studies.

RESULTS: Nineteen interventions included mobile phone reminders (n=2), social protection (n=2), adherence counseling and education (n=4), psychosocial support (n=5) and differentiated models of care (n=6). ART adherence was assessed using viral load (n=11), self-report medication adherence (N=8), pharmacy records (n=7), and CD4 cell count (n=5). Almost half of the studies (n=9) had high methodological rigor, with a total score ≥ to the median score of 16 on a 23 point scale. The major methodological strength was multi-component interventions (n=14), and the major weakness was the use of pre-post designs without comparison groups (n=8). Seven interventions were facility-based, seven community-based, and five delivered in combined settings. Most interventions (n=16) significantly improved medication adherence and reduced viral load. All but one intervention for each of the three delivery settings were effective.

CONCLUSIONS: The most common ART adherence support interventions for adolescents/young adults in SSA are psychosocial support programs and differentiated models of care. Despite better expertise of professionals in facilities compared to lay health workers peers, or family members, community-based interventions, and interventions in combined settings, are equally effective as those delivered in health facilities. Community-based ART adherence delivery and support interventions may be an effective, low-cost strategy to improve ART adherence in SSA. Future research is needed to compare the cost-effectiveness of community-based interventions versus those in health facilities.

PED0821

SOCIAL NETWORK CORRELATES OF UNSUPPRESSED VIRAL LOAD AMONG PERINATALLY-INFECTED ADOLESCENTS IN CAPE TOWN, SOUTH AFRICA

M.I. Mulawa[1,2], N. Phillips[3], J. Moody[4], L.B. Hightow-Weidman[5], D.J. Stein[3,6], H.J. Zar[7,8], J. Hoare[3]
[1]Duke University, School of Nursing, Durham, United States, [2]Duke University, Duke Global Health Institute, Durham, United States, [3]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [4]Duke University, Department of Sociology, Durham, United States, [5]University of North Carolina, Institute of Global Health and Infectious Diseases, Chapel Hill, United States, [6]South African Medical Research Council, Unit on Risk & Resilience in Mental Disorders, Cape Town, South Africa, [7]University of Cape Town, Department of Paediatrics and Child Health, Cape Town, South Africa, [8]South African Medical Research Council, Unit on Child and Adolescent Health, Cape Town, South Africa

BACKGROUND: Developmental theories suggest that adolescents are particularly sensitive to the social networks in which they are embedded, but little is known about the social networks of perinatally-infected adolescents living with HIV in sub-Saharan Africa. This study was nested within the Cape Town Adolescent Antiretroviral Cohort (CTAAC), a longitudinal cohort of perinatally-infected adolescents on antiretroviral therapy (ART) recruited from public-sector healthcare services across Cape Town, South Africa. The purpose was to identify social network-level correlates of unsuppressed viral load among perinatally-infected adolescents living with HIV.

METHODS: Detailed social network data (including emotional support, instrumental support, and medical support networks) were collected using a customized touchscreen-based interviewer-administered network assessment during the 36-month CTAAC visit from 61 adolescents ages 12 – 16 years. Viral load (VL) testing was also conducted during the 36-month visit. Demographic characteristics were measured at the CTAAC baseline visit. Multivariable logistic regression was conducted to examine social network-level factors associated with an unsuppressed VL (>= 50 copies/mL) controlling for age, gender, race, home language, and highest level of education completed.

RESULTS: 34.4% of adolescents living with HIV (n = 21) had an unsuppressed VL at 36-months (mean = 2,371.9 copies/mL). Among adolescents with an unsuppressed VL, the mean VL was 6,704.5 copies/mL and median was 100 copies/mL. Adolescents with an unsuppressed VL had smaller medical support networks compared to those with a suppressed VL (2.3 vs. 3.3 people in the medical support network, respectively). Increasing size of medical support networks were significantly associated with a decreased odds of having a unsuppressed VL (aOR = 0.60= 0.046) in an adjusted model. Size of instrumental and emotional support networks were not significantly associated with odds of having an unsuppressed viral load.

CONCLUSIONS: The size of medical support networks among perinatally-infected adolescents living with HIV in Cape Town is significantly associated with having an unsuppressed viral load. While more research is needed, interventions seeking to improve clinical outcomes in this population should consider efforts to enhance medical support networks.

PED0822

HIV HEALTH LITERACY AMONG ADOLESCENTS LIVING WITH HIV IN NORTHERN MOZAMBIQUE

J. Falcao[1], K. Brittain[2], A. Zerbe[1], E. Pimentel De Gusmao[1], L. Myer[2], E.J. Abrams[1,3]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [2]School of Public Health & Family Medicine, University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [3]Vagelos College of Physicians & Surgeons, Columbia University, New York, United States

BACKGROUND: Health literacy may have a significant impact on HIV-related outcomes, including access to timely diagnosis, treatment initiation and adherence and retention to antiretroviral therapy (ART). Health literacy is one of the WHO pillars for quality health care for adolescents living with HIV (ALHIV) but there are few data from African ALHIV from high-burden settings.

METHODS: The CombinADO study aims to develop and test an adolescent-focused intervention to improve health outcomes among ALHIV in Mozambique. As part of formative work we conducted a cross-sectional survey of ALHIV (15-19 years) attending HIV services at three health facilities in Nampula, Mozambique, between June-December 2019. Adolescents completed questionnaires assessing demographic and medical characteristics as well as HIV knowledge; viral load (VL) results were abstracted from routine medical records. HIV knowledge was assessed using 14 true/false items and summed this into a scale for analysis.

RESULTS: HIV knowledge questions were completed by 61 boys and 143 girls [median age 18 years; IQR, 16-19]. Most boys (87%) were currently in school, versus 51% of girls. Overall, 46% reported having their own cellphone. Only 4% knew the names of the drugs in their ART regimen. Of the 126 adolescents that reported having VL testing in the past year, most (82%) did not know the result. Among 116 adolescents with documented VL results within 6 months of the survey, 31% of boys and 48% of girls had VL <50 copies/mL. The median knowledge score was 9 (IQR 7-11), with no difference across gender or age. Knowledge was poor on items assessing the meaning of an "undetectable" VL result and the implications of this for sexual transmission. In a multivariable model adjusted for gender and age, higher levels of knowledge were strongly associated with being in school (p<0.001) and having own cellphone (p=0.041). Controlling for age and gender, higher knowledge was significantly associated with better rated health; as well as with an increased odds of VL <50 copies/mL.

CONCLUSIONS: Our findings highlight the importance of assessing health literacy as part of ART adherence support for ALHIV. Interventions to build comprehensive health literacy in this context may promote adherence and perceived health status.

PED0823

A QUALITATIVE LONGITUDINAL STUDY OF ADOPTION AND DISCLOSURE NARRATIVES AMONG U.S. FAMILIES WITH INTERNATIONALLY ADOPTED CHILDREN LIVING WITH HIV

A. Bingaman[1], R. Olivero[2], C. Crowell[3], S. Alger[4], C. Fair[1]
[1]Elon University, Public Health Studies, Elon, United States, [2]Helen DeVos Children's Hospital, Infectious Disease, Grand Rapids, United States, [3]Seattle Children's Hospital, Infectious Disease, Seattle, United States, [4]George Washington University, Milken Institute School of Public Health, Washington, United States

BACKGROUND: The number of internationally adopted children living with HIV (IACH) in the U.S. is increasing, yet little is known about their families' experiences. This project explores parents' adoption and HIV disclosure narratives, both of which may shape adjustment to the HIV diagnosis as well as their child's identity development.

METHODS: A purposive snowball sample of 24 parents (23 mothers) of 27 IACH were recruited at two pediatric infectious disease clinics. Parents completed two semi-structured audio-recorded phone interviews one year apart. The first interview centered on the adoption story and HIV disclosure decisions. The follow-up interview focused on parents' and children's experiences within their families and communities. Using constant comparison, transcripts were analyzed for emergent themes and changes over time.

RESULTS: All parents identified as white and 22 as Christian. Mean age of children at enrollment was 9.2 years (range 2-19, 15 females, 27 currently on ART, 25 virally suppressed). Analyses revealed that adoption and disclosure narratives were dynamic and changed over time. Parents took cues from their child in order to determine how much adoption and HIV-related information to divulge. Parents wrestled with when to share potentially traumatic adoption-related information and decided to withhold information based on the child's age and maturity, nature of the adoption story, faith, and contact with the birth family. Parents revisited adoption narratives as children matured and began to acknowledge racial/ethnic/cultural differences between themselves and their adoptive parents. Adoption narratives were shaped by level of HIV disclosure to the child and became increasingly complex as children gained understanding of their own HIV status. Parents indicated that "HIV is socially, but not medically difficult". They discussed medical aspects of their child's diagnosis with them first and subsequently sought to help their child prepare for HIV-related stigma by normalizing HIV in the home and building their child's confidence.

CONCLUSIONS: Adoption and HIV disclosure narratives play an important role in the development of IACH, as adopted children learn to manage their illness and develop their own unique identity across the lifespan. Understanding these narratives may help healthcare providers offer higher quality individualized comprehensive care to IACH.

PED0824

VIOLENCE IS ASSOCIATED WITH ART NON-ADHERENCE AMONG ADOLESCENT BOYS AND YOUNG MEN IN WESTERN KENYA

K. Wilson[1], K. Agot[2], J. Dyer[3], J. Kibugi[2], J. Badia[2], R. Bosire[2], J. Neary[4], K. Beima-Sofie[4], I. Inwani[5], S. Shah[6], G. John-Stewart[7], P. Kohler[3]
[1]University of Washington/ITECH, Global Health, Seattle, United States, [2]Impact Research and Development Organization, Kisumu, Kenya, [3]University of Washington, Global Health; Child, Family, and Population Health Nursing, Seattle, United States, [4]University of Washington, Global Health, Seattle, United States, [5]Kenyatta National Hospital/University of Nairobi, Pediatrics, Nairobi, Kenya, [6]Northwestern University, Bioethics Program at Lurie Children's Hospital, Chicago, United States, [7]University of Washington, Global Health, Medicine; Epidemiology, Pediatrics, Seattle, United States

BACKGROUND: Adolescents and young adults (AYA) in sub-Saharan Africa experience high burdens of violence and HIV, and there are global targets to eliminate both problems by 2030. Guidelines recommend screening for partner and non-partner violence within adolescent-friendly HIV care. However, the relationship between violence and antiretroviral (ART) adherence among AYA is poorly defined. We evaluated recent violence and ART adherence among AYA in HIV care in Western Kenya.

METHODS: This cross-sectional analysis included HIV-positive AYA ages 10-24 who were aware of their HIV status, on ART, and enrolled in an ongoing cohort study at 9 large HIV clinics in Kisumu and Homa Bay counties, Kenya. Surveys assessed demographics, partnerships, violence, and ART use. Recent violence was defined as experiencing any act of physical, sexual, or emotional violence by another person in the last 6 months, adapted from a World Health Organization tool. Self-reported poor adherence was defined as missing two consecutive days of ART in the prior month. Generalized linear models with a binomial link were used to estimate relative risks (RR). Multivariable models adjusted for age and relationship status. Analyses were stratified by gender.

RESULTS: Among 967 AYA, the median age was 17 (Interquartile range [IQR] 15-20) and most were female (67.2%). Fewer males than females were in a relationship (25.0% vs. 55.7%). Prevalence of any recent violence was similar for males (16.5%) and females (17.1%), and the most common type was physical (males, 13.6%, females, 10.6%), followed by emotional (males, 6.6%, females, 8.0%) and sexual violence (males, 0.6%, females, 3.1%). Poor adherence was reported by 9.2% of males and 8.0% of females. Among males, recent violence was associated with significantly higher risk of poor adherence (RR=3.80, 95%CI 2.49-5.83, p<0.001), which persisted in multivariable analysis (adjusted RR [aRR] 3.62, 95%CI 2.16-6.10, p=0.001). In contrast, recent violence was not associated with poor adherence among females (RR 1.04, 95% CI 0.58-1.84, p=0.90; aRR1.07, 95%CI 0.66-1.74, p=0.78).

CONCLUSIONS: Nearly a fifth of AYA in HIV care reported recent violence. Recent violence was associated with poor ART adherence among males but not females, suggesting the need to develop gender-tailored violence and adherence interventions.

PED0825

IMPORTANCE OF CAREGIVER-CHILD RELATIONSHIPS IN HIV MANAGEMENT FOR CHILDREN LIVING WITH HIV

T. Dlamini[1], D. Kisiyombe[2], N. Miller[1]
[1]Pact, Programs, Mbabane, Eswatini, [2]Pact, Strategic Information, Mbabane, Eswatini

BACKGROUND: Eswatini has made great strides towards achieving the 95/95/95 UNAIDS targets to combat HIV. The progress is lagging in children and adolescents who have only attained 73.9% viral load suppression[i]. Caregivers have a role in children's treatment adherence support and viral suppression. The Triple R project is using family centred approaches to enhance capacity of caregivers helping children living with HIV in Eswatini

[i] Swaziland HIV Incidence Measurement Survey (SHIMS) 2: 2016-2017

DESCRIPTION: Pact's USAID-funded Triple R project supports C/ALHIV between 0-17 years by prioritising caregiver-child relationship building and strengthening through early childhood development (ECD) and positive parenting skills. Other services include home visits, education support, nutritional assessments, immunization tracking, HIV Testing, treatment initiation, adherence tracking, HIV status disclosure support, and SRH services. Through parenting skills sessions, caregiver-child pairs learn positive parenting strategies and practice acquired parenting skills. Caregivers of babies and younger children receive home-based ECD education and mentorship.

The project has reached 2134 caregiver-child pairs with parenting skills including 38 caregivers of C/ALHIV. Twenty C/ALHIV who were lost to follow-up on treatment were identified and returned to care. Five HIV positive malnourished children were referred for clinical nutritional support and 19 children who were not immunized were linked to services

LESSONS LEARNED: Parents and caregivers play a critical role in the care of C/ALHIV, yet often need support to provide positive parenting and link children and adolescents to critical services. Family centered interventions result in improved and lasting caregiver-child interpersonal relationships. Caregivers that are informed about health issues are better positioned to identify missed milestones for their C/ALHIV and seek appropriate support.

CONCLUSIONS/NEXT STEPS: A good caregiver-child interpersonal relationship is key in realizing the 95/95/95 targets. It enables psychosocial support at the household level to encourage status disclosure, adherence and retention in treatment which are critical to a healthy life for C/ALHIV. Strategies targeting male caregivers' participation in interventions directed at improving the lives of C/ALHIV are also needed.

PED0826

POPULATION CHARACTERISTICS AND IMPLICATIONS FOR ADHERENCE AND RETENTION INTERVENTIONS AMONG ADOLESCENTS LIVING WITH HIV IN MOZAMBIQUE

A. Zerbe[1], K. Brittain[2], J. Falcao[1], E. Pimentel De Gusmao[1], L. Myer[2], E.J. Abrams[1,3]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [2]School of Public Health & Family Medicine, University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa, [3]Vagelos College of Physicians & Surgeons, Columbia University, New York, United States

BACKGROUND: Despite a heavy burden of HIV, little is known about adolescents living with HIV (ALHIV) in Mozambique. As part of the CombinADO study, we sought to characterize ALHIV enrolled in HIV care to understand potential for adherence and retention interventions.

METHODS: We conducted a cross-sectional survey of ALHIV (15-19 years) attending HIV services at three facilities in Nampula, Mozambique, collecting information on demographics, medical history and sexual and reproductive health (SRH). Recent viral load (VL) results were abstracted from clinical records.

RESULTS: Between June-December 2019, 208 ALHIV were surveyed [median age, 18 years; inter-quartile range (IQR), 16-19); 70% female]. Overall, 57% (n=119) reported being in a relationship and 59% had disclosed their HIV status to current partner. Among girls, 57% reported a current or previous pregnancy ("ever pregnant girls"), with median age at first sex 16 years. Among boys and girls reporting no pregnancies ("never pregnant girls"), 52% and 38% reported ever having had sex, with the median age at first sex 15 and 17 years, respectively. Low levels of condom use at last sex were reported (42% among boys and never pregnant girls). Age at which adolescents learned their HIV status was highest among ever pregnant girls (median age: 18 years, versus 15 years among never pregnant girls and 14 years among boys). Similarly, self-reported age at ART initiation was highest among ever pregnant girls: 12 years for boys, 15 years for never pregnant and 18 years for ever pregnant girls. Of 117 ALHIV with VL within 6 months of the survey, 42% had VL<50 copies/mL. Boys were less likely to have VL<50 copies/mL compared to girls (31% vs 47%), with no difference according to pregnancy status among girls.

CONCLUSIONS: These data suggest high levels of viremia among both female and male ALHIV. Further information related to routine VL monitoring are needed to understand the low numbers of ALHIV with VL results. Further, there is an urgent need for evidence-based approaches and services tailored to ALHIV in order to successfully reach and engage this population-- to improve adherence and retention and ultimately, achieve viral suppression.

PED0827

PEER SUPPORT GROUPS PLUS: A FAMILY-BASED, INTEGRATED CASE MANAGEMENT APPROACH TO IMPROVE ADHERENCE, VIRAL LOAD SUPPRESSION, AND RESILIENCE IN ADOLESCENTS LIVING WITH HIV

E. Babu Ndyabahika[1]
[1]World Education, Inc., The Bantwana Initiative, Kampala, Uganda

BACKGROUND: In Uganda, the adolescent viral load suppression rate (70%) continues to lag behind that of adults (95%). Ugandan adolescents struggle with a complex set of clinical and socioeconomic challenges like poor treatment literacy, stigma, poverty, and absence of caregiver and social supports, impeding adherence and successful transition to adult care. Efforts to address these gaps are critical to build adolescent resilience and to achieve and sustain epidemic control in Uganda.

DESCRIPTION: Under USAID/Uganda Better Outcomes for Children and Youth in Eastern and Northern Uganda, the Bantwana Initiative of World Education, Inc. (WEI/Bantwana) delivers a differentiated service package to build resilience and mitigate the risks and impact of HIV and violence among 138,000 vulnerable children and caregivers, including 19,038 caregivers and adolescents/children living with HIV (A/CLHIV). To improve adolescent adherence, WEI/Bantwana layered a package of treatment literacy, parenting, economic strengthening, and protective asset-building supports on existing facility-level psychosocial Peer Support Groups for ALHIV. Reaching 132 caregivers and 138 adolescents across six high-volume sites, sessions aimed to improve positive family communication and joint understanding of the importance of adherence, build youth resilience, and equip families with simple skills to boost income. Trained clinic and community-based social protection structures delivered relevant modules, and para-social workers coordinated adherence support with clinic structures through case management.

LESSONS LEARNED: Caregivers can be powerful allies in adolescent adherence when they have practical knowledge and supports. Pre- and post-test data shows that adolescents' disclosure of their HIV status to family, teachers, and friends increased (72% to 90%). Understanding of treatment literacy improved (72% to 90%) for caregivers and youth, caregiver attendance at clinic appointments increased (62% to 95%), and positive caregiver involvement improved (27% to 85%). Coordinated service delivery at facility and community levels strengthened important relationships and understanding among caregivers, adolescents, and health and social welfare cadres for improved results.

CONCLUSIONS/NEXT STEPS: Findings reinforce the benefits of an integrated HIV and social protection package and family-based approach for improved adolescent adherence. Increased caregiver involvement in tackling HIV-related stigma holds promise for greater uptake and maintenance of positive behaviors for adolescents, which is critical for strengthening and sustaining Uganda's epidemic control achievements.

PED0828

QUALITY OF ELECTRONIC MEDICAL RECORDS AND VIRAL SUPPRESSION AMONG CHILDREN LIVING WITH HIV ON ART IN KENYA

B. Odeny[1], N. Puttkammer[1], L. Abuogi[2], I. Mukui[3], E. Kinywa[4], P. Oyaro[5], R. Patel[1]
[1]University of Washington, Seattle, United States, [2]University of Colorado, Denver, Denver, United States, [3]Ministry of Health, Nairobi, Kenya, [4]Department of Health, Kisumu, Kenya, [5]Health Innovations Kenya, Kisumu, Kenya

BACKGROUND: Electronic Medical Records (EMRs) systems are increasingly being implemented across HIV clinics in sub-Saharan Africa, and high quality data may improve clinical outcomes. We sought to determine whether EMR data quality was associated with viral load (VL) outcomes among children living with HIV (CLHIV).

METHODS: We analyzed pre-enrollment VL results from March 2018 to December 2019 for children (<15 years old) enrolled in an on-going randomized controlled trial, Opt4Kids (which seeks to determine the

impact of point-of-care VL testing to improve VL suppression among CLHIV on ART), in two high-volume facilities in Kisumu County, Kenya. We analyzed cross-sectional data extracted from the Kenya District Health Information System (DHIS2) reporting data system in March 2018. The DHIS2 is updated quarterly using summary health data from facility-based EMRs. We developed a novel composite score, ranging from 0-14, for data quality based on passing logic checks for 14 HIV-related indicators including numbers of persons tested for HIV, numbers on care, and on ART. We used multivariate, mixed effects, multilevel logistic regression models with random effects, adjusting for children's and their caregiver's sociodemographic and clinical characteristics and clustering within facility, to assess associations between data quality and children's viral suppression (defined as VL <1000copies/ml).

RESULTS: VL results for 279 (85%) children were available for analysis. Median age was 9 years (interquartile range [IQR] 6-11), 50% were female, and median duration on ART was 6 years (3-8.5). Majority of the children (86%) and their caregivers (85%) were virologically suppressed. The two facility data quality scores were 5 and 8. A higher data quality score was associated with greater viral suppression compared to a lower data quality score (adjusted odds ratio [AOR]=4.24, 95% confidence interval [CI] 1.78-10.11, p=0.011). Increasing time on ART was associated with a lower likelihood of viral suppression (AOR=0.78, 95% CI 0.63-0.98, p=0.03).

CONCLUSIONS: The health facility with stronger EMR data quality demonstrated significantly greater viral suppression in CLHIV. Further research with additional health facilities is needed to explore the association between EMR data quality, other facility characteristics, and clinical outcomes.

HIV AND THE WORKPLACE: POLICIES, RESPONDING TO STIGMA AND/OR DISCRIMINATION, UNEMPLOYMENT, RETURN TO WORK AND REHABILITATION

PED0829

ADDRESSING HIV/AIDS, SEXUAL HARASSMENT, STIGMA, AND DISCRIMINATION TOWARDS WOMEN LIVING WITH HIV AT THE WORKPLACE: THE CASE OF FLOWER FARMS IN UGANDA

E. Nekambi[1], J. Agwang[2,3], E. Vleeshouwers[4], D. Montero[4]
[1]Uganda Flower Exporter Association, Director, Kampala, Uganda, [2]National Organization of Peer Educators, Kampala, Uganda, [3]National Organization of Peer Educators, Country Director, Kampala, Uganda, [4]Hivos, Open, Den Haag, Netherlands

BACKGROUND: In Uganda, young women and girls continue to be disproportionately affected by HIV: 73% of new infections are among girls aged 15-24. This is the same demographic group that does the bulk of the unskilled, low-paid work in the cut flower sector. Flower farms are economical and sociocultural centers that significantly influence the life of people in the country. People live nearby, or on their job, children go to the (sometimes farm-owned) neighboring schools, and the farms provide health services. Stigma, discrimination, and sexual harassment at work remain a significant barrier for women workers.

DESCRIPTION: Three partners have joined forces to address discriminatory practices towards women living with HIV/AIDS in flower farms in Uganda and reduce new HIV infections. We use an area-based approach, focusing on flower farms where the potential for change is huge. By providing quality and stigma-free health information, the project aims to role-model positive behavior around sexual education, HIV/AIDS, and gender equality. Young women and girls facing the HIV/AIDS burden are additionally affected by (partner) violence and unequal gender norms. The program aims to establish mechanisms for reducing sexual harassment, including the adoption and implementation of an HIV and sexual harassment policy and providing sexuality education. We work closely with workers, children, and farm management to sensitize them about the relation between HIV, gender equality, and sexual harassment.

LESSONS LEARNED: Until now, seven flower farms developed mechanisms for reducing sexual harassment and HIV/AIDS issues at the farm. Active involvement of the government, farm owners, and civil society is essential to increase ownership, trust, and sustainability. This includes working with local schools to provide quality sexuality education. Despite progress, due to Uganda's legal framework, it is not possible to provide inclusive and comprehensive sexuality education as the country is increasingly hostile towards the LGBTI+ community.

CONCLUSIONS/NEXT STEPS: An area-based approach has the potential to change local realities. It increases awareness on flower farms, collective action, and improved working conditions. Working at farms allows for close and direct involvement with managers and farm owners. This also enables us to work at different levels and with various members of the community.

PED0830

TARGETING HIV STIGMA AMONG HEALTHCARE PROVIDERS IN A MEDICAL CENTER OF SOUTHERN TAIWAN: TOWARDS ZERO DISCRIMINATION

H.S. Toh[1], H.-C. Ku[2], W.-P. Chen[2], H.-C. Wang[2], C.-T. Liao[3], H.-J. Tang[4]
[1]Chimei Medical Center, Department of Intensive Care Medicine, Tainan City, Taiwan, Province of China, [2]Chi Mei Medical Center, Infection Control Center, Tainan City, Taiwan, Province of China, [3]Chi Mei Medical Center, Division of Cardiology, Department of Internal Medicine, Tainan City, Taiwan, Province of China, [4]Chi Mei Medical Center, Division of Infectious Diseases, Department of Internal Medicine, Tainan City, Taiwan, Province of China

BACKGROUND: With the scale-up of antiretroviral therapy coverage, new HIV infection and AIDS-related death are decreasing in the past few years. However, HIV stigma remains a critical issue, even in the medical environment. This project aims to understand the current status of HIV stigma among healthcare workers after the propaganda of "U=U".

DESCRIPTION: A "U = U" propaganda program was conducted in the medical centre in 2018. A standardised questionnaire was utilised to measure HIV stigma and discrimination among health facility staff after the program from December 2018 to January 2019. All staff willing to complete the questionnaire were included regardless of their profession and position. Data was collected with a mobile user interface and was analysed with descriptive statistics.

LESSONS LEARNED: A total of 550 valid questionnaires were collected. The responders are from a variety of departments, and 84% of them are female. Strikingly, 42% of them used to take care of HIV patients in the past years. Regarding the knowledge of HIV, about one-third of them still curious about the reproductive right of HIV-infected women. The anxiety of HIV infection soared while performing invasive procedures, and nearly 40% of them would try not to have body contact with the patients. Besides, approximately 35% of the responders ever saw or heard of any discrimination towards HIV-infected patients. Also, people have much more stigma against

substance users among the various high-risk groups. Lastly, 71% of the responders felt comfortable when working together with a colleague with HIV infection.

CONCLUSIONS/NEXT STEPS: Building a friendly medical environment with zero discrimination is pivotal in providing multidisciplinary holistic care to HIV, especially in the ageing HIV population. This project provides an in-depth understanding of the concern and fear of healthcare providers while taking care of HIV-infected patients. People still had anxious about HIV transmission even with standard personal protective equipment. Understanding the attitude of the frontline staff, providing sufficient skills training and safety measures such as PEP, are at a priority in making the policy of targeting HIV stigma. Further continuing education is necessary, not only to novices but also to those who are already in the field.

PED0831

SECTORIAL PARTNERSHIP AND UP-SCALE OF CAMPAIGN ON VCT@WORK (VOLUNTARY COUNSELLING & TESTING AT WORKPLACES) PAVED THE WAY TO ACHIEVE 90-90-90 IN INDIA

A. Verma[1], N. Goel[1], R. Rana[1], U. Das[1], G. Sharma[2], J. Cheema[2], S. Walia[2], N. Rawat[2], B. V[2]
[1]National AIDS Control Organization, Department of Health & Family Welfare, New Delhi, India, [2]NACO, Department of Health & Family Welfare, New Delhi, India

BACKGROUND: HIV positivity among migrants and informal workers engaged in various occupations in diversified economy is major concern. Non-availability of evidences, insufficient data and inadequate situational analysis in resource constraint work-settings diminishes scope of HIV prevention, early detection and treatment in India.

DESCRIPTION: National HIV testing data for the period of April 2018-March 2019 was done by NACO in collaboration with ILO. This analysis was based on overview of HIV testing among workers engaged in major occupational sector, gender representation and HIV sero-reactivity in different occupations and geographical distribution and used as critical evidence to strengthen sectoral partnership, collaborative action and scale-up VCT@Work campaign. Analysis shown following results;

- 18.12 million People tested for HIV, out of which, 14.57 million were workers (Approx 80%). The participation of male, female and transgender were 54.4%, 45.4% and 0.2% respectively. 0.143 Million people diagnosed with HIV positive and 0.083 million were workers. Of total HIV positive adults, 62 % were male, 37.5 % female, and 0.5 % were TS/TG.
- Overall HIV sero-reactivity for adults is 0.8 %, while for workers it is 0.6%, which is, three times higher than average national HIV prevalence of 0.22%.
- HIV sero-positivity is high among workers engaged in occupational sectors like non-agricultural, self-employed and service sectors.

LESSONS LEARNED: This analysis has given the scope of sectoral partnership and paved way for strategic intervention in 155 high priority districts to achieve target on 90-90-90. Results are as follow;

- Action plan developed for 29 states.
- 1400 industries were approached with campaign on VCT@work to strengthen HIV intervention at workplaces.
- Multi-disease diagnose approach with HIV testing leads high coverage. Messages are established on 'No HIV Stigma at Workplace'.
- Adoption of workplace policy to reduce social stigma & discrimination related to HIV.
- 2500 master trainers and 65,000 Para-medical are trained. HIV related services (Counselling, Testing and treatment) expanded.

CONCLUSIONS/NEXT STEPS: Analysis of national HIV data helped to re-look HIV sero-reactivity among workers engaged in various occupational sectors, VCT@work campaign for prevention, early detection and linkages to achieve target 90-90-90 in 155 high priority districts and further scale- up in 500 more districts in India.

LIVING WITH HIV AND CO-INFECTIONS AND/OR CO-MORBIDITIES

PED0832

TOBACCO USE AND HEALTH-RELATED QUALITY OF LIFE AMONG INDIVIDUALS RECEIVING TREATMENT FOR HIV IN CAPE TOWN, SOUTH AFRICA

A. Stanton[1], J. Lee[2], M. Wirtz[1], L. Andersen[3], J. Joska[3], S. Safren[2], R. van Zyl-Smit[4], C. O'Cleirigh[1]
[1]Harvard Medical School/Massachusetts General Hospital, Psychiatry, Boston, United States, [2]University of Miami, Psychology, Coral Gables, United States, [3]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [4]University of Cape Town, Medicine, Cape Town, South Africa

BACKGROUND: Tobacco use is the leading cause of preventable death worldwide, and prevalence rates are high among people living with HIV (PLWH), especially among men. In high-income countries, tobacco use has been linked to low health-related quality of life (HRQOL). Comparatively little research has examined the relationship between tobacco use and HRQOL among PLWH in low and middle-income countries (LMICs), even though LMICs bear the greatest burden of the negative health impacts of both tobacco use and HIV.

METHODS: This study measured associations between habitual tobacco use and HRQOL in a sample of 289 PLWH receiving antiretroviral therapy for HIV in Cape Town, South Africa. Participants were being evaluated for inclusion in a study that sought to increase engagement in HIV care by treating co-morbid clinical depression. Linear regression models measured the effect of gender on tobacco use severity (assessed by the WHO-ASSIST) and on each of the five HRQOL functional impairment domains (assessed by the SF-21). Separate multivariable regression models were used to predict the effects of habitual tobacco use on the HRQOL domains.

RESULTS: The prevalence of habitual tobacco use was 23.9% (48.1% among men, 15.5% among women). Habitual tobacco use was associated with decreased cognitive functioning for the whole sample ($b = -8.99$, $p < .05$) and with lower levels of pain-related impairment for men ($b = 18.1$, $p < .05$). Although men reported more tobacco use ($b = 8.50$, $p < .001$), they reported less pain-related limitations than women ($b = 8.70$, $p < .05$).

CONCLUSIONS: Among smokers living with HIV in our sample, men reported higher rates of habitual tobacco use than women. Habitual tobacco use was associated with cognitive impairment in the whole sample and with less pain-related impairment among men. Future smoking cessation treatments tailored to PWLH may benefit from strategies that consider pain management as one of the pathways to habitual tobacco use and recognize that motivations for use may differ between men and women.

PED0833

HIV AND COMORBIDITIES: THE IMPACT OF COMORBIDITIES ON HEALTH-RELATED QUALITY OF LIFE IN PEOPLE LIVING WITH HIV IN ITALY

E. Foglia[1], B. Menzaghi[2], G. Rizzardini[3], G. Cenderello[4], E. Garagiola[1], L. Ferrario[1]
[1]LIUC - Università Cattaneo, Castellanza, Italy, [2]Valle Olona Hospital, Busto Arsizio, Italy, [3]Fatebenefratelli Sacco Hospital, Milano, Italy, [4]ASL-1 Imperiese, Sanremo, Italy

BACKGROUND: The chronic nature of HIV infection and the aging of people living with HIV (PLHIV) are factors contributing to a higher probability of developing comorbidities. The study aims to investigate the impact of comorbidities on Health-Related Quality of Life (HRQoL), in an Italian cohort of 564 PLHIV.

METHODS: Demographics (age and gender) and clinical information (HIV risk factors, presence of comorbidities, CD4 cell count and viral load) were collected. HRQoL, HIV symptoms and depression factors were measured by EQ-5D questionnaire, ISS-QoL scale and CES-D scale, respectively. Adherence to ART was assessed by validated questionnaire. T-test and one-way ANOVA were used to compare the HRQoL across different patient sub-groups. The hierarchical sequential linear regression model was used to explore the determinants of HRQoL. All analyses were conducted with a significant level of 0.05.

RESULTS: The PLHIV assessed had a mean age of 48.5 years old and 80.7% were male. The median follow-up was 3 years. Most PLHIV reported good adherence (91.8%), were virologically suppressed (96.3% with viral load ≤37 copies), and in good immunological status (76.2% with CD4 >500 cells/mm3). Almost half (47.5%, N=268) of the sample presented with comorbidities, HCV co-infection (21.8%), and cardiovascular disease (25.7%) being especially common.

Patients with good immunological status (p=0.031), successful virological suppression (p=0.011), adherence to ART regimen (p <0.001), and presence of mild and moderate HIV symptoms (p<0.001), reported better HRQoL. Moreover, patients with a higher number of comorbidities reported worse HRQoL (p<0.001), particularly in the presence of cardiovascular diseases (p=0.018), diabetes (p=0.028) and neurocognitive impairment (p<0.001).The results of the regression analysis indicated that good adherence (β=-0.104, p=0.031), with mild and moderate HIV symptoms (β=-0.478, p<0.001), absence of HCV infection (β=-0.080, p<0.001) or neurocognitive impairment (β=-0.166, p<0.001) were independent predictors of better HRQoL.

CONCLUSIONS: Results raise awareness of the impact of comorbidities on HRQoL in a real-world setting, supporting the need for additional interventions to promote well-being in the ageing population, HCV eradication prioritization, and evidence-based decision-making process from the policy makers' perspective.

PED0834

TECHNOLOGY BASED EVALUATION FOR NEUROCOGNITIVE IMPAIRMENT FOR PEOPLE LIVING WITH HIV IN PRIMARY CARE SETTINGS IN HARARE, ZIMBABWE

P. Nyamayaro[1], D. Chibanda[1], J. Hakim[1], H. Gouse[2]
[1]University of Zimbabwe, Harare, Zimbabwe, [2]University of Cape Town, Cape Town, South Africa

BACKGROUND: Because many people (~50%) living with HIV also present with associated neurocognitive impairment (NCI), screening for neurocognitive disorders should be an integral part of treatment. However, few cognitive screening tools have been developed for screening for HIV-associated NCI in low-resource settings and none have been developed for use in Zimbabwe. NeuroScreen is an android app based cognitive screener that has been validated to screen for NCI in people living with HIV and takes approximately 20-25 minutes to administer. We assessed lay counselor and patient experience using NeuroScreen to screen for NCI. Our aim was to o establish acceptability and feasibility of routine screening for NCI using NeuroScreen.

METHODS: 138 HIV+ participants were recruited from two primary care clinics in the western townships of Harare, Zimbabwe.The participants completed the NeuroScreen assessment and a Technology Use Questionnaire.In order to gauge whether using NeuroScreen in this setting is feasible, in depth interviews were conducted with three primary care HIV counsellors.To understand patient experience with using NeuroScreen, five HIV+ participants who had completed an assessment were interviewed.

RESULTS: From the Technology Use Questionnaire, 73% (N=101) of the participants had never used a tablet before. However 96% (N=133) of those participants found the Neuroscreen easy to use and interact with. The NeuroScreen was found to be acceptable because it provides simple instructions and the tasks are entertaining to the participants. Participants enjoyed the interactive nature of the tasks and the ability to be in control of the assessment. Using the Neuroscreen was also perceived as a means of improving mental capabilities that would aid in antiretroviral therapy adherence. The counsellors found the NeuroScreen feasible to use due to the short duration of tasks and it's automated scoring.

CONCLUSIONS: Technology based evaluations for NCI are feasible and acceptable in Zimbabwe. Participants viewed the assessment as empowering because they are in control when using the NeuroScreen on an android tablet. Routine assessment of NCI in adults attending primary care clinics using technology based evaluations is therefore possible in this setting. This is key in identifying people with NCI and providing the necessary interventions.

PED0835

ALCOHOL USE ASSOCIATED WITH LOWER CD4 COUNTS AMONG HIV-INFECTED WOMEN IN RUSSIA

A. Capasso[1], P. Safonova[2], J. Sales[3], J. Brown[4], N. Belyakov[2], V. Rassokhin[2], R. DiClemente[1]
[1]New York University, School of Global Public Health, New York, United States, [2]First Saint Petersburg State Pavlov Medical University, Saint Petersburg, Russian Federation, [3]Emory University, Atlanta, United States, [4]University of Cincinnati, Cincinnati, United States

BACKGROUND: In 2014, almost one million people lived with HIV in Russia, with women comprising an increasing proportion of infections. WHO estimates that 5.8% of Russian women are heavy episodic drinkers and 2.6% have an alcohol use disorder. Alcohol use has been associated with decreased antiretroviral (ARV) adherence. In spite of the alcohol and HIV epidemics among Russian women, this population remains understudied. We examined the association of problematic alcohol use with ARV adherence among 250 HIV-infected women, aged 19-35, in St. Petersburg, Russia.

METHODS: Data from participants were collected at baseline via ACASI and medical records review. Problematic alcohol use was measured by the Alcohol Use Disorders Identification Test (AUDIT) with scores summed and dichotomized (Yes ≥8; No 8<). ARV adherence measures included:

1) forgetting to take 1+ ARV in past 7 days;
2) adjusting ARV regime;
3) ARV self-efficacy;
4) perceived benefits of adherence;
5) ARV side-effects and
6) ARV expectancies.

We also tested the association of problematic alcohol use with HIV symptomatology and CD4 count (CD4 count > 325 copies/μL=0; CD4 count ≤ 325 copies/μL=1). Chi-square and t-test analyses examined associations of adherence and health outcomes with alcohol use. Covariate adjusted logistic regression models were performed for each of the ARV adherence outcomes and CD4 count.

RESULTS: Young women with problem drinking behaviors were more likely than those who did not to forget taking ARV medication [Adjusted Odds Ratio (AOR)=6.8, 95% CI=1.5-8.4) and to adjust their medication regime (AOR=1.8, 95% CI 1.2-2.7). Women with problematic drinking also had more burdensome HIV-related symptoms than those without (AOR=1.03, 95% CI=1.0-1.1) and had lower CD4 counts (AOR=2.6, 95% CI=1.0-6.8). No significant differences were found with respect to ARV self-efficacy, ARV expectancies, perceived benefits of adherence, and ARV side effects.

CONCLUSIONS: Problematic drinking was associated with lower ARV medication adherence and CD4 counts, and more HIV-related symptoms. In addition to routine screening and referral for problematic alcohol use, findings underscore the need to develop and deliver alcohol treatment services in HIV care settings in Russia that are acceptable and feasible for HIV-infected women.

PED0836

IMPACT OF PHYSICAL ACTIVITY ON HEALTH OUTCOMES IN PLWH IN CENTRAL AMERICA

L. Larson[1], H. Marroquin[2], D. Ortiz[2], K. Franco[2], A. Spec[1], R. Pinzon[2], J. Melendez[2], C. Mejia-Chew[1], J. Samayoa[2], J. O'Halloran[1]
[1]Washington University in St. Louis, Department of Medicine, Division of Infectious Disease, St. Louis, United States, [2]Unidad de la Atencion Integral de WIH e Infecciones Cronicas del Hospital Roosevelt, Guatemala City, Guatemala

BACKGROUND: Exercise is a strong component of treatment and prevention regimens for hypertension, diabetes, and obesity, and is recommended by the CDC and WHO to promote general health and wellbeing. Data on the positive impacts of exercise is sparse for people living with HIV (PLWH) in Central America. Here we examine the association of exercise with hypertension, diabetes, and obesity in a cohort of PLWH in Guatemala.

METHODS: We performed an analysis of baseline data from PLWH enrolled in a prospective cohort based at a large HIV clinic in Guatemala City between July and December 2019. Demographics, clinical and anthropometric data were collected through interviews and chart review. Total physical activity was determined by summing weekly minutes of moderate and intense physical activity related to work, transportation, and recreational activities. Physical activity groups were defined based on WHO guidelines. Baseline characteristics were compared between groups using chi-squared analysis. Variables with p <0.2 were included in the binary logistic regression models built for each outcome of interest.

RESULTS: Of the 709 PLWH, 402 (56%) were male, and 322 (45.4%) were 40 years of age or older. 37.9% of the cohort reported more than primary education, and a majority (86.3%) reported non-indigenous ethnicity. In total, 112 patients (15.8%) were obese, 63 (8.9%) had hypertension, and 38 (5.4%) had diabetes. In logistic modeling, after adjusting for age and gender, exercise was associated with decreased risk of hypertension (OR=0.46, 95% CI 0.28, 0.78 p =0.003). Physical activity was not associated with outcomes of obesity or diabetes. Age and gender were stronger predictors for these outcomes.

	Active N=437 N(%)	Sedentary N=272 N(%)	OR (95% CI)	p-value
Age ≥ 40 years	131 (30.0%)	191 (70.2%)	0.824 (.608-1.12)	0.212
Male	286 (65.4%)	116 (42.6%)	0.398(.291-.543)	<0.001
Ethnicity (not indigenous)	376 (86.0%)	236 (86.8%)	0.862 (.548-1.36)	0.521
High school education	173 (39.6%)	96 (35.3%)	1.178 (.858-1.617)	0.312
Body mass index >30	67 (15.3%)	45 (16.5%)	0.897 (.594-1.356)	0.607
Current tobacco use	58 (13.3%)	26 (9.6%)	1.448 (0.887-2.363)	0.137
Hypertension	28 (6.4%)	35 (12.9%)	0.464 (0.275-0.781)	0.003
Diabetes	22 (5.0%)	16 (5.9%)	0.848 (0.437-1.645)	0.626

[Table 1: Baseline demographics by exercise group]

CONCLUSIONS: An active lifestyle was associated with lower risk of hypertension but not diabetes or obesity in this cohort. Further analysis is required to determine what other traditional risk factors or HIV related parameters are influencing these outcomes within the cohort.

PED0837

ASSOCIATION OF CONCURRENT DEPRESSION, ANXIETY AND POSTTRAUMATIC STRESS DISORDER WITH HEALTHCARE UTILIZATION AMONG PEOPLE LIVING WITH HIV/AIDS IN FLORIDA

X. Zhang[1], Y. Xu[2], Z. Zhou[3], X. Chen[3], R.L. Cook[3], R.F. Oman[1], T.A. Larson[1]
[1]University of Nevada, School of Community Health Sciences, Reno, United States, [2]Duke University, Department of Psychiatry and Behavioral Sciences, Durham, United States, [3]University of Florida, Department of Epidemiology, Gainesville, United States

BACKGROUND: Little is known about the prevalence and risk of concurrent depression, anxiety and posttraumatic stress disorder (PTSD) on healthcare utilization among people living with HIV/AIDS (PLWHA). This study investigated the relationships between these concurrent conditions and HIV clinic visits, overnight hospitalization and emergency/urgent care visits among PLWHA.

METHODS: PLWHA who were 18 years or older in Florida participated in the study from 2014 to 2018. We measured current depression, anxiety and PTSD using the Patient Health Questionnaire (PHQ-8), Generalized Anxiety Disorder scale (GAD-7) and Primary Care PTSD Screen (PC-PTSD), respectively. Participants' HIV clinic visits, overnight hospitalization and emergency/urgent care visits in the past 6 months were collected through survey methods. We used dichotomous variables for missed HIV visits (yes, no), number of overnight hospitalization (0-1, >=2), and number of emergency/urgent care visits (0-1, >=2). We stratified the sample by the number of concurrent depression, anxiety and PTSD and investigated the associations with missed HIV clinic visits, overnight hospitalization and emergency/urgent care visits.

RESULTS: Among 876 participants, 134 (15.3%) had one condition, 130 (14.8%) had two and 142 (16.2%) had all three of depression, anxiety and PTSD. Participants with any one condition showed higher proportions of missed visits, having 2 or more overnight hospitalization and having 2 or more emergency/urgent care visits in the past 6 months. Participants having any one of the three conditions showed significantly worse service utilization outcomes than par-

ticipants having none of them. There is no significant difference in terms of service utilization outcomes between participants who had 1 to 3 mental health conditions. Participants with all three conditions showed the highest odds of missed HIV visits (AOR 2.16, 95% CI 1.34-3.49), having 2 or more overnight hospitalization (AOR 2.85, 95% CI 1.69-4.81), and having 2 or more emergency/urgent care visits (AOR 2.53, 95% CI 1.59-4.04) compared to participants with none of them.
CONCLUSIONS: The study underscores the importance of mental health services in the screening and treatment of PLWHA. People with mental disorders may need additional support and care to improve HIV care, utilization of services and outcomes.

PED0838

EXPERIENCES OF RACISM, HOMOPHOBIA, AND STIGMA IN HEALTHCARE SETTINGS AND MEDICATION ADHERENCE AMONG BLACK SEXUAL MINORITY MEN LIVING WITH HIV IN LOS ANGELES COUNTY, CALIFORNIA

I.W. Holloway[1], A.M. Ochoa[1], G. Ruballos[1], E.S. Wu[1], M. Hearns[1], G. Victorianne[1], C.C. Paneda[1], G. Garth[2], T. Smith[3], N. Milburn[4]
[1]University of California, Social Welfare, Los Angeles, United States, [2]AMAAD Institute, Los Angeles, United States, [3]APLA Health, Los Angeles, United States, [4]University of California, UCLA Semel Institute, Los Angeles, United States

BACKGROUND: Black, sexual minority men (BSMM) are disproportionately impacted by HIV. Among those living with HIV, medication adherence is a key target of individual-level treatment and population-level HIV prevention. However, BSMM face numerous structural barriers to healthcare engagement, which impact their ability to maintain treatment adherence. We studied structural barriers to HIV medication adherence, including experiences of racism, homophobia, and HIV stigma in healthcare settings.
METHODS: BSMM living with HIV in Los Angeles County, California were recruited via social media and social service organizations (N=115) for an intervention study and completed a baseline survey online that included a previously validated measure of HIV medication adherence. We examined the association between HIV medication adherence and a range of structural barriers, including poverty, housing instability, criminal justice involvement and experiences of racism, homophobia, and HIV stigma in healthcare settings using multivariable logistic regression analysis.
RESULTS: Fifty-eight percent of participants reported living below the federal poverty line; 48% experienced housing instability in the past year; 39% had been involved with the criminal justice system in the past 5 years; and only 7% were employed full-time. Despite these challenges, 98% had been to an HIV medical appointment at least once in the past year; 93% report taking their prescribed medications, and 86% got tested for STIs at least once every 6 months. In multivariable analysis, those with access to healthcare were twice as likely to report excellent HIV medication adherence (aOR=1.95). Experiencing racism in healthcare settings was negatively associated with HIV medication adherence, such that a 1-point increase in experiences of racism was associated with a 40% decrease in the likelihood of excellent HIV medication adherence (aOR=0.60).
CONCLUSIONS: BSMM in our sample reported high levels of HIV medication adherence despite numerous structural barriers to health (e.g., housing instability, criminal justice involvement). After controlling for important structural barriers, experiences of racism in healthcare settings remained negatively associated with HIV medication adherence. To achieve goals of ending the HIV epidemic, policies that go beyond prohibiting discrimination in healthcare settings and seek to shift provider-level practices, including specific interventions to reduce racism in healthcare settings, are warranted.

PAIN MANAGEMENT AND PALLIATIVE CARE

PED0839

PREDICTORS OF THE PYSCHONEUROLOGICAL SYMPTOM CLUSTER IN PEOPLE LIVING WITH HIV

J. Zuniga[1], D.E. Jang[1], A. Garcia[1]
[1]The University of Texas at Austin, School of Nursing, Austin, United States

BACKGROUND: Approximately 70% of persons living with HIV (PLWH) report daily symptoms including, even when their HIV is well controlled, which can negatively impact their quality of life and work life productivity. Symptom prevalence is associated with medication regimen, disease progression, chronic inflammation and immune activation. Symptoms often occur in clusters or patterns because symptoms are highly correlated with each other and they rarely occur alone. The psychoneurological cluster includes depressive symptoms, anxiety, fatigue, sleep disturbance and pain. The purpose of this study is to investigate the predictors of this cluster in order to better address the negative impact and build a foundation for intervention.
METHODS: For this descriptive correlational study we used a de-identified secondary dataset created by the Center for AIDS Research (CFAR) Network of Clinic Systems (CNIS) which includes 8 clinics from around the country. We examined six patient-centered variables and demographics (age, gender, and race/ethnicity, diabetes diagnosis) in the CNICS dataset: the; Alcohol Use Disorder Identification Test (AUDIT) for alcohol use; Lipid Research Center Questionnaire (LRCQ) for physical activity; Adult AIDS Clinical Trials Group (AACTG) for HIV medication adherence; and EuroQol (EQ5D) for QOL. For the outcome variables of psychoneurological cluster, we selected specific symptoms from the HIV Symptom Index. We used logistic regression to examine the predictors of psychoneurological cluster.
RESULTS: Of the 3,131 PLWH included in this study, 12% (389) experienced the psychoneurologic symptom cluster. The logistic regression model explains 11.8% to 20.8% of the variance in having a psychoneurological cluster and correctly classified 85.1% of cases. Medication adherence, QOL, Opioid use, and race/ethnicity influenced the psychoneurological cluster among PLWH. When controlling for other predictors, as medication adherence, QOL, opioid use, or race (reference: white) increases by 1 point, the odds of having psychoneurological cluster increase by 0.995, 0.53, 3.39, and 0.65(black)/0.72 (Latino) respectively. The comorbid condition of diabetes was not a significant predictive.
CONCLUSIONS: The psychoneurological cluster is a group of highly burdensome symptoms for PLWH. These symptoms may be side effects of treatment. However there are differences between race/ethnicity groups. This may speak to differences in symptom expression, or in symptom treatment. Further research is needed.

PED0840

LOOKING GOOD, FEELING BAD: THE IMPACT OF SPIRITUAL CARE ON CLINICAL OUTCOMES OF PEOPLE LIVING WITH HIV IN A PRIMARY HEALTH CENTRE IN COASTAL KENYA

A. Shamsudin[1,2], I. Fauz[3], S. Yonge[1], B. Opiyo[1], R.U. Yusuf[1], H. El-Busaidy[4], M. Kerich[2], A. Omar[3]
[1]Technical University of Mombasa, Mombasa, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology, Mombasa, Kenya, [3]County Government of Kilifi, Kilifi, Kenya, [4]County Government of Kwale, Health, Kwale, Kenya

BACKGROUND: HIV infected individuals may appear physically healthy but may be suffering from significant spiritual pain which impacts on their clinical outcomes and ultimately affects their quality of life. Spiritual pain may manifest as feelings of guilt, anger, worthlessness, hopelessness, helplessness or condemnation. Total pain management addresses the spiritual pain of patients as they cope with chronic diseases. Not many researchers have investigated the relationship between spiritual care and clinical outcomes in Kenya. The aim of this intervention was to offer spiritual care as an integral component of palliative care for people living with HIV (PLWH).
DESCRIPTION: The intervention was implemented in a primary health center in Coastal Kenya. The HIV clinic staff observed that their patients' spiritual pain was largely ignored. In addition, the HIV clinic registered low enrolments of newly diagnosed HIV infected patients and a high defaulter rate among currently registered patients. The clinic staff was trained to use a standardised spiritual assessment tool to screen patients for spiritual distress at the initial visit as part of the social history and at follow-up visits as appropriate. Patients who screened positive were offered targeted spiritual support by trained spiritual counsellors. Monthly debriefing and review meetings were held with the clinic staff to review progress. Patient enrolment, defaulter tracing, uptake of Isoniazid Preventive Therapy (IPT), viral load suppression and adherence to clinic appointment date were monitored on a monthly basis.
LESSONS LEARNED: This intervention offered an opportunity to uncover patients' coping mechanisms and support systems which are important in formulating holistic individualized treatment plans. Over a period of one year, the following improvements were noted:
1. 37% increase in new enrolments of PLWH
2. 80 out of 117 defaulters returned to the clinic (68%)
3. IPT uptake improved from 11% to 79%
4. Viral load suppression improved from 71% to 84%
5. Adherence to clinic appointment dates improved from 67% to 98%

CONCLUSIONS/NEXT STEPS: Spiritual care ought to be considered as an important component for every patient's holistic well-being. Addressing spiritual pain and distress in PLWH might be a cost effective intervention in improving the outcomes of HIV care and treatment programs.

PEER SUPPORT: LESSONS LEARNED, ACCESS TO SERVICES AND HEALTH OUTCOMES

PED0841

PROJECT 100: EVALUATING THE IMPACT OF A UK NATIONAL PEER-SUPPORT PROGRAMME ON ADULT PEER-MENTORS LIVING WITH HIV AND PARTNER AGENCIES

G. Brough[1], S. Fraser[1], D. Hamadache[2]
[1]Positively UK, London, United Kingdom, [2]Independent HIV Consultant, London, United Kingdom

BACKGROUND: Peer-support helps people living with HIV improve their well-being and clinical outcomes. We aimed to evaluate how a 4-year national peer-support programme impacted the health and well-being of volunteer peer-mentors and identify the barriers and facilitators of engagement in offering peer-support services.
DESCRIPTION: Positively UK's 'Project 100' peer-support programme delivered a 3-day standardised peer-mentor training to >700 adults living with HIV between 2015 and 2019, working with >100 clinical and voluntary sector partners. It provided access to accredited qualifications in peer-support and HIV treatment literacy, alongside organisational support, policies and protocols on how best to implement peer support, in line with UK national standards for HIV peer-support, also developed as part of this project (latterly incorporated within the BHIVA Standards of HIV Care).
Our mixed-method independent evaluation included clinic and programmatic questionnaires, an anonymous online survey, focus group discussions (FGDs) and separate semi-structured telephone interviews (TI) to collect qualitative and quantitative data on the experiences and achievements of peer-mentors and partner organisations.
LESSONS LEARNED: Since becoming peer-mentors, >90% of the online survey respondents stated feeling good about themselves, having increased personal strength, confidence in reaching their goals and access to opportunities in life. 87% and 74% reported being better informed and better able to manage their HIV, health and well-being, respectively. 77% were more open about their HIV status and >70% more comfortable seeking help and happier being themselves around most people.
Participants in TI and FGDs also reported increased confidence and self-esteem, improved organisational, communication and mentoring skills, better knowledge and understanding of HIV and the HIV community and improved mental health, describing their experience as "inspirational" "empowering" and "life changing". >93% would recommend peer mentoring as a peer-mentor or a mentee.
Maintaining accountability and ownership over their own volunteers was essential to regional partners with the training bringing structure and consistency to the delivery of peer-support nationally. The main limitations were engaging and getting referrals from HIV clinical services, although some clinics supported their own volunteers where voluntary sector services were unavailable locally.
CONCLUSIONS/NEXT STEPS: Nationally delivered standardised peer-support training resulted in transformative benefits for individuals, services and the HIV sector.

PED0842

KEY DRIVING FACTORS FOR LATE ART INITIATION AND RISKS FOR GETTING LOST FROM HIV-SERVICE ARE IDENTIFIED IN PEER-BASED PSYCHO-SOCIAL STUDY IN ODESSA, UKRAINE

K. Zverkov[1], K. Liezhentsev[1], S. Yesypenko[2]
[1]Era of Mercy, Odessa, Ukraine, [2]Odessa regional Center for Social Diseases, Odessa, Ukraine

BACKGROUND: Ukraine has been scaling up ART since 2004 and is currently covering more than 150 000 patients with ARV treatment that is transferred from GFATM to national and local fundings. However, decades of opened stigma and discrimination in healthcare settings, social marginalization of HIV patients from marginalized groups and remaining verticality of HIV-service resulted in late presenting for ART still in 2019 with median CD4 cell rate below 150 cells. Such situation does not allow to fully benefit from ART access both on individual and community level.Most of "late-breakers" are also not visiting AIDSW-centers since HIV diagnose and presenting on treminal stages - in Odessa region only there are up to 4000 patients in the database that have not been visiting clinic for significant period of time (from1 to 7 years).

METHODS: Our study identified key risk factors for late presenting for treatment and for being lost from HIV-service. Our organization has access to HIV+ people who are withdrawn from HIV service for multiple reasons. We have provided 100 in-depth interviews with respondents that: - just started ART on 3-4 Stage of duisease progression (incl. TB co-infection); - avoiding HIV clinic and reject HIV treatment. All respondents have been randomized by age, social status, education and specific anamnesis features. Quality of Life score has been assessed in all respondents using WHO QOL assessment tool.

RESULTS: We have identified following risk factors: - poor/absence of counselling after HIV test and stigma in AIDS center; - demonization of ART in the community; - being a women is identified as a risk factor for quitting ART. Inprisonment, shift to "stimulant and alcohol" use are driving factors for getting lost. All respondents have shown extremely low QoL index (less than 30 in transformed score).

CONCLUSIONS: Comprehensive analysis and development of psychosocial portraite of "late-presenter" gave us striking picture of multiple factors that lead to failure of effectiev ART utilization. In order to address these scope of problems there is an urgent need to design and implement specific program for "patients with special needs"to address their problems and ensure full benefit from ART and high quality of life.

PED0843

PROMOTING VIRAL LOAD SUPPRESSION AMONG FEMALE SEX WORKERS LIVING WITH HIV IN MALAWI THROUGH COMMUNITY-LED SOLUTIONS: LESSONS FROM LINKAGES PROJECT IN ZOMBA AND MACHINGA DISTRICTS, MALAWI

M. Kaonga Mkandawire[1], D. Chilongozi[2], M. Ruberintwari[2], L. Banda[2], C. Akolo[3]
[1]FHI 360 Malawi Country Office, EpiC, Lilongwe, Malawi, [2]FHI 360, EpiC, Lilongwe, Malawi, [3]FHI 360 HQ, EpiC, Washington DC, United States

BACKGROUND: The 2015-2016 Malawi Population-Based HIV Impact Assessment estimates 62.3% of female sex workers (FSW) in Malawi are HIV positive. Through the USAID/PEPFAR-funded LINKAGES project, FHI 360 supports the country's response to the epidemic by working with volunteer peer educators (PEs) and peer navigators (PNs) from the FSW community to deliver HIV services. We describe the FSW-led strategies the project implemented to facilitate adherence to antiretroviral therapy (ART) among FSWs living with HIV and their impact on viral load outcomes.

METHODS: Between October 2016 to September 2018, LINKAGES established 48 support groups for FSWs living with HIV in 56 clustered hotspots in Machinga and Zomba districts. HIV Positive Key Population selected leaders amongst themselves in each cluster to be trained as Peer Navigators (PNs). PNs are medication-adherent role models living with HIV who are trained to provide HIV services that increase linkage and medication adherence to ART at community level. PN work in collaboration with community ART support group peers to promote positive living, ART adherence, creating demand for viral load (VL) and index testing, nutrition counselling, psychosocial support, screening for tuberculosis and sexually transmitted infections, gender-based violence screening and reporting.

RESULTS: As of September 2018, a total of 923 FSWs living with HIV and on ART were linked to support groups. Of these, 328 FSWs were eligible for VL testing with 265 having their dry blood spot samples collected for VL testing with the support of PNs. Of these 265, 88.8 % (235/265) received their results and 88.9% (233/265), including 29 FSWs who defaulted on ART and were identified by their peers and re-initiated on treatment, were virally suppressed (<1000 copies/ml). During this period, no death was recorded among the HIV-positive cohort.

CONCLUSIONS: Programmes providing care and treatment services for FSWs should consider recruiting and involving PNs to maximize the benefits of ART, especially viral suppression. The involvement of PNs with the collaboration of ART support groups enhance sustained adherence to ART to improve viral load outcomes.

PED0844

SUSTAINING TREATMENT ADHERENCE AND VIRAL SUPPRESSION AMONG HIV POSITIVE WOMEN THROUGH A ROBUST PEER APPROACH

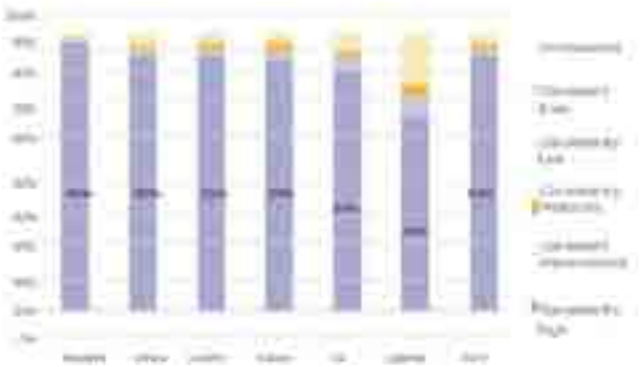
A.M.N. Mbule[1], C. Hofmeyr[1], N. Kwendeni[1], F. Burtt[1], F. Mpungu[1], K. Schmitz[1], E. Scheepers[1]
[1]mothers2mothers, Cape Town, South Africa

BACKGROUND: Supporting clients living with HIV to adhere to their antiretroviral therapy (ART) is necessary to maintain good health and achieving viral suppression. Through peer led Mentor Mother Model, each one-on-one interaction with a client includes conducting an adherence assessment. Clients identified as having poor adherence to ART or un-suppressed viral load are provided with intensified education and enhanced support. The Mentor Mothers actively link eligible clients to a viral load test and assist clients to interpret the viral load result

METHODS: A retrospective cohort analysis was conducted among a sample of 5,372 pregnant women and new mothers who enrolled in the m2m programme between 1 January and 30 June 2016 in Eswatini, Kenya, Lesotho, Malawi, South Africa, and Uganda. The 7-day recall and 5-point adherence behaviour and efficacy scale were used to assess adherence to ART during all interactions with a Mentor Mother from enrolment until the end of 2018.

RESULTS: Measured as the percentage of days in the past week that a client took medication, averaged over multiple measurements, 94% of the multi-country sample had an average adherence rate of >95% (n=5,372). Over 92% of the multi-country sample displayed con-

sistently high levels of remaining adherent to ART, aggregated, only South Africa and Uganda achieved below 90% on this measure. A total of 1470 women had at least one viral load test recorded. Of these women, 92% achieved viral suppression, defined by the World Health Organization as a viral load below 1000 copies/ml.



[Figure. Consistency in maintaining adherence to ART by country in the m2m programme]

CONCLUSIONS: m2m's peer model is effective in supporting adherence to antiretroviral therapy. The available viral load test data indicate that most of m2m's HIV positive clients achieve viral suppression, thereby significantly reducing the risk of morbidity and mortality, greatly contributing to the prevention of HIV transmission from mother to child.

PED0845

BENEFITS OF EMPOWERING PARENTS OF CHILDREN LIVING WITH HIV & AIDS TO OVERCOME STIGMA WITHIN RURAL COMMUNITIES IN UGANDA: LESSONS FROM NYAKAGYEME IN RUKUNGIRI

P.C. Kiruhira[1], P. Namutosi[2], A. Muyama[3], C.C. Wamundu[4]
[1]Alliance for Community Health Initiative, HIV & AIDS, Kampala, Uganda, [2]MILDMAY, Kampala, Uganda, [3]Ministry of Defense Uganda, HIV &AIDS, Kampala, Uganda, [4]Uganda Peoples Defense Forces, Directorate of AIDS, Kampala, Uganda

BACKGROUND: There is overwhelming evidence that early initiation of antiretroviral therapy can lead to positive treatment outcomes. The ministry of health of Uganda introduced the policy test and in 2016. However, about 33% of children living with in Uganda are not on treatment. One of the major reasons is stigma. Alliance for Community Health Initiative is reducing stigma through conducting focused community dialogues.

DESCRIPTION: We formed 12 groups of ten people with five of them people living with HIV. The groups were encouraged to freely discuss about effects of stigma among children with a HIV with a view of finding ways of supporting parents with children living with HIV to access ART. The facilitators helped groups appreciate the benefits of early treatment for children by sharing facts. The discussions were conducted twice a moths for each group for a period of two years. As a result of this intervention, the enrollment of children living with HIV on ART increased from 20% to 70% within Kiyaga Health Centre IV. School attendance rate of children living with HIV increased from 15% to 58% within Nyakagyeme Sub County in Rungiri

LESSONS LEARNED: Providing a forum for members of the community with special needs is like parents with children with HIV & AIDS is critical in improving access to services. Providing convenient timings for the focus groups was very important for ensuring maximum attendance and participation in the focus groups. Best practices from one community can spread to other communities with limited structural support. Above all parents have a big role to play in ensuring access to treatment by children living with HIV and AIDS.

CONCLUSIONS/NEXT STEPS: Parents with children with HIV face a lot of challenges in ensuring that their children access treatment due to high stigma rates within the community. However, with good structured interventions like community focus groups, can help parents overcome such challenges with enormous benefits to both the children and the rest of the community members. The lessons gained will be shared by partners and other communities

PED0846

EXPERIENCES OF USING MENTOR MOTHERS TO INTEGRATE ECD COMPONENTS INTO PMTCT PROGRAMME IN HIGH BURDEN SETTING IN MALAWI

T. Mayani[1]
[1]mothers2mothers, Programmes, Lilongwe, Malawi

BACKGROUND: Malawi was the first country to conceive and implement Option B+ in 2011. The government of Malawi launched a 2018-23 National Strategic Plan for Integrated Early Childhood Development (ECD), but the emphasis has been on children who are over 3 years old and attending Community Based Child Care Centres. There has been a gap in advocacy to ensure that the 0-3 age group receives the necessary stimulation and proper support for development. Prevention of mother-to-child transmission of HIV (PMTCT) programmes present an opportunity for motivating mothers to stimulate children for healthy milestone development. Yet, there is limited evidence on the impact of ECD interventions in Malawi in relation to PMTCT programming. [111]

DESCRIPTION: In 2018, mothers2mothers (m2m) launched a programme integrating ECD and nurturing care support into its PMTCT programme at facility and community levels. Mentor Mothers are employed in the facility and in the community to ensure linkage of clients (pregnant and lactating women) between facility and community for close follow up and retention in care, at the same time supporting and tracking parents' care for and stimulation of infants through regular interactions and assessment of developmental milestones. Upon testing HIV positive, clients are registered by the facility Mentor Mothers using a customized mHealth application, and then linked to Community Mentor Mothers for regular household visits. [103]

LESSONS LEARNED: In the period between September 2018 to August 2019. 2,049 children, both HIV positive and negative, were assessed on their developmental milestones, 441 at 3 months, 419 at 6 months, 377 at 9 months, 433 at 12 months, 233 at 18 months, 121 at 24 months and 15 at 36 months. Children on track for their developmental milestones included 86% of the children at 3 months, 83% at 6 months, 82% at 9 months, 90% at 12 months, 75% at 18 months, 92% at 24 months, and 65% at 36 months. [109]

CONCLUSIONS/NEXT STEPS: The findings were encouraging, suggesting that mothers appear to be learning new skills in stimulating HIV-exposed infants which lead to positive attainment of appropriate developmental milestones. [26]

PED0847

SEGMENTED WHATSAPP HIV SUPPORT GROUPS FOR KPS IN CENTRAL AMERICA

J. Rivas[1], B. Palma[2], S. Lungo[3]
[1]Universidad Rafael Landivar, Public Health, Guatemala, Guatemala, [2]Universidad de San Carlos de Guatemala, Psychology, Guatemala, Guatemala, [3]Universidad Rafael Landivar, Marketing, Guatemala, Guatemala

BACKGROUND: Once patients have received a positive diagnose for HIV the main challenges are to overcome personal and environmental barriers to remain adherent. The life expectancy of a person living with HIV increases significantly when they are in treatment and constant support. Support groups are an important tool to maintain linkage and adherence to treatment but the main barrier is having the time and space to conduct sessions periodically. Social networks are now an indispensable communication tool in any area of our life, allowing us to take advantage of immediate connectivity by reducing the time and distance gaps to communicate. WhatsApp offers ease, speed and versatility to be used from friendship to business purposes.

DESCRIPTION: In 2018, the Pan-American Social Marketing Organization (PASMO), through the USAID-funded Combined Prevention program started a WhatsApp support group strategy. Segmented by age, interests and time elapsed since diagnosis, groups of 6 to 10 participants were structured, to share information, answer common questions and to meet once a week. It also includes comprehensive care staff moderators (doctors, psychologists, nutritionists), to generate more interest from the participants.

LESSONS LEARNED: Promoted at integral care clinics, among users of the Program and in social networks through Facebook advertising, 22 groups of different profiles of men who have sex with men, women, newly diagnosed people, people with adherence problems and even participants from countries outside the region were created.

On average, 16 sessions were held per group to cover the structured curricula of the program and also include their needs, doubts and objectives set by the group. Three of each four member groups successfully completed the process and established long-term support and communication links.

CONCLUSIONS/NEXT STEPS: The WhatsApp support group strategy has allowed HIV positive people to have holystic support from a simple, safe and accessible tool that contributes to adherence when carrying out specific interventions and strengthen support networks by eliminating the gaps related to time and distance.

The next step is to use the Whatsapp strategy to contact HIV partners (index testing) for notification, referrals and HIV testings.

PED0848

CASA LA RED, UN ESPACIO SALUDABLE - CENTRO CULTURAL- (CAFE TEMATICO. BIBLIOTECA. CENTRO DE TESTEO. ACONDICIONAMIENTO FISICO)

F.M. Parodidi[1]
[1]Red de Personas con VIH/SIDA Mar del Plata, Ejecutivo, Mar del Plata, Argentina

BACKGROUND: "House the net" Es un espacio saludable, libre de estigma y discriminación, pensado, desarrollado y ejecutado por personas que viven con el VIH, con el objetivo de contenernos, desarrollar y generar políticas de cambio a nivel local, nacional e internacional.

DESCRIPTION: Casa de la red. Es un proyecto que comenzó en 2005 cuando la Red se toma para recuperar y llevar a cabo sus actividades, una antigua casa de 115 años en el centro histórico de la ciudad de Mar del Plata, que busca generar un lugar libre de estigma y discriminación donde Contenernos y organizarnos para luchar por los derechos humanos de las personas con VIH, acceso a la salud, trabajo, vivienda, alimentación saludable, acceso a terapias complementarias, tener la mejor calidad de vida posible y poder mostrar el rostro positivo de las personas con VIH .

LESSONS LEARNED: Hemos aprendido que somos los más interesados en generar políticas de apoyo y cuidado para las personas con vih / sida, generando espacios para desarrollar y mostrar el rostro positivo de las personas con vih, favoreciendo disminuir más rápidamente el estigma y la discriminación asociada al vih y Mejorar Nuestra Calidad de Vida.

Para este, hemos creado un centro de asesoramiento integral, con confirmación de confianza rápida y gratuita, con asesoramiento previo y posterior a la prueba, apoyo y seguimiento a aquellos que dan positivo hasta que se inserta en el sistema de salud. donde las personas pueden acceder y socializar en el café, restauran la temática de las comidas saludables, que funcionan en el comedor y el parque de la casa, rodeadas de murales y controles en un marco de cordialidad, donde se aconseja a las personas sobre alimentos específicamente y aceite de cannabis. Una terapia complementaria a los antirretrovirales y la disminución de la polifarmacia. Los asistentes pueden asistir y participar en el cultivo y procesamiento del aceite de cannabis.

CONCLUSIONS/NEXT STEPS: Hemos logrado un lugar único en la ciudad, una referencia para todas las personas con VIH y la sociedad en general, donde puede desarrollar habilidades, generar debates, cambiar políticas y desarrollar modelos más allá de los vigentes en atención, asesoramiento y apoyo.

POSITIVE HEALTH, DIGNITY, PSYCHOLOGICAL WELL-BEING AND MENTAL HEALTH

PED0849

FACTORS ASSOCIATED WITH RESILIENCE AMONG OLDER PEOPLE LIVING WITH HIV

J. Berko[1], P. Mazonson[1], T. Loo[1], P. Grant[2], A. Zolopa[2,3], F. Spinelli[3], D. Short[3]
[1]Mazonson & Santas, Inc., Larkspur, United States, [2]Stanford University, Palo Alto, United States, [3]ViiV Healthcare, Raleigh, United States

BACKGROUND: Resilience, the ability to bounce back from stressful circumstances, may be important in helping older people (age 50+) living with HIV (PLWH) age successfully, but limited data exist regarding factors that contribute to resilience.

METHODS: Data were utilized from the Aging with Dignity, Health, Optimism and Community (ADHOC) cohort, an observational study that collects patient-reported outcomes (PROs) on socioeconomic, psychosocial, and health factors among older PLWH from ten clinics across the U.S. Resilience was measured using the Connor-Davidson Resilience Scale 2 (CD-RISC), a validated instrument where higher scores indicate greater resilience. Bivariate analyses were performed to determine the associations between resilience and PROs. Factors significantly associated with resilience at the $p<0.2$ level were then included in a multivariate model.

RESULTS: Of 1,051 participants, 896 (86%) were male and the mean age was 59 years (SD 6.1 years). Scores on the CD-RISC ranged from 0-8, with a mean of 6.35 (SD 1.49). Factors positively associated with resilience in bivariate analyses (p<0.05) included age, education level, current employment, income, being married or in a long-term relationship, number of close family and friends, and social support. Factors negatively associated with resilience (p<0.05) included internalized stigma, depression and anxiety. Years since HIV diagnosis, being male, and being gay were positively associated with resilience at the p<0.2 level. In the linear regression model, current employment and higher levels of social support were associated with greater resilience (p<0.05), whereas depression and anxiety were associated with lower resilience (Table 1). Higher income was marginally associated with greater resilience (p = 0.06).

Characteristic	β	(SE β)	p-value
Currently employed	0.22	0.10	0.03
Income level	0.04	0.03	0.06
Interpersonal support	0.37	0.09	< 0.01
Depression score	-0.13	0.04	< 0.01
Anxiety score	-0.18	0.04	< 0.01
Adjusted R^2=0.25, F = 23.63, p<0.001			

[Table 1: Multivariable regression results for factors significantly associated with resilience among older PLWH.]

CONCLUSIONS: To increase resilience, some factors identified in this study (e.g., employment and socioeconomic status) require community-wide interventions, while other factors (e.g., depression and anxiety) are treatable by medical providers. All of these factors represent targets for interventions to increase resilience among older PLWH.

PED0850

EFFECT MEASURE MODIFICATION OF SOCIAL SUPPORT IN THE ASSOCIATION BETWEEN HAZARDOUS DRINKING AND DEPRESSION SYMPTOMS AMONG ART CLIENTS IN VIETNAM

M. Nguyen[1], D. Dowdy[2], C. Latkin[3], H. Hutton[4], G. Chander[2], C. Frangakis[5], K. Lancaster[6], T. Sripaipan[1], Q. Bui[1], H. Tran[1], V. Go[1]
[1]Gillings School of Global Public Health, University of North Carolina, Health Behavior, Chapel Hill, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [4]Johns Hopkins Bloomberg School of Medicine, Psychiatry and Behavioral Sciences, Baltimore, United States, [5]Johns Hopkins Bloomberg School of Public Health, Biostatistics, Baltimore, United States, [6]College of Public Health, Ohio State University, Epidemiology, Columbus, United States

BACKGROUND: In Vietnam, hazardous drinking is a widespread behavior among people living with HIV (PWH), and this population is also vulnerable to depression due to social stigma and discrimination. Research on the association between hazardous drinking and depression symptoms among PWH in Vietnam remains scarce, and no studies have explored how social support changes this association. This study aims to evaluate the association between hazardous drinking and depression symptoms among PWH in Thai Nguyen, Vietnam and to examine the role of social support as an effect modifier in this association.

METHODS: This is a secondary analysis using baseline data from a three-arm randomized controlled trial of two interventions aiming to reduce alcohol use among hazardous drinking HIV-positive ART clinic patients in Thai Nguyen, Vietnam. The screening survey administered to determine enrollment eligibility was used for the analysis. A score of 8 or more on the Alcohol Use Disorders Identification Test (AUDIT) and a score of 5 or more on the Patient Health Questionnaire-9 indicated hazardous drinking and having depression symptoms, respectively. Social support was measured with a 5-question version of the Medical Outcomes Study Social Support Instrument. Crude and adjusted prevalence ratios (cPRs; aPRs) of the association between hazardous drinking and depression symptoms stratified by level social support were calculated.

RESULTS: More than a quarter of participants had symptoms indicative of depression (26.2%), and the prevalence of hazardous alcohol use was 38.3%. Overall, hazardous drinking was significantly associated with increased likelihood of having depression symptoms (cPR=1.19 (95% CI 1.00-1.43); aPR=1.25 (95%CI 1.04-1.51)). Social support was a significant effect modifier: Hazardous drinking and depression symptoms were not associated among those with high social support (aPR=0.99; 95%CI 0.74-1.33), but were associated among those with medium (aPR=1.24; 95%CI 0.92-1.69) and low social support (aPR=1.71; 95%CI 1.25-2.35).

CONCLUSIONS: The associations between hazardous drinking and depression symptoms among PWH in Vietnam differed significantly depending on level of social support. Future interventions for hazardous drinking PWH in Vietnam and in other low-resource settings focus on the most vulnerable group of PWH with low levels of social support and incorporate components of social support from family, friends or peers of PWH.

PED0851

POSITIVELY SPEAKING - A PODCAST EXPLORING THE EXPERIENCES OF PEOPLE LIVING WITH HIV/AIDS

L. Creal[1], A. Crawford[1], A.L. Ceranto[1]
[1]Casey House Hospital, Toronto, Canada

BACKGROUND: Casey House is Canada's first and only stand-alone hospital for people with HIV/AIDS providing inpatient and outpatient programs to people with complex physical and psychosocial challenges. Positively Speaking, a 6-episode podcast, was created to build trust within a healthcare environment and give voice to peoples' lived experience. The project offered an avenue to engage the broader community and challenge stigma through the power of narrative and the reach of the podcast medium.

DESCRIPTION: The concept, topics and content of this podcast project were client driven, based on the principles of GIPA/MEPA. Thirty-Four clients participated in the project through: engagement sessions, advisory committee meetings and collaborative tools such as dotmotcracy. The development and production of season one started in September 2018, culminating in a launch and appreciation event in November 2019, with the first episode going online in December 2019. The topics chosen by clients were long-term survivors, relationships, mental health, housing, isolation and living positively with HIV.

The podcast was supported by Casey House Hospital and Foundation and developed by three staff: peer manager, volunteer manager and a social worker. Production was by the RTA School of Media at Ryerson University.

LESSONS LEARNED: Clients who participated reported a greater sense of purpose and engagement. Hospital staff and community identified the podcast as an important teaching tool to challenge

stereotypes within healthcare. Broadcast quality podcasts can be produced in a community setting, offering multiple benefits for participants. However, high-quality productions are time intensive and require dedicated staff and professional support. Clients benefited from practice sessions and were more comfortable being interviewed by someone, and in a place, that was familiar.

CONCLUSIONS/NEXT STEPS: The podcast project strengthened the connection between clients and the hospital. Our clients appreciated, and were empowered by, the opportunity to share their stories and some saw it as their legacy to future generations. Casey House unconditionally supported this initiative as a client engagement tool and will continue to do so with the development of future seasons by providing greater resources and dedicated staff time, continued partnership with media experts, and an integrated evaluation strategy.

PED0852

MENTAL HEALTH PROBLEMS IMPACT ADHERENCE MORE IN MALE THAN FEMALE ADOLESCENTS WITH HIV IN MOZAMBIQUE

N. Nguyen[1], C.A. Mellins[1], J. Falcao[2], K. Brittain[3], A. Zerbe[2], I. Wilson[4], B. Kapogiannis[5], E.J. Abrams[2]

[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, New York, United States, [2]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [3]Division of Epidemiology & Biostatistics, School of Public Health & Family Medicine, University of Cape Town, Cape Town, South Africa, [4]Brown University School of Public Health, Department of Health Services, Policy and Practice, Providence, United States, [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States

BACKGROUND: Despite the importance of mental health (MH) for HIV health outcomes and the growing numbers of adolescents living with HIV (ALHIV) globally who are at risk for poor outcomes, few studies have examined the MH needs of this population and gender differences in low resource contexts.

METHODS: Using data from a survey conducted with 208 ALHIV, ages 15-19 living in Nampula, Mozambique, we examined the relationship between MH and ART adherence. Participants were screened for anxiety (GAD-7), depression (PHQ-9), and trauma and PTSD symptoms (CPSS-V). Self-reported ART adherence was measured using a validated scale (Wilson, 2016); suboptimal adherence was defined as <90%. Differences in anxiety, depression, and adherence by gender were each assessed using chi-squared tests; differences in mean number of traumas and PTSD symptoms were each assessed using t-tests. The association between MH outcomes and adherence<90% was estimated using logistic regression, controlling for age and allowing for interaction by gender.

RESULTS: Relatively few screened positive for depression (12%) or anxiety (12%). Participants reported many traumatic events (mean: 11), with limited PTSD symptoms. Nearly half (44%) reported adherence between 80-90%, though only 35% reported adherence ≥90% and 46% missed ≥1 dose in the past month. There were no gender differences in MH or ART adherence but the association of MH with adherence was greater for males compared to females. Among males, higher anxiety (odds ratio [OR]=1.32, 95% confidence interval [CI]: 1.07-1.62), depression (OR=1.27, 95% CI: 1.05-1.54), trauma (OR=1.11, 95% CI: 1.02-1.20), and PTSD symptom (OR=1.85 95% CI: 1.17-2.93) scores were all associated with significantly greater odds of adherence<90%; in contrast, MH was not associated with adherence among females (Table).

	Odds ratios (OR) and 95% confidence intervals (CI) for the association between mental health and self-reported adherence <90%		
	Overall (controlling for age and sex)	Males (controlling for age)	Females (controlling for age)
Anxiety (assessed using the GAD-7, modeled as a continuous variable)	1.11 (1.01, 1.21)	1.32 (1.07, 1.62)	1.05 (0.95, 1.16)
Depression (assessed using the PHQ-9 modified for adolescents, modeled as a continuous variable)	1.13 (1.04, 1.22)	1.27 (1.05, 1.54)	1.08 (0.99, 1.19)
Trauma (assessed using the CPSS-V, trauma and PTSD symptoms, modeled as continuous variables)	1.03 (1.00, 1.07)	1.11 (1.02, 1.20)	1.00 (0.97, 1.04)
PTSD symptoms (assessed using the CPSS-V, trauma and PTSD symptoms, modeled as continuous variables)	1.24 (1.00, 1.54)	1.85 (1.17, 2.93)	0.97 (0.75, 1.26)

[Table.]

CONCLUSIONS: Despite growing up with significant adversity, including a highly stigmatized illness, these ALHIV demonstrated resilience, with relatively few screening positive for MH challenges. However, MH was a significant barrier to high ART adherence among young men, highlighting the urgent need for tailored mental health interventions for this vulnerable population.

PED0853

COUNTERING THE NARRATIVE: EXPLORING THE RELATIONSHIP BETWEEN WELLNESS AND RESILIENCE WITHIN BLACK MEN WHO HAVE SEX WITH MEN WHO ARE LIVING WITH HIV (BMSM+)

N.J. Heard[1], L. Kimbrough[1]

[1]Roosevelt University, Counseling and Human Services, Chicago, United States

BACKGROUND: In the United States, 1 in 2 men who have sex with men with African ancestry (BMSM) will be diagnosed with HIV in their lifetime; and studies suggest that resilience serves as a protective factor against the transmission of HIV. Still little is known about the role of resilience among BMSM already living with HIV (BMSM+), especially in the context of overall wellness. The aim of this study was to examine if measured resilience could predict wellness, a holistic psychological measurement of well-being.

METHODS: A descriptive, correlational research design was used to analyze the association between resilience and wellness (using a multi-dimensional assessment) within a nationally represented sample (N = 249). Multi-factor ANOVAs were run as post-hoc analyses to examine how resilience and wellness varied given demographic variables.

RESULTS: Descriptive statistics indicated that BMSM+ have lower levels of resilience, and similar overall wellness when compared to the assessments' norming samples. Though, BMSM+ statistically significantly differ in the dimensions of physical, social, and spiritual wellness. This study established that resilience predicts wellness in BMSM+, where for every one-point increase in resilience there would be a .49 increase in wellness.

Furthermore, there were significant differences in resilience and wellness given demographic variables. Participants with an undetectable HIV viral load (n = 188) had higher levels of resilience and wellness. Additionally, more formal education was associated with higher levels of resilience and wellness. Participants who: contracted HIV via mother-to-child (n = 8); were very religious (n = 20) or not at all religious (n = 89); or were partnered (n = 52) had lower levels of wellness when compared to their counterparts within the sample.

CONCLUSIONS: These results suggest that care continuum stakeholders missioned with improving the wellness and well-being of BMSM+ should consider including resilience within their interventions. Along with prior research, this study highlighted the complex role of religion in regard to the wellness of BMSM+, necessitating individualized application. Contrary to prior research, in the context of BMSM+ wellness the type of social support matters, where romantic relationships may not be equivalent to other types of social support among BMSM+.

PED0854

MENTAL HEALTH WELL-BEING IS ASSOCIATED WITH HIGHER LEVELS OF ANTIRETROVIRAL DRUG CONCENTRATIONS IN HAIR AMONG A COHORT OF WOMEN LIVING WITH HIV IN THE UNITED STATES

A. Leddy[1], L. Sheria[1], E. Frongillo[2], C. Sykes[3], A. Kashuba[3], T. Wilson[4], A. Adedimeji[5], D. Merenstein[6], P. Bacchetti[1], M. Cohen[7], E. Wentz[8], A. Adimora[3], I. Ofotokun[9], L. Metsch[10], J. Turan[11], B. Tamraz[1], S. Weiser[1]
[1]University of California, San Francisco, United States, [2]University of South Carolina, Columbia, United States, [3]University of North Carolina at Chapel Hill, Chapel Hill, United States, [4]State University of New York Downstate Medical Center, Brooklyn, United States, [5]Albert Einstein College of Medicine, Bronx, United States, [6]Georgetown University Medical Center, Washington, United States, [7]Stroger Hospital, Chicago, United States, [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [9]Emory University School of Medicine, Atlanta, United States, [10]Columbia University, New York, United States, [11]University of Alabama at Birmingham, Birmgingham, United States

BACKGROUND: Mental health status is an established determinant of self-reported antiretroviral therapy (ART) adherence, but limited research has studied this association using objective measures of adherence. We examined the association of a global measure of mental health well-being with ART concentrations in hair, an objective and validated measure of drug adherence and exposure, among women living with HIV (WLHIV) in the United States.

METHODS: We analyzed longitudinal data collected semiannually from 2013 through 2015 from the Women's Interagency HIV Study, a multisite, prospective cohort study of WLHIV and HIV-negative controls. The sample comprised 998 person-visits from 566 WLHIV reporting ART use. We assessed mental health using the validated Medical Outcome Study HIV Health Survey (MOS-HIV) mental health summary scale, which captures mental health domains of health-related quality of life. Scores range from 0-100 with higher scores indicating better mental health. ART concentration in hair was measured using high-performance liquid chromatography with mass spectrometry detection for regimens including darunavir, atazanavir, raltegravir, or dolutegravir. We conducted multivariable three-level linear regressions accounting for repeated measures and the ART medication(s) taken at each visit, adjusting for sociodemographic characteristics (age, race/ethnicity, income, and education) and kidney function.

RESULTS: At baseline, mean age was 48 (standard deviation (SD): 9), and 67% of participants were virally suppressed with a mean of 10 years on ART (SD: 6). The median score of the MOS-HIV mental health summary score was 56 (interquartile range: 49-63). In the multivariable model, each one point higher score in mental health well-being was associated with a 1.12-fold higher ART concentration in hair (95% confidence interval: 1.01, 1.23; p<0.05).

CONCLUSIONS: In a longitudinal study, mental health well-being was associated with higher ART concentrations in hair, suggesting that better mental health is associated with better ART adherence and/or drug absorption. The direction and pathways for this relationship should be examined and interventions seeking to improve ART adherence among WLHIV should consider and address the role of mental health.

PED0855

CLINIC-PSYCHO-BEHAVIORAL DETERMINANTS OF HEALTH RELATED QUALITY OF LIFE AMONG PEOPLE LIVING WITH HIV: THE ROLE OF RESILIENCE

C. Zeng[1], X. Li[1], S. Qiao[1], X. Yang[1], Z. Shen[2], Y. Zhou[2]
[1]University of South Carolina, South Carolina SmartState Center for Healthcare Quality, Columbia, United States, [2]Guangxi CDC, Nanning, China

BACKGROUND: With the availability of antiretroviral therapy (ART), HIV infection has subsequently evolved to a chronic condition. As the life expectancy increases among people living with HIV (PLWH), perceived health-related quality of life (HRQoL) is becoming a prominent and important patient-reported outcome in HIV care. Prior research demonstrated CD4 counts, depression, and ART adherence were the conventional clinic-psycho-behavioral determinants of HRQoL. However, data regarding the role of resilience were limited. Therefore, this study aimed to explore the influence of resilience on HRQoL.

METHODS: Data was derived from a prospective cohort study which was conducted from November 2016 to January 2018 in Guangxi, China. PLWH who were receiving ART were selected as the study sample. Participants were assessed on their socio-demographic characteristics, HRQoL, CD4 counts, depression, ART adherence, and resilience at baseline, 6-month, and 12-month follow-ups. CD4 counts were categorized as <350, 350~500, and ≥500 cells/μl. Hierarchical multiple linear mixed effect models were employed to assess the association of HRQoL with CD4 counts, depression, ART adherence, and resilience with adjusting for the repeated measures and covariates (e.g., socioeconomic status [SES], BMI, age).

RESULTS: Among the 414 participants who were receiving ART, mean values of their HRQoL were 121.1 (±17.6), 121.9 (±15.4), and 105.2 (±14.6) at baseline, 6-month, and 12-month follow-ups, respectively. Hierarchical regression analyses indicated that the proportion of variance explained by the model is 6% (R^2) while adjusting for the repeated measures and covariates. After the conventional clinic-psycho-behavioral determinants of HRQoL were added, the proportion of variance explained by the model increased by 24%. The final model in which resilience was added, the proportion of variance explained by the model increased by 5%. Age (β=-0.11, p=0.03) and depression (β=-1.64, p=0.04) were negatively associated with HRQoL while BMI (β=0.49, p<0.01) and SES (β=1.34, p<0.01) were positively related to HRQoL. Resilience surpassed conventional clinic-psycho-behavioral determinants and could significantly improve HRQoL (β=0.48, p<0.01).

CONCLUSIONS: PLWH experienced worse HRQoL with time increase. Resilience surpassed conventional clinic-psycho-behavioral determinants and positively influence HRQoL among PLWH. To improve HRQoL and prolong survival of PLWH, resilience-based approach is needed to help them cope with stressful conditions of HIV infection.

PED0856

HIGH RATES OF SUICIDAL THOUGHTS AND ATTEMPTS AMONG TRANS WOMEN IN SÃO PAULO, BRAZIL

F.D. Moura[1], E. Wilson[2], W. McFarland[2], H. Xien[2], M.C.B. Costa[1], M.A.M. Veras[1], Divas Research Project
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Public Health, São Paulo, Brazil, [2]San Francisco Department of Public Health, San Francisco, United States

BACKGROUND: Trans women are among the populations most highly affected by HIV globally. In Brazil, trans women experience severe social, economic, and health care discrimination, making them one of the most marginalized and under-served communities in the country. We hypothesize that factors leading to marginalization and HIV risk also affect mental health. We examined suicidal thoughts and attempts among trans women at high risk of HIV in São Paulo, the largest city in the Western Hemisphere.

METHODS: Data are from the DIVAS Project, a cross-sectional study conducted among trans women via RDS between 2016-2017 in São Paulo, Brazil. Procedures included a structured questionnaire and HIV testing. Descriptive analysis and factors associated with suicidal thoughts and attempts were examined.

RESULTS: Of the 386 eligible participants, half identified as "travesti" (51.6%), while others identified as trans women (35.2%) or woman (12.7%). One third were Catholic (35.2%), most were non-white (72.2%), >25 years (74.4%), and with an incomplete secondary education (55.1%). HIV prevalence was 35.2%, and 32.7% engaged in sex work in the past month. About half (n= 205; 53.1%) had suicidal thoughts; of these, 63.4% attempted suicide, including 22.9% in the past year. Lifetime suicidal thoughts were associated with having no religious affiliation (aOR 3.87, 95%CI 2.04-7.37), being in a relationship (aOR 3.96; 95%CI 1.83-8.57), being married (aOR 3.50, 95%CI 1.78-6.86), and social support (β: -0.02, p<0.01). Suicide attempt in the last year was associated with "woman" gender identity vs. "transwoman" (aOR 8.89, 95%CI 1.80-43.78), having no religious affiliation (aOR 4.37, 95%CI 1.27-15.05), recent sex work (aOR 2.79, 95%CI 1.03-7.57) and age (β: -0.02, p<0.01).

CONCLUSIONS: Trans women in São Paulo have a high prevalence of suicidal thoughts and attempts, predicting very high mortality risk over their lifetimes. Over one-third also tested HIV+, which may be related to having unmet mental health needs. Personal as well as structural factors may explain the rates of suicidal thoughs and suicidal attempts among transgender people. Meeting the unmet mental health needs and other supportive services and policies should be prioritized for this population that also bears a disproportionate burden of HIV in Brazil and the world.

PED0857

THE POSITIVE EMOTIONS AMONG SEROPOSITIVE MEN WHO HAVE SEX WITH MEN IN HIGH DENSE STIGMA CITY'S OF INDONESIA: A QUALITATIVE STUDY

M. Mahathir[1], T. Asharyadi[2], B. Mulyadi[3]
[1]Universitas Andalas, Faculty of Nursing, Community Health Nursing Department, Padang, Indonesia, [2]Universitas Adiwangsa Jambi, Community Health Nursing, Jambi, Indonesia, [3]STIKES Indonesia, Community Health Nursing, Padang, Indonesia

BACKGROUND: Indonesia is facing a rapid growth in the intensity of stigma during this decade, with the effects of past efforts to break down the stigma starting to fade. The socio culture and religious strictness only straiten the dynamic of the progress of HIV acceptance within the community. Men who Have Sex with Men (MSM) doubtlessly have to hold down the double burden of a stigma which further impacts upon their life choices. It is very crucial to develop inner strength among seropositive MSM to help them to tackle the destructive social environment which surrounds them. This study explores the positive emotions experienced by seropositive MSM who adhered to their medication in most stigmatized environment city in Indonesia.

METHODS: The study was conducted by carrying out phenomenological research. In-depth interviews were conducted with 22 seropositive MSM who adhered their medication. The data analysis in this study used the Stevick-Colaizzi-Keen data analytical method.

RESULTS: Three significant themes were found to represent the positive emotions among seropositive MSM. The themes were mindful acceptance of the disease, HIV progress optimism and spiritual guidance enforcement. Seropositive MSM acknowledge self-acceptance is essential to start to stand up against the disease. Seropositive MSM would feel much comfortable with their life if they felt accepted by themselves. HIV progress until now also boosts their optimism to live longer. Seropositive MSM believe the fights against the disease will never end but they believe there are people who are striving to eliminate the disease forever. They also feel relieved that what they have now is better compared to what they were expecting before getting to know the disease. Seropositive MSM also feel that being spiritual makes them feel better. They believe their God will always be beside them and that this only a test to make them a better person.

CONCLUSIONS: Positive emotions marked by inner strength would impact seropositive MSMs' self-determination. It is important to support the HIV affected population to gain more their inner strengths to fight against the negativity of the disease. It also reminds us of the need for well evidenced strategies to boost affected popoulations involvement to themselves.

PED0858

GENDER DIFFERENCES IN PERCEPTIONS OF HEALTH AND WELL-BEING AMONG ADULTS ON ART IN MALAWI

J. Paul-Schultz[1], R.M. Hoffman[1], M. Mphande[2], B.A. Banda[2], H. Sigauke[2], V. Kumwenda[2], K. Dovel[1], A. Amberbir[2], A. Moses[2], S. Gupta[2], C. Moucheraud[3]
[1]David Geffen School of Medicine at UCLA, Los Angeles, United States, [2]Partners in Hope, Lilongwe, Malawi, [3]UCLA Fielding School of Public Health, Los Angeles, United States

BACKGROUND: Antiretroviral therapy (ART) has drastically improved lifespan -- however few studies have been conducted about the well-being of individuals as they age with HIV, or explored gender differences in well-being, particularly in resource-limited settings such as Malawi.

METHODS: We conducted a survey at a large, free ART clinic in Lilongwe, Malawi. Eligible participants were ≥30 years old, experienced on ART, and not acutely ill. The survey was adapted from validated tools including the WHO Disability Assessment Scale (WHODAS). Viral load results were extracted from medical records (suppressed: <200 copies/mL). Data were collected between June-August 2019. Differences between men and women were assessed using t-tests. Multivariable models included covariates for age, household wealth and education.

RESULTS: We surveyed 134 adults: 49% women, median age 51 years (IQR 42, 58), median 9 years on ART (IQR 6, 11). A higher proportion of women demonstrated viral suppression compared to men (89.2%

versus 78.1%, aOR 0.32 for suppression among men vs. women, p-value <0.05, 95% CI 0.11, 0.97); median 4.5 months since most recent viral load). Men had significantly higher self-rated health (5.3 versus 4.6 on a scale of 0-8, p-value <0.001), lower rates of disability as assessed by WHODAS (2.5 versus 6.7 on a scale of 0-48, p<0.001) with a particular difference in the domain of functioning (i.e., standing, walking, learning and concentration) (Table 1). These relationships persisted in multivariable models.

	Among all (n= 134)	Among females (n= 66)	Among males (n= 68)	Multivariable model OLS coefficient (β) on male gender (95% CI)
General health, mean (median)	4.9 (5)	4.6 (5)	5.3 (5)***	0.78*** (0.39, 1.18)
Social isolation, mean (median)	4.4 (5)	4.4 (4.5)	4.4 (5)	-0.01 (-0.54, 0,56)
Feelings of stigma, mean (median)	3.3 (4)	3.4 (4)	3.3 (3)	-0.13 (-0.52, 0.25)
WHODAS total, mean (median)	4.6 (3)	6.7 (6)	2.5 (2)***	-3.97*** (-5.41, -2.52)
WHODAS functioning domain, mean (median)	2.4 (1.5)	3.8 (3)	1.0 (0)***	-2.56*** (-3.49, -1.63)
WHODAS tasks domain, mean (median)	0.4 (0)	0.8 (0)	0.1 (0)**	-0.71*** (-1.09, -0.33)
WHODAS relationships domain, mean (median)	1.8 (2)	2.2 (2)	1.4 (0)*	-0.71† (-1.41, 0.003)

General health scored 0 (worst) to 8 (best), includes: perceived health today, health today versus 1 year ago
Social isolation scored 0 (worst) to 6 (best), includes level of agreement with: lacking companionship, feeling left out, feeling lonely
Feelings of stigma scored 0 (worst) to 6 (best), includes level of agreement with: If people knew my HIV status, they wouldn't give me a job, Sometimes I feel worthless because I am HIV positive
WHODAS total scored 0 (no disability) to 48 (most disability), includes: difficulties with standing for long periods of time (F), walking long distances (F), learning new tasks (F), concentration (F), difficulties with taking care of household responsibilities (T), bathing (T), getting dressed (T), difficulties with day-to-day activities (T), difficulties with joining in community activities (R), dealing with or talking to strangers (R), maintaining friendships (R), being emotionally affected by health problems (R)
WHODAS functioning domain scored 0 (no disability) to 16 (most disability) includes items noted with (F) above
WHODAS tasks scored 0 (no disability) to 16 (most disability) includes items noted with (T) above
WHODAS relationships scored 0 (no disability) to 16 (most disability) includes items noted with (R) above

Asterisks indicate level of significance for comparison of difference between females and males: †p<0.1, *p < 0.05, **p < 0.01, ***p < 0.001
Bivariate analyses use t-test for means. Multivariable models specified as OLS, and contain covariates for age (continuous), household wealth (quintile based on asset index) and level of educational attainment (categorical: no formal education, some primary, finished primary, some secondary, finished secondary, beyond secondary).

[Table 1: Wellbeing factors of men and women]

CONCLUSIONS: These pilot data suggest that there may be important sex differences in perceptions of health and wellbeing, with men reporting themselves as healthier and having higher functional status as compared to women, despite lower rates of viral suppression. More research should be done on gender-sensitive approaches to measuring wellbeing and health, and how to leverage such information to ensure holistic care for men and women in ART programs.

PED0859

HOW MENTAL HEALTH SHAPES ART INITIATION AMONG HETEROSEXUAL AND GAY OLDER ADULTS NEWLY DIAGNOSED WITH HIV IN UKRAINE

Y. Rozanova[1], I. Zaviryukha[2], T. Kiriazova[2], O. Zeziulin[2], A. Allen[3], V. Yaryy[4], E. Mamedova[5], F. Altice[1], S. Shenoi[1]
[1]Yale University, Internal Medicine, New Haven, United States, [2]Ukrainian Institute on Public Health Policy, Kiev, Ukraine, [3]State University of New York, Downstate, New York, United States, [4]Kiev City Narcological Hospital "Sociotherapy", Kiev, Ukraine, [5]Kiev City Clinical Hospital N° 5, Kiev, Ukraine

BACKGROUND: Ukraine has the worst HIV epidemic in Eastern Europe and Central Asia, the only world region with increasing HIV incidence and mortality. Adults ≥50 years constitute 37% of Ukrainians and 15% of all new HIV diagnoses. As older people with HIV (OPWH) (defined as ≥50 years) in Ukraine present with later stage HIV and multiple morbidities, antiretroviral therapy (ART) as soon as possible is essential for preserving long-term clinical outcomes. In 2018 less than 30% of OPWH were linked to ART within 6 months of diagnosis, with same-year mortality 3-11 times higher than the age-matched general population. As LGBQT stigma persists in older generations in Ukraine, we qualitatively explored how mental health in diverse OPWH may shape ART initiation.
METHODS: In 2018-2019, we conducted in-depth interviews with 16 male (3 MSM) and 14 female OPWH within 6 months of diagnosis, as well as two male-only, and two female-only focus groups (6-8 OPWH in each, 4 MSM) in Kyiv. Audio-recorded and transcribed data were inductively analyzed for themes.
RESULTS: In Ukrainian OPWH accounts, HIV diagnosis was the most traumatic event of their life, threatening their "decent woman" or "strong man" identity, their essential social and family roles, and their (hetero)sexual status. OPWH experienced severe anxiety and depressive symptoms including fear, loss of sleep and appetite, hopelessness, apathy, and suicidal ideation, leading to self-destructive behaviors like heavy drinking. While older MSM described wider networks of acquaintances than heterosexual men, all older men preferred self-reliance in coping with the diagnosis, and were more vulnerable to mental health problems and delayed ART in the absence of one close confidante (often a female relative but never a child; seldom a male mate). Conversely, older women reported seeking and receiving emotional support to manage mental stress and instrumental help to link to ART, often from female friends and more rarely from family members (including children).
CONCLUSIONS: As Ukraine strives to achieve the 95-95-95 HIV care goals by 2030, understanding mental health implications of HIV diagnosis and coping strategies among diverse OPWH is crucial for developing evidence-based peer-led programs to reduce time to ART and improve mental health among OPWH.

PED0860

MENTAL HEALTH EVALUATION AND PSYCHOLOGICAL FOLLOW-UP IN HOSPITALIZED PEOPLE LIVING WITH HIV

V. Barrientos-Casarrubias[1], E. Gutiérrez-Velilla[1], N.P. Caballero-Suárez[1]
[1]Instituto Nacional de Enfermedades Respiratorias, Departamento de Investigación en Enfermedades Infecciosas, Mexico City, Mexico

BACKGROUND: Mental Health (MH) problems are more common among people living with HIV (PLWH) than in the general population. It is important to timely detect MH problems and carry out an

adequate psychological follow-up since poor MH may contribute to suboptimal patterns of antiretroviral treatment adherence, loss to follow up, and, as a consequence, worse health outcomes and higher morbidity/mortality. The objective of this study was to evaluate MH symptoms and psychological follow-up in hospitalized PLWH in a third-level hospital in Mexico City.

METHODS: Observational, retrospective, cross-sectional study. Mental health evaluation was performed with a semi-structured interview and the Hospital Anxiety and Depression Scale (HADS). The psychological follow-up evaluation was carried out with the review of assisted appointments to the hospital's outpatient mental health service. PLWH who were hospitalized between October 2018 and November 2019 were included in the study.

RESULTS: 121 PLWH hospitalized received a MH evaluation during the study period. Of these, 90.1% (n=109) were males, the mean age was 36.5 years (SD=9.5) and 42.1% (n=51) had recent HIV diagnosis (≤4 months). Regarding psychological symptoms, 23.9% (n=29) showed depressive symptoms and 36.6% (n=44) anxiety symptoms; 57.9% (n=70) reported trouble sleeping, 32.2% (n=39) loss/increased appetite and 18.2% (n=22) suicidal ideation. Regarding psychological follow-up, only 30.6% (n=37) had at least one assisted MH appointment as outpatient. PLWH with a recent HIV diagnosis (≤4 months) had more probability of continuing MH care as outpatients (41.2% vs. 22.9%, p=0.031).

CONCLUSIONS: We identified an important frequency of mental health problems in hospitalized PLWH. We also observed a low rate (30%) of attendance to MH appointments after hospitalization. An adequate and timely MH intervention (psychological and/or psychiatric) is key to manage mental health problems and strengthen medical follow-up, and adherence to antiretroviral treatment resulting in HIV control. A better integration of MH care services must be warranted, especially in hospitalized patients in third level care facilities.

OUTCOMES OF A RANDOMIZED CONTROLLED CLINICAL TRIAL OF "FUERTES" AN INTERVENTION TO IMPROVE ART ADHERENCE AMONG MSM LIVING WITH HIV IN MEXICO

Z. Andrade-Romo[1,2], G. La Hera-Fuentes[1,3], L.E. Ochoa-Sánchez[1], J.S. Andrade-Pérez[4], G. Amaya-Tapia[5], L. Castro-León[6], L. Chavira-Razo[1,7], T. Aramburo-Muro[1], S. Bautista-Arredondo[1,8]
[1]National Institute of Public Health of Mexico, Health Economics and Health Systems Innovations, Cuernavaca, Mexico, [2]University of Toronto, Dalla Lana school of Public Health, Toronto, Canada, [3]National Institute of Public Health, Cuernavaca, Mexico, [4]Hospital Civil de Guadalajara "Dr. Juan I. Menchaca", Servicio de Infectologia, Guadalaja, Mexico, [5]Hospital General de Occidente, Servicio de Infectologia, Zapopan, Mexico, [6]CAPASITS Villahermosa, Villahermosa, Mexico, [7]University of Toronto, Rotman School of Management, Toronto, Canada, [8]University of California, School of Public Health, Berkeley, United States

BACKGROUND: Worldwide optimal adherence to antiretroviral therapy (ART) among men who have sex with men (MSM) living with HIV is still a challenge to reduce HIV transmission. Mental health problems are one of the most significant barriers to ART adherence among MSM living with HIV. Although multiple interventions have been implemented around the world, almost none have shown consistent effects in the long term.

METHODS: From November 2017 to January 2020, we implemented a multicenter, parallel, randomized controlled trial of the intervention "FUERTES" with 151 MSM receiving ART in three HIV clinics in Mexico. The objective of the intervention was to improve ART adherence among MSM initiating treatment and measure health outcomes at one, four, and ten months. The intervention group received FUERTES for a maximum of six months. We evaluated adherence using medication possession ratio, self-report through the AACTG questionnaire, CD4 count, and viral load. We assessed mental health using various questionnaires: the PHQ-9 for depression, the AUDIT for alcohol abuse, and the DAST-10 for addiction to drugs. We performed a descriptive analysis. Baseline and follow up characteristics were compared between the two groups applying t-test and chi-square test as appropriate. Mental health outcomes were expressed as percentages and described the trends over the study period.

RESULTS: We found no differences regarding ART adherence between groups. However, at four months, 20.55% of the control group participants reported having a moderate to severe depression compared to 5.6% of the intervention group (p=0.008), and 18.84% vs. 7.35% respectively at ten months (p=0.047). Regarding drug abuse, 10.96% of the control group participants reported having a considerable high drug consumption at four months, compared to 1.41% of the intervention group (p=0.018). We did not find any differences in baseline CD4 count, viral load, or socioeconomic characteristics.

CONCLUSIONS: FUERTES has the potential to improve medium-term mental health and substance abuse outcomes of MSM living with HIV in Mexico. Although our intervention did not have a direct impact on adherence outcomes, its effect on the participant's mental health might influence adherence in the long-term. Therefore, we will measure adherence in three years to identify any differences between groups.

PED0862

MEETING THE FOURTH 90: EVALUATING THE MENTAL HEALTH OF AN URBAN POPULATION OF PEOPLE LIVING WITH HIV IN A GREATER LONDON CLINIC

H. Mortimer[1], C. Fowler-Williams[1], S. Dunin De Skrzynno[1], I. Cormack[1]
[1]Croydon University Hospital, London, United Kingdom

BACKGROUND: Looking beyond achieving an undetectable viral load as the goal of therapy has been iterated in recent international targets for HIV management: the so-called 'fourth 90' encompassing working towards a better quality of life for people living with HIV (PLWH). It is well documented that PLWH, especially women, have a disproportionate burden of mental health problems and improving the identification and treatment of mental health problems in PLWH has been identified as a priority. Annual screening for mental health problems is recommended by the British HIV Association Standards of Care 2018. We prospectively studied and evaluated mental health problems in a greater London HIV clinic using validated self-report questionnaires.

METHODS: Clinic attenders at Croydon University Hospital from June 2019 to January 2020 were asked to complete the Insomnia Severity Index (ISI), Generalised Anxiety Disorder Assessment (GAD-7) and Patient Health Questionnaire 9 (PHQ9). Scores were recorded along with patient demographics, drug history and social behaviours.

RESULTS: Of the 265 clinic attenders over the period, 135 (51%) identified as black African, 29 (11%) as black Caribbean and 131 (51%) were women. 259 (97%) were offered the questionnaires, only 1 declined. 86 (33%) of the 258 who completed the questionnaires had scores consistent with at least moderate depression, with 50 (19%) scoring

for severe depression. 92 (36%) scored for at least moderate anxiety with 46 (18%) scoring for moderately-severe anxiety. 39 (15%) had scores consistent with clinical insomnia. Further analysis is continuing to look for associations between mental distress and gender, ethnicity, sexuality, highly-active-antiretroviral-therapy (HAART) regimen and drug and alcohol use.

CONCLUSIONS: High rates of depression and anxiety were identified reflecting the challenges in achieving good emotional health to meet the 'fourth 90' target in this population. Routine screening using mental health questionnaires was found to be feasible and acceptable to patients. Where specific antiretroviral agents were thought to be contributing to poor mental health these patients were offered alternative therapies where appropriate. Further investigation into existing services is ongoing to identify unmet needs and look into opportunities to improve support with psychiatric interventions to improve emotional well being.

PED0863

INSOMNIA AND CD4 COUNT IN HIV POSITIVE PATIENTS

A. Najafi[1], S. Akbarpour[1], S. Ghodrati[1], K. Sadeghniiat[1], M. Mahboobi[2], P. Afsar Kazerooni[2]
[1]Occupational Sleep Research Center, Baharloo Hospital, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Ministry of Health and Medical Education, Center for Disease Control (CDC), Tehran, Iran, Islamic Republic of

BACKGROUND: Patients with AIDS experience higher prevalence of insomnia. Insomnia could affect patients' quality of life. Limited epidemiological information about insomnia in HIV positive patients is available in Iran. In this study, we aimed to assess prevalence of insomnia and its association with CD4 count in a HIV positive population.

METHODS: A cross-sectional study was performed among HIV patients referred to Voluntary Counselling and Testing (VCT) centers, Tehran, Iran. A total of 84 HIV positive patients were enrolled in the study. Validated Persian version of Insomnia Severity Index (ISI) questionnaire was used by interviewers. ISI>8 was defined as insomnia. The data was analyzed by independent T-test and descriptive statistics.

RESULTS: Among a total of 84 patients, 69(82%) were men. Participants' mean (SD) of age and BMI were 39.8(9.6) years and 24(4.1) kg/m2, respectively. Mean ISI score was 7.2. Thirty-nine percent (n=33) reported insomnia. Insomniac participants were more likely to have less CD4 count compared to non-insomniacs (469(264) for non-insomniacs vs. 550(335) for insomniacs). However, the trend was not statistically significant.

CONCLUSIONS: Patients with HIV and concomitant insomnia were more likely to have lower count of CD4. This important possible association needs more investigation in larger population of HIV positive patients. Further investigation of insomnia and the possible association with CD4 count would be useful in our future trends for AIDS management and prognosis.

PREVENTION INTERVENTIONS AND THEIR EFFECTS ON THE LIVES AND RELATIONSHIPS OF PEOPLE LIVING WITH HIV

ATTITUDES TOWARD AND EXPERIENCES WITH DISCUSSING PRE-EXPOSURE PROPHYLAXIS (PREP) WITH SEXUAL PARTNERS AMONG HIV-INFECTED ADOLESCENTS AND YOUNG ADULTS IN THE U.S.

B. Spicer[1], C. Lehmann[1,2], T. Mullins[1,2]
[1]Cincinnati Children's Hospital Medical Center, Division of Adolescent Medicine, Cincinnati, United States, [2]University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States

BACKGROUND: Sexual partners of HIV-infected youth are a key population for pre-exposure prophylaxis (PrEP). However, little is known about whether HIV-infected youth in the U.S. are aware of PrEP and willing to discuss it with partners. We examined the attitudes and experiences of HIV-infected youth engaged in HIV medical care toward discussing PrEP with sexual partners.

METHODS: Fifteen individual, in-depth, semi-structured interviews were conducted between 4/2019 and 12/2019 with 15-24-year-olds recruited from an outpatient HIV clinic. Interviews assessed demographics, PrEP knowledge, sexual behaviors, and constructs from the Theory of Planned Behavior as related to discussing PrEP with partners: barriers, facilitating factors, and experiences with and intentions toward discussing PrEP with partners. Past disclosure of HIV status was not assessed: failure to disclose to a partner is a felony under state law. Transcripts were analyzed using framework analysis. The study was IRB approved.

RESULTS: Mean age was 18.2 years (SD1.7). Eight participants were cis-female, 5 cis-male, and 2 transgender female. Twelve acquired HIV sexually and 3 perinatally. The majority were sexually active (14/15); most of those had opposite sex partners only (9/14), and 5/14 reported recent condomless sex. Most youth (12/15) were aware of PrEP. Barriers to discussing PrEP with partners included participant-related factors (n=10; i.e., discomfort disclosing HIV status, concerns about partners' negative reactions), partner-related factors (n=5; i.e., not open to PrEP, unfamiliar with PrEP), and relationship factors (n=4; i.e., lack of trust, new relationship). Facilitating factors included educating partners about PrEP (n=6), partners meeting with the participant's clinician (n=2), and framing PrEP as a desire to protect partners (n=2). Seven participants had discussed PrEP with a partner; these conversations often occurred when disclosing HIV status. Ten participants reported comfort with disclosing HIV status to future partners; 8 participants reported high intention to discuss PrEP with future partners.

CONCLUSIONS: Although many HIV-infected youth had some knowledge about PrEP, only half of sexually active youth had discussed PrEP with a partner. Uptake by sexual partners of HIV-infected youth may be improved by interventions to educate all youth about PrEP and offering opportunities for partners of HIV-infected youth to meet with clinicians to discuss PrEP.

PED0865

FACTORS ASSOCIATED WITH THE PERCEPTION OF A NEGATIVE IMAGE THAT USING PREP REFLECTS TO OTHERS: RESULTS OF THE ANRS-PREVENIR STUDY

C. Protiere[1], G. Gaubert[1,2], L. Sagaon-Teyssier[1,2], M. Mimi[1,2], M. Mora[1,2], L. Assoumou[3], L. Beniguel[3], J. Bellet[3], D. Rojas Castro[1,4,5], D. Michels[4], J. Ghosn[6], D. Costagliola[3], J.-M. Molina[7], B. Spire[1,2]
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Marseille, France, [2]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]Institut Pierre Louis d'Epidémiologie et de Santé Publique, Sorbonne Université, INSERM, Paris, France, [4]AIDES, Paris, France, [5]Coalition PLUS, Community-Based Research Laboratory, Paris, France, [6]University Paris Diderot, Sorbonne Paris Cité, Bichat Hospital, Assistance Publique Hôpitaux de Paris, Paris, France, [7]Hospital Saint-Louis, Assistance Publique Hôpitaux de Paris, Paris, France

BACKGROUND: Effectiveness of HIV pre-exposure prophylaxis (PrEP) strongly depends on adherence. Psychosocial factors have been identified as barriers to the use of PrEP. However, little is known about the intrinsic barriers to its use, such as the individual representations of PrEP. We aimed identifying the factors associated to the perception of a negative image that using PrEP reflects to others.

METHODS: The ANRS-Prevenir study started in 2017, offers prevention based on daily or on-demand PrEP to seronegative volunteers at high risk of HIV infection in the Ile-de-France region. Participants provided information about PrEP representations in a self-administered questionnaire at enrolment. The outcome was constructed with the answer to the following statement: "In your opinion, PrEP can make you look bad/reflect a negative image to others". "Completely agree" and "Tend to agree" were grouped in "yes"=1; "Completely disagree" and "Tend to disagree" in "no"=0. Logistic regression was implemented. Covariates included socioeconomic, behavioral, psychosocial, and clinical characteristics (STIs at enrolment and/or a score of past STIs) as well as PrEP status at enrolment (PrEP-experienced vs. PrEP-beginners).

RESULTS: Among 3067 participants, 2657 completed the enrolment questionnaire. The outcome was constructed for 2563 (96.5%). For 32.6%, using PrEP may them look bad/reflect a negative image to others. The probability of perceiving that a negative image is reflected to others by the use of PrEP decreases with age [aOR=0.98, p<0.001] and self-esteem [aOR=0.97, p=0.019]. Participants stimulated by their main partner to use PrEP [aOR=0.65, p<0,001] and those using daily PrEP [aOR=0.98, p<0,001] are less likely to perceive that using PrEP reflects a negative image to others. However, the probability of this perception increases with depression [aOR=1.02, p=0.007]. No association was found for STIs (at enrolment (p=0.166)/score of past STIs (p=0.254)), and PrEP status (p=0.317).

CONCLUSIONS: For the youngest and those psychologically vulnerable, the perception of a negative image that using PrEP reflects to others could become a barrier for its use. Understanding the factors associated to this negative image is crucial for targeting support for these users. Our results should be confronted with participants' follow-up. They suggest ways to strengthen the use of PrEP among high-risk populations.

PED0866

PREP TALK: ATTITUDES AND EXPERIENCES OF HIV-INFECTED ADOLESCENTS AND YOUNG ADULTS TOWARD DISCUSSING PRE-EXPOSURE PROPHYLAXIS (PREP) FOR SEXUAL PARTNERS WITH CLINICIANS

B. Spicer[1], C. Lehmann[1,2], T. Mullins[1,2]
[1]Cincinnati Children's Hospital Medical Center, Division of Adolescent Medicine, Cincinnati, United States, [2]University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States

BACKGROUND: Maximizing uptake of pre-exposure prophylaxis (PrEP) by sexual partners of HIV-infected youth depends upon these youth being aware of and educated about the role of PrEP in HIV prevention. Thus, we explored the attitudes and experiences of HIV-infected youth engaged in HIV medical care toward discussing PrEP for sexual partners with their clinicians.

METHODS: Between April and December 2019, we recruited fifteen youth 15-24-years-old from appointments at an HIV clinic for individual, in-depth, semi-structured interviews. Interviews based on the Theory of Planned Behavior assessed demographics, sexual behaviors, and constructs related to discussing PrEP for partners with clinicians: perceived barriers, facilitating factors, and experiences with and intentions toward discussing PrEP for partners with clinicians. Transcripts were analyzed using team-based framework analysis. The study was IRB approved.

RESULTS: Mean age was 18.2 years (SD1.7). Most (n=8) were cis-female, 5 were cis-male, and 2 were transgender female. Twelve acquired HIV sexually and 3 perinatally. The majority were sexually experienced (14/15); of these, 5 reported sex without a condom in the prior 6 months. Although most participants reported no barriers to discussing PrEP with their clinicians (n=11), other participants reported barriers including discomfort discussing sex (n=1) and desire to have another person present to start the PrEP conversation (n=1). Facilitating factors around clinician behaviors included initiating conversations about PrEP (n=2), strategizing with the patient about how to discuss PrEP with a partner (n=1), and discussing PrEP with the partner at participant medical visits (n=1). Thirteen participants had discussed PrEP with a clinician; 9 reported that the clinician provided education about PrEP, 8 reported that the conversation was comfortable, and 6 reported that the clinician started the conversation. Fourteen participants reported being very or somewhat likely to discuss PrEP for partners with a clinician in the future.

CONCLUSIONS: Most HIV-infected youth in our sample reported no barriers to discussing PrEP with clinicians and had participated in such conversations. However, the occurrence of conversations about PrEP can be optimized by clinicians in several ways, including initiating conversations about PrEP, strategizing with patients about how to discuss PrEP with partners, and being willing to discuss PrEP directly with partners.

PED0867

BEYOND HIV PREVENTION: MOTIVATIONS, CHALLENGES, AND BENEFITS OF SAFER CONCEPTION CARE AMONG MEN LIVING WITH HIV SEEKING TO FULFILL REPRODUCTIVE GOALS IN RURAL UGANDA

A. Kaida[1], M. Owembabazi[2], H. Ezegbe[1], E. Atukunda[2,3], E. Musinguzi[2], C. Kyampire[2], S. Natukynda[2], P. Smith[1], L.T. Matthews[4], M. Bwana[2,3]
[1]Simon Fraser University (SFU), Faculty of Health Sciences, Burnaby, Canada, [2]Mbarara University of Science and Technology (MUST), Mbarara, Uganda, [3]Mbarara Regional Referral Hospital, Mbarara, Uganda, [4]University of Alabama at Birmingham, Birmingham, United States

BACKGROUND: In Uganda, an estimated 30-50% of men living with HIV (MLWH) desire children, and half have an HIV-uninfected pregnancy partner. Yet, men are poorly engaged in HIV care and reproductive health programming. Among MLWH enrolled in a pilot program in rural Uganda, we examined motivations, challenges, and benefits of safer conception care.

METHODS: We recruited MLWH (≥18 years) who desired a child in the next year with an HIV-uninfected female partner (Nov 2018-Sept 2019). At enrollment, participants (and partners if present) were offered safer conception counselling (which supports reproductive goals while minimizing HIV risks) with 3- and 6-month follow-up. Participants completed a questionnaire and testing for STIs and HIV-RNA. Female partners were tested for pregnancy and HIV. We conducted 40 individual semi-structured exit interviews with a subset of male participants (n=20) and female partners (n=20) to explore experiences of engaging in safer conception care. Data were analysed using thematic analysis.

RESULTS: Among 20 enrolled men, median age was 33 [IQR:28-35], number of children was 3 [IQR: 2-5], all were on ART, and 85% were virally suppressed (<40 copies/mL).

Primary motivations for engaging in safer conception care included a desire to increase family size and/or gender composition; a desire for an HIV-uninfected baby; and to protect female partners from HIV acquisition. Few participants were previously aware of or used any safer conception strategies but were eager to adopt these practices, including partner PrEP.

Challenges included fears about HIV disclosure; uncertainty about the effectiveness of ART for HIV prevention; frustration about delays in conceiving; and navigating power inequities in couple decision-making.

Benefits included gaining knowledge and support for realizing reproductive goals; eliminating HIV transmission risk worries; accessing other sexual and reproductive health services (e.g., STI testing/treatment); and improving marital relationship and sexual intimacy.

CONCLUSIONS: MLWH are eager to engage in novel HIV care that incorporates family building goals. The challenges and benefits of safer conception care extend beyond the HIV prevention messaging of Undetectable=Untransmittable to include gendered couple-dynamics and opportunities to enhance sexual intimacy. Attending to these contextual factors presents opportunity to better engage men and their partners in safer conception and HIV care.

PED0868

DIS-EASE WITH TRAUMA: REFLECTIONS ON THE SYSTEMIC INTEGRATION OF TRAUMA-INFORMED HIV CARE

A.M. Ochoa[1], C.C. Paneda[1], L. Cordero[1], K. Maxwell[1], M. Gonzalez[2], K. Parker[2], I. Holloway[1]
[1]University of California, Social Welfare, Los Angeles, United States, [2]Christie's Place, San Diego, United States

BACKGROUND: People living with HIV (PLWH) experience disproportionate rates of trauma compared to the general population and trauma among PLWH is associated with poor treatment adherence, co-occurring health issues and increased risk behavior. Trauma-informed care (TIC) is an innovative healthcare model that recognizes trauma exists, responds to trauma appropriately, and resists re-traumatizing clients. Our research sought to better understand California's progress in integrating TIC practices throughout its system of HIV care.

METHODS: Community-based participatory research (CBPR) methods were used to recruit a sample of Ryan White-funded HIV service providers familiar with TIC (N=20). Participants completed a qualitative, semi-structured interview through Zoom, an online conferencing platform. Interview topics included participants' experiences with TIC and facilitators/barriers they experienced in delivering TIC in diverse settings. Interviews were audio recorded, transcribed verbatim, and analyzed initially using a rapid assessment process (RAP) in conjunction with community partners. Finally, researchers coded transcripts using an iterative process to identify core themes across transcripts.

RESULTS: Participants were diverse in terms of geographic area, services offered and size of organization. While participants clearly demonstrated awareness of TIC, its basic elements and how TIC is implemented within their organizations, most participants indicated such practices were implemented in the absence of a formal policy to integrate such practices into their agency's operations. Invested leadership to sustain TIC practices was presented as a facilitator to TIC integration, particularly in light of the many competing interests faced by HIV service organizations. Participants identified that funding is needed for programmatic changes that facilitate safety for clients and provide capacity building trainings for providers across disciplines and organizations.

CONCLUSIONS: Findings indicate that systemic integration of trauma-informed HIV care has yet to make significant progress in California, and implementation is highly dependent on individual-level skill and capacity. Given our understanding of the role trauma plays in the lives of PLWH, systemic integration of trauma-informed HIV care is fundamental to ensuring that all people have access to appropriate and competent care. Future policies supporting systemic integration of TIC may include cultivating champions of TIC within agencies, developing funding, and providing on-site trainings.

SEXUAL AND REPRODUCTIVE HEALTH, FERTILITY, FAMILY PLANNING, PREGNANCY AND ABORTION

PED0869

ATTITUDES TOWARD PREGNANCY AMONG WOMEN ENROLLED IN PREVENTION OF MOTHER-TO-CHILD TRANSMISSION OF HIV (PMTCT) SERVICES IN MOSHI, TANZANIA

E. Knippler[1,2], R. Mwamba[2], J. Coleman[2,3], B. Knettel[2], L. Minja[4], G. Kisigo[2,5], J. Ngocho[5,6], C. Cichowitz[7], B. Mmbaga[2,4,5,6], M. Watt[2]
[1]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, United States, [2]Duke Global Health Institute, Durham, United States, [3]Duke University, Department of Psychology and Neuroscience, Durham, United States, [4]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [5]Kilimanjaro Christian Medical Center, Moshi, Tanzania, United Republic of, [6]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [7]Massachusetts General Hospital, Center for Global Health, Boston, United States

BACKGROUND: Attitudes toward pregnancy may impact health seeking behavior and therefore health outcomes. For pregnant women living with HIV, feelings about being pregnant may be influenced by their HIV status. This study examined attitudes toward the current pregnancy among pregnant women enrolled in prevention of mother-to-child transmission of HIV (PMTCT) services in Moshi, Tanzania.

METHODS: 200 pregnant women living with HIV were enrolled in an observational cohort. Participants completed a baseline survey during their second or third trimester of pregnancy. Attitudes toward pregnancy were measured using an eight-item scale with questions about pregnancy intention and feelings about the current pregnancy (α=0.913). Univariable and multivariable regression models examined factors associated with attitudes toward pregnancy, including interpersonal factors, emotional well-being, and pertinent demographic variables.

RESULTS: Attitudes toward the current pregnancy were generally positive, with 87% of participants reporting feeling happy about being pregnant. 71% of participants reported that their pregnancy was intended. Pregnancy intention was significantly higher among women diagnosed with HIV during the index pregnancy (n=74; 78.7%), compared to women with an established HIV diagnosis (n=68; 64.2%). Univariable analyses indicated participants who were in stable relationships, had higher levels of partner and social support, and had disclosed their HIV status had more positive attitudes toward their pregnancy; participants who were older, had more children, had an established HIV diagnosis, and had higher levels of depression and food insecurity had less positive attitudes toward their pregnancy. In the final multivariable model, having higher levels of partner support (B=.168; 95% CI: .051, .285) was significantly associated with more positive attitudes toward the current pregnancy; having an established HIV diagnosis (B=-2.087; 95% CI: -3.811, -.362) and more children (B=-1.962; 95% CI: -2.818, -1.106) were significantly associated with less positive attitudes.

CONCLUSIONS: Women in PMTCT programs require psychosocial support to process their feelings toward pregnancy in the context of their HIV status. Programs should meaningfully engage women's partners to encourage support. Comprehensive family planning services for women living with HIV, including strategies for safe conception and access to contraceptives, is necessary.

PED0870

DISCUSSING REPRODUCTIVE PLANS WITH HEALTHCARE PROVIDERS AMONG SEXUALLY ACTIVE WOMEN LIVING WITH HIV

T.R. Feyissa[1,2], M. Harris[3], D. Loxton[3]
[1]Wollega University, Public Health, Nekemte, Ethiopia, [2]University of Newcastle, Research Centre for Generational Health and Ageing, Faculty of Health and Medicine, Newcastle, Australia, [3]University of Newcastle, Health and Medicine, Newcastle, Australia

BACKGROUND: Discussing reproductive plans with healthcare providers among women living with HIV (WLHIV) can assist in promoting safe reproductive health practices, but little research has been undertaken in this area.

METHODS: A facility-based cross-sectional survey was conducted in western Ethiopia from March to June 2018 using systematic random sampling. A total of 475 sexually active WLHIV aged 18-49 years were interviewed. Descriptive and multivariate logistic regression analyses were conducted.

RESULTS: One hundred twenty seven (26.8%) participants reported becoming pregnant in the last five years after being aware of their HIV-positive status; 33.6% reported they intended to have children in the future, 26.9% were ambivalent about having children.

Only 30.7% reported having had a general discussion with healthcare providers at the HIV clinics and 16.8% had a personalized discussion regarding their reproductive plans. WLHIV accessing health centers for antiretroviral therapy (ART) were less likely to report both general (AOR=0.26; 95%CI 0.15–0.46) and personalized (AOR=0.29; 95%CI 0.14–0.61) discussions compared with women who accessed ART through hospitals.

Unmarried sexually active women were less likely to report both general (AOR=0.47; 95%CI 0.24–0.92) and personalized (AOR=0.27; 95%CI 0.11–0.67) discussions than married women.

CONCLUSIONS: WLHIV are both having and intending to have children, highlighting the need for safe conception practices. Discussions with healthcare providers can deliver support that reduces the risk of vertical and horizontal HIV transmission.

Our findings indicate that delivery of safe conception discussions occur inconsistently and underscore the need for policy and provider-training regarding inclusive (married and unmarried) discussions at all health facilities providing ART.

PED0871

CONDOMLESS SEX AMONG ADOLESCENTS AND YOUNG ADULTS WITH PERINATALLY-ACQUIRED HIV OR PERINATAL HIV-EXPOSURE IN AN ERA OF U=U AND PREP

C.A. Mellins[1], N. Nguyen[1], R. Robbins[1], C.S. Leu[2], J.F. Raymond[1], S. Espinel[1], C. Dolezal[1], R.H. Remien[1], A. Wiznia[3], E.J. Abrams[4]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, Psychiatry, New York City, United States, [2]Columbia University, Mailman School of Public Health, New York, United States, [3]Albert Einstein College of Medicine, Jacobi Medical Center, New York City, United States, [4]ICAP at Columbia University, Mailman School of Public Health, ICAP, New York City, United States

BACKGROUND: Even with PrEP available and knowledge that undetectable=uninfectious, condomless sex among adolescents and young adults (AYA) is a persistent concern in HIV-prevalent communities with rising rates of STIs, unplanned pregnancy, and treatment non-adherence. In a longitudinal cohort study (CASAH) of AYA with perinatally-acquired HIV (AYAPHIV) or perinatal HIV-exposure,

but uninfected (AYAPHEU), we examined longitudinally condomless sex and its association with HIV-status, sociodemographics, psychiatric disorders, and viral load (VL).

METHODS: Participants included 340 New York City-based AYAPHIV and AYAPHEU, primarily Black and Latinx, recruited at ages 9-16 years, and re-interviewed every 12-18 months over six follow-up (FU) visits (ages 19-28 at FU6). At each visit, sociodemographics, psychiatric disorder (DISC), recent condomless sex (past 3 months), PrEP (at FU6) and) VL (PHIV only) data were collected. Using linear regression, we examined differences in percentage of visits with condomless sex by HIV-status, gender, race/ethnicity, and psychiatric burden over time. Among AYAPHIV, we assessed the relationship between condomless sex and VL>400 copies/mL by FU using GEE. Analyses controlled for age.

RESULTS: Both groups reported condomless sex: 56% at one or more visits; 39% at 2 or more visits, and 16% at ≥50% of visits. The mean proportion of total visits with condomless sex did not differ by gender or race, but was higher among AYAPHEU vs AYAPHIV (24% vs 19%, p=0.015), Latinx vs not-Latinx (0.25 vs. 0.17 p=.013), and AYA with increasing psychiatric comorbidities (0.44) or persistent anxiety (0.23) vs AYA with low-levels of psychiatric disorder (0.17; p<0.05) over time. Among AYAPHIV, condomless sex was not associated with VL (p=.305); however, 75% of AYAPHIV had VL>400 at more than half of visits. Among AYAPHEU, few (.02%) had ever taken PrEP.

CONCLUSIONS: Frequent condomless sex leaves AYAPHIV and AYAPHEU at risk for STIs and pregnancy. Latinx AYA and AYA with increased psychiatric burden may also be vulnerable to sexual risk-taking. Limited viral suppression, limited PrEP use, and condomless sex in this cohort suggest potential for health risks, including HIV transmission/infection. Culturally-tailored, combination interventions focused on sexual health, mental health, viral suppression, and prevention tools (including PrEP) are urgently needed for these populations in vulnerable communities to promote well-being.

PED0872

FERTILITY DESIRE AND ASSOCIATED FACTORS AMONG WOMEN RECEIVING ANTIRETROVIRAL THERAPY IN YOGYAKARTA, INDONESIA

D.K. Rukmi[1], I.W.W. Sari[1], A. Lutfiyati[1]
[1]Jenderal Achmad Yani Yogyakarta University, Nursing, Sleman, Indonesia

BACKGROUND: Women living with HIV/AIDS (WLWHA) in Indonesia face a lot of stigma in their community and healthcare settings, and their desire to have their own biological children was suppressed. However, some positive changes in desire to have children may be apparent with the introduction of antiretroviral therapy (ART) and fertility desire may also have implications for unprotected sexual intercourse. There is limited knowledge on fertility desire of WLWHA receiving HIV care in Yogyakarta, Indonesia. Hence, the present study seeks to explore the extent of fertility desire and its associated factors among WLWHA in the area.

METHODS: This is a cross-sectional quantitative research. Participants were 303 WLWHA on ART in 5 districts of Yogyakarta between March to August 2019. WLWHA with hysterectomy and permanent contraception were excluded. Data were collected using a questionnaire. Descriptive statistics, chi square and logistic regression were employed in analyzing the data.

RESULTS: More than half of the participants (50.8%) desire to have at least one biological child without gender preference. Bi-variate correlations showed that reproductive age (younger women), formal employment, and not having a living biological child were correlated with greater fertility desire (p<.05). Logistic regression further indicated that reproductive age (p=.032; AOR: 9.44;95%CI: 1.21 to 73.75) and a smaller number of living children (p=.000; AOR: .09;95%CI: .04 to .23) were the strongest factors associated with fertility desire among WLWHA in Yogyakarta.

CONCLUSIONS: We found that WLWHA with ART in Yogyakarta desire to have their own biological children. Since fertility concerns are an integral part of HIV patient care, health workers can help the groups of WLWHA who desire to have biological children in making the right reproductive decisions by letting them know the benefits and risks of childbirth, as well as measures to prevent the spread of HIV.

PED0873

BEYOND PREVENTION: RECOGNIZING THE CONCERNS ABOUT SEXUAL WELLBEING AMONG WOMEN POST HIV DIAGNOSIS

A. Carter[1,2], B. Gormley[2,3], S. Patterson[4], M. Kestler[5,6], C. Hankins[7,8], C. Logie[9], L.A. Brotto[5], W. Tharao[10], M. Lee[2], J. Li[3], E. Ding[3], A. de Pokomandy[11], M. Loutfy[12,9], A. Kaida[2]
[1]The Kirby Institute, UNSW Sydney, Sydney, Australia, [2]Simon Fraser University, Burney, Canada, [3]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [4]Health Education North West, Liverpool, United Kingdom, [5]University of British Columbia, Vancouver, Canada, [6]Oak Tree Clinic, Vancouver, Canada, [7]McGill University, Montreal, Canada, [8]London School of Hygiene and Tropical Medicine, London, United Kingdom, [9]University of Toronto, Toronto, Canada, [10]Women's Health in Women's Hands, Toronto, Canada, [11]McGill University Health Centre, Montreal, Canada, [12]Women's College Research Institute, Toronto, Canada

BACKGROUND: The sexual wellbeing of women living with HIV (WLWH) has largely been overlooked in public health research. We assessed the prevalence and correlates of experiencing concerns and distress about sexual wellbeing among women post HIV diagnosis.

METHODS: We analyzed national, cross-sectional survey data from the Canadian HIV Women's Sexual and Reproductive Health Cohort Study. WLWH (cis and trans, n=1154) were asked, "Since knowing your HIV status, have you ever experienced any concerns about your sexual wellbeing?" Concerns included sexual self-esteem (e.g., feeling sexually unattractive), emotional aspects of sex (e.g., sexual dissatisfaction), physical aspects of sex (e.g., sexual practices), sexual function (e.g., orgasm difficulties), and relationships (e.g., abusive partners). Women reporting any concerns were asked, "How much distress, if any, did this concern cause you?" Responses were no, mild/moderate, or severe distress. Two logistic regression models identified correlates of

(1) ever experiencing a sexual concern and;

(2) experiencing severe distress about a sexual concern.

RESULTS: 56% reported sexual concerns post-diagnosis, related to sexual self-esteem (42%), emotional (38%) and physical aspects of sex (28%), sexual functioning (32%), and relationships (37%). Among those who had concerns, 92% described any distress. Reports of severe distress were highest for relationships (31%), but prevalent across all areas of concern (21–22%). The first model revealed higher adjusted odds of having a sexual concern among women reporting violence as an adult, a recent intimate relationship, or an 'unsatisfactory' current sex life. Lower adjusted odds were observed for Indigenous women, married/partnered women, women reporting that sex was 'neither an important nor unimportant' part of their lives, and women with higher resilience and mental health scores. In the sec-

ond model, women reporting higher HIV-related stigma, older age, sexual dissatisfaction, or knowing >20 WLWH had higher adjusted odds of severe distress due to a sexual concern, while peer support was protective. Only 34% had talked to anyone about the impact of HIV on their sexual wellbeing beyond preventing transmission.

CONCLUSIONS: Multi-level sexual wellbeing promotion initiatives—including sexual concern assessment, violence against women services, stigma reduction strategies, and peer support programs that build resiliency and mental health—could advance women's sexual health.

PED0874

POSTPARTUM CHALLENGES TO SUSTAINED HIV VIRAL LOAD SUPPRESSION: THE ROLE OF HOUSEHOLD STRUCTURE IN KAZAKHSTAN

Z. Nugmanova[1], C.-A. Swain[2], J. Urbaeva[3], L.-A. McNutt[2]
[1]Asfendiayrov Kazakh National Medical University, Epidemiology, HIV-Infection Division, SPH, Almaty, Kazakhstan, [2]University at Albany, Institute for Health and the Environment, Albany, United States, [3]University at Albany, School of Social Welfare, Albany, United States

BACKGROUND: Routine HIV screening of pregnant women, and antiretroviral treatment for those infected, has dramatic reduced mother-to-child transmission. However, after delivery viral load among women living with HIV commonly spikes. Programs specifically design to assist new mothers in maintaining their own health are largely lacking. The purpose of this study was to determine the challenges women face during the postpartum period that could guide program development to improve treatment adherence and quality of life.

METHODS: Adult women seeking treatment at the Almaty AIDS Center between May and September 2018, during research periods, were invited to participate in a cross-sectional study. The questionnaire modules focused on the month immediately after the most recent live birth. Factors studied included household structure, support on tasks related to housework, and support for care of the newborn. Descriptive statistics (e.g., percentages) and tests of association (e.g., Fisher's Exact Tests) were computed. The study was approved by the research ethics committee of the Asfendiyarov Kazakh National Medical University.

RESULTS: The 212 women who had a recent live delivery were included in this analysis. During the 30 days after delivery, women reported they always or most of the time responded to the baby crying (98.5%), changed diapers (95.9%), fed the baby (82.1%), cooked meals (72.6%) and cleaned the house (70.4%). Women living with the baby's father reported receiving less help compared to women living apart from the baby's father ($p<0.01$); this finding held true regardless of whether someone else (e.g., grandparent, parent, friend) was in the household. In general, women were not enthusiastic to visiting nurses providing support at the home. Only 30% of women stated they welcomed a visiting nurse to support medical needs (e.g., education, deliver medications).

CONCLUSIONS: In areas of Central Asia where women are primarily HIV infected by their male partners, developing services to support new mothers is complex. Simple fixes, such as providing visiting nurses to support medication adherence are unlikely to be successful without education on the functions of support services and pilot programs to develop culturally acceptable approaches.

PED0876

CONTRACEPTIVE DECISION-MAKING AMONG WOMEN LIVING WITH HIV IN GHANA AND KENYA

A.J. Bell[1], E. Were[2], T. Agyarko-Poku[3], K. Wools-Kaloustian[4], C. Moyer[5]
[1]University of California at San Francisco, San Francisco, United States, [2]Moi University, Eldoret, Kenya, [3]Ghana Health Service · Suntreso Hospital, Kumasi, Ghana, [4]Indiana University School of Medicine, Indianapolis, United States, [5]University of Michigan, Ann Arbor, United States

BACKGROUND: With increased availability of antiretroviral therapy and improved survival for people living with HIV, more HIV-positive women are leading full reproductive lives. Little is currently known about the contraceptive decision-making process among women living with HIV (WLWH) in Ghana and Kenya.

METHODS: This cross-sectional study was conducted at HIV treatment and care clinics from June – August 2014 in Kenya and from December 2015 – February 2016 in Ghana. A convenience sample of 600 WLWH and aged 15-39 years were enrolled (Ghana, N=300; Kenya, N=300).

RESULTS: Ghanaian and Kenyan women differed significantly in their knowledge and use of family planning (FP) methods. More Ghanaian women were aware of FP methods when compared with their Kenyan counterparts ($p<0.001$ and $p = 0.03$). Kenyan women used hormonal methods such as injectables and implants more than Ghanaians ($p<0.001$). The majority of women in both Ghana and Kenya thought that it was important for a FP method to prevent pregnancy (99.3% and 97.0%), prevent sexually transmitted infections (93.0% and 84.3%), have no risks or side effects (98.0% and 97.3%), have health benefits (99.3% and 98.33%), and need not to be taken daily (92.3% and 50.3%). Ghanaian and Kenyan women differed significantly with regard to wanting a method that prevents pregnancy ($p=0.03$), protects against sexually transmitted infections ($p <0.001$), does not need to be taken daily ($p<0.001$), and can be taken without family, partners, or friends knowing (80.7% vs. 14.0%, $p<0.001$). In both Ghana and Kenya, only 8 (of 600) women had complete agreement between FP characteristics deemed important and the features of the method they indicated that they were most likely to use.

CONCLUSIONS: Characteristics deemed important by WLWH in Ghana and Kenya are not in agreement with the characteristics of the contraceptive method that they indicate they are most likely to use. Previous use of a family planning method was significantly positively associated with identifying that method as the most likely to be used. Lack of integration of family planning into HIV care and treatment is the likely driver of differences in findings between Ghana and Kenya.

PED0877

CERVICAL CANCER SCREENING AMONG WOMEN LIVING WITH HIV IN METRO VANCOUVER: IMPLICATIONS FOR SCALE UP OF ACCESS TO INTEGRATED WOMEN-CENTRED AND TRAUMA-INFORMED HIV CARE AND PRACTICE

K. Deering[1,2], R. Walia[2], P. Duff[2], F. Ranville[1], M. Kestler[2], M. Erickson[2,1], M. Braschel[1], K. Shannon[2,1,2]
[1]Centre for Gender and Sexual Health Equity, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada

BACKGROUND: While women living with HIV (WLWH) have greater risk of acquiring human papilloma virus (HPV) and developing cervical cancer compared to the general population, there remains limited research on drivers of annual cervical cancer (ACC) screening,

particularly in the context of universal health care and resource-rich settings. The objective of this study was to examine the correlates of and barriers to ACC screening among WLWH in Metro Vancouver.

METHODS: Data were drawn from a longitudinal community-based open cohort of 350+ cisgender and trans WLWH (14+ years) who lived and/or accessed care in Metro Vancouver, Canada (2014-present) (Sexual Health and HIV/AIDS: Women's Longitudinal Needs Assessment "SHAWNA"). Participants completed baseline and six-monthly follow-up interviews. Our sample was restricted to cisgender participants, age 21 and older. Bivariate and multivariable logistic regression with generalized estimating equations (GEE) was performed to identify the longitudinal correlates of ACC screening, as recommended by Canadian cervical cancer guidelines.

RESULTS: Overall, 266 WLWH were included (932 observations, 2014-2018), with 69.2% reporting cervical cancer screening in the last year at baseline. The median age of participants was 45 years, and over half (52.3%; N=139) were Indigenous. Over the study period, 24.8% (66) reported any sexual/reproductive health testing barriers, with 9.0% (24) reporting systems-level factors (e.g., geographic barriers, difficulty making appointments), 7.9% (21) reporting anticipated negative experiences associated with cervical cancer screening (including past trauma/discomfort) and 7.5% (20) reporting provider-level factors (e.g., lack of provider of preferred gender), among other barriers. In multivariable analysis, accessing women-centred HIV care (i.e., Oak Tree Clinic, the only HIV practice in our setting providing women-centred, trauma-informed specialized clinical care to women, children and their families living with HIV)(adjusted odds ratio (AOR):2.65;95% confidence interval(CI):1.83-3.85), and inconsistent condom use (AOR:1.76;95%CI:1.15-2.69) were associated with increased odds of ACC screening. Reporting any sexual/reproductive health testing barriers was associated with reduced odds of ACC screening (AOR:0.38;95%CI:0.24-0.59).

CONCLUSIONS: Cervical screening among WLWH in our setting was low compared to women in the general population, with approximately one-third not meeting recommendations for annual cervical cancer testing. These findings highlight the need for increased access to women-centred, trauma-informed integrated sexual and reproductive health care for WLWH.

CONCEPTUALIZING SOCIAL AND STRUCTURAL FACTORS AND THEIR IMPACTS

PED0878

EMPOWERING OR RACIST? SHARING INFORMATION ABOUT HIV-RELATED HEALTH INEQUITIES AND STRUCTURAL RISK FACTORS FOR HIV ACQUISITION WITH WOMEN IN THE U.S.

R.G. Logan[1], W. Wilson[2], S. Wulf[2], T. Williams[3], S. Davis[3], S. Graves[3], S. Weber[2], J. Mims[3], K. Wilson[3], P. Rolle[3], C. Dehlendorf[2,4,5], D. Seidman[2]
[1]University of South Florida, Tampa, United States, [2]University of California, Department of Family & Community Medicine, San Francisco, United States, [3]State of Florida, Department of Health, Duval County Health Department, Jacksonville, United States, [4]University of California, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [5]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: Cisgender Black women have a 1 in 48 lifetime risk of acquiring HIV in the U.S., and Black women in the South are disproportionately affected. Black women use pre-exposure prophylaxis (PrEP) significantly less than their white counterparts due to many factors, including lack of awareness of HIV risk and vulnerabilities and access to PrEP. Further, Black women's historic and continued subjugation in society – intersectional oppressions of race and gender - increase HIV vulnerability. This study explored how women respond to information about structural determinants of HIV risk when offered universal HIV prevention education.

METHODS: Focus groups and interviews were conducted in Jacksonville, Florida and San Francisco, California to obtain feedback on a decision support tool about HIV prevention. Participants provided feedback on information presented on a tablet describing structural determinants of HIV risk including racism, discrimination, and limited access to resources. Local HIV epidemiology was presented by zip code, gender, and race/ethnicity. Data were analyzed thematically.

RESULTS: Eight focus groups (n=43) and 20 interviews were conducted with predominantly cisgender women of reproductive age. Participants self-identified as Black (47%), white (32%), Hispanic (10%), and other race/ethnicity (10%). Two-thirds completed at least some college education. Two central themes emerged: empowerment and discrimination. Participants who viewed the HIV inequities and structural determinants information favorably described feeling "empowered" by accessing information specific to their communities. These participants, who tended to be younger and in California, appreciated identification of racism and discrimination as contributing causes. For others, particularly older respondents in Florida, identifying higher HIV rates among already marginalized communities was perceived as "singling out" these groups; some even described naming structural determinants as "racist." When exploring ways to convey information about structural vulnerabilities to HIV, a minority of respondents preferred talking with a provider rather than independently reading about sensitive information.

CONCLUSIONS: Participants had differential reactions to information about structural determinants of HIV inequities, ranging from empowering to harmful. In general, respondents appreciated local data specific to their communities. To reduce harm, information must be presented in a trauma-informed manner, and providers must be prepared to continue conversations about structural determinants during clinic visits.

PED0879

INTERSECTING EXPERIENCES OF FOOD INSECURITY, VIOLENCE, SUBSTANCE USE AND POOR MENTAL HEALTH MAY INFLUENCE HIV PREVENTION AND TREATMENT BEHAVIORS AMONG US WOMEN: EVIDENCE OF A SYNDEMIC IN NEED OF ATTENTION

A. Leddy[1], J. Shieh[1], A. Conroy[1], I. Ofotokun[2], S. Weiser[1], P. Tien[1]
[1]University of California, San Francisco, United States, [2]Emory University School of Medicine, Atlanta, United States

BACKGROUND: Food insecurity and gender based violence (GBV) are associated with increased risk for HIV and suboptimal engagement in care. Limited research has explored how syndemic factors such as food insecurity and GBV intersect to influence HIV-related behaviors. To fill this gap, we conducted a qualitative study with women living with or at risk of HIV in the US.

METHODS: We conducted 24 in-depth interviews with women enrolled in the San Francisco and Atlanta sites of the Women's Interagency HIV study (WIHS), an ongoing cohort study of women living

with and at risk of HIV. Participants were purposively sampled so that half were living with HIV and all reported experiencing food insecurity and physical, sexual or emotional GBV in the past year. Semi-structured interviews asked about women's experiences with food insecurity and GBV, perspectives on how food insecurity and GBV are related, and how such experiences impact behaviors including condomless sex and treatment adherence. Interviews were audio recorded, transcribed and analyzed using an inductive-deductive approach.

RESULTS: A predominant theme that emerged centered on how food insecurity and violence co-occur with substance use and poor mental health to influence HIV-related behaviors. Women described how co-occurring experiences of food insecurity and violence negatively impacted their mental health, with many noting how substances were used to "feel no pain." Substance use was described to perpetuate experiences of food insecurity, GBV, and poor mental health in a vicious cycle. Further, women noted that these intersecting experiences led them to engage in risky behaviors including exchanging sex for drugs or food and condomless sex and prevented women living with HIV from accessing their HIV appointments and adhering to HIV treatment.

CONCLUSIONS: Our findings revealed that food insecurity, GBV, substance use, and poor mental health co-occur in important ways to negatively influence HIV prevention and treatment behaviors. These findings provide preliminary evidence of a syndemic that goes beyond the more widely-studied "SAVA" (substance use, AIDS, and violence) syndemic, warranting new attention. Future quantitative research is needed to elucidate the synergistic effects of multiple factors including food insecurity, GBV, substance use, and mental health, on HIV-related behaviors.

PED0880

RETHINKING HOW 'SEX-FOR-FISH' SHAPES HIV VULNERABILITY: OCCUPATIONAL HIERARCHIES IN UGANDAN FISHING VILLAGES

E.V. Moore[1], F. Lukabwe[2], C. Ssekyewa[2], N. Nakyanjo[2], C.E. Kennedy[3], J.S. Hirsch[4], F. Nalugoda[2], J.S. Santelli[1]
[1]Columbia University Mailman School of Public Health, Heilbrunn Department of Population and Family Health, New York, United States, [2]Rakai Health Science Program, Kalisizo, Uganda, [3]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [4]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States

BACKGROUND: The fishing villages surrounding Lake Victoria have become HIV "hot spots" with HIV prevalence rates as high as 40% for women and 20% for men. These high prevalence rates are commonly attributed to labor mobility and quick access to cash among fisherfolk; in combination, those two phenomena are thought to normalize and facilitate transactional sexual arrangements and increase unprotected, commercial, and cross-generational sex. Research to date has illuminated how East Africa's lucrative fishing industry produces unique socio-economic dynamics that shape fisherfolks' sexual health; this research has overlooked heterogeneity within fishing communities. Addressing that gap, this paper examines the various gendered, generational, and occupational hierarchies that produce differential vulnerabilities to HIV within Lake Victoria's fishing villages.

METHODS: Ethnographic data were collected from two fishing villages in Uganda's Rakai district, including 8 focus group discussions and 12 in-depth interviews with sixty community members (young men ages 17-24, young women ages 17-24, older women ages 35-70, older men ages 35-70) and key informant interviews with twenty community leaders.

RESULTS: Our analysis reveal a nuanced, locally salient set of occupational hierarchies that affect fishing village residents' labor mobility, social lives, and sexual engagements. For example, young men (17-24) at the lakeshores work as "boat-pushers," "net-detanglers," or "boat managers," yet only older fishermen earn enough money to provide for their households, wives, and children. The younger men who work at the lakeshores are not "fishermen" and cannot afford to establish independent households.

Therefore they either buy sex from sex workers or engage in "sugar mommy" relationships with older women (35+) who own small bars and restaurants in the area. Other gendered, generational, and occupational differences in the landing sites may also deferentially shape HIV vulnerability.

For example, recent national regulations limiting fishing have made it more difficult for young men to earn incomes, which may encourage them to exchange sex for money.

CONCLUSIONS: In addition to the need to target Lake Victoria's fishing villages for HIV prevention and treatment interventions, our analyses suggest a need to tailor policies and programs to respond to residents' differential social, gendered, and generational positionings and associated HIV risk.

INTERPERSONAL PATIENT SATISFACTION FACTORS MORE STRONGLY CORRELATED WITH RETENTION IN CARE THAN STRUCTURAL FACTORS AMONG ADULTS RECEIVING HIV SERVICES IN RURAL MOZAMBIQUE

C. De Schacht[1], E. Ntasis[1], L. Calvo[2], J. Matsimbe[3], S. Martinho[2], E. Graves[4], H. Kassim[5], I.C. Carlos[5], C.W. Wester[4,6], S. Van Rompaey[1], G. Amorim[7], C. Audet[4,8]
*[1]Friends in Global Health, Maputo, Mozambique, [2]Friends in Global Health (*at time of study), Quelimane, Mozambique, [3]Friends in Global Health, Quelimane, Quelimane, Mozambique, [4]Vanderbilt Institute of Global Health, Nashville, United States, [5]Provincial Health Directorate, Quelimane, Mozambique, [6]Vanderbilt Institute of Global Health (VUMC), Department of Medicine, Nashville, United States, [7]Vanderbilt University Medical Center (VUMC), Department of Statistics, Nashville, United States, [8]Vanderbilt Institute of Global Health (VUMC), Department of Health Policy, Nashville, United States*

BACKGROUND: Retention in care is compromised by multiple factors. Patient satisfaction, reflecting service quality, potentially acts as a covariate influencing retention. The study aimed to assess satisfaction among adults receiving HIV services in Zambézia Province, Mozambique, and its association with 6-month retention.

METHODS: Exit-interviews with HIV-positive adults were completed between December 2017 and February 2019 in 20 health facilities. Satisfaction surveys, using a 4-tiered Likert scale, assessed eight components: wait time, health professionals' availability, respect, attention received, information received, opportunity to ask questions, usefulness of providers, and overall evaluation. Clinical data were extracted from electronic patient files. Regression analyses assessed the effect of combined satisfaction scores on retention (defined as having an antiretroviral therapy pick-up in the period between 5.5-8.5 months from interview date), using restricted cubic splines, adjusting for age, sex, education and health facility type. Individual logistic regressions measured the impact of individual satisfaction questions on retention, adjusting for the same factors.

RESULTS: Among 2,749 interviewed adults, mean age was 33 years (sd 10yrs); 2,036 (74%) were female, 305 (11%) had no formal education. Overall mean satisfaction score was 69% (sd 19%). By varying the satisfaction score from first to third quartile, the odds of being retained was 2.01 (95%CI:1.56–2.60) for women and 1.76 (95%CI:1.18–2.61) for men. A weak correlation existed between satisfaction regarding wait time and 6-month retention, while the odds of being retained was positively correlated with a higher satisfaction regarding the information received, the opportunity to ask questions, and being cared for with respect (Table 1).

Satisfaction Score	Respect OR (95% CI)	Attention given to patient concerns OR (95% CI)	Information received about your disease OR (95% CI)	Opportunity to ask questions and receive responses OR (95% CI)	Time spent with provider to talk about concerns OR (95% CI)	Wait time OR (95% CI)	Opinion on overall service quality OR (95% CI)	Overall helpfulness of providers OR (95% CI)
Not satisfied	Ref.	Ref.	Ref.	Ref.	Ref.	Ref.	Ref.	Ref.
Somewhat satisfied	0.99 (0.68–1.44)	0.85 (0.53–1.34)	1.32 (0.87–2.00)	1.72 (1.09–2.71)	0.85 (0.64–1.12)	1.20 (0.97–1.49)	1.26 (0.64-2.49)	0.90 (0.45–1.78)
Satisfied	2.06 (1.38–3.06)	1.62 (1.02–2.57)	2.52 (1.61–3.96)	3.14 (1.94–5.08)	1.02 (0.75–1.38)	1.35 (1.02–1.78)	2.44 (1.22-4.89)	1.41 (0.71–2.79)
Very satisfied	2.10 (1.35–3.27)	1.85 (1.10–3.11)	2.56 (1.55–4.23)	3.22 (1.92–5.41)	1.55 (1.21–2.00)	1.13 (0.91–1.40)	1.67 (0.80-3.50)	1.82 (0.90–3.69)

[Table 1. Probability of being retained, for each individual question (compared to baseline score), adjusted for sex, age, education level, and type of health facility]

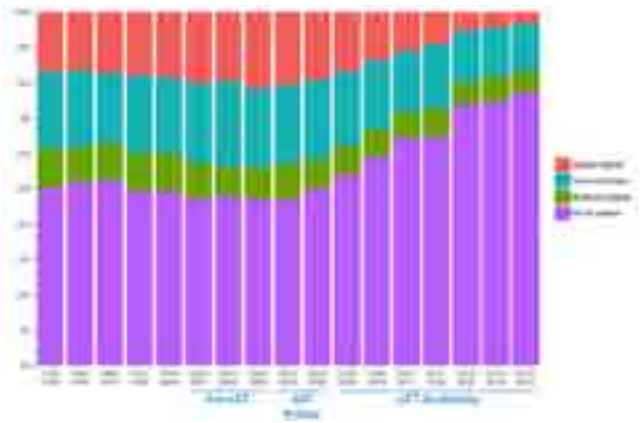
CONCLUSIONS: While patient satisfaction regarding wait time was weakly correlated with retention, interpersonal factors related to provider-patient interaction appeared to be the main drivers of retention. A positive health worker's attitude, provision of undivided attention towards patients, and delivering accurate information about the patient's health increased satisfaction and retention to care. In order to promote empathetic care, clinical mentoring should be directed towards improvement of interpersonal communication skills.

PED0882

COMMUNITY-LEVEL IMPACT OF ART ON ORPHANHOOD AMONG ADOLESCENTS, RAKAI COMMUNITY COHORT STUDY 2000-2018

J.S. Santelli[1], I. Chen[2], D. Nabukalu[3], T. Lutalo[3], E. Spindler[1], L. Chang[4], K. Grabowski[4], S. Grilo[1], P. Kreniske[5], F. Nalugoda[3], S. Hoffman[5], J. Kagaayi[3], M. Wawer[4], D. Serwadda[3], F. Makumbi[3]
[1]Columbia University Mailman School of Public Health, Heilbrunn Department of Population and Family Health, New York, United States, [2]Columbia University Mailman School of Public Health, Biostatistics, New York, United States, [3]Rakai Health Science Program, Kalisizo, Uganda, [4]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [5]New York State Psychiatric Institute and Columbia University, HIV Center for Clinical and Behavioral Studies, New York, United States

BACKGROUND: Orphanhood increased in the 1980s and 1990s in sub Saharan Africa (SSA) due to HIV-related mortality among parents. Thus, increasing access to antiretroviral treatment (ART) in SSA should reduce orphanhood. In Rakai District, Uganda, ART was introduced in 2004. We examined longitudinal trends in reported orphanhood in the Rakai Community Cohort Study (RCCS) and we compared HIV prevalence and use of ART among communities, attempted to ascribe declines in orphanhood to HIV-related factors.
METHODS: We used data from the RCCS from 30 communities followed continuously from 2000 to 2018. We examined trends in maternal, paternal and double orphanhood among adolescents 15-19 years before and after 2004. We assessed the association of community-level HIV prevalence and self-reported ever use of ART with orphanhood using multivariable multinomial logistic regression which controlled for age and used a cluster-robust sandwich estimator of variance to account for within-community correlation.
RESULTS: Orphanhood in Rakai declined from about half of adolescents before 2004 to only one quarter by 2018 (test for trend p<0.001). Ever use of ART among HIV+ residents rose from 11% in 2004 to 78% in 2018. In regression models, a 10% higher community HIV prevalence (Relative Risk Ratio=1.03, 95% CI 1.01-1.06) and a 10% lower ART use among women (RRR=1.10, 95% CI 1.07-1.13) were associated with higher risk of maternal orphanhood. Similar results were found for paternal orphanhood. Use of ART by women had a larger effect than ART use by men. An absolute increase of 10% in ART usage among HIV+ women was associated with a 17% decrease in risk of double orphanhood, while an absolute increase of 10% in ART usage among HIV+ men was associated with a 9% decrease in risk of double orphanhood.



[Figure. Orphanhood, adolescents, Rakai community cohort study, 1994-2018]

CONCLUSIONS: Availability of ART in Rakai, Uganda since 2004 has substantially reduced orphanhood among adolescents.

PED0883

FACTORS AFFECTING ART RETENTION AMONG PLHIV IN HIGHLANDS PAPUA, INDONESIA

W. Jumalasari[1], S. Sulami[1], W. Indrasari[2], C. Wong[3], C. Francis[4]
[1]Family Health International (FHI 360) - LINKAGES Project, Monitoring and Evaluation (M&E) and SI (Strategic Information), Jakarta, Indonesia, [2]Family Health International (FHI 360) - LINKAGES Project, Research Coordinator, Jakarta, Indonesia, [3]Family Health International (FHI 360) - LINKAGES Project, Scientist, Singapore, Singapore, [4]Family Health International (FHI 360) - LINKAGES Project, Chief of Party, Jakarta, Indonesia

BACKGROUND: Papua province, Indonesia has an estimated HIV prevalence of 2.3% compared to 0.6% in the rest of the country. In three Papua highlands districts (Jayawijaya, Yalimo, and Lanny Jaya), attrition rates of people living with HIV (PLHIV) on antiretroviral therapy (ART) are similarly high, with up to 67% of total ART patients failing to return to HIV treatment services after three months on treatment. The LINKAGES project, funded by USAID and PEPFAR and led by FHI 360, conducted a qualitative study in 2019 to explore cultural beliefs around health and sickness and to identify barriers and facilitators affecting HIV treatment retention.
METHODS: A qualitative descriptive analysis was conducted through focus group discussions (FGDs) among community members and in-depth interviews (IDIs) of PLHIV and key informants.

Overall, 13 FGDs were conducted (total of 96 participants) as well as 38 IDIs with PLHIV and 29 with key informants. Data analysis using NVIVO 12.

RESULTS: Participants described a sick person as someone who is incapacitated and bedridden; as such, a person living with HIV will typically not avail HIV treatment services in Papua until they present with physical symptoms, and they may stop treatment as soon as they feel well. Traditional healing methods were cited as typically used before biomedical medicine—or in conjunction with ART—with participants highlighting "effective" traditional treatments such as herbal therapies. Stigma and discrimination against people who are HIV positive were found to affect both ART uptake and retention, as participants described feeling afraid of being scolded or abandoned by family and community. Individuals who dropped out of care or missed ARV doses described feeling better, having transportation issues or work commitments, and/or not accepted by family as the main reasons for treatment stoppage. Those retained or re-engaged in treatment highlighted their desire to stay alive and to remain healthy so as to get married or have children.

CONCLUSIONS: Newly decentralized ART services in the Papua highlands will not optimize ART initiation and retention without community engagement strategies that mobilize religious and community leaders, traditional healers, and PLHIV "role models" in ART socialization and retention efforts.

PED0884

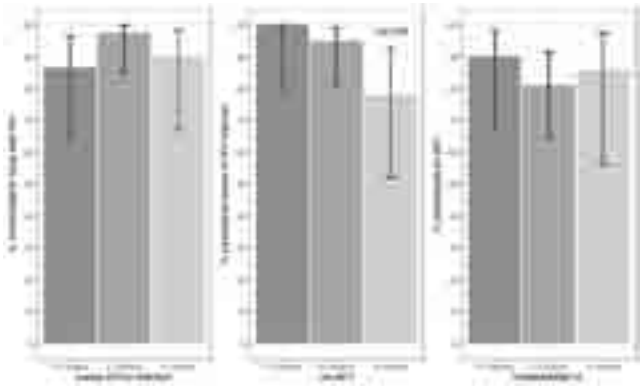
SYNDEMIC PSYCHOSOCIAL FACTORS ARE BARRIERS TO THE HIV CARE CONTINUUM AMONG TRANS WOMEN IN SAN FRANCISCO

L. Coelho[1], D. Trujillo[2], S. Sicro[2], E. Daza[2], J. Meza[2], M. Bella[2], C. Sanz Rodriguez[2], B. Grinsztejn[1], J. Lin[2], W. McFarland[2], E.C. Wilson[2]
[1]Fundação Oswaldo Cruz (FIOCRUZ), Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]San Francisco Department of Public Health, Center for Public Health Research, San Francisco, United States

BACKGROUND: Syndemic psychosocial factors (encompassing multiple adverse individual, social, and structural conditions) synergistically produce negative health outcomes for vulnerable populations. The objective of the present analysis is to determine if syndemic factors adversely affect the HIV care continuum among trans women – the population most severely affected by HIV worldwide.

METHODS: We assessed the association of syndemic factors on steps of the HIV care continuum in a community-recruited sample of trans women in San Francisco (2018-2019), including:
(1) HIV infection awareness,
(2) ART uptake, and;
(3) virologic suppression (self-report).
A syndemic score was created using history in last year of suicide attempt or plan, binge drinking, drug use (injection/non-injection), violence (intimate partner violence, physical abuse, sexual abuse), imprisonment, homelessness, and sex work. HIV care continuum endpoints were assessed for their association with increasing number of syndemic factors in logistic regression analysis.

RESULTS: Of 82 transgender women living with HIV, 77 (93%) were aware of their infection, 70 (85%) were using ART, and 59 (72%) were virally suppressed. Most (82%) trans women experienced at least one syndemic factor, with the most common being drug use (66%), homelessness (56%), and binge drinking (46%). Having 4 or more syndemic factors was associated with lower ART uptake (aOR 0.39, 95%CI 0.16, 0.77), but not with infection awareness or viral suppression. Injection drug use (aOR 0.10, 95%CI 0.01, 0.70) and imprisonment (aOR 0.11, 95%CI 0.01, 0.86) were independently associated with lower ART use. All participants (100%) who were not using ART were homeless compared to 54% of those using ART (p=0.04).



[Figure.]

CONCLUSIONS: Experiencing multiple syndemic factors was associated with poor ART use among trans women in San Francisco. Homelessness, injection drug use, and history of imprisonment were individually associated with ART use and should be priorities for interventions.

PED0885

DECOMPOSING SOCIOECONOMIC INEQUALITIES IN HIV TESTING IN 16 SUB-SAHARAN AFRICAN COUNTRIES: THE ROLE OF EPIDEMIOLOGICAL AND MACRO-ECONOMIC FACTORS

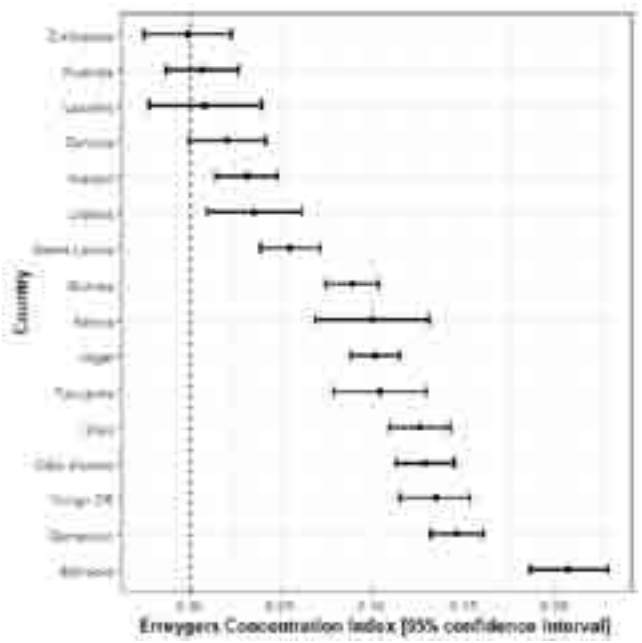
P.A. Ante-Testard[1], T. Benmarhnia[2], A. Bekelynck[3], R. Baggaley[4], E. Ouattara[5], L. Temime[1], K. Jean[1]
[1]Conservatoire National des Arts et Métiers, Modélisation, Épidémiologie et Surveillance du Risque Sanitaire (MESuRS), Paris, France, [2]University of California, Department of Family Medicine and Public Health, San Diego, United States, [3]Programme PAC-CI, Abidjan, Cote D'Ivoire, [4]World Health Organization, Department of HIV and Global Hepatitis Programme, Geneva, Switzerland, [5]Centre Hospitalier Universitaire de Bordeaux, Department of Infectious and Tropical Diseases, Bordeaux, France

BACKGROUND: Although socioeconomic inequalities in the uptake of HIV testing have been widely reported, their drivers remain poorly understood. For instance, it is unclear whether the epidemiological or the macro-economic factors are acting as the main drivers of inequalities. To address this issue, we measured and decomposed socioeconomic inequalities in HIV testing in sub-Saharan Africa (SSA).

METHODS: We used data from recent Demographic and Health Surveys conducted between 2008 and 2016 in 16 SSA countries. We calculated the country-specific Erreygers Concentration Index (values range from -1 to 1 with 0 indicating equality) to estimate socioeconomic inequalities in recent (<12 months) HIV testing. Inequalities were decomposed using the Recentered Influence Function (RIF) regression method to assess which country-level factors (between GDP per capita and HIV prevalence) contributed most to these disparities.

RESULTS: We analyzed 16 surveys conducted among 315,847 participants (≥15 years old). Significant positive ECI values ranging from 0.03 [95% CI 0.01; 0.05] to 0.21 [0.19; 0.23] (Figure), indicating concentration of HIV testing among the wealthier, were observed in 12 out of 16 countries. No inequalities were seen in Zimbabwe, Rwanda, Lesotho and Zambia. Decomposition analysis showed that an increase

in HIV prevalence decreased inequality in recent testing (Coefficient -0.006 [-0.011; -0.002]); while, GDP per capita had no apparent effect on inequality (Coefficient 0.025x10^{-3} [-0.033x10^{-3}; 0.084x10^{-3}]).



[Figure.]

CONCLUSIONS: Despite the overall increase in testing in recent years, important socioeconomic inequalities in its access remained in majority of SSA countries. Preliminary results suggest that the level of HIV epidemic, which also drives the response level of HIV programs, is associated with inequalities in HIV testing. Meanwhile, GDP per capita (a national indicator of economic development) is not. Next steps of this research will integrate a wider range of epidemiological and socioeconomic variables. These results may help understand the underlying mechanism generating socioeconomic inequalities in health.

MEDIATORS OF THE RELATIONSHIP BETWEEN ADOLESCENT MOTHERHOOD AND INCIDENT HIV INFECTION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN SOUTH AFRICA (HPTN 068)

N.L. Bhushan[1], M.C. Stoner[2], K. Kahn[3], R. Twine[3], A.E. Pettifor[4,3], A.K. Groves[5]
[1]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [2]RTI International, Women's Global Health Imperative, San Francisco, United States, [3]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, Johannesburg, United States, [4]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, [5]Drexel University, Community Health and Prevention, Philadelphia, United States

BACKGROUND: Adolescent girls and young women (AGYW) who become mothers before the age of 19 face additional social and economic strains that may increase their likelihood of engaging in high risk sexual partnership and subsequent vulnerability to HIV infection. Yet, limited evidence exists regarding how early childbearing may affect HIV risk. We hypothesize that adolescent mothers have a higher incidence of HIV because they are more likely to engage in high risk sexual partnerships that are associated with HIV infection including having transactional sex and age-disparate partnerships (>5 years).

METHODS: We used data from the HIV Prevention Trials Network (HPTN) 068 study in rural South Africa (2011-2017). AGYW, aged 13-20, were followed approximately annually for up to 6 years. We use the parametric g-formula to estimate the total effect of time-varying, early motherhood (having a live birth before age 19) on incident HIV infection and the controlled direct effect for mediation through partner characteristics. The controlled direct effect represents the effect of adolescent motherhood on HIV not operating through transactional sex and age-disparate partnerships. We calculated hazard ratios (HR) and risk ratios (RR) over the study period. Confidence intervals were calculated using the standard deviation of results from 200 bootstrap samples.

RESULTS: Early mothers were more likely to be engaged in transactional sex (RR 2.14; 95% CI 1.08, 4.22), have age-disparate partnerships (2.05; 95% CI 1.09, 3.86) and a higher incidence of HIV infection over the study period (HR 1.41; 95% CI 1.34, 1.45). The hazard ratio for HIV incidence was 1.23 (95% CI: 1.17, 1.29) when holding both partner age and transactional sex constant, showing attenuation from the total effect (HR 1.41) and indicating partial mediation.

CONCLUSIONS: Age-disparate partnerships and transactional sex were associated with early motherhood and partially mediated the relationship between early motherhood and HIV incidence. Young mothers are more likely to engage in risky partnerships putting them at increased risk of HIV. However, risky partnerships explain only a portion of the effect of early motherhood on HIV infection, suggesting that other structural and social factors may also work to increase their HIV risk.

PED0887

POLICING PRACTICES AND HIV RISK AMONG FEMALE SEX WORKERS WHO USE DRUGS IN KAZAKHSTAN

T. Mukherjee[1], T. McCrimmon[2], G. Mergenova[3], S. Primbetova[3], A. Terlikbayeva[3], S. Witte[2], N. El-Bassel[2]
[1]Columbia Mailman School of Public Health, Epidemiology, New York, United States, [2]Columbia University, School of Social Work, New York, United States, [3]Global Health Research Center of Central Asia, Almaty, Kazakhstan

BACKGROUND: Transactional sex to support drug habits provides an important link between women who use drugs and the general population. Female sex workers who use drugs (FSW-UD) in Eastern Europe and Central Asia continue to experience one of the highest rates of HIV incidence globally. A major challenge to HIV prevention efforts in the region include policing practices. Therefore, we examined associations between police violence, detention and several HIV risk factors among FSW-UD.

METHODS: Findings were drawn from baseline interviews of Project Nova, a combination HIV risk reduction and microfinance intervention. Study participants were women who used drugs, engaged in sex work and were recruited from two cities in Kazakhstan. Four-hundred women were enrolled and completed computer-assisted self-interviews between February 2015 and May 2017. Interviews assessed sociodemographic and sex work characteristics, criminal justice history, substance use and police violence. Associations between police violence and detention, and HIV, sexually transmitted infection (STI), number of clients, needle sharing, and condom use was examined using multivariate logistic regression.

RESULTS: Ninety-six (24%) reported experiencing police violence, and 116 (29%) reported being detained by the police in the past 90 days. Ninety-three (23%) reported living with HIV, and 85 (21%) re-

ported a STI in past 90 days. Women reported 20.7 (SD: 39.8) different clients, on average, 125 (31%) reported at least one instance of condomless sex, and 36 (9%) reported sharing needles. Logistic regression analyses showed that police violence was associated with greater odds of having more clients (aOR: 2.54, 95% CI: 1.48, 4.35), needle sharing (aOR: 4.52, 95% CI: 2.00, 10.23) and STIs (aOR: 2.39, 95% CI: 1.36, 4.22). Recent detention was associated with a greater odds of needle sharing (aOR: 3.44, 95% CI: 1.56, 7.57) and STIs (aOR: 1.94, 95% CI: 1.14, 3.32).

CONCLUSIONS: Police violence and detention are associated with HIV risk factors including a greater number of clients, needle sharing, and STIs. The integration of policing and public health has been successfully implemented in other settings and may be a novel approach to HIV prevention among FSW-UD in Kazakhstan. Interventions to increase police accountability through sensitization workshops, advocacy and institutional accountability are a recommended strategy.

PED0888

PERCEIVED SOCIAL SUPPORT AMONG ADOLESCENTS AND YOUNG ADULTS LIVING WITH HIV

J. Neary[1], K. Beima-Sofie[2], J. Dyer[2], K. Agot[3], K. Wilson[2], R. Bosire[3], J. Badia[3], J. Kibugi[3], S. Shah[4], I. Inwani[5,6], P. Kohler[7], G.C. John-Stewart[8]
[1]University of Washington, Epidemiology, Seattle, United States, [2]University of Washington, Global Health, Seattle, United States, [3]Impact Research and Development Organization, Kisumu, Kenya, [4]Northwestern University, Medical School/Bioethics Program at Lurie Children's Hospital, Chicago, United States, [5]University of Nairobi, Nairobi, Kenya, [6]Kenyatta National Hospital, Nairobi, Kenya, [7]University of Washington, Psychosocial and Community Health, Global Health, Seattle, United States, [8]University of Washington, Global Health, Medicine, Pediatrics, Epidemiology, Seattle, United States

BACKGROUND: Adolescents and young adults living with HIV (ALHIV) have poorer retention in care and medication adherence than adults. Social support among ALHIV is not well characterized and may influence medication adherence, engagement in care, and clinical outcomes.

METHODS: The Data-informed Stepped Care to Improve Adolescent Outcomes (DiSC) cohort includes ALHIV 10-24 years receiving HIV care at nine health facilities in Western Kenya. The 12-item Multidimensional Scale of Perceived Social Support (MSPSS) was used to assess perceived social support from family, friends, and significant others (4 items each). Response options for each item were on a 5-point Likert-type scale. Means and t-tests were used to compare older (15-24 years) and younger (10-14 years) ALHIV.

RESULTS: Among 1,144 ALHIV, median age was 17 years (interquartile range: 14-20); 26% were younger (10-14 years) and 74% were older (15-24 years). Thirty-four percent were male and 70% were enrolled in school. The overall mean MSPSS score was 3.46 (range: 1-5; standard deviation [SD]=0.61); 3.86 (SD=0.79) for family, 3.34 (SD=0.94) for friends, 3.24 (SD=1.13) for significant other subscales.

Mean MSPSS scores did not differ between males and females. Compared to younger ALHIV (mean overall MSPSS: 3.28), older ALHIV had higher mean overall MSPSS scores (3.53; p<0.001). Compared to older ALHIV, younger ALHIV reported higher perceived family support (3.96 vs. 3.82; p=0.010) but lower friend (3.23 vs. 3.37; p=0.019) and significant other support (2.59 vs. 3.47; p<0.001).

School enrollment was associated with higher mean MSPSS scores among ALHIV 20-24 years (3.79 vs 3.55; p=0.004), driven by more support from friends and family. Secondary and college education was associated with higher MSPSS scores among ALHIV 15-24 years compared to primary education (3.64 and 3.83 vs. 3.37, respectively; p<0.001 for both).

MSPSS scores were associated with resilience scores in ALHIV (β: 0.083; p<0.001 after adjusting for age), and were not associated with depression.

CONCLUSIONS: Older, educated, and more resilient ALHIV have higher perceived social support. While family support is higher in younger than older ALHIV; as ALHIV age, friends play a critical role in providing support. Leveraging social support or addressing under-supported ALHIV could improve ALHIV health outcomes.

PED0889

FROM SOCIAL TO SELF-REGULATION: THE PREVALENCE AND IMPACT OF SOCIAL NETWORK CONTROL ON ART ADHERENCE AMONG TRANS WOMEN LIVING WITH HIV

M. Hill[1], D. Robinson[2], T. Kershaw[3], E. Wright[4], A. Radix[5], T. Cooper[6], N. Hansen[7]
[1]Private, Atlanta, United States, [2]University of Georgia, Sociology, Athens, United States, [3]Yale University, New Haven, United States, [4]Georgia State University, Sociology, Atlanta, United States, [5]Callen-Lorde Community Health Center, New York, United States, [6]Advocates for Better Care Atlanta, Atlanta, United States, [7]University of Georgia, Health Promotion & Behavior, Athens, United States

BACKGROUND: Despite an increased focus on HIV disparities among trans women, information on the social networks of seropositive trans women is scarce. Social control describes the tactics that network members use to directly influence others. Though the effects of social control on self-regulation in areas ranging from diet to diabetes are well-documented, more remains to be known about social control among trans women living with HIV.

This study seeks to contribute knowledge by exploring how different methods might impact trans women's adherence to anti-retroviral therapy.

METHODS: From February to August 2019, 231 trans women living with HIV in the US took a 20-30-minute egocentric survey asking about the tactics that their social network members used to promote ART adherence. Descriptive statistics were calculated to determine the prevalence and sources of social control methods. Relationships between social control variables and ART adherence were examined via hierarchical logistic regression.

RESULTS: On average, participants were 32 years old and had been diagnosed for nearly 5 years. Over half were White (62%), employed (68%), stably housed (71%), and were optimally ART adherent (69%). Most of the network members who were aware of participants' HIV status persuaded or encouraged them to adhere to their medication (83%), while less than half (41%) pressured them. Among various network members, most chosen family (75%), friends (87%), and partners (92%) used persuasive tactics, while a lesser percentage pressured them (chosen family = 18%, friends = 40%, partners = 65%). Most providers used persuasive (88%) and/or pressuring tactics (81%). After adjusting for co-variates, analyses showed that a higher proportion of network pressure was associated with lower odds of adherence (aOR = .97, p < .01) while increased persuasion was marginally associated with increased adherence odds (aOR = 1.02, p = .01).

CONCLUSIONS: Findings suggest that the tone and delivery of treatment support messages may have implications for HIV treatment. While positively encouraging tactics from social network members may promote ART adherence, critical messages may have the op-

posite effect. More expansive research is needed to understand the short- and long-term impacts of social regulation on self-regulation among trans women living with HIV.

PED0890

DIFFERENTIAL ROLES OF STIGMA AND DEPRESSION ON HIV CARE CONTINUUM OUTCOMES AMONG MSM AND PWID IN INDIA

N. Prata Menezes[1], G.M. Lucas[2], A. McFall[1], E.U. Patel[1], A.K. Srikrishnan[3], C.K. Vasudevan[3], S. Anand[3], S.S. Solomon[1,2,3], D.D. Celentano[1,2], S.H. Mehta[1]
[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, [3]YR Gaitonde Centre for AIDS Research and Education, Chennai, India

BACKGROUND: We previously demonstrated that MSM fared significantly better across the HIV care continuum compared to PWID in a large multi-city study across India. In this analysis, we assessed whether stigma and depression impacted care continuum outcomes differently in men who have sex with men (MSM) and people who inject drugs (PWID) in India to potentially explain these differences.

METHODS: Between 2016 and 2017, we recruited 10,005 MSM and 11,721 PWID using respondent-driven sampling (RDS) across 21 Indian cities. Multilevel Poisson regression models using scaled RDS-II weights were used to explore the association between depression, 4 stigma indices (enacted, vicarious, felt/normative, internalized) and care continuum outcomes among HIV-infected participants. Models assessed whether associations of depression (using the PHQ-10 tool) and each stigma index (modeled separately) with care continuum outcomes differed for MSM vs. PWID using adjustment and interaction terms. Models were adjusted for age, gender, recent substance use, recent incarceration, and region.

RESULTS: We recruited 1,713 HIV-infected MSM (median age: 33 years) and 2,517 HIV-infected PWID (median age: 36 years; 87% male). Compared to MSM, PWID reported higher moderate/severe depression (25% vs. 11% MSM), enacted stigma (42% vs. 36% MSM), felt/normative stigma (85% vs. 69% MSM), and internalized stigma (88% vs. 68% MSM). Adjustment for depression, stigma and other covariates, did not appreciably attenuate associations between MSM vs. PWID and engagement in HIV care (adjusted prevalence ratio for MSM vs. PWID [APR]: 1.68; 95% CI: 1.05, 2.68), ART use (APR: 1.82; 95% CI: 1.23, 2.70) or viral suppression (APR, 1.64; 95% CI, 0.96, 2.80). In adjusted models, statistically significant interactions were observed between MSM/PWID status and enacted stigma and ART use (p=0.04) and community stigma and engagement in HIV care (p=0.01). No differences were observed in the association between depression and any HIV care outcome among MSM and PWID.

CONCLUSIONS: While PWID report higher levels of stigma and depression than MSM, differences in stigma and depression did not appear to fully explain differences in engagement across the HIV care continuum. However, given the high burden and impact on HIV care outcomes, incorporating population-specific, psychosocial interventions may improve HIV clinical outcomes.

PED0891

CONCEPTUALISING THE "CORE" PACKAGE OF SERVICES FOR ORPHANED AND VULNERABLE CHILDREN IN SOUTH AFRICA ABSTRACT

Y. Makubedu[1], W. Botes[2]
[1]South African Government, Department of Social Development, Pretoria, South Africa, [2]Pact South Africa, Government Capapcity Building and Support Programme, Pretoria, South Africa

BACKGROUND: Social and structural barriers continue to undermine the biomedical advances of ARV treatment in South Africa. Despite having the world's largest ARV treatment program, orphaned and vulnerable children and adolescents remain highly vulnerable: 14% of children are orphaned, 500 000 children live with HIV, adolescent girls and boys enter sexual debut early, 1 in 3 children are exposed to sexual violence, 27% of children are stunted, and only 1 in 2 children matriculate.

DESCRIPTION: Addressing these drivers is a necessity to ensure better outcomes for children and to reach epidemic control. The Department of Social Development launched a "core" package of services that draws on an ecological approach to mobilise protective resources to build a resilient system supportive of the community, family and child. It operationalises services for sustained change across 7 domains:

- Child care & protection: addressing exposure to violence, substance abuse and neglect.
- Psychosocial support: improving mental health.
- HIV/Aids support: promoting known status, ART uptake and adherence, mitigating sexual and substance risk-taking behaviour.
- Health promotion: promoting access to health care, general and sexual reproductive health, targeting support for children with disabilities.
- Food & Nutrition: strengthening adequate nutrition, tracking growth to address stunting.
- Economic strengthening: linking adolescents and families to social-protection and government incentives for job creation
- Educational support: improving access and supporting participation in schooling and linking school leavers with training opportunities.

LESSONS LEARNED: The pilot indicates that the Core package is effective in identifying and linking hard-to-reach and highly vulnerable children to services. The Core package achieved improved management and tracking of HIV related concerns as a result of taking an ecological rather than health only approach. Specifically, this approach proved effective in promoting ‚known status' and supporting HIV testing for at-risk children. Lastly, integrating case management and evaluation practice in the operational planning from the onset improved data quality and short-term outcomes of improved linkages.

CONCLUSIONS/NEXT STEPS: The implementation of integrated services across sectoral boundaries is a bold departure form a pure welfare or health approach. The continued implementation of the Core Package will be critical to securing longer-term gains in reducing the effect of engrained social and structural barriers.

PED0892

HOUSING INSTABILITY AND HIV RISK: EXPANDING OUR UNDERSTANDING OF THE IMPACT OF EVICTION AND OTHER FORCED MOVES

A.K. Groves[1], L.M. Niccolai[2], D.E. Keene[2], P. Schlesinger[2], A. Rosenberg[2], K. Blankenship[3]
[1]Drexel Dornsife School of Public Health, Community Health and Prevention, Philadelphia, United States, [2]Yale School of Public Health, New Haven, United States, [3]American University, Washington DC, United States

BACKGROUND: Housing instability is a well-established social determinant of health, and some attention has been paid to eviction as an abrupt and disruptive event. However, no studies have examined the impact of forced moves conceptualized more broadly (i.e., inclusive of both official and other forced moves by landlords) on HIV risk, even though forced moves may fragment social networks, affect economic vulnerabilities and increase likelihood of unsafe sexual practices. The study purpose is to comprehensively measure forced moves, and to examine the association between forced moves and HIV risk.

METHODS: Data are from baseline survey interviews with 400 low-income New Haven residents in a study about criminal justice involvement, housing, and HIV risk. We used bivariate and multivariate logistic regression analyses to examine associations between experiencing a forced move in the past two years (i.e., eviction and other landlord-related factors such as threats of eviction, foreclosure, increasing rent) and HIV risk in the past six months (i.e., unprotected sex, concurrency, exchange of sex for a place to live and selling sex), while adjusting for confounding.

RESULTS: One-fifth of participants reported a forced move (of these, 21% reported a formal eviction, 56% reported an informal eviction and 23% reported both). Forced move was associated with higher odds of unprotected sex (AOR: 2.09, 95%CI: 1.23-3.55), concurrency (AOR: 2.59. 95% CI:1.48-4.52), exchange of sex for a place to live (AOR: 5.40 95% CI: 1.94-15.02), and selling sex (AOR: 3.72, 95% CI:1.70-8.18), after adjustment for other covariates.

CONCLUSIONS: Housing instability, including both formal evictions and other types of forced moves, is associated with unsafe sexual practices. Our results highlight the importance of broadening conceptualization of forced moves to fully capture its impact on HIV risk. Longitudinal, mixed-methods research is needed to further assess the mechanisms through which forced moves impact sexual practice. While the current strategic plan to Ending AIDS in America by 2030 focuses primarily on biomedical approaches to prevent, diagnose and treat HIV; the potential impact of structural interventions on HIV prevention, and in particular, those which promote access to stable and affordable housing, should not be overlooked.

PED0893

THE IMPACT OF STRESSFUL LIFE EVENTS ON DEPRESSION AMONG THAI YOUTH LIVING WITH PERINATALLY-ACQUIRED HIV: FINDINGS OF BOTH RESILIENCE AND RISK

A.F. Santoro[1], R.N. Robbins[1], C. Ferraris[1], T. Puthanakit[2], K.M. Malee[3], R. Paul[4], C.A. Mellins[1], L. Aurpibul[5]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, Department of Psychiatry, New York, United States, [2]Chulalongkorn University, Department of Pediatrics, Bangkok, Thailand, [3]Northwestern University Feinberg School of Medicine, Department of Psychiatry and Behavioral Science, Chicago, United States, [4]Missouri Institute of Mental Health/University of Missouri-St. Louis, St. Louis, United States, [5]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand

BACKGROUND: Adolescents and young adults living with perinatally-acquired HIV (AYA-PHIV) must manage the daily challenges of living with a chronic, highly-stigmatized, transmittable illness, while also navigating the same developmental pressures as their peers. In addition to HIV-specific concerns (e.g., daily medication-taking), AYA-PHIV also report high rates of non-HIV-specific stressful life events (SLEs; e.g., social/environmental stressors) and depression. This study examined the relationship between non-HIV-specific SLEs and depression among AYA-PHIV and uninfected peers (perinatally HIV-exposed-and-uninfected; HIV-unexposed-and-uninfected).

METHODS: One hundred Thai AYA (50 PHIV, 50 uninfected; mean age=18.24) – two-thirds from the RESILIENCE Study – completed items on social/environmental stressors (i.e., SLEs) experienced over the last 12 months (e.g., family death, loss of health insurance) and the Children's Depression Inventory (CDI: 13-17 years) or Center for Epidemiological Studies-Depression Scale (CES-D: ≥18 years). CDI and CES-D scores ≥17 and ≥16, respectively, indicated clinically significant depressive symptoms. A two-way ANOVA tested interaction effects of HIV Status and SLEs on depression. Chi-square and odds ratios were conducted to assess group differences.

RESULTS: AYA-PHIV had higher rates of 1≥ SLEs than uninfected peers (44% vs. 26%) and significantly higher odds of ≥2 SLEs (OR 4.42; 22% vs. 6%). Among all participants, the most prevalent SLEs were having a very sick (23%) or hospitalized (14%) family member. ANOVA results indicated a significant interaction effect (HIV Status x SLEs) on depression. AYA-PHIV and uninfected peers with 0 SLEs reported similar rates of depression (18% vs. 19%). However, AYA-PHIV with ≥1 SLEs endorsed significantly higher rates of depression than uninfected peers with ≥1 SLEs (59.1% vs. 23.1%). Among AYA-PHIV, those with ≥1 SLEs had 6.64 times the odds of having clinically significant depressive symptoms compared to those with none.

CONCLUSIONS: Growing up with HIV is stressful on its own. Without additional stressors, many AYA-PHIV effectively manage their mental health and report similar rates of depression as their uninfected peers. However, when faced with additional, non-HIV-specific stressors, AYA-PHIV may experience depressive symptoms at higher rates than their uninfected peers. The high burden and impact of non-HIV-specific stressors on AYA-PHIV necessitate additional efforts to monitor and mitigate, such as interventions that support stress management.

PED0894

RETENTION IN CARE AND REASONS FOR TRANSFER OR STOPPING CARE AMONG HIV-INFECTED PATIENTS ON ART IN KISUMU COUNTY, KENYA

F. Odhiambo[1]
[1]*Kenya Medical Research Institute (KEMRI), Biostatistics, Kisumu, Kenya*

BACKGROUND: Retention into HIV treatment is an important factor in epidemic control efforts. However, significant retention losses continue to occur. Despite the importance of retention, little is known about the current HIV care status of living patients no longer retained in care and the reasons why.

METHODS: We used a retrospective study design involving 12 health facilities in Kisumu County, Kenya where demographic and clinical variables were collected from adults 18 years and older. Eligible patients had at least one clinic visit between September 2016 and August 2018 and were lost to follow-up (LTFU) defined as 90 days late for their last scheduled visit. Reasons for being not in care or a silent transfer to another facility were classified as structural (e.g. transportation costs, work schedule), clinic-based (e.g. long waiting times, staff attitude) or psychosocial reasons (i.e. stigma, disclosure).

RESULTS: Of 778 LTFU patients selected for intensive tracing, 495 (63.6%) were female and the median age was 31 (26,38). Outcomes were ascertained from 640 (82%) of which 591 (92%) were alive including 434 (73%) with care status determined: 189 (44%) had stopped care and 245 (56%) were silent transfers. Of those that stopped care, psychosocial reasons accounted for 51% of the barriers, led by feeling well/don't need treatment (22%) and disclosure (8%). Structural reasons accounted for 20% of the barriers and led by work interference (14%) and family obligations (5%). Of those that silently transferred, structural reasons accounted for 79% of the barriers, led by new clinic proximity (62%) and moving (9%). Psychosocial reasons, specifically disclosure concerns, accounted for 7% of barriers.

CONCLUSIONS: After accounting for outcomes among traced patients, over half of patients who were considered LTFU were actually in care at other clinics. Psychosocial and structural barriers contribute significantly towards stopping care or transferring out silently, respectively, and need to be addressed to facilitate improved care engagement, along with intensive tracing to determine actual outcomes of LTFU patients.

PED0895

ADDRESSING LOSS TO FOLLOW UP: REASONS FOR DIS-ENGAGEMENT AND RE-ENGAGEMENT IN CARE BY PATIENTS AT A LARGE HIV CARE PROGRAM IN KENYA

S. Okutoyi[1], E. Meassick[2], D. Achwoka[2], S. Kimaiyo[3], C. Komen[3]
[1]*United States Agency for International Development, HIV Treatment Team, Nairobi, Kenya,* [2]*United States Agency for International Development, Nairobi, Kenya,* [3]*AMPATHPlus/Moi University, Eldoret, Kenya*

BACKGROUND: Long term retention in care is critical to achieving lifesaving benefits of anti-retroviral therapy (ART). While remaining engaged in care is critical to achieving viral suppression, studies in sub-Saharan Africa note that up to 30% of people living with HIV (PLHIV) cycle in and out of care. We sought to characterize reasons patients dis-engaged from care at a large program in Kenya.

DESCRIPTION: We reviewed program data from USAID-funded AMPATH-plus program, that works in 10 counties and represents 10% of PLHIV on treatment in Kenya. We included patients who had missed their appointments and not returned to care between October 2018-September 2019. Patients who had missed at least 1 visit > 28days were included in the analysis. Patients who returned to care less than 28 days after missed appointments were excluded. We analyzed client tracing outcomes from defaulter tracking registers. Outcomes and reasons for LTFU were extracted from client files. A pareto analysis was conducted for the most common reasons for disengagement of care.

LESSONS LEARNED: Of 4532 loss to follow up (LTFU) identified, 3067 (67.7%) were female and 1465 (32.3%) were males. Slightly over a half (56%) had been lost for a period of less than 6 months and 44% between 6 -12 months. Over a quarter, 1,007 (28%) of the PLHIV who were LTFU had been on ART for less than a year. Close to two thirds, 2875 (63%) of patients were traced; 1584 (34%) returned to care, 114 (2.5%) were identified to be self-transferred out and 20 (0.5%) found to be deceased. Amongst the PLHIV's who returned to care majority (34%) reported distance as a reason for missing their appointment, 25% reported work commitments and 10% reported financial constraints. Other reasons for LTFU included institutionalization e.g. prison or school, stigma and poor provider-patient communication.

CONCLUSIONS/NEXT STEPS: Most reasons for failure to return to care can be addressed by patient centered approaches mainly differentiated care models, patient literacy, and improved work flows by the health care workers. Despite the highest risk of LTFU being among newly ART initiated clients, long-term retention strategies are necessary for treatment experienced clients.

PED0896

KNOWLEDGE, ATTITUDE AND BEHAVIOURAL RISK FOR HIV/AIDS AMONG IN-SCHOOL ADOLESCENTS IN SOUTH-WESTERN NIGERIA: A MIXED-METHODS APPROACH

O. Kanma-Okafor[1], M. Kilanko[1], A. Sekoni[1]
[1]*College of Medicine, University of Lagos, Department of Community Health and Primary Care, Lagos, Nigeria*

BACKGROUND: Over 4% of young people in Nigeria are living with HIV A curriculum of education on HIV prevention is already in use in many Nigerian schools. The need therefore arises to assess the knowledge, attitude and behavioural risk for HIV/AIDS among these adolescents in order to develop a meaningful method to scale up preventive strategies among the adolescents. The aim of the study was to assess the knowledge, attitude and behavioural risk regarding HIV/AIDS among in-school adolescents in Ipokia Local Government Area in Ogun State Nigeria.

METHODS: A cross-sectional descriptive study was carried out in schools from May to August of 2018 among 400 senior secondary school students (133 males, 267 females) selected by multistage sampling, using mixed methods of data collection. The quantitative data was collected using a semi-structured, pre-tested questionnaire while the qualitative data was collected through Focus Group Discussions. Data was analysed using SPSS 25.0. The chi-square and T test were used to test associations. The level of significance was set at $p<0.05$. The qualitative data analysis was done using the thematic method.

RESULTS: Majority (84.8%) of students had heard about HIV/AIDS, but about one third of them (37.5%) had poor knowledge about HIV/AIDS, 65.0% of them had positive attitudes towards HIV/AIDS and a lower proportion (23.8%) engaged in behaviour that put them at risk of HIV/AIDS (multiple sexual partners, unprotected sex, alcohol and

drug abuse etc.). Poor knowledge was significantly associated with negative attitudes towards HIV/AIDS (p=0.053) and increased risky behaviour (p=0.020). A positive attitude was also associated with low behavioural risk (p=0.036). Having at least one parent in the adolescent's life significantly influenced knowledge (p=0.004) and attitude (p=0.002), whereas having an empowered mother (educated and employed) was associated with reduced behavioural risk (p=0.035).

CONCLUSIONS: The adolescents in this study lacked the detailed knowledge necessary to help the prevention of HIV/ infection. However, they had mostly positive attitudes probably due to the influence of culture, but this did not translate into avoiding risky behaviour. If their behaviour is to improve, better effort should be made at improving adolescent health education, strengthening families and empowering mothers.

PED0897

THE OUTCOME OF PERSONS LIVING WITH HIV ON ANTI-RETROVIRAL THERAPY REPORTED AS LOST-TO-FOLLOW-UP

M. Morka[1], C. Laniyan[2]
[1]Texila America University, Managua, Nicaragua, [2]Consultant, Abuja, Nigeria

BACKGROUND: Loss of persons living with HIV on antiretroviral treatment (ART) is a major challenge to achieving the global HIV treatment goal of retaining 90% of clients in care. The retention in care is fundamental towards achieving viral suppression and breaking the chain of HIV transmission. This study was undertaken to determine the actual statuses of people living with HIV (PLHIV) who dropped out of ART in Nigeria.

METHODS: It is a cross-sectional study with multi-staged sampling design that used probability proportionate to size of PLHIV loss to follow up (LTFU) for selection of 22 health facilities across 12 states in Nigeria. Study participants were selected using computer generated random numbers. The study was conducted in January 2019.

RESULTS: There were 4,979 PLHIV reported as LTFU that participated in the study. Majority of them were females 3,318 (67%), while males were about a third (1,661). About half of the clients assessed were married (55%), a third had no formal education and two-thirds were unemployed. Efforts to contact the study participants was successful in approximately 60% (3,005) of the clients. Of the 1,974 (40%) participants not reached for interview, majority (73%) could not be traced due to wrong or absence of contact information. However, a small proportion 3% (56) of 1,974 declined interview and 19% although listed in the facility register did not have matching folders. Of the clients contacted (3,005), a third were dead 1,063 (35%), one-quarter discontinued ART but alive in the community 740 (25%), 23% self-transferred to other facilities while 17% (524) were still active on treatment in the study facilities.

CONCLUSIONS: To curb the menace of LTFU in HIV program, active clients tracking, operationalizing options of differentiated service delivery models, optional clinic days on weekends and public holidays, periodic conduct know-your-client exercises, client clinic appoint reminder mechanism should be fully instituted.

PED0898

DESCRIBING THE STRUCTURE AND CHARACTERISTICS OF TRANS WOMEN LIVING WITH HIV'S PERSONAL NETWORKS

M. Hill[1], D. Robinson[2], T. Kershaw[3], T. Cooper[4], E. Wright[5], A. Radix[6], N. Hansen[7]
[1]Private, Atlanta, United States, [2]University of Georgia, Sociology, Athens, United States, [3]Yale University, New Haven, United States, [4]Advocates for Better Care Atlanta, Atlanta, United States, [5]Georgia State University, Sociology, Atlanta, United States, [6]Callen-Lorde Community Health Center, New York, United States, [7]University of Georgia, Health Promotion & Behavior, Athens, United States

BACKGROUND: Though a few recent studies have analyzed the networks of cis people living with HIV, very little is known about those of trans people living with HIV. The present study seeks to address this gap by exploring the structure, composition, and interconnectedness of the egocentric networks of trans women living with HIV, in addition to, exploring how they construct and navigate their networks for different issues.

METHODS: 231 trans women living with HIV in the US took a 20-30 survey asking them to describe the characteristics of up to 21 people within their social circle. Data collection via an online instrument took place from February to August 2019. Network data were divided according to the people with whom participants confided in about important, HIV, and gender-related issues. Descriptive statistics and bivariate analyses were used to characterize the types of people, resources, and relationships within each network, as well as, to enumerate the size and degree of interconnectedness of each network.

RESULTS: Participants were a mean age of 32 and had been diagnosed for 5 years. Overall, their networks consisted of an average of 5 people. Participants confided in about half of the people within their networks about multiple issues. They were significantly more likely to confide in cis males and trans females ($p = .02$) about multiple issues. Chosen family ($p<.01$), spouses ($p<.01$) and friends ($p<.01$) were also identified as salient confidants, whereas health providers ($p<.01$) were not. HIV disclosure, perceived support, and gender affirmation were high across all networks (≥70%, ~80%, ~70%), yet significantly greater support ($p < .01$) and affirmation ($p < .01$) were perceived from confidants for multiple issues. Additional data highlight significant differences in HIV disclosure, communication, and conflict with network members.

CONCLUSIONS: Findings indicate this sample of trans women living with HIV were embedded within diverse communities with social resources which have been linked to resilience, such as, support and affirmation. Notable differences between network members highlight potential change agents who may be pivotal to reducing population disparities and improving health outcomes. Additional research is needed to develop network-level interventions which capitalize on community strengths.

PED0899

PATHWAYS TO HOUSING STABILITY AND VIRAL SUPPRESSION FOR PEOPLE LIVING WITH CO-OCCURRING HIV, MENTAL HEALTH AND SUBSTANCE USE DISORDERS

S. Rajabiun[1], K. Davis-Plourde[2], H. Cabral[2,2]
[1]University of Massachusetts, Public Health, Lowell, United States, [2]Boston University, Biostatistics, Boston, United States

BACKGROUND: People living with HIV (PLWH) with co-occurring substance use or mental health diagnoses who are homeless have poorer health outcomes compared to other HIV populations. Navigation models may be an effective intervention to achieve more stable housing, improve retention in care, and reach viral suppression. This study examines the mechanisms by which navigation works to achieve housing stability and health outcomes for this vulnerable population.

METHODS: This was a prospective study of 700 unstably housed PLWH enrolled in a patient navigation intervention across nine sites in the United Stated from 2013-2017. Data were collected via interview and medical chart review at baseline, post 6 and 12 months. Type and dose of patient navigation activities were collected via a standardized encounter form. We used a path analysis with housing stability at 6 months as the mediator to examine the direct and indirect effects of socio-demographics and risk factors and patient navigation on viral suppression and retention in care at 12 months.

RESULTS: Housing stability was associated with male gender, younger age, virally suppression at baseline, having a lower risk for opiate use, fewer years experiencing homelessness, being food secure, increased self-efficacy to obtain resources, and a longer length of time living with HIV. Stable housing, fewer unmet needs, being at moderate to high risk for opiate use, and being virally suppressed at baseline had a direct effect on being virally suppressed at 12 months. The intensity of patient navigation contact did not have a direct effect on housing stability and had a negative relationship with viral suppression. Recent diagnosis with HIV, women, better social support, and higher intensity of patient navigation contact had a direct effect on better retention in HIV primary care at 12 months.

CONCLUSIONS: In this sample of PLWH who experience homelessness, housing stability had a significant direct effect to viral suppression. Patient navigation activities did not have a direct effect on housing stability and viral suppression but they were directly related to retention in care. These results identify key populations and factors to target resources for clinics and policymakers to achieve housing stability and improve HIV health outcomes.

BEYOND INTERPRETATION: A CASE FOR CULTURALLY TAILORED MODELS OF CARE AND PEER SUPPORT FOR SPANISH-DOMINANT LATINXS LIVING WITH HIV IN THE SOUTH

J. Sherbuk[1], K. Petros De Guex[1], D. Anazco Villarreal[1], K. McManus[1], T. Flickinger[1], R. Dillingham[1]
[1]University of Virginia, Division of Infectious Diseases and International Health, Charlottesville, United States

BACKGROUND: Latinx people living with HIV(PLWH) experience worse health outcomes. Challenges to care, including language barriers, discrimination, and concerns about immigration status, are exacerbated by the current anti-immigration climate. We aimed to explore the lived experience of Spanish-speaking Latinx PLWH in the South to better understand how to improve care for this vulnerable population.

METHODS: We conducted semi-structured interviews in Spanish to explore participants' lived experience. Participants were Spanish-speaking Latinx patients recruited from a Ryan White HIV/AIDS Program clinic or a community-based organization in a region with a low density of Spanish-speaking PLWH. Interviews were analyzed using the grounded theory approach.

Theme	Example Quote
Language Barrier	"I can't be myself with the doctor for the simple reason that she doesn't speak Spanish well, [and] I don't speak English well…She's not going to understand me. I'm better off not telling her anything."
Cultural Barrier	"Even though [my doctor] speaks Spanish, she doesn't understand a lot of things the way I am expressing them to her. So, that's a limitation because it doesn't allow for good communication, or fluid communication, with her."
Stigma related to Spanish language	"Sometimes you can't communicate and there are also people who don't like it when we speak Spanish. It bothers them…And you feel like you don't have a right to say anything because you're receiving assistance, and this is the only thing that should matter – no matter how they treat you. But this is false – it's the language barrier."
Inaccurate Interpretive Services	"The interpreter didn't use the correct words and there was a misunderstanding, so my friend got frustrated. The information was not correctly given [and] my friend got more stressed. And, when he wants to reply to a doctor, [the interpreter] may change a word or verb, so the message is not as strong, not as powerful."
Insensitive behavior by an Interpreter	"The [clinic interpreter] who told me [about my HIV diagnosis], she said to me, "Listen, girl! You're going to die." And it was very hard. I think they should have told me some other way…I was alone."
Isolation of Spanish-speaking PLWH	"Not many people who speak Spanish talk about their illness; not that I know of anyway – especially in this clinic, I don't know anyone. So, no; I don't believe I have a support network."
Peer support as a positive example of living well with HIV	"When I was depressed, I talked to someone who was specialized in that…but what really did help me a lot was when I spoke with [a peer with HIV] because he was in my same situation and I saw him in such good spirits. I said to myself, "He doesn't look sick [laughter]. He's moving a thousand miles an hour!" I'd say, "No. I can do it, too," and it helped me a lot to talk to him."

[Table.]

RESULTS: Twenty-two participants completed interviews, including 10 men, 10 women, and 2 transgender women with mean age of 41.1(SD 11.6) years. All were foreign born. Language was the most commonly identified barrier to care. Participants described a lack of support and separation between patients and clinicians due to language and cultural barriers. Contributing factors related to interpretation included:
(1) underutilization of available services,
(2) errors by inadequately trained interpreters,
(3) concerns regarding confidentiality due to presence of in-person interpreters,

(4) cultural differences in expression and understanding of illness, and;
(5) insensitive behavior by interpreters.
Participants identified relationships with care team members and especially with Spanish-speaking PLWH to be a source of positive reinforcement and a way to overcome feelings of stigma and isolation.
CONCLUSIONS: Spanish-speaking Latinx PLWH report concerns about HIV care rooted primarily in language barriers resulting in isolation, lack of support, and hesitancy to confide in clinicians. These barriers may contribute to disparities in outcomes for Latinx PLWH. New interventions are needed to overcome barriers, to foster community, and ensure culturally tailored models of care. Potential interventions include training specialized interpreters in HIV care, ensuring proper credentialing, and increasing access to peer support. mHealth interventions may allow for expansion of peer support in communities with less dense populations of Latinx PLWH.

PED0901

SUBJECTIVE SOCIAL STATUS IN RELATION TO INTERNALIZED HOMOPHOBIA, HIV SELF-STIGMA, AND MISSED HIV APPOINTMENTS AMONG MSM LIVING WITH HIV AND PROBLEMATIC SUBSTANCE USE IN THE UNITED STATES

A. Batchelder[1], K. Mayer[2], M. Bustamante[2], A. Thiim[2], C. O'Cleirigh[1]
[1]Massachusetts General Hospital/Harvard Medical School & The Fenway Institute, Psychiatry, Boston, United States, [2]Fenway Health, The Fenway Institute, Boston, United States

BACKGROUND: Internalized homophobia and HIV self-stigma have been associated with sub-optimal engagement in HIV care among men who have sex with men (MSM). While the definition of stigma has been debated, it consistently involves beliefs that specific identities are of lower social status than others. The role of subjective social status, or an individual's perception of their hierarchical rank in society, may account for the relationships between internalized homophobia and HIV self-stigma and sub-optimal engagement in HIV care.
METHODS: In a sampled 202 MSM living with HIV and problematic substance use in the United States, we used logistic and linear regression and bootstrapping techniques to investigate direct and indirect relationships between internalized homophobia, HIV self-stigma, subjective social status, and missing one or more HIV appointments in the past 6 months that were not rescheduled.
RESULTS: The sample was 22% Black, 69% White, 29% Hispanic, 61% reported ≤$20,000 annual income, and 8% reported current detectable viral load. Both internalized homophobia and HIV self-stigma were associated with greater odds of missing one or more HIV appointment (OR=1.33, 95%CI:1.01,1.75 and OR=1.24, 95%CI: 1.06,1.46, respectively). Subjective social status was associated with internalized homophobia (b=0.295, p<0.001) and HIV self-stigma (b=0.492, p<0.001). Additionally, subjective social status was associated with greater odds of missing one or more HIV appointments (OR=1.24, 95%CI: 1.06,1.46).
While detectable viral load was underrepresented in this sample, results indicated a potential relationship between subjective social status and odds of viral detectability (OR=1.26, 95%CI: 0.99,1.61). Notably, we found full indirect effects of subjective social status on the association between internalized homophobia and both HIV self-stigma and missing any HIV appointments.
CONCLUSIONS: Our findings indicate that subjective social status may account for the relationships between internalized homophobia and both HIV self-stigma and sub-optimal engagement in HIV care among a sample of MSM living with HIV and problematic substance use in the United States. While longitudinal work is needed to assess these pathways, additional clinical focus on perceptions of low social status may benefit individuals living with HIV who are sub-optimally engaged in care and experience internalized stigma related to their sexual orientation and HIV-status.

PED0902

MALE PERSPECTIVE ON THEIR ROLE IN RETENTION OF WOMEN IN HIV CARE IN MALAWI: PRELIMINARY RESULTS OF QUALITATIVE STUDY

I. Triulzi[1], C. Somerville[2], S. Salimu[3], I. Palla[1], H. Sangarè[3], S. Orlando[4], F. Ciccacci[5], L. Palombi[4], G. Turchetti[1]
[1]Scuola Superiore Sant'Anna, Istituto di Management, Pisa, Italy, [2]Graduate Institute of International and Development Studies, Gender Center, Geneva, Switzerland, [3]Drug Resource Enhancement against AIDS and Malnutrition Program DREAM, Blantye, Malawi, [4]University of Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [5]UniCamillus, International University of Health and Medical Science, Rome, Italy

BACKGROUND: HIV positive women report that low support of male partners is a barrier to adherence and retention to HIV care. Our aim is to unpack the role, impact and context of male partner engagement with women's HIV care access.
METHODS: A qualitative study involving semi-structured focus group discussions (FGDs) and in-depth interviews (IDIs) accessing care at DREAM facilities in Southern Malawi were performed. We recruited 41 participants for FGDs and 9 for IDIs from January 2019 to July 2019. We conducted 6 FGDs, one with concordant couples, one with discordant couples, three with HIV positive men and one with HIV positive women. We conducted 5 IDIs with HIV positive patients and 4 IDIs with expert clients as key informants. All data were digitally recorded, transcribed verbatim and analyzed using grounded theory approach.
RESULTS: Our preliminary findings confirm that men have a significant role towards supporting women to access and remain in care in very specific areas. These include provision of transport and other material needs like food; and providing verbal support on drug adherence and appointment scheduling and reminders. Issues around disclosure, attitudes to women, condom use and family planning followed gender orders that were found to be barriers to retention. Gender relations at household and system level were found to impact women's retention in health systems.
CONCLUSIONS: The study highlights the significance of gender determinants of retention of HIV positive women in health care systems. The engagement of male partners in specific support roles, including transport and other actions in maintaining appointments are considered beneficial and effective. We recommend both community and facility-based interventions including peer-to-peer support through expert clients, men-centered activities at the clinic and community reach-outs through popular places like the chief, church, village banks.

RELATIONSHIP POWER, ANTIRETROVIRAL ADHERENCE, AND PHYSICAL AND MENTAL HEALTH AMONG HIV-POSITIVE WOMEN IN RURAL KENYA

R.L. Burger[1], A.R. Mocello[1], C.R. Cohen[1], E.A. Frongillo[2], S. Dworkin[3], E. Weke[4], P. Wekesa[4], E.A. Bukusi[4], S.D. Weiser[1]
[1]University of California, San Francisco, United States, [2]University of South Carolina, Columbia, United States, [3]University of Washington, Seattle, United States, [4]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya

BACKGROUND: Gender-based power imbalance is a known risk factor for intimate partner violence but little is known of its association with HIV treatment outcomes, mental health, and physical health. We aimed to understand the impact of sexual relationship power on adherence to antiretroviral therapy (ART), and physical and mental health status among HIV-infected women in the Nyanza region in Kenya.

METHODS: As part of a cluster-randomized controlled trial of a multisectoral agricultural and financial intervention to improve health outcomes among HIV-infected farmers in western Kenya (NCT02815579), we performed a cross-sectional analysis at baseline to determine the association of sexual relationship power with ART adherence and physical and mental health. We analyzed 382 HIV-positive women. Relationship power was measured using the Sexual Relationship Power Scale (SRPS), a validated measure consisting of two subscales: relationship control and decision-making dominance. The overall scale and each subscale were divided into tertiles for analysis. Our primary outcomes were excellent ART adherence (>95%), measured using the visual analogue scale; physical and mental health status using the Medical Outcomes Study (MOS)-HIV Survey physical health score and mental health score (continuous, range 0-100); and dichotomous depression using the Hopkins Symptom Check-List. We used multivariable regression to test for associations between the SRPS and subscales adjusting for sociodemographic and social factors.

RESULTS: Participants had a median age of 38 years, 60.7% were married, and 20.4% had some secondary education. Relationship control was associated with depression and MOS-HIV mental health, but not with ART adherence. There was a non-significant trend towards improved physical health. Women with the highest and middle tertiles for relationship control had a 4.70 point (p=0.041) and 5.17 point (p=0.014) greater mental health score, respectively, compared to women in the lowest tertile. Women with the highest and middle tertiles for relationship control had a 0.37 (p=0.0017) and 0.55 (p=0.071) lower odds of depression, respectively, compared to women in the lowest tertile.

CONCLUSIONS: Low sexual relationship power, specifically low relationship control, may contribute to poor mental health among HIV-infected women. Longitudinal studies are needed to understand how these factors are related over time to guide intervention development among women living with HIV.

PED0904

UNDERSTANDING HIV VULNERABILITY IN A US POPULATION OF DOMINICAN AMERICAN WOMEN AGES 50 AND OVER

M. Odlum[1], S. Yoon[2]
[1]Columbia University, School of Nursing, New York, United States, [2]Columbia University Medical Center, New York, United States

BACKGROUND: Women in vulnerable populations, face a multitude of adverse life experiences that contribute to HIV risk including poverty, racism, ageism, violence and unemployment. HIV risk and transmission factors amongst these populations, including Latinos, are associated with cultural perceptions and traditional gender roles. Although interventions exist, efforts have mainly focused on the intrapersonal aspects of HIV risk without much attention to interpersonal, social or environmental factors. In fact, rates are declining for almost all women except those over 50. For these reasons, the current study sought to understanding the beliefs and perceptions of HIV risk for older Dominican women (N=60) as the US-CDC calls for country-specific HIV risk profiles for Latino communities to support prevention efforts.

METHODS: Focus group discussions were conducted and guided by the Theory of Gender and Power (TGP) constructs of: 1) Affective influences/social norms; 2) Gender-specific norms and 3) Power and Authority. Natural language processing (NLP) was also conducted to identify and depict topics in focus group data. Topics were detected and summarized through descriptive statistics, classification, visualization, and clustering.

RESULTS: Topic Clusters identified through NLP were: 1) Violence; 2) interpersonal relationship dynamics; 3) sexual relationship dynamics; 4) Financial Constraints; 5) Condom/Sex Negations; 6) STDs/STIs; 7) Substance Abuse; 8) Community Engagement and Support; and 9) Food Insecurity.

CONCLUSIONS: The steadily changing factors associated with the demographic profile of the AIDS epidemic, challenges HIV prevention strategies to remain relevant and up-to-date, particularly in populations of women over 50, where the understanding of risk remains under explored. Our findings confirm previous findings of risk perceptions and provide additional insight into aging-related aspects of HIV risk for older Latino women.

ECONOMIC TRANSITIONS AND SOCIAL AND CULTURAL CHANGES AFFECTING HIV AND THE HIV RESPONSE

PED0905

ECONOMIC PRIVATIZATION AND WOMEN'S HIV VULNERABILITY IN UGANDA

E.V. Moore[1], D. Isabirye[2], R. Nambi[2], N. Nakyanjo[2], J.S. Hirsch[3], F. Nalugoda[2], J.S. Santelli[1]
[1]Columbia University Mailman School of Public Health, Heilbrunn Department of Population and Family Health, New York, United States, [2]Rakai Health Science Program, Kalisizo, Uganda, [3]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States

BACKGROUND: The privatization of Uganda's coffee industry the in the 1990s may have contributed to socioeconomic circumstances that left women disproportionately vulnerable to HIV in the fol-

lowing decades. In the rural Masaka area of south-central Uganda, which was devastated by the HIV epidemic in the 1990s, coffee had long been the sole industry, and therefore the region's primary source of cash wages. From 1950-1990, coffee processing – farming, hulling, sorting, and grading – was organized by a series of state-backed, collectively controlled cooperatives that bought and sold coffee at a fixed price. In 1990, following decades of political turbulence and facing foreign debt repayment to the World Bank and IMF under structural adjustment, the Ugandan government ended support for the coffee cooperatives, which were unable to compete with multinational private buyers and collapsed. In the years following, thousands of people, especially women, faced unemployment; women had outnumbered men as workers in large cooperative-owned factories.

METHODS: This paper draws from 28 key informant interviews and one focus group discussion with men and women formerly employed by Uganda's coffee cooperatives as managers, administrators, farmers, and casual laborers. We also draw from archives of national newspapers documenting increasing crime and sex work in the Masaka region following the collapse of the coffee industry.

RESULTS: Our analysis suggests that the collapse of Uganda's coffee industry led to gendered imbalances in the cash economy, which may have exacerbated women's HIV vulnerability in two ways. First, many formerly employed female laborers were forced into marriages or sex work in order to afford rent and school fees for their children. Second, others migrated to nearby trading centers and fishing villages around Lake Victoria, where foreign and national investments in the fishing industry were beginning to yield returns and where sex work was rampant.

CONCLUSIONS: The Masaka area case study demonstrates the importance of understanding how political economic change shapes health behavior and how the gendered social organization of the labor market may exacerbate disparities in HIV vulnerability. We further argue that economic policies must be evaluated for their impacts on health inequality.

PED0906

SOCIAL CONTRACTING: A WAY FORWARD IN HIV PREVENTION AMONG THE FEMALE SEX WORKERS IN GUYANA

S. Shipley[1], N. Tamayo-Jimenez[1], R. Moore[1], K. Gordon-Boyle[2]
[1]National AIDS Programme Secretariat Guyana, Georgetown, Guyana, [2]Ministry of Public Health Guyana, Georgetown, Guyana

BACKGROUND: The Key population in Guyana is disproportionately affected by HIV and AIDS. This community is classified as; Men Who have Sex with Men, Female Sex Workers (FSWs), Transgender persons, Miners and Loggers. The HIV prevalence among the group is between 3-6 times higher than the general population. Over the years, the National Programme has depended heavily on civil society organizations (CSOs) for the delivery of a defined package of HIV prevention services to reach these groups. In 2017 the local Sustainability Plan prioritized the continued engagement of CSOs, and identified this as critical for a sustainable and effective HIV response.

DESCRIPTION: In June 2019 the National AIDS Programme contracted a sex worker led organization to deliver a defined package of services to FSWs in region 4.This organization was asked to reached 1000 FSW with said services and test 90% for HIV, Syphilis and Hepatitis B. Peer educators visited traditional and nontraditional hotspots four times weekly to deliver services. The outreach team included peer educators and HIV Peer counselors/Tester. Deliverables and funding were assigned in phases.

LESSONS LEARNED: The HIV prevention package of services was delivered to 1066 female sex workers. The acceptance rate for HIV testing was 100%. Between July –December 2019, with a monthly target of 200 FSWs, an average of 177 FSWs were reached monthly. Each reached benefited from risk assessment in HIV testing, Sexual Risk, Substance Abuse, mental health and violence screening. Further, prevention commodities such as condoms and lubricants were given along with BCC materials. Referral and navigation to care, treatment and support services were also offered to those who were interested. The beneficiaries included migrant populations, however the language presented a challenge in service delivery.

CONCLUSIONS/NEXT STEPS: The results of this pilot have proven to be successful in reaching female sex workers in region 4 with a defined package of services. The pilot also highlighted the importance of ensuring our outreach tools are compatible to ensure migrant populations can benefit from the same level and quality of services.

INTEGRATED CARE FOR VENEZUELAN MIGRANTS IN THE BORDERLANDS: A MODEL OF CLIENT-CENTERED APPROACH IN CUCUTA AND BUCARAMANGA, COLOMBIA

L. Andrade Forero[1], S. Ávila[1], L.L. Meneses Ovallos[1], T. Zambrano Numa[1], J.M. Suárez Peña[1], J.L.S. Mesones[2], A. Schwartz Benzaken[3], M. Pedrola[4], F. Rick[3]
[1]AIDS Healthcare Foundation Colombia, Cucuta, Colombia, [2]AIDS Healthcare Foundation Peru, Lima, Peru, [3]AIDS Healthcare Foundation, Manaus, Brazil, [4]AIDS Healthcare Foundation Argentina, Buenos Aires, Argentina

BACKGROUND: Due to a humanitarian crisis, 3.8 million refugees have left Venezuela. Over 1.4 million have crossed into Colombia. Most migrants cannot access the Colombian health care system. Since 2018, AIDS Healthcare Foundation (AHF) is the only organization providing access to free HIV care in Cucuta and Bucaramanga, two major border crossing cities in Colombia. This study describes how a client-centered approach and integrated care model are being used to serve migrants.

METHODS: On the same day, our clinics provide diagnosis, professional multidisciplinary care, opportunistic infections care, antenatal care including prophylaxis to exposed infants, vaccinations, condom distribution, nutritional support and ART. Data from November 2018 to October 2019 were collected in both clinics. This is a descriptive cross-sectional study for clients enrolled in the two clinics.

RESULTS: A total of 7,282 clients were tested for HIV, among them 4,408 (60.5%) were Venezuelans. In the Venezuelan cohort, 23.9% (1,055) had an HIV positive result, however only 158 (15%) were newly diagnosed as positive. 2,038 Venezuelan pregnant women were tested for HIV, of whom 27 (1.32%) were HIV positive. 3 (13%) HIV exposed infants tested positive. 957 (91%) positive clients linked to the AHF clinics, while the rest were linked to the Colombian health system. Of the clients linked to AHF, 892 (93%) are in care, and 856 (96%) are on ART. All clients initiated ART in less than 14 days; 779 (91.2%) initiated within 7 days. For the clients in care, the CD4 counts were as follows:

24.5% had CD4<200/mL; 22.3% had CD4 of 201- 350/mL; 91% achieved viral suppression (VL<1000 cp/mL) within two months on ART. The mortality rate was 1.6%, of which 11.8% was attributed to TB.

CONCLUSIONS: Despite vulnerabilities faced by Venezuelans, the AHF model achieved high adherence and a low mortality. This model has proven effective in reaching displaced people. It demonstrates how government agencies and non-governmental organizations can work together to overcome challenges associated with migration. The model could be replicated in other parts of the world facing humanitarian crises and population displacement.

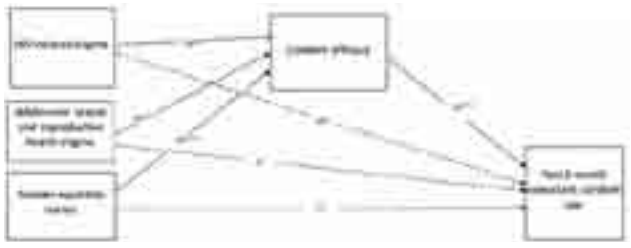
PED0908

PATHWAYS BETWEEN INTERSECTIONAL STIGMA, GENDER EQUITABLE NORMS, AND CONDOM OUTCOMES AMONG URBAN REFUGEE AND DISPLACED YOUTH IN KAMPALA, UGANDA

C. Logie[1], M. Okumu[2], S. Mwima[3], P. Kyambadde[3], R. Hakiza[4]
[1]University of Toronto, Social Work, Toronto, Canada, [2]University of North Carolina, Chapel Hill, United States, [3]Ministry of Health, Kampala, Uganda, [4]Young African Refugees for Integral Development, Kampala, Uganda

BACKGROUND: Social inequities elevate HIV vulnerabilities among youth in humanitarian contexts. Condom efficacy—knowledge, intention, and relationship dynamics that facilitate condom negotiation—is understudied among refugee youth. We examined social-ecological factors (stigma, gender equitable norms [GEN], depression) associated with condom efficacy and use among urban refugee youth in Kampala, Uganda.

METHODS: We conducted a cross-sectional survey with refugee youth aged 16-24 in Kampala's informal settlements. In multivariable regression analyses we examined associations between adolescent sexual and reproductive health (SRH)-related stigma, HIV-related stigma, and GEN with condom efficacy and recent (past 3-month) consistent condom use among sexually active participants. In path analyses we tested: direct effects of stigma (adolescent SRH-related, HIV-related) and GEN on condom efficacy, and indirect effects via depression; and direct effects of stigma (adolescent SRH-related, HIV-related) and GEN on recent consistent condom use, and indirect effects via condom efficacy.



*[Figure. Pathways from stigma and gender equitable norms to recent consistent condom use via condom efficacy among sexually active urban refugee youth aged 16-24 in Kampala, Uganda (N=251) Note: *p<0.05, **p<0.01, ***p<0.001]*

RESULTS: Among participants (mean age: 19.59, SD: 2.59; women: n=333, men: n=112), 62.5% were sexually active. Of these, 53.3% reported consistent condom use. In multivariable analyses, lower adolescent SRH-related (β= -0.18, p<0.001) and HIV-related (β= -0.18, p<0.001) stigma and higher GEN (β=0.15, p<0.001) were associated with condom efficacy. Among sexually active participants, GEN was associated with increased (AOR: 1.07, 95%CI: 1.01-1.13), and adolescent SRH-related stigma with reduced (AOR: 0.92, 95%CI: 0.84-0.99), odds of recent consistent condom use. There were direct pathways from lower stigma (adolescent SRH-related, HIV-related) and higher GEN to condom efficacy. Depression partially mediated the pathway from HIV-related stigma to condom efficacy. Condom efficacy mediated pathways from stigma (HIV-related, adolescent SRH-related) and GEN to consistent condom use.

CONCLUSIONS: Consistent condom use was low and associated with community (lower stigma, gender equity), interpersonal (condom efficacy), and intrapersonal (reduced depression) factors. Gender transformative and intersectional stigma reduction approaches are needed to increase sexual agency and wellbeing among urban refugee youth in Kampala

PED0909

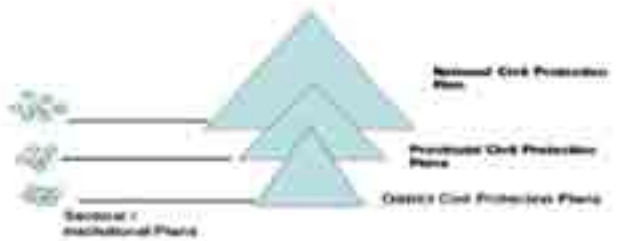
"ACTION NOW FOR BENEFITS LATER" MAINSTREAMING HIV INTO HUMANITARIAN EMERGENCIES: THE ZIMBABWE CASE

S. Mpofu[1], A. Manenji[2], R. Yekeye[3], A. Mpofu[4]
[1]NAC, Programmes, Harare, Zimbabwe, [2]NAC, CEO, Harare, Zimbabwe, [3]NAC, Operations, Harare, Zimbabwe, [4]NAC, M&E, Harare, Zimbabwe

BACKGROUND: Humanitarian crises are a result of droughts, floods, internal displacements, conflicts, wars and tsunamis. In Zimbabwe the most common emergencies include floods, cyclones and drought. When these emergencies occur Orphans, and Vulnerable Children (OVC) People Living with HIV (PLHIV), the chronically ill, the elderly, People with Disability girls and women become more vulnerable than other population groups e,g, malnutrition, exploitation, abduction, sexual and gender based violence in humanitarian settings which expose them to HIV, TB and STI Infection. Prevention/ treatment services get disrupted leading to increased risk of HIV infection.

Cyclone IDAI affected 4216 households in Chimanimani and Chipinge districts, resulting in 6969 PLIHIV ART Clients getting disruption, 353 deaths and 326 missing persons (Civil Protection, 2019). The DRR programme aims at mainstreaming HIV into Disaster Risk Reduction to prevent new infections and minimise service disruption.

DESCRIPTION: National AIDS Council, ZAN UN-OCHA and Department of Civil Protection trained 300 participants from Coordinating bodies on mainstreaming HIV and AIDS into Humanitarian. The training was targeting flood prone districts and resulted in commitment by Civil Protection Committees chairs to include HIV issues in the District Civil Protection plans and inclall usion of NAC officers and PLHIV in all CPC structures shown below:



[Figure. Levels of emergency preparedness planning]

LESSONS LEARNED:

- Sub populations groups such as Adolescent Girls, women, Pregnant mothers, OVC, the elderly, PWD, PLHIV and key populations become more vulnerable during emergencies and there is need to take extra precaution to address their needs during emergencies.

- Disaster Risk Preparedness is essential to prevent populations from HIV infections during emergencies to avert human suffering.

CONCLUSIONS/NEXT STEPS:

- Refresher training should be conducted Civil protection Committees as there has been staff turnover
- Training of non-traditional prone districts need to be sensitise to mainstream HIV into emergencies.
- A data base of vulnerable groups should be established to enable quick identification of affected populations during emergencies.

PED0910

ROLE OF CIVIL SOCIETY ADDRESSING THE COMPLEX HUMANITARIAN EMERGENCY IN VENEZUELA

A. Molina[1], J. Aguais[1]
[1]AID FOR AIDS International, New York, United States

BACKGROUND: AID FOR AIDS' (AFA) Chronic Disease Response Program aims to diminish the impact of HIV in Latin America and the Caribbean by redistributing antiretroviral treatment (ART) as a response mechanism to severe shortages. Initially, the program was developed to address the complex humanitarian emergency in Venezuela, where new HIV infections were estimated to have increased by 24% from 2010 to 2016, while only 12.78% of people registered in the National AIDS Program were receiving ART in 2018[1]. Nevertheless, it has grown to address shortages in countries such as Colombia and Ecuador, facing a high influx of Venezuelan migration.

DESCRIPTION: AFA developed an innovative mechanism without being labeled as "humanitarian aid" to surpass governmental obstacles that had been preventing people in Venezuela from accessing healthcare. This mechanism consists of five (5) key steps: 1) AFA secures donations from pharmaceutical companies through established partnerships with ViiV Healthcare, Gilead Sciences, Mylan Pharmaceuticals and Novartis International AG. 2) Pharmaceutical companies send medicines to the United Nations Humanitarian Response Depot (UNHRD) in Panama. 3) UNHRD handles, stores and ships medicines to Venezuela. 4) UNAIDS and other allies receive medicines in Venezuela. 5) Civil society monitors the distribution of medicines in Venezuela.

LESSONS LEARNED: This innovative way to respond to complex scenarios, and the developed mechanism turned AFA into the main provider of antiretroviral and antimalarial medication in Venezuela in 2018, ensuring treatment for 35,000 people with HIV and 440,000 antimalarial treatments. In 2019, AID FOR AIDS sent ART for 11,000 people with HIV in the region, in countries such as Colombia, Dominican Republic, Ecuador, Panama, and Venezuela.

CONCLUSIONS/NEXT STEPS: Going forward, AFA seeks to continue providing treatment for 16.7% of Venezuelans with HIV who cannot take TLD, as part of the Master plan for strengthening the HIV, tuberculosis and malaria developed as the result of a joint PAHO/WHO and UNAIDS technical mission while scaling up the program to address the need of Venezuelans in the region. Civil society has shown to have the capacity to respond to complex public health scenarios in an immediate and effective manner. Furthermore, this program has demonstrated its applicability to any medical condition.

PED0911

YOUTHS ENGAGE IN THE PREVENTION OF HIV AND NEW INFECTIONS IN HUMANITARIAN SETTINGS IN THE SOUTH WEST REGION OF CAMEROON

F. Nkweleko Fankam[1], A. Ngo Bibaa Lundi[2,2], E. Njomo Omam[3], K. Azah A.[1]
[1]Reach Out NGO, Health, Buea, Cameroon, [2]Reach Out NGO, Health Department, Buea, Cameroon, [3]Reach Out NGO, Management, Buea, Cameroon

BACKGROUND: Aside the high HIV prevalence in the Southwest Region of Cameroon (7.2%) far above national prevalence(4.2%) *as at 2018*, the ongoing deteriorating humanitarian crisis in the two anglophone Regions (South and North West) of the country continue to fuel the likelihood of new HIV infections. The destruction of community structures and burning of houses and schools has left over 400.000 persons including students to be internally and externally displaced and the further targeting and kidnapping of health workers even worsen the situation with more constrains of offering effective services.

Limbe Health District has become a host community to thousands of these internally displaced population(IDPs)and the shutdown of schools,lack of income and an enabling environment for sexual violence,increased drug use all contributes to challenges in offering a comprehensive HIV package

DESCRIPTION: Taking into consideration humanitarian principles, a community peer to peer approach of both displaced youths and youths from host communities was used to reach out to adolescent population with HIV education/testing, targeted street campaigns, STIs education and referrals for testing and communication for behavior change. This project is an extension of a project that started in 2018 targeting non scholarised youths in the touristic city of Limbe,in this phase, since the project locality was highly concentrated with IDPs and every youth in the community was basically idle, a youth friendly spaces strategy was incorporated in a bit to keep them busy while reaching out to them with HIV/STIs education, testing and treatments.

LESSONS LEARNED: forty youths(40) both boys and girls were identified and trained to carry out community HIV/STIs sensitization, animate youth friendly spaces and refer cases to selected hospitals or selected nurses meet with the client at their homes. So far, a total of 3800youths(2250girls&1550boys) have been reached both during youth-friendly-spaces and during campaigns with HIV/STI education and HIV testing of which 15(9 girls/6 boys) were positive and they were all referred and placed on treatment, 218(68%girls and 31%boys) had asymptomatic signs of a sexually transmitted infection.

CONCLUSIONS/NEXT STEPS: Capacity building of these youths to get involve in active search for lost cases, gender based violence cases and index tracing will be incorporated in future

PED0912

ECONOMIC EMPOWERMENT AS A CATALYST FOR REDUCTION OF HIV AND GENDER BASED VIOLENCE (GBV) IN CONFLICT AREAS IN NIGERIA

„ Falola-Anoemuah[1], F. Iyamu-Obi[1], A. Okorokwu[1], E. Nwafor[1], M. Egemba[1], D.A. Owolabi[2,2]
[1]National Agency for the Control of AIDS (NACA), Community Prevention and Care Services, Abuja, Nigeria, [2]UNDP, HIV Health and Development, Istanbul, Turkey

BACKGROUND: The intersection of poverty, gender-based violence and HIV is noted in literature especially in conflict settings. Conflicts and insurgency is affecting several States in Nigeria with the north-east zone as the epicenter. According to United Nations Commissioner for Refugees (UNHCR) 2018 report, Nigeria has 1,918,508 Internally Displaced Persons (IDP) as at August 31, 2018. 94% of them were displaced by the Boko Haram insurgency in the north- east. In order to reduce HIV and GBV among women and girls in conflict settings, NACA in collaboration with UN Women and State level partners, commenced economic empowerment project for women and girls in conflict settings. Livelihood programmes were executed to empower vulnerable women and girls in a sustainable manner.
DESCRIPTION: Benue State, north-central Nigeria was purposively selected being a conflict-affected area coupled with the fact that most humanitarian aids are concentrated in the North East. The target population were women and girls in conflict areas as well as those living or affected by HIV/AIDS in IDP camps. Qualitative method was used to collect baseline information prior to the intervention. Observation schedule was used to capture the general environment in the camp, interview and focus group discussion guides were used to elicit information from key informants and to conduct group discussions among the cohorts. They were then selected for economic empowerment and skill to tackle GBV.
LESSONS LEARNED: Many of those interviewed affirmed the need for acquiring economic skills as an important priority for their survival in the IDP camp and after leaving the camp. Beyond provision of livelihood support such as food, clothing and shelter, Nigerian government and her partners need to collaborate on sustainable economic empowerment programmes for vulnerable women and girls. Such intervention include market value chain. Also, findings from the baseline indicated the likelihood of GBV as there are complaints of favoritism with regards to aids distribution by camp and aid workers.
CONCLUSIONS/NEXT STEPS: Scale up of the livelihood interventions by government, partners, humanitarian international bodies and philanthropist is critical. The economic empowerment and livelihood opportunities would minimize sexual and gender based violence experienced by vulnerable women and girls especially in conflict situations.

PED0913

ASSESSMENT OF HEALTH-RELATED OUTCOMES IN PLWH IN PUERTO RICO AFTER THE HURRICANES IRMA AND MARIA

M. Marzán-Rodríguez[1], C.E. Rodríguez-Díaz[2], S. Miranda De León[3], G. Jovet-Toledo[1], S.M. Malavé-Rivera[1]
[1]University of Puerto Rico, San Juan, Puerto Rico, [2]George Washington University, Washington DC, United States, [3]Puerto Rico Department of Health, Puerto Rico HIV Surveillance System, San Juan, Puerto Rico

BACKGROUND: On September 2017, hurricanes Irma and Maria devastated Puerto Rico (PR). Dire pre-existing socio-economic and political factors in the island increased vulnerability of people living with HIV (PLWH), making it urgent to understand the impact of the hurricanes on their health in light of potential future events. This study aimed to assess health-related outcomes of PLWH after Hurricanes Irma and Maria.
METHODS: We conducted a retrospective cohort study using secondary data from the PR HIV Surveillance System. The 2-year study period consisted of pre-hurricanes (2016-2017) and post-hurricanes (2017-2018) to identify potential statistical differences. A 20-fold multiple imputation with chain equations (MICE) was used for CD4 and viral load missing values using sociodemographic (e.g., age, sex, HIV risk factor, etc.) variables as predictors. Log-linear regressions explored factors associated with CD4 and viral load counts. We used R software to perform all analyses.
RESULTS: A total of N=20,496 PLWH were reported for the study period, mean age was 50.8 (±12.7 years). Most (69.8%) were males and the most common risk factor for HIV was adult heterosexual contact (36.5%). During the 2-year study period, subjects had an average of 3.6 medical visits. A total of N=307 subjects (1.5%), died during post-hurricanes study period. Of these, 31.3% reported HIV-related cause of death. The average number of visits pre-hurricanes period was 2.1 (±1.4 visits) compared to 1.6 (±1.2 visits) post-hurricanes. Adjusted model for mortality post-hurricanes period resulted in a reduction of CD4 count by ~39% (p=0.008). While having died post-hurricanes period resulted in an increase of 1,832% (p=0.049) viral load count. No statistical differences were identified for age, sex and medical appointments.
CONCLUSIONS: Data suggest that following a similar emergency situation, PLWH can be at risk of increased viral load and significant reduction in CD4 count. This outcome can be related not only to access to care, but to factors that influence adherence including transportation issues, lack of basic needs, among other structural factors. Response efforts should emphasize on assuring PLWH continuation in HIV care. This is critical to reduce not only potential complications, but also to reduce HIV-related deaths in future emergencies.

INTERGENERATIONAL AND/OR TRANSACTIONAL SEX

PED0914

KEY DETERMINANTS OF HIGH SEXUALLY TRANSMITTED INFECTIONS (STIS) IN MAZOWE DISTRICT, MASHONALAND CENTRAL PROVINCE, ZIMBABWE

E. Muzulu[1], R. Yekeye[1], A. Mpofu[2], A. Manenji[1]
[1]National AIDS Council, Programmes, Bindura, Zimbabwe, [2]National AIDS Council, Monitoring and Evaluation, Harare, Zimbabwe

BACKGROUND: The study sought to establish key determinants of ever increasing sexually transmitted infections (STIs) in Mazowe district, Mashonaland Central province in Zimbabwe. Despite intense and integrated service provision by many stakeholders, STI trends in the district have continued to increase over the last three years. The study therefore sought to measure the knowledge, attitudes and perceptions of people accessing services at various health care points in the district, with the objective of coming up with stronger interventions for STI prevention.

METHODS: A 1:1 unmatched case control design was used in the study.Data was collected for a period of twenty (20) days from randomly sampled health sites. A case was any new patient seen at any health center in the district from 1 August 2019 to 31 August 2019, and treated for an STI (as defined by the clinical protocol). A control was any new patient at any health center in the district, who reported sexual activity but without a diagnosed STI during the same period. Using chi-square and t-test, respondents with a history of STIs were compared with those who said they had not experienced an STI; on demographic, knowledge, attitude and practice variables.

RESULTS: A total of 602 cases and 602 controls were interviewed.Using multivariate analysis to control for confounding factors,the following variables were statistically significant in determining whether or not, one gets infected with an STI; religion, especially Muslim ($p<0.001$), source of income, especially sex work ($p,<0.001$), being paid for sexual services in foreign currency ($p<0.001$), unavailability of STI medicines in public health centers ($p<0.002$), failure to use a condom every time one has sex ($p<0.001$), having taken alcohol the last time one had sex ($p<0.002$), and having an STI before ($p<0.001$), and having more than two sexual partners in the last three months ($p<0.001$).

CONCLUSIONS: Religion, selling sex, being paid for sexual services in foreign currency,unavailability of STI medicines in public health centers, failure to use a condom every time one has sex, having taken alcohol the last time one had sex,having an STI before, and, number of sexual partners in the last three months were independently associated with contracting STIs.

PED0915

TRANSACTIONAL SEX AND ASSOCIATIONS WITH PSYCHOSOCIAL AND HIV PREVENTION ENGAGEMENT OUTCOMES AMONG URBAN REFUGEE AND DISPLACED YOUTH IN KAMPALA, UGANDA

C. Logie[1], M. Okumu[2], S. Mwima[3], R. Hakiza[4], H. Abela[1], P. Kyambadde[3], S.G. Sherman[5]
[1]University of Toronto, Social Work, Toronto, Canada, [2]University of North Carolina, Chapel Hill, United States, [3]Ministry of Health, Kampala, Uganda, [4]Young African Refugees for Integral Development, Kampala, Uganda, [5]Johns Hopkins University, Baltimore, United States

BACKGROUND: Half of the world's 70 million forcibly displaced persons are under 18 years, live in urban areas, and most experience social and economic marginalization. Transactional sex among urban refugee youth is understudied, particularly regarding gendered experiences. We examined psychosocial and HIV-related vulnerabilities associated with transactional sex among urban refugee youth in Kampala, Uganda.

METHODS: This cross-sectional survey included a peer-driven sample of refugee youth aged 16-24 living in Kampala's informal settlements. We oversampled for adolescent girls who are overrepresented in Uganda's HIV epidemic. We conducted gender-disaggregated hierarchical block multivariable regression analyses for continuous outcomes, and multivariable logistic regression for categorical outcomes, to examine associations between transactional sex (TS) and *psychosocial* (depression, social support, violence) and *HIV-related* (HIV testing, adolescent sexual and reproductive health [SRH] stigma, condom use) outcomes, adjusting for sociodemographic (age, education, time in Uganda, income) factors.

RESULTS: Among 324 girls, 26.54% (n=86) reported past 12-month TS (67.4% for money only, 32.6% for money and other goods [e.g. accommodation, food, transport, drugs]), 62.8% of TS-engaged girls had ever tested for HIV. Among 88 boys, 47.7% (n=42) reported past 12-month TS (21.4%: money only; 78.6%: money and other goods); 50.0% of TS-engaged boys had a lifetime HIV test. In multivariable analyses with boys, adjusting for socio-demographics, TS was associated with: depression (adjusted R^2[AR^2]=0.08, p=0.04); lower resilience (AR^2=0.08, p=0.02); lifetime sexual violence (AOR: 10.80, 95%CI: 1.1-108.5); adolescent SRH stigma (AR^2: 0.14, p=0.038); and lower HIV testing odds (AOR: 0.31, 95%CI: 0.11-0.85). Among girls, in multivariable analyses adjusting for sociodemographics, TS was associated with: lower social support (AR^2=0.21, p<0.001); lifetime physical violence (AOR: 5.94, 95%CI: 2.78-12.67); lifetime sexual violence (AOR: 5.85, 95%CI: 3.23-10.62); past 12-month intimate partner violence (AOR: 3.55, 95%CI: 1.1-11.23); lower adolescent SRH stigma (AR^2=0.11, p<0.001); higher condom efficacy (AR^2=0.21, p<0.001); and past 3-month consistent condom use (AOR: 4.49, 95%CI: 1.43-14.11).

CONCLUSIONS: Transactional sex is common among Kampala's urban refugee youth and associated with psychosocial vulnerabilities. Yet HIV cascade engagement varied by gender: TS was associated with girls' increased condom use and boys' reduced HIV testing. Gender, refugee, and youth-tailored HIV cascade strategies are needed with urban refugee youth.

PED0916

HE PROMISED HE WOULD GET ME OUT OF HARDSHIPS: DYNAMICS OF POVERTY AND TRANSACTIONAL SEX AMONG TANZANIAN ADOLESCENTS IN AN INTEGRATED SOCIAL PROTECTION PROGRAMME

L. Kajula[1], R.L. Kirkegaard[2], U. Gilbert[3], T. Palermo[4]
[1]UNICEF Office of Research - Innocenti, Social and Economic Policy, Dar es Salaam, Tanzania, United Republic of, [2]UNICEF, AIDS Section, New York, United States, [3]UNICEF Tanzania, Children and AIDS Section, Dar es Salaam, Tanzania, United Republic of, [4]State University of New York at Buffalo, Department of Epidemiology at Environmental Health, Buffalo, United States

BACKGROUND: Transactional sex is driven by structural factors including poverty. Social protection initiatives may be an effective tool in protecting youth from transactional sex and its consequences, including HIV, early pregnancy and gender-based violence. This current intervention combines household-level cash transfers with adolescent-focused complementary programming to reduce HIV, abuse and exploitation. We examine intervention impacts and the lived experiences of adolescents in Tanzania and how poverty contributes to exploitation.

METHODS: The Ujana Salama Tanzania "Cash Plus" study on Youth Well-Being and Safe, Healthy and Productive Transitions to Adulthood is a randomised-control trial targeted to adolescents in households receiving the government's Productive Social Safety Net (PSSN) cash transfer programme. The cash plus intervention was layered onto the PSSN and comprised livelihoods and life skills training, mentoring and a productive grant, and linkages to existing government health services. We use three rounds (2017-2019) of qualitative (N=40) and quantitative (N=2,100) data from adolescents (aged 14-19 at baseline) to explore the dynamics of poverty and transactional sex and estimate intent to treat impacts using ANCOVA models.

RESULTS: Quantitative findings show that, at baseline, among those ever having had a romantic relationship, 8% reported having started the relationship for financial reasons, and this increased to 28% among treatment youth and 31% among control youth by Wave 3. While there were no intervention impacts on this outcome, there were positive impacts on livelihoods participation and starting businesses, which may mitigate future risk of transactional sex. In qualitative interviews, some female participants report being given money or promises of "a better life" including marriage or funds to start a small business. Most relationships that resulted in pregnancy subsequently experienced the disappearance of the men. Experiences of unplanned pregnancy in these relationships amplified their already stressful lives, limiting their educational and future productive opportunities.

CONCLUSIONS: While aiming to address structural drivers of sexual exploitation that may lead to HIV through a government-run, multi-sectoral cash plus intervention, this intervention did not reduce transactional sex. Further economic strengthening and linkages to family planning services are crucial to protect adolescents from unwanted consequences of transactional sex among this vulnerable population.

PED0917

TRANSACTIONAL SEX AMONG INDIGENOUS ADOLESCENTS OF THE COMARCA NGÄBE-BUGLÉ OF PANAMA: PRACTICES, NORMATIVE BELIEFS, AND EFFECT ON HIV AND SEXUALLY TRANSMITTED INFECTIONS

A. Gabster[1,2], P. Mayaud[1], J.M. Pascale[2], B. Cislaghi[3]
[1]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [2]Instituto Conmemorativo Gorgas de Estudios de la Salud, Genomica y Proteomica, Panama City, Panama, [3]London School of Hygiene and Tropical Medicine, Public Health and Policy, London, United Kingdom

BACKGROUND: Transactional sex (TS) has been a major focus of sexual health research and interventions, especially among young women in sub-Saharan Africa. The Comarca Ngäbe-Buglé (CNB) is the largest-populated indigenous region in western Panama, home to people of Ngäbe and Buglé ethnicities. Currently, few data focus on TS practices and normative beliefs among Indigenous adolescents in the Americas, and implications for HIV and sexually transmitted infection (STI) risk.

METHODS: We conducted a mixed-methods study between January and November 2018, which consisted of the inclusion of 700 school-going adolescents (14-19y) who completed a self-applied questionnaire and provided blood and urine samples tested for HIV, syphilis, chlamydia, and gonorrhoea. Additionally, we performed 20 semi-structured in two sites of the CNB with adolescents, using participant guided vignettes to elicit descriptive and injunctive norms around transactional sex in the CNB.

RESULTS: In both the qualitative and the quantitative study, we found that having been offered TS was frequently reported by male (15.5%) and female (18.8%) adolescents. People offering TS were reported to be older men/male teachers, and less often, older women/female teachers. Household-level economic indicators were not associated with TS. Normative beliefs were found to be generally accepting of TS among both male and female participants. Having been offered TS and holding normative beliefs in favor of TS were associated with reported forced sex in both sexes and increased HIV/syphilis seropositivity in males. There were no associations with other reproductive and STI outcomes. In the qualitative study, we found that participants generally felt adolescents held agency in deciding to engage in TS, except when there is a great need for the item offered.

CONCLUSIONS: TS is common among Indigenous adolescents of CNB, and normative beliefs of the behavior are generally positive. However, having been offered TS was associated with negative outcomes such as increased reported forced sex and HIV/syphilis seropositivity. Interventions should not necessarily just focus on eliminating the transactional component of sexual encounters, but also overcome the perceived limited agency held by adolescents and increase their adoption of condom use at all sexual encounters.

MEDIA, CULTURAL AND RELIGIOUS REPRESENTATIONS OF HIV AND OF KEY POPULATIONS

PED0918

SEXUALLY EXPLICIT MEDIA CONSUMPTION AND ASSOCIATION WITH UNPROTECTED ANAL SEX IN MEN WHO HAVE SEX WITH MEN IN BRAZIL

A. Queiroz[1], Á.F.L. Sousa[2], A.A. Martins[3,4], I. Fronteira[5], O.P. Frota[3], I.A.C. Mendes[2]

[1]Universidade Nova de Lisboa, Escola Nacional de Saúde Pública, Lisbon, Portugal, [2]Universidade de São Paulo, Escola de Enfermagem de Ribeirão Preto, Ribeirão Preto, Brazil, [3]Universidade Federal do Mato Grosso do Sul, Campo Grande, Brazil, [4]Universidade Federal de Mato Grosso do Sul, Campo Grande, Brazil, [5]Universidade Nova de Lisboa, Instituto de Higiene e Medicina Tropical, Lisbon, Portugal

BACKGROUND: Sexually Explicit Media (SEM) comprises any type of material describing genitals or explicit sexual acts. The effect of SEM consumption on Men who have sex with men (MSM) sexual health has been associated with a higher prevalence of vulnerable behaviors, specially with recent changes in SEM regarding the absence of condoms in the scenes (bareback or condom free). SEM consumption is significant in Brazil, with 28.5 billion visitors per year in the world's most popular pornographic website. The country was in 10th place among the countries that most accessed Pornhub, with the predominant search for gay pornography. Within these bareback term searches, it is becoming increasingly popular, to a point of, almost, being unanimous. Our goal is to evaluate the bareback consumption of SEM by men who have sex with men (MSM) in Brazil and its association with condomless anal intercourse (CAI).

METHODS: We created a Facebook® page, with a link directing stakeholders to the study questionnaire. Included were users who resided in Brazilian territory, identified themselves as cisgender men, were 18 years old or older and had sex with another man in the last 12 months. Data were collected in September 2017, tabulated and analyzed and by uni- and bivariate inferential statistics and logistic regression.

RESULTS: 2248 MSM participated in the survey, with a mean age of 24.4 years. Having multiple sex partners, preferring movies with bareback scenes, judging this practice to be a fetish and performing it, having a casual partnership, and being aware of a partner's negative HIV status were factors that increased the chances of engaging in CAI. While not having bareback as a fetish, being in a stable relationship and having an HIV-positive partner are protective conditions.

CONCLUSIONS: SEM consumption is associated with MSM without condoms. These findings may help design interventions to target the aspects associated with CAI as well as sex education for young adults. Health messages that highlight the potential risks of engaging in CAI could be disseminated on sites or apps frequently accessed by MSM, or even displayed directly into bareback SEM as warning messages.

PED0919

HIV IN THE MEDIA. RESEARCH ON HIV AND AIDS COVERAGE IN SPANISH-SPEAKING ONLINE MEDIA IN LATIN AMERICA AND THE CARIBBEAN

D.L. Mora Bello[1,2]

[1]McCain Institute, Next Generation Leaders Program, Washington DC, United States, [2]buho Media, Bogota, Colombia

BACKGROUND: The use of negative words that generate stigmatizing or discriminatory content are highly used by journalists and the media in Latin America and the Caribbean. Ignorance of adequate language increases barriers generated by stigma and discrimination for people with HIV.

METHODS: Analysis of 4002 mentions of HIV or AIDS in 2194 news articles from 19 Spanish-speaking countries in Latin America and the Caribbean during October and November 2016, evaluating the words of adequate and inappropriate use of greater presence, infections and related diseases, more named populations and more recurrent issues in the HIV and AIDS coverage.

RESULTS: The negative or inappropriate words of greater use by the media in terms of articles are disease 639/2194 (29.1%), contagious 220/2194 (10%), carrier 193/2194 (8.8%), AIDS as HIV 186/2194 (8.4%) and STD 104/2194 (4.7%).

The diseases or infections that most relate to HIV or AIDS in media by number of mentions are Hepatitis 110/4002 (2.75%), Tuberculosis 95/4002 (2.37%), Malaria 60/4002 (1.50%), Syphilis 52/4002 (1.30%), Ebola 25/4002 (0.62%), HPV 19/4002 (0.47%), Influenza 16/4002 (0.40%), Gonorrhea 14/4002 (0.35%).

The populations that are most visible in the study by mentions are children 1252/4002 (31.3%), youth 996/4002 (24.9%) woman 960/4002 (24%), gay/msm 612/4002 (15,3%), male 592/4002 (14.8%), drug user 368/4002 (9.2%), sex worker 272/4002 (6.8%), transgender 268/4002 (6.7%), bisexual 76/4002 (1.9%) and lesbian 60/4002 (1.5%) and issues: prevention 1252/4002 (31.3%), treatment 1164/4002 (29.1%), research 976 / 4002 (24.4%), advances 892/4002 (22.3%), diagnosis 584/4002 (14.6%), discrimination 292/4002 (7.3%) and stigma 252/4002 (6.3 %).

CONCLUSIONS: One in 3 statements about HIV or AIDS in Latin American online media has inappropriate words that can influence the generation of barriers to people with HIV due to stigma and discrimination. Populations with the highest incidence of HIV are not the protagonists of the news about HIV or AIDS, children and young people are the most visible. Issues such as stigma and discrimination are those with less media circulation, making the problem invisible.

MIGRATION AND HIV

PED0920

SEX, MONEY, AND MIGRATION: DECONSTRUCTING GENDER NORMS AND BENDER-BASED VIOLENCE TO IMPROVE ACCESS TO HIV SERVICES FOR FEMALE MIGRANTS IN THAILAND

N. Chaiprakobwiriya[1]

[1]Raks Thai Foundation, Program Quality Department, Bangkok, Thailand

BACKGROUND: Despite existing laws on domestic violence, a 2018 study found that 15% of Thai women had experienced psychological, physical, and/or sexual violence. Female migrants from Myan-

mar and Cambodia are even more at risk for gender-based violence (GBV) due to multi-dimensional vulnerability. This study investigates harmful gender norms and barriers to accessing services for migrant populations to improve HIV prevention services.

DESCRIPTION: From November–December 2019, Raks Thai Foundation (a member of CARE International) conducted a gender analysis applying CARE Social Analysis and Action (SAA) as a key conceptual framework.This study is a thematic evaluation research for the project "Stop TB and AIDS through Reach–Recruit–Test–Treat–Retain," funded by The Global Fund (GFATM). The study sites included four of the most migrant-populated provinces: Chonburi, Samut Sakhon, Songkla and Chiang Mai. Participatory Action Research (PAR) was used with eight focus groups (disaggregated by sex and occupation) and semi-structured interviews. Seventy-two male and female migrants from Cambodia and Myanmar and their local service providers were included.

LESSONS LEARNED: The findings revealed that economic violence is an entry point for psychological, physical, and sexual violence. The pressure of sending remittance back home and indebtedness were major causes of verbal and physical violence in migrant households. In addition to formal structural barriers to services like lack of Thai language skills, valid documentation, and economic independence, female migrants were confined by double gender norms—at home and in Thailand.

Female migrants internalized the role of obedient housewife from home, and in Thailand, they endured hardship and abuses because of their perceived inferiority as poor non-Thai citizens, reducing their ability to negotiate safe sex, sexual pleasure, sexual violence, and access to support services.

The data also highlighted that HIV-positive female migrants experienced psychological violence from the perceived guilt of transmitting the disease to their partners.

CONCLUSIONS/NEXT STEPS: The study sheds light on harmful gender norms that significantly influence GBV, heightening the risk of nonconsensual sex, sexual violence, and HIV infection. Comprehensive and intersectional HIV services incorporating language support, GBV screening, prevention, and response addressing harmful gender norms should be implemented to reach vulnerable female migrants.

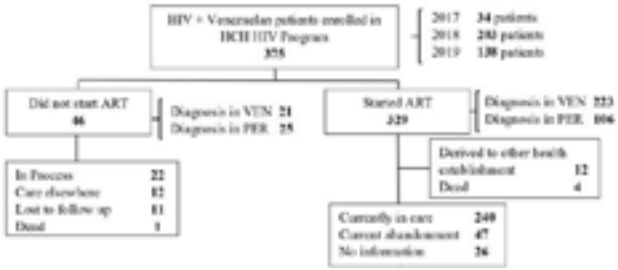
[1]Instituto de Medicina Tropical „Alexander von Humboldt", Lima, Peru, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Instituto de Medicina Tropical „Alexander von Humboldt", HIV Program, Lima, Peru

BACKGROUND: Due to a huge crisis extensive to health services, until January 2019 approximately 8000 people living with HIV from Venezuela had migrated. As Peru was until November2019 one of the main destinations for such migrants, we describe the health status and epidemiological trends of PLHIV from Venezuela at the largest HIV program in Lima.

METHODS: We collected and revised the baseline and follow-up routine data of all PLHIV from Venezuelan enrolled in the HIV program at the study center since January 2017, with end of follow-up by November 2019.

RESULTS: The study center registers 375 Venezuelan PLWH; this represented 4.2% (2017), 20.1% (2018) and 16.1% (2019) of the HIV program's annual enrolments. The median age was 30 years (IQR 25;36), 90.7% were men, and 8 pregnancies out of 35 women. The proportion with diagnosis in Peru changed from 12% in 2017 to 58.7% in 2019; of those entering in AIDS stage from 9% to 29.9%. The median baseline CD4+ count was 398 (IQR 233;612); 24.1% were on viral suppression at enrollment. By November 2019, 239 (83.6%) were still in care, and 46 (12.3%) had not started ART. Out of 47 (16.4%) who were lost to follow-up, 13 (27.6%) had left Peru. Among 170 (57.4%) with a viral load measure between 3 to 9 months, 118 (69.4%) achieved viral suppression; 52(30.6%) were on virologic failure. HIV/TB coinfection lead the hospitalization diagnosis (7 out of 22 hospitalizations in 22 cases). Five deaths (1.3%) were reported due to different causes.



[Figure. Patients Flowchart]

CONCLUSIONS: The worsening clinical outcomes at arrival on the last year, increasing report of new HIV diagnosis and suboptimal rates of viral suppression for migrants from Venezuela in Peru call for actions oriented to early diagnosis and simplified access to health services, as well a better understanding of additional barriers for adherence in this population.

PED0922

HIGH RATES OF FIRST-TIME TESTERS: THE TWIN CHALLENGE OF MOBILITY AND CASE-IDENTIFICATION AMONG MOBILE AND KEY POPULATIONS IN CROSS-BORDER AREAS OF EAST AFRICA

W. Gakuo[1], B. Kitungulu[2], D. Muroki[2]
[1]United States Agency for International Development, Health, Population and Nutrition Office, Nairobi, Kenya, [2]FHI360, Nairobi, Kenya

BACKGROUND: Contributing up to 25% of new HIV infections in most regions of Sub-Sahara Africa, cross-border mobile and key populations have specific needs that need to be addressed to achieve the ambitious 90:90:90 goals of case identification, treatment, and viral suppression for HIV epidemic control. Identification as well as treatment enrollment and adherence among mobile populations pose challenges for national HIV and AIDS programs designed to address care for residents within their borders.

METHODS: We reviewed program data from a USAID-funded experiential learning program - Cross-Border Integrated Partnership Project (CB-HIPP) for three years (2017- 2019). CB-HIPP works across 12 cross-border sites on the Kenya/Uganda, Kenya/Tanzania, Rwanda/Tanzania and, Uganda/Rwanda borders. This includes work with 115 private and public sector facilities in these cross-border sites, most of which are on the Northern Transport corridor and Lake Victoria shores in East Africa. De-identified data was extracted from health facility HTS and ART registers and used to estimate proportions of

new testers and mobility patterns among different categories of clients. Clients from other nationalities or sub-national units were considered mobile.

RESULTS: Overall, 57,356 individuals were tested, with 11,314 (20%) new testers. Highest yield was from index-case testing – partner notification services from voluntary testing and counseling and mobile testing/outreaches, at 33%. Of the new testers 113 (1%) were MSMs, 2,942 (26%) were FSWs and the rest were other priority populations including truckers and fisher folk. Mobility was highest along the Sio Port/Port Victoria/Majanji border point. Positivity yields were 2.1% overall while it varied between 4.3-6.3% among the mobile population and 2.9-8.3% among first time testers. This mobile population had lower linkage rates at (65%) and suppression rates (73%) than resident populations in these sub-national units in these cross-border areas.

CONCLUSIONS: Targeting mobile and other cross-border populations helps to find first time testers. Linking positive clients to treatment services and retaining them on treatment is key to epidemic control. Surveillance across borders through a public health approach to share information about mobile clients is needed to address this challenge in the EA region, particularly in the islands and along the shores of Lake Victoria where HIV prevalence is high.

POLITICAL AND STRUCTURAL FACTORS

PED0923

INTERSECTIONAL STRUCTURAL HATE: THE EFFECTS OF STRUCTURAL ANTI-BLACK AND ANTI-LGBTQ STIGMA FOR SEXUAL MINORITY MEN

D. English[1], J. Carter[2,3], C.A. Boone[4,5,6], N. Forbes[7], L. Bowleg[4,5,6], D.J. Malebranche[8], A.J. Talan[3], H.J. Rendina[3,2]
[1]Rutgers University, School of Public Health, Newark, United States, [2]The Graduate Center of the City University of New York (CUNY), Health Psychology and Clinical Science, New York City, United States, [3]Hunter College of the City University of New York (CUNY), Psychology, New York City, United States, [4]George Washington University, Washington DC, United States, [5]D.C. Center for AIDS Research- HIV Cure Scientific Working Group, Washington DC, United States, [6]Intersectionality Training Institute, Washington DC, United States, [7]Fordham University, Psychology, Bronx, United States, [8]Morehouse School of Medicine, Atlanta, United States

BACKGROUND: Although there has been recent research investigating the effects of structural anti-LGBTQ stigma on psychological and HIV-related health outcomes among sexual minority men (SMM), limited evidence exists on how multiple types of stigma at the structural level intersect to negatively influence these outcomes. Specifically, it is unclear how the intersection of structural anti-LGBTQ and anti-Black stigma affect Black SMM. The present study examined associations from structural anti-LGBTQ stigma, structural anti-Black stigma, and their intersection to psychological and HIV-related health outcomes among SMM.

METHODS: Participants were a national sample of 6,916 seronegative SMM (1,379 Black; 5,537 White) in 2017-2018. We used indicators of state-level stigma: the categorical Human Rights Campaign State Equality Index, which assesses statewide anti-LGBTQ policies (e.g., sodomy criminalization), and the continuous state racism index (Medic et al., 2018), which assesses anti-Black policies through residential segregation and inequities in incarceration, education, economic resources, and employment. Outcomes were self-reported anxiety, depressive symptoms, perceived burden, heavy drinking, and HIV testing. In separate structural equation models (SEM) for White and Black participants, we examined the associations between stigma indicators and their interaction on outcomes. We adjusted models for US region, population density, SES, income, employment, insurance status, age, sexual identity, gender identity, and relationship status.

RESULTS: For Black participants, the anti-Black stigma variable was significantly positively associated with anxiety symptoms (β=0.20), perceived burden (β=0.41), and heavy drinking (β=0.20). The structural anti-LGBTQ stigma variable was significantly associated with anxiety symptoms (β=0.08), perceived burden (β=0.20), heavy drinking (β=0.07), and HIV testing frequency (β=-0.13). The interaction term was significantly positively associated with perceived burden (β=0.38) and heavy drinking (β=0.20). Positive associations from anti-Black stigma to perceived burden and heavy drinking were stronger at high levels of anti-LGBTQ stigma. Neither of the stigma variables was significantly associated with outcomes for White SMM.

CONCLUSIONS: Results indicate that the negative health effects of anti-LGBTQ policies are compounded by the effects of anti-Black policies for Black SMM. They also suggest that Black SMM may benefit more than their White counterparts from the repeal of these policies. To reduce racial health inequities for Black SMM, structural and intersectional intervention is imperative.

PED0924

GENDER MINORITY POLICY AND INSTITUTIONALIZED STIGMA AGAINST TRANS WOMEN IN NEPAL

M. Dhakal[1], S. Banik[2], H. Xie[3], S. Sharma[1], R. Lama[1], A. Rai[1], S. Chhetri[1], J. Lin[3], S. Arayasirikul[3], E.C. Wilson[3]
[1]Blue Diamond Society, Kathmandu, Nepal, [2]Baldwin Wallace University, Public Health and Prevention Science, Berea, United States, [3]San Francisco Department of Public Health, Trans Research Unit for Equity, San Francisco, United States

BACKGROUND: Trans women in Nepal are constitutionally recognized as a gender minority, and have the option of changing their legal identification documents to a third gender category of "other." Despite the passing of this policy, trans women still face extreme discrimination, human rights violations and are socially isolated, all of which are associated with increased HIV risk. This analysis was conducted to assess trans women's opinion of the effects of the gender minority policy and to examine use of the "other" category in gender identity documentation among trans women in Nepal.

METHODS: In 2019 our team conducted a population-based HIV behavioral risk survey of trans women in Kathmandu, Nepal. The survey data were descriptively analyzed to examine the experiences of the opinions of and use of the gender minority policy in Nepal.

RESULTS: Of the 200 trans women participants in the study, only 13.5% of participants thought that having an "other" gender category constitutionally recognized has been positive for trans women, and 90% believe that the gender minority policy is a barrier to marriage, employment, and other social institutions including lack of provision for the public system. Only 5% had changed their gender marker to "other" on their passport, citizenship card and/or marriage certificate while 91.5% had changed their name. Only one third expressed a desire to change their gender marker to "other" on legal identity documents. One quarter (24.5%, N=49) would prefer to change their identity to female. The need for medical evaluation was reported as the main barrier to gender marker change.

CONCLUSIONS: The implementation of the gender minority policy in Nepal may be negatively affecting trans women and preventing full social and political inclusion of this community into Nepali society. Most notably, identifying as "other" is a barrier to employment opportunities and marriage in Nepal, which are essential safety net institutions. Efforts to address discrimination and social exclusion of trans women that lead to HIV and other health and wellness risks will likely have to address the challenges with the gender minority policy in Nepal.

PED0925

THE INFLUENCE OF VICTIMIZATION BY LAW ENFORCEMENT AND DRUG SELLING TRADERS ON THE SOCIAL NETWORK RISK CHARACTERISTICS OF PEOPLE WHO USE DRUGS ON THE U.S.-MEXICO BORDER

J. Lechuga[1], G. Perez[2], O. Beltran[3], A. Varela[1], S. Lopez[1], R. Ramos[2], M.E. Ramos[3]
[1]The University of Texas at El Paso, Public Health, El Paso, United States, [2]Alliance of Border Collaboratives, El Paso, United States, [3]Programa Compañeros, Ciudad Juarez, Mexico

BACKGROUND: People who use drugs (PWUDs) are disproportionately affected by HIV due to engagement in high risk behaviors (e.g. condomless sex and sex exchange for money or drugs) and such behaviors are diffused through social networks. Structural level factors (e.g., law enforcement abuse and violence from members of the drug distribution economy) may also influence social network risks
METHODS: Participants who used crack or heroin in the last 30 days residing in Ciudad Juarez (CJ), Mexico (53%) or El Paso, Texas (47%), were recruited via respondent driven sampling to answer a social network survey. Two generalized estimating equations (GEE), to control for non-independence of observations, were computed to explore the influence of gender, city of residence, victimization by law enforcement and from members of the drug distribution economy, and the interaction of gender and city of residence on engagement in condomless sex and exchange of sex for money or drugs with a member of the social network
RESULTS: Among 369 individuals (72% male), 67% in CJ and 25% in El Paso, reported that they had been victims of law enforcement abuse and 44.5% in CJ and 44.3% in El Paso reported violence from members of the drug distribution economy. The first GEE indicated that gender, city of residence, and their interaction, were not associated with engagement in condomless sex with a member of the social network; law enforcement abuse ($\beta = .42$, $p < .01$) and violence from members of the drug distribution economy ($\beta = .48$, $p < .01$) were significantly associated. The second GEE indicated that living in CJ ($\beta = 1.14$, $p < .05$), law enforcement abuse ($\beta = .67$, $p < .01$), violence from members of the drug distribution economy ($\beta = .58$, $p < .01$), and the interaction of gender and city of residence ($\beta = -.95$, $p < .01$) were significantly associated with exchange of sex for money or drugs with a member of the social network.
CONCLUSIONS: Our findings indicate that binational strategies to reduce law enforcement abuses and the violence associated with the drug distribution economy may reduce the HIV risk of PWUDs.

BACKGROUND: People who inject drugs (PWID) lag behind other key populations in HIV care continuum outcomes, and experience persistent racial disparities in these outcomes. The impacts of criminal justice reform and increasing drug treatment access have largely been investigated in the context of substance use and justice-related outcomes, but not in relation to HIV.
METHODS: This study explored whether reducing incarceration rates and increasing drug treatment access may influence vulnerability (sero-disordant sexual and injection partnerships) to HIV infection among PWID. We developed two agent-based models (ABM) of sexual partnerships among PWID and non-PWID, and needle-sharing partnerships among PWID in Baltimore, Boston, Miami, New York City, and San Francisco over 3 years. One ABM estimated changes in average discordance among PWID as a function of decreasing ZIP code-level incarceration rates by MSA and race/ethnicity (Black, Latino, White). The second estimated discordance as a function of increasing ZIP code-level drug treatment access by MSA and race/ethnicity. Each ABM was parameterized and validated using National HIV Behavioral Surveillance data and prior literature. Informed by research documenting associations of prisoner release with increases in community-level HIV prevalence, reductions in incarceration rates were fixed at 5% and 30%, and were respectively modeled to increase ZIP code-level HIV prevalence by 2% and 12%. Increases in drug treatment were fixed at 30% and 58%.
RESULTS: Reductions in ZIP code-level incarceration rates by 30%, and associated increases in ZIP code-level HIV prevalence by 12%, were significantly associated with 3-year increases in average sero-discordance among PWID ranging 3%-14%. This association varied by MSA and race/ethnicity. Regardless of race/ethnicity and MSA, increasing drug treatment access by any magnitude and reducing incarceration rates by 5% were estimated to result in no significant change in average sero-discordance among PWID.
CONCLUSIONS: Reductions in incarceration rates may lead to short-term increases in sero-discordant partnerships among some racial/ethnic groups of PWID in some cities by increasing community-lev-

el HIV prevalence. If confirmed in future research, opportunities to offset increases in community-level HIV prevalence following incarceration reform by increasing HIV testing, engagement in care, and positive community reintegration among men and women released from correctional settings, should be strengthened.

PED0927

HIV-RELATED STIGMA AND ITS DETERMINANTS AMONG PRISONERS IN NIGERIA

A. Anosike[1], B. Olakunde[2], C. Ezeokafor[1], E. Ikomi[1], O. Amanze[3]
[1]National Agency for the Control of AIDS, Research Monitoring and Evaluation, Abuja, Nigeria, [2]National Agency for the Control of AIDS, Community Prevention and Care Services, Abuja, Nigeria, [3]National Agency for the Control of AIDS, Performance Management, Abuja, Nigeria

BACKGROUND: In sub-Saharan Africa, HIV-related stigma and discrimination remain widespread and continue to hinder the uptake of HIV prevention, treatment, and care services. However, in prisons, where inmates are vulnerable to HIV infection, there is dearth of data on the prevalence of stigma and discrimination against people living with HIV. This study aimed to assess HIV-related stigma and its determinants among prisoners in Nigeria.

METHODS: A cross-sectional study was conducted between August 2018 and March 2019. Systematic random sampling method was used to obtain a study sample of 2,511 prison inmates from 12 prisons across the six geopolitical zones of Nigeria. Data analysis was done using descriptive statistics, chi-square tests, and multivariate logistic regression. Significance level of < 0.05 was considered statistical significant. Stigma was computed based on the selection 1 to 3 options out of three HIV related stigma questions on fear of casual contact with PLWH, by the respondents. Data analyses were conducted using SPSS software version 21.

RESULTS: Most of the respondents were between 25-35 years (51%), male (92.4%), single (64.7%), Christian (70%), and had primary school (39.0%) as their highest level of education. Less than half (48.1%) of the inmates had certain misconceptions about HIV transmission. The most common misconception was that HIV could be transmitted through mosquito bites (28.9%). Stigma was high among inmates (72.5%). Only about two-fifths of respondents were willing to eat with a person living with HIV (PLWH) while about 60% were willing to associate or share a cell with a PLWH. Factors associated with HIV-related stigma among inmates were: traditional religion (aOR=3.4, 95%CI: 1.09-10.57); tertiary education (aOR= 0.3, 95% CI: 0.20 - 0.54); secondary education (aOR= 0.3, 95% CI: 0.16 - 0.44), primary education (aOR= 0.2, 95% CI: 0.11 - 0.31), and having misconceptions about HIV transmission (aOR=1.7, 95% CI: 1.30-1.87).

CONCLUSIONS: HIV-related stigma among prisoners was high. There is a need to implement programs on HIV awareness and education as well as anti-stigma interventions in Nigerian prisons.

PED0928

INTEGRATING SCREENING AND MANAGEMENT OF HIV, TB, VIRAL HEPATITIS AND STIS AMONG INCARCERATED INDIVIDUALS IN 13 STATES OF INDIA

A. Hazra[1], S. Rajan[2], S. Mudaliar[1], B. Singh[2], A. Lincoln[2], M. Mistry[1], L. Ramakrishnan[1], S.S. Raghavan[1]
[1]Solidarity and Action Against The HIV Infection in India (SAATHII), New Delhi, India, [2]National AIDS Control Organisation (NACO), New Delhi, India

BACKGROUND: India has 1,401 prisons housing 410,000 inmates, 113% of their capacity. High risk sexual activities and needle-sharing increases their risk for HIV, STIs and viral hepatitis, whereas overcrowding, high turnover, poor nutrition, and substance abuse increase their TB risk. To address these, Government of India initiated scale-up of integrated services in October 2017, and SAATHII, a national NGO, provided technical assistance in 13 states with support from EJAF.

DESCRIPTION: Special Secretary of Health, responsible for National AIDS Control Organisation and National TB Elimination Program, led the initiative and brought together nodal agencies of HIV, STI, TB and Hepatitis. Subsequently, officials from 880 prisons and closed settings were sensitized. Inmates were counselled and screened by government and SAATHII teams using multi-prong strategies. The scope of available health services where available (169 prisons) were expanded to include HIV and TB counseling and screening and sputum collection, whereas camp-based screening was conducted where health services were unavailable. Conversely, STI, HBV and HCV screening were carried out only in prisons where test kits and trained human resources were available. Those detected positive with HIV, STI, HCV and HBV were linked to the government treatment facilities through accompanied referrals, whereas TB drugs were administered by the prison officials through DOT.

LESSONS LEARNED: The project screened 412,924 inmates for HIV, 2,92,486 for TB, 1,09,697 for STI, 35,397 for HBV, and 8,659 for HCV, which resulted in the detection of 1412 HIV+, 501 TB, 704 STI, 526 HBV, and 110 HCV cases. Among these 83% of HIV+, 94% of TB, 87% of HBV, 77% of HCV and 100% of STI cases were initiated on treatment and are in follow-up. Lack of adequate health infrastructure, human resources, inadequate supply of STI and viral hepatitis test kits and drugs for the treatment of viral hepatitis were the main challenges at the prisons.

CONCLUSIONS/NEXT STEPS: HIV interventions offer an opportunity to integrate diagnosis and treatment of TB, HBC, HBV and STIs in the prisons and future expansion to consider single window system for sample collection, drug dispensing and outcome monitoring.

PED0929

PEER-LED PRISON HIV/AIDS INTERVENTION PROGRAMME FOR ENHANCING AND SUSTAINING OWNERSHIP

R. Sinate[1], A. Lincoln[2], B.G. MANG[1]
[1]Emmanuel Hospital Association, Partnership Projects, New Delhi, India, [2]National AIDS Control Organisation, HIV Prevention in Prison and Close Settings, New Delhi, India

BACKGROUND: As per 2017 figures in India, there were 1361 prisons, with capacity of 3,91,574 and total of 4,50,696 prisoners at the end of the year. Overcrowding, violence, inadequate ventilation combined with inadequate personal hygiene, malnutrition and poor health services increases the vulnerability to HIV, hepatitis and tuberculo-

sis. Virtually most of the prisoners will return to their communities, many within a few months to a year. Hence health in prisons and other closed settings is therefore closely connected to the health of the wider society. The Peer Led Prison HIV/AIDS Intervention Programme aims at Improving Testing for People Most at risks for HIV and linking them to ART and other health related services within prison settings.

DESCRIPTION: Peer Led Prison HIV/AIDS Intervention programme has been implemented by National AIDS Control Organization with their development partners in India across 31 states with 895 Implementation sites. Addressing the health care needs of prison inmates by institutionalizing provision of key essential services within the prison settings and facilitating ownership of the programme through trained Peers Volunteers for enhancing access to HIV and other health related services are the main focus of the programme. Formation of State Oversight Committee for Prison HIV/AIDS Intervention Programme with key stakeholders including trained Peers Volunteers has been one of the key factors in scaling up, strengthening and sustaining the programmes.

LESSONS LEARNED: 6610 prison inmates were identified and 6363 were trained as "Peer Volunteer" across 895 implementation sites. These trained Peer Volunteers enhanced sensitization of their fellow inmates leading to increased access to HIV and other health related services.412924 prison inmates were screened for HIV, 1412 detected HIV positive and 1189 were linked to ART. 16856 were screened for Tuberculosis, 501 diagnosed for TB and 472 put on treatment. 8659 screened for Hepatitis C, 110 found reactive and 85 put on treatment.

CONCLUSIONS/NEXT STEPS: The identified Peer Volunteers among prison inmates and prison authorities should be acknowledge and consider by the Prison Department and National AIDS Control Authorities for technical support.

SEXUAL- AND/OR GENDER-BASED VIOLENCE AND EXPLOITATION (INCLUDING IN CONFLICT SETTINGS)

PED0930

THE VOICES OF YOUTH: FINDINGS FROM THE FIRST YOUTH-LED KEY STAKEHOLDER MEETING ON CHILD SEXUAL ABUSE ON KALANGALA ISLAND IN UGANDA

A. Namusoke[1]
[1]People In Need Agency - PINA Uganda, Community Education, Wakiso, Uganda

BACKGROUND: Youth engagement is an important catalyst for system changes to improve support for programmatic and policy efforts. However, engaging marginalized youth presents a significant challenge because they are often disconnected from and distrust the systems/environments in which they live. This paper describes processes, outcomes, and lessons learned from engaging youth in program policy advocacy efforts to address child sexual abuse on Kalangala Island in Uganda. Kalangala Island has one of the highest HIV prevalence rates in Uganda (27%).

DESCRIPTION: Young people (ages 12 – 24) were mobilized to engage government representatives and community members to raise awareness about the challenge of child sexual abuse, and to develop an action plan to prevent this abuse and address the needs of survivors. The theme was "Prioritizing girls' voices". Participants were selected from shelters taking care of survivors. Participants first engaged in a day long pre- adolescent dialogue during which adolescents were introduced to global fund processes and shared their experiences of sexual violence, their perceptions of current gaps in services and their aspirations.The meeting also identified key concerns to emphasize during the stakeholder meeting. All activities were youth-led. The meeting with stakeholders focused on sharing survivor testimonies, discussing the limitations and gaps in current policies and programs, and identifying potential strategies through group discussions, panel sessions, question and answer and a video recording on the situation analysis of child sexual abuse.

LESSONS LEARNED: Meaningful youth participation is an important mechanism for building youth's resilience, and developing programs that address their pertinent needs. Meeting highlighted numerous key gaps and opportunities for addressing child sexual violence and HIV and these included: developing comprehensive trauma services for survivors; re-building trusting with organizations in-charge of youth's well-being; developing community-based systems for identifying victims and linking them to care, and strengthening health systems to better respond to the health needs of survivors.

CONCLUSIONS/NEXT STEPS: Youth engagement in advocacy and policy planning is critical to the strengthening youth's capacity and promoting skills that promote youths' sense of belonging, connectedness and self-esteem. Experience indicates that this mechanism also contributes to building youth's resilience and improving the relevance of policies and programs targeted towards youth.

PED0931

RELATIONSHIP BETWEEN CASH TRANSFERS AND INTIMATE PARTNER VIOLENCE AMONG WOMEN LIVING WITH HIV IN TANZANIA: A RANDOMIZED TRIAL

R. Hémono[1], C. Fahey[1], E. Katabaro[2], R. Mfaume[3], P. Njau[2,4], S. I. McCoy[1]
[1]University of California, School of Public Health, Berkeley, United States, [2]Health for a Prosperous Nation, Dar es Salaam, Tanzania, United Republic of, [3]Shinyanga Regional Medical Office, Shinyanga, Tanzania, United Republic of, [4]National AIDS Control Programme, Ministry of Health, Community Development, Gender, Elderly, and Children, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Cash transfers can improve HIV-related outcomes including adherence to antiretroviral therapy (ART) and viral suppression. However, some studies suggest that cash transfers increase intimate partner violence (IPV), a relationship not well-studied in women living with HIV (WLHIV). We investigated the association between short-term cash transfers and IPV among WLHIV.

METHODS: We conducted a secondary analysis of a three-arm randomized controlled trial evaluating the impact of cash transfers on viral suppression among ART initiates in Tanzania (n=530) from 2018-2019. Adults attending four clinics were randomized 1:1:1 to receive the standard of care (SOC) or one of two monthly cash transfer amounts (~$11 or $4.5 USD), conditional on visit attendance during the first 6 months of ART. Sexual, physical, and emotional IPV and controlling behaviors (jealousy, accusations, limiting contact) were measured through an in-person survey among married and unmarried women who were in a relationship at both baseline and endline (6 months). The average treatment effect in the combined cash group vs. SOC was measured using linear probability models with difference-in-differences estimation.

RESULTS: The analysis included 105 WLHIV (65.7% cash, 34.3% SOC), of whom 70.5% were married and 96.8% lived with their husband or partner. At baseline, 38 (36.2%) women reported IPV, which decreased in both the cash (37.7% to 29.0%) and SOC (33.3% to 25.0%) groups over the next 6 months (-0.4 percentage point difference, 95% CI -27.2, 26.5). Controlling behaviors declined in the cash group (75.4% to 63.8%) and increased in the SOC group (66.7% to 72.2%), representing a -17.2 percentage point difference (95% CI -43.6, 9.3).

	SOC (n=36)			Cash (n=69)			
	Baseline	Endline	Difference	Baseline	Endline	Difference	Difference-in-Differences (95% CI)
IPV	12 (33.3%)	9 (25.0%)	-8.3	26 (37.7%)	20 (29.0%)	-8.7	-0.4 (-27.2 to 26.5)
Controlling behaviors	24 (66.7%)	26 (72.2%)	5.6	52 (75.4%)	44 (63.8%)	-11.6	-17.2 (-43.6 to 9.3)

[Table.]

CONCLUSIONS: There were no significant differences in changes in IPV and controlling behaviors from baseline to 6 months between study groups, suggesting that small, monthly cash transfers do not increase IPV among WLHIV initiating ART. Notably, cash may potentially mitigate controlling behaviors which are important risk factors for violence. Additional research on the safety and potential benefits of cash transfers with larger sample sizes is needed.

PED0932

CHILDHOOD SEXUAL VIOLENCE AS A PREDICTOR OF HIV RISK BEHAVIORS AND NEGATIVE HEALTH OUTCOMES IN ADOLESCENT GIRLS AND YOUNG WOMEN: ADDRESSING VIOLENCE IN HIV PREVENTION PROGRAMMING IS CRITICAL

J. Saul[1], C. Cooney[1], A. Howard[2], T. Beamon[1], M. Borgman[1], J. Hegle[3], A. Auld[4], P. Patel[3]
[1]U.S. Department of State, Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, DC, United States, [2]Strategic Innovative Solutions, Atlanta, United States, [3]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [4]U.S. Centers for Disease Control and Prevention, Lilongwe, Malawi

BACKGROUND: HIV prevention programming for adolescent girls and young women (AGYW) must be responsive to the complexities that put them at risk for HIV acquisition. One structural factor potentially contributing to the vulnerability of AGYW is sexual violence (SV). This abstract explores the influence of SV during childhood on subsequent HIV risk behaviors and health outcomes of AGYW.

METHODS: Data were collected in four countries through nationally representative Violence Against Children Surveys (VACS). Participants in the VACS were 13-24 year old males and females; however, this analysis focused on 19-24 year old females. Logistic regression analyses were conducted using SAS 9.4 to assess the association between childhood SV and subsequent HIV risk behaviors and health outcomes.

RESULTS: For AGYW who experienced SV in childhood in Nigeria and Malawi, there was a 2.9-9.0 times increased odds of having risky partnerships (multiple sexual partners or transactional sex) in the past 12 months. SV in childhood was associated with 1.9-3.3 times increased odds of inconsistent condom use among AGYW in Haiti, Nigeria, and Malawi. In addition, AGYW in Haiti with a history of childhood SV had 1.7 times increased odds of ever having symptoms or a diagnosis of STIs. AGYW who experienced childhood SV also experienced 2.4-5.6 times increased odds of SV in the past 12 months in Haiti, Malawi, and Zambia. AGYW in Nigeria had 2.5 times increased odds of physical intimate partner violence in the past 12 months.

	Zambia 2014 (N=419)	Nigeria 2014 (N=805)	Malawi 2013 (N=447)	Haiti 2012 (N=670)
HIV risk behaviors	SV before 18 AOR (95% CI)	SV before 18 AOR (95% CI)	SV before 18 AOR (95% CI)	SV before 18 AOR (95% CI)
Risky sexual partnerships (Transactional sex or multiple sexual partners) in the last 12 months[1]	1.8 (0.6-5.9)	2.9 (1.1-7.7)[2*]	9.0 (2.2-37.9)[2*]	1.6 (0.6-4.3)
No/low (infrequent) condom use in the last 12 months[1]	2.5 (1.1-5.5)*	3.1 (1.7-5.6)*	3.5 (0.9-13.7)*	1.9 (1.0-3.7)*
Sexual violence in the last 12 months	3.7 (1.7-8.0)*	1.4 (0.8-2.7)	5.6 (3.2-9.8)*	2.4 (1.4-4.2)*
Physical intimate partner violence in the past 12 months	1.6 (0.8-3.6)[3]	2.5 (1.2-5.3)*	0.9 (0.3-31)	N/A
Symptoms or diagnosis of an STI (ever)	1.5 (0.7-3.3)	1.8 (0.9-3.5)**	1.3 (0.5-3.4)	1.7 (1.1-2.7)*

Models include control variables for ever-married, ever-pregnant, and orphaned before age 18
*Statistically significant result (p>0.05)
** Statistically significant at the 0.5<p<0.1 level
[1]Among those who had sex in the past 12 months
[2] Interpret result with caution, 30% < RSE < 50% for related point estimate
[3]All those with physical IPV in the past 12 months were married, so ever married was not a control variable

[Table. HIV risk behaviors and health outcomes among 19-24 year old females by experience of sexual violence (unwanted sexual touching, attempted forced sex, coerced sex, or forced sex) before age 18]

CONCLUSIONS: SV during childhood is associated with higher levels of sexual risk behaviors and STIs – all factors that are related to HIV acquisition. In addition, childhood SV is associated with continued violence in young adulthood, which could contribute to continued HIV risk. Ongoing investments in integrated programming, such as the PEPFAR DREAMS program that provides layered evidence-based HIV and violence prevention and response, are critical to addressing HIV among AGYW.

PED0933

ADDRESSING PARTNER VIOLENCE AMONG CLIENTS OFFERED ASSISTED PARTNER NOTIFICATION: THE USAID RHITES-NORTH LANGO EXPERIENCE IN NORTHERN UGANDA

S. Engulu[1], G. Okello[2], P. Donggo[3], M. Makumbi[4]
[1]JSI USAID Regional Health Integration to Enhance Services, HIV Services, Lira, Uganda, [2]JSI USAID Regional Health Integration to Enhance Services, Family Health, Lira, Uganda, [3]JSI USAID Regional Health Integration to Enhance Services, HIV Prevention Care and Treatment Services, Lira, Uganda, [4]JSI USAID Regional Health Integration to Enhance Services, Admininstration and Management, Lira, Uganda

BACKGROUND: Uganda revised HIV prevention, care and treatment guidelines 2018 recommend Assisted Partner Notification (APN) as a critical strategy to achieve HIV testing of partners at risk. Trained providers assist people with known HIV positive status who consent, to identify and notify their sexual partners of HIV exposure and offer HIV testing. Lango sub-region in northern Uganda has a HIV prevalence of 7.2%, above the national rate 6.4%, high rate of gender based violence (GBV), which is a threat to HIV epidemic control and hampers efforts to identify missing positives.

DESCRIPTION: The USAID supported RHITES-N, Lango project implements APN at 70 facilities in northern Uganda. The project trained and mentored health workers on APN, including GBV screening, timely support and monitoring of reported cases, counseling on pre-

ventive techniques, seeking timely help, referrals and involvement of other stakeholders, conducted focused community dialogue meetings and radio talk shows.

LESSONS LEARNED: Between October 2018 to September 2019, 8,742 index clients were interviewed for APN eliciting 12,434 partners, 11,101 were notified of HIV risk and 9,427 tested with 2,656 identified as HIV positive. Among clients APN services, 55 cases of GBV were reported, 53 among females and 2 among males. Of the 55 cases, two encountered sexual violence while 53 physical violence. Interventions led to decline of GBV cases from 13 in Oct-Dec 2018, 20 cases in Jan-March 2019 to 5 cases during July-Sept 2019 period.

[Figure. Decline in proportion of GBV cases reported following APN Oct 2018 to Sept 2019]

CONCLUSIONS/NEXT STEPS: APN is effective in identification of new HIV positives among sexual partners of index clients as we move towards HIV epidemic control 2020, however the threat posed by GBV has potential to slow down efforts made. Establishing timely preventive response strategies to prevent GBV occurrence, building health workers skills and capacity to respond and engagements with community is critical for sustained epidemic control.

FORCED SEXUAL INITIATION IS ASSOCIATED WITH SUBSEQUENT SEXUAL RISK BEHAVIORS AMONG BLACK WOMEN SEEKING STD SERVICES IN BALTIMORE, MARYLAND, USA

J.K. Stockman[1], M. Smith[1], K. Tsuyuki[1], J.C. Campbell[2]
[1]University of California, Department of Medicine, Division of Infectious Diseases and Global Public Health, La Jolla, United States, [2]Johns Hopkins University School of Nursing, Baltimore, United States

BACKGROUND: Forced sex is an established risk factor for HIV acquisition. In the U.S., Black women are disproportionately affected by forced sex and HIV. Forced sexual initiation, or forced first vaginal/anal sexual intercourse, is understudied among Black women. We sought to examine the associations between forced sexual initiation and subsequent sexual risk behaviors among Black women in Baltimore, Maryland, USA.

METHODS: Between 2015 and 2018, 305 Black women aged 18-44 years were recruited from Baltimore City STD clinics into a retrospective cohort study on forced sex and HIV risk. Using survey data, separate logistic and linear regression analyses were conducted to examine associations. Forced sexual initiation was defined as first vaginal and/or anal sexual intercourse that was unwanted and pressured, threatened, physically forced, or forced with alcohol and/or drugs. Dependent variables were ever had a one-night stand; ever exchanged sex for food or money; ever diagnosed with an STI; ever had condomless sex with a high-risk partner; lifetime number of steady sex partners; and lifetime number of casual sex partners.

RESULTS: Of 275 women with non-missing data, 18% reported forced sexual initiation. Women with a history of forced sexual initiation were more likely to have had a one-night stand (84.1% vs. 64.3%; p=0.01), exchanged food or money for sex (46.5% vs. 14.6%; p<0.0001), and have a greater number of lifetime casual sex partners (median = 3, IQR = 1,6 vs. median = 2, IQR = 1,4; p<0.05) compared to their counterparts. Forced sexual initiation was marginally associated with a lifetime STI diagnosis (90.0% vs. 79.6%; p=0.10). No significant associations were observed for condomless sex with a high-risk partner and number of steady sex partners. Forced sexual initiation was independently associated with ever having had a one-night stand (OR: 2.49; 95% CI: 1.04, 5.99). Forced sexual initiation was also independently associated with ever exchanging sex for food or money (OR: 5.71; 95% CI: 2.59, 12.59).

CONCLUSIONS: Our findings highlight the critical need for the development of HIV prevention interventions that increase self-worth and empowerment, while promoting pre- and post-exposure prophylaxis for young Black girls affected by forced sexual initiation.

PED0935

PATTERNS OF RISKY SEXUAL BEHAVIORS AND ASSOCIATED FACTORS AMONG YOUTHS AND ADOLESCENTS IN VIETNAM

L. Hoang Nguyen[1], L. Vu Gia[2], G. Vu Thu[2], D. Nguyen Ngoc[3]
[1]National University of Vietnam, Hanoi, Vietnam, [2]Nguyen Tat Thanh University, Hanoi, Vietnam, [3]Duy Tan University, Hanoi, Vietnam

BACKGROUND: Youths and adolescents are particularly vulnerable to unprotected sexual practices. Updated evidence about risky sexual behaviors in these population is essential to develop contextualized interventions. This study was conducted for the purpose of clarifying current awareness, attitudes and practices regarding sexual behaviors among Vietnamese young people.

METHODS: A cross-sectional study was conducted in five provinces including Hanoi, Cao Bang, Kon Tum, Binh Thuan, Dong Thap to collect data of youths and adolescents (16-30 years old). Information concerning sociodemographic characteristics, substance use and sexual behaviors were collected via self-reported questionnaire. Multivariate Logistic regression was employed to identify factors associated with sexual behaviors.

RESULTS: Among 1,200 participants, 73.5% ever had sexual intercourses in their lifetime. There were 67.0% of youths and adolescents who wanted to use condom when having sex; but only 48.1% of those who ever had sex during lifetime used condom at last sexual intercourse. Participants who lived in urban area are more likely to not want to use condom (OR=1.48, p-value < 0.01) and had unintended pregnancy (OR=1.86, p-value <0.01) than rural area counterparts. Higher age has positive association with not wanting to use and not using condom. People who use substances like shisha and heroin are more likely to not using condom (OR=10.5, p-value < 0.01). Participants using alcohol or other stimulants before having sex had higher likelihood of unintended pregnancy. Meanwhile, gender and employment are also associated with attitude and practice on sexual behaviors of respondents. The number of sex partners have negative association with want to use condom (OR=2.18, p-value < 0.01).

CONCLUSIONS: This study indicated that, although the awareness of young population in Vietnam on sexual protection was significantly high, risky sexual behaviors remained popular. Sexual-related education programs on the consequences of alcohol and other stimulants use as well as multiple sex partners should be developed to protect them from unsafe sex and reduce unexpected consequences.

SOCIETAL STIGMA TOWARDS PEOPLE LIVING WITH HIV AND KEY POPULATIONS

PED0936

DIFFICULTIES MEN HAVING SEX WITH MEN (MSM) FACE IN ACCESSING HIV HEALTH CARE SERVICES IN PUBLIC HOSPITALS IN UGANDA

J.C. Masembe[1], C. Benoni[2]
[1]Mbale School of Clinical Medicine and Community Health, Clinical Medicine and Community Health, Mblae, Uganda, [2]Homeland Training Services, Research, Kampala, Uganda

BACKGROUND: HIV infections in Uganda among men having sex with men are hardly quantifiable. Even in the presence of actors and facilities targeting infected people, clients from sexual minorities communities hardly access these facilities. This study set out to explore the barriers that restrict access to HIV and AIDS treatment among men who have sex with men in Uganda, within the areas of Kampala and Entebbe.

METHODS: MSM (n=400) who visit secret clinics within Kampala and Entebbe, Uganda were interviewed using a standard questionnaire. Clinics, that treat members of sexual minorities, do it at the back of the law, thus the term secret clinics. Questionnaires were both self-administered and face to face interviews carried out by trusted members of MSM groups. The major focus of the questions was the barriers faced by msm in accessing testing, counselling and treatment service for HIV/AIDS, in public hospitals. A ground theory was used to the data got through the interviews. The study was conducted between Jan-Sept. 2019 at the height of a rumored, re-introduction of the anti-homosexuality bill in the parliament of Uganda.

RESULTS: It was realised that men who have sex with men were experiencing a great deal of difficulties in accessing public health care services. Out of the 400 40% had HIV, only 2% have ever dared to go and seek medical help from public health services, and only after declining to reveal their true sexual identity. There was a low awareness on the risks of having unprotected anal sex at 30%, 60 % had homophobic related fears if they were to attend a public health service, 25% msm were actively involved in the business of selling sex. 10% decried the apparent looming backlash if the anti homo sexuality bill is re-tabled in parliament. 90% of the sample suggested that the law was against them.

CONCLUSIONS: MSM vulnerability to HIV/AIDS is on the increase. Yet msm face ever growing homophobic tendencies. There is also lack of enabling law that support sexual minority group like msm in Uganda. There is great need for advocacy so that government can drop the anti-Homosexuality.

PED0937

ASSOCIATION BETWEEN DURABLE VIRAL SUPPRESSION AND FOUR DIMENSIONS OF HIV STIGMA AMONG PERSONS LIVING WITH DIAGNOSED HIV, SAN FRANCISCO MEDICAL MONITORING PROJECT, 2015-2017

W. Kornbluh[1], L. Phan[1], Q. Vinson[1], A.J. Hughes[1]
[1]San Francisco Department of Public Health, HIV Epidemiology Section, San Francisco, United States

BACKGROUND: Achieving and maintaining viral suppression is crucial for people living with HIV (PLWH) to remain healthy and prevent viral transmission. Doing so may be complicated by HIV stigma, categorized in four dimensions: disclosure concerns, concerns with public attitudes towards PLWH, personalized stigma, and negative self-image.

METHODS: San Francisco Medical Monitoring Project, a CDC-funded HIV surveillance program, collected interviews and medical record abstractions (MRA) on PLWH from June 2015 to May 2018; data were weighted to account for non-response, reporting delay and selection probability. Stigma dimensions were self-reported during the interview. Durable suppression, from MRA data, was defined as all viral load test results in the prior 12 months being undetectable (<200 copies/ml). Weighted logistic regression assessed associations between sociodemographic factors and each of the four HIV stigma dimensions. Weighted logistic regression determined if stigma was associated with durable suppression after controlling for confounders.

RESULTS: Of the 545 participants, most were men, aged 55+ years, White, and self-identified as Lesbian/Gay. Disclosure concerns were higher for Asian/Pacific Islanders, college education, and an HIV diagnosis 5-9 years prior to interview. Concerns with public attitudes were higher for Latinx, foreign born, and homeless individuals. Personalized stigma was greater for those aged 35-54 years and homeless. Negative self-image was higher in those aged 35-44 years and Multiracial/Other individuals. None of the four HIV stigma dimensions were significantly associated with not having durable suppression in crude logistic regression (p>0.05). However, after controlling for confounders using multivariate logistic regression, we found that concerns with public attitudes resulted in higher odds of not being durably suppressed (AOR=1.78, p=0.045) and those with personalized stigma had significantly lower odds of not being durably suppressed (AOR=0.43, p=0.005).

CONCLUSIONS: We found that each HIV stigma dimension has distinct associations with sociodemographic factors, suggesting a need for culturally sensitive approaches to stigma reduction. The positive association between concerns with public attitudes and not being durably suppressed may indicate a mechanism by which stigma extrinsically deters PLWH from engaging in care. The negative association between personalized stigma and not being durably suppressed may indicate an intrinsic effect of stigma to motivate PLWH to engage in care.

PED0938

PREDICTORS OF HIV STIGMA ATTITUDES AMONG MEN ACCOMPANYING THEIR PARTNERS TO ANTENATAL CARE IN TANZANIA

G. Kisigo[1], J. Ngocho[2], L. Minja[1], H. Osaki[1], R. Mwamba[3], B. Knettel[3], J. Renju[2], B. Mmbaga[2], M. Watt[3]
[1]Kilimanjaro Clinical Research Institute, Data Management Unit, Moshi, Tanzania, United Republic of, [2]Kilimanjaro Christian Medical College University, School of Public Health, Moshi, Tanzania, United Republic of, [3]Duke University, Duke Global Health Institute, Durham, United States

BACKGROUND: HIV-related stigma is a barrier to the success of programs targeting the prevention and treatment of HIV. In the majority of low- and middle-income countries, men play a critical role in defining and shaping social constructs, including HIV stigma. The aim of this study was to describe HIV stigmatizing attitudes and identify factors associated with stigma among men in Tanzania.

METHODS: This study used baseline data of a randomized control trial assessing the impact of a counselling intervention to reduce HIV stigma. A total of 489 adult men were enrolled when accompanying

their partners for routine HIV testing during antenatal care at two public health centers in the Kilimanjaro region of Tanzania between April and September 2019. Participants completed a structured survey using audio computer assisted self-interviewing technology. HIV stigmatizing attitudes were measured using a modified version of Personal and Attributed Stigma Scale, which has 18 items (range: 0-54). A cut-off score of 14 was used to identify men with high stigmatizing attitudes.

RESULTS: The mean (± SD) age of the men was 30 ± 7 years. About half (48%, n=232) met the study criteria for high stigmatizing attitudes towards people living with HIV/AIDS (PLWHA). In a multivariate model, men with a primary education or lower had 2.14 times (95% CI 1.44, 3.18) odds of having high stigmatizing attitudes than those with secondary or high, younger men (18-25 years) were twice as likely as older men (40 years and above) to hold high stigmatizing attitudes (OR=2.44, 95% CI 1.21, 4.93), and an increase in perceived availability of social support was associated with less likelihood of having stigmatizing attitudes (OR=.95, 95% CI 0.92, 098).

CONCLUSIONS: In this setting, men who were younger with lower levels of education and less perceived availability of social support were more likely to hold stigmatizing attitudes toward PLWHA. Comprehensive community-based stigma reduction programs to provide a supportive environment for men are crucial to increase uptake of HIV testing and treatment services. These programs might have larger impact if they are incorporated into primary school curriculum and designed to target men in their social networks.

PED0939

NOT GETTING TO ZERO HIV STIGMA IN SAN FRANCISCO

D. Miller[1], H. Xie[1], D. Veloso[1], J. Lin[1], W. McFarland[1]
[1]San Francisco Department of Public Health, San Francisco, United States

BACKGROUND: San Francisco has the goal of achieving zero HIV stigma by 2030 as part of the broader endeavor to end the epidemic. While dramatic reductions in new HIV infections and AIDS-related deaths have been achieved over the last several years, programs to reduce HIV stigma lag behind biomedical interventions to reduce transmission and mortality. To assess current perceptions of HIV stigma and gauge a baseline trajectory for change, we examined data from surveys of low-income persons (the population at highest risk for heterosexually-acquired HIV) conducted in 2016 and 2019.

METHODS: Low-income men and women were recruited using respondent-driven sampling for a face-to-face interview on HIV risk behavior, knowledge, and perceptions. Eligibility criteria were San Francisco residence, annual income <$15,000, sex with the opposite sex in the past 12 months, and age 18-60. The indicator of perceived stigma was ranking how strongly they agreed with the statement, "Most people in San Francisco would discriminate against someone with HIV."

RESULTS: There were 234 and 361 participants in 2016 and 2019, respectively. Demographic characteristics were similar for both time points: ~70% were Black Americans, 50% had income <$13,000, and one-third were homeless. HIV prevalence was 3.0% in 2016 and 2.5% in 2019. Majorities agreed with the statement that most San Franciscans would discriminate against people with HIV with no improvement between 2016 (58.9%) and 2019 (52.4%, p=0.170). Black (62.2%) and Latinx (59.3%) Americans perceived greater HIV stigma than their White (33.3%) counterparts (p=0.026). Young participants (<25) perceived greater HIV stigma (78.7%) than their older counterparts (55.5%,p=0.012). Differences in greater perceived HIV stigma remained been consistent between 2016 and 2019.

CONCLUSIONS: Overall progress in getting to zero new HIV infections in San Francisco has recently stalled for Black and Latinx Americans. Our data find that no progress has been made in reducing HIV stigma in our city, which is perceived more strongly by minority men and women and, dishearteningly by youth. Unless greater effort is placed on reducing HIV stigma among low-income youth and persons of color, our city will not reach our Getting to Zero goals by 2030.

PED0940

THE BLOOD FACTOR: IDENTITY, COMMUNITY AND AGING AMONG PEOPLE LIVING WITH HEMOPHILIA AND HIV

S. Schwartz[1], T. Perry[2], C. Kaplan[1], D. Francis[3]
[1]University of Southern California, Social Work, Los Angeles, United States, [2]Wayne State University, Social Work, Detroit, United States, [3]University of California, Hemophilia Department, San Francisco, United States

BACKGROUND: Hemophilia is a genetic blood disorder, chiefly affecting males, in which the liver fails to produce the protein factors needed in the clotting process, resulting in potentially dangerous bleeding after injuries. Before 1992, treatment for a 'bleed' involved intravenous transfusions of the missing factor from donated human blood, which resulted in exposure to the HIV virus. During the 1970s and 1980s, approximately one-half of individuals with hemophilia contracted HIV from contaminated blood products, with some inadvertently infecting their partners and children. The intersection of HIV and hemophilia is one of the greatest medical disasters in global history; however, it has received limited attention outside of the hemophilia community. This qualitative study redresses that gap through analysis of narratives of individuals and families impacted by HIV via hemophilia treatment.

METHODS: Thirty-two telephone interviews were conducted with long-term survivors, family members, and professionals. Non-probability snowball sampling procedures recruited participants. The interviews elicited personal narratives and reflections, were audio-recorded, transcribed and uploaded to NVivo11 for analysis. Historical documents such as publications, television reports and films provided contextual data. An inductive narrative approach guided data analysis.

RESULTS: The data illuminates complex, multifaceted relationships among the hemophilia community, government, medical providers, pharmaceutical companies and society. These complicated relationships took place in the wider context of homophobia, stigma and AIDS-related hysteria. Participants recalled initial shame, fear and coping through social withdrawal in order to hide their hemophilia to avoid stigma and assumptions of HIV status, which affected formation of collective identity. Over time, however, some individuals and families began to demand research, treatment and policy change. Advocacy re-engaged and empowered the community to organize, educate and advance safety protocols for blood product manufacturing and distribution. Long-term survivors now face physical, emotional and social challenges as they age with hemophilia and HIV.

CONCLUSIONS: The AIDS crisis of the 1980s and 1990s further marginalized an already vulnerable community and continues to traumatize long-term survivors, posing new challenges as they age. This narrative analysis illuminates human resilience in the face of trauma and provides insight into the ways that the often-neglected hemophilia community found its voice and built networks for effective advocacy.

PED0941

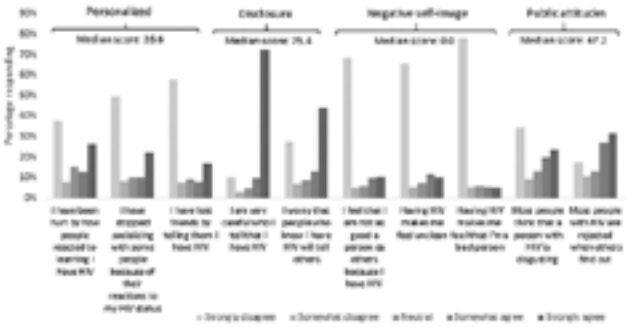
HIV STIGMA AMONG A NATIONAL PROBABILITY SAMPLE OF ADULTS WITH DIAGNOSED HIV—UNITED STATES, 2017–2018

L. Beer[1], Y. Tie[1], H.B. Demeke[1], A. Lemons-Lyn[1], R. Marcus[1], D.H. McCree[1], M. Padilla[1], R.L. Shouse[1], Medical Monitoring Project
[1]*Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States*

BACKGROUND: HIV stigma—a recognized barrier to testing, care and treatment outcomes—is a challenge to achieving the goals of the U.S. Ending the HIV Epidemic initiative. We report nationally representative stigma scores, overall and by domain, among U.S. adults with diagnosed HIV, stratified by sociodemographic and clinical characteristics.

METHODS: The Medical Monitoring Project collects data on stigma using a 10-item Likert scale from a probability sample of U.S. adults with diagnosed HIV. Scores were calculated for overall stigma and stigma by domain, and ranged from 0 (no stigma) to 100 (highest stigma). Using weighted data collected 6/2017–5/2018 from 4,222 persons, we calculated median stigma scores and 95% confidence intervals (CI) overall and by stigma domain (personalized, disclosure, negative self-image, public attitudes), and stratified by selected characteristics. We assessed differences in stigma, overall and by domain, between groups based on non-overlapping CIs.

RESULTS: Figure 1 presents individual responses to the stigma scale statements. Overall, the median stigma score was 38.6 (CI:37.6-39.5). By domain, median scores were: personalized 26.6 (CI:24.4-28.8), disclosure 75.4 (CI:72.6–78.3), negative self-image 0.0 (CI:0.0–2.1), and public attitudes 47.2 (CI:44.8–49.6). Overall stigma was higher among women compared with men, and among persons experiencing poverty or homelessness compared with persons who did not. Stigma was higher among persons who were not taking antiretroviral therapy (ART), were nonadherent to ART, missed HIV care visits, and visited the emergency room. Disclosure and public attitudes stigma were higher among black compared with white persons.



[Figure 1. Response to the HIV stigma scale statements among adults with diagnosed HIV—United States, 2017–2018]

CONCLUSIONS: Many U.S. adults with diagnosed HIV experienced disclosure or public attitudes stigma. Overall stigma was associated with poorer treatment and visit adherence, suggesting that stigma reduction interventions are needed to improve HIV care continuum outcomes. Interventions that focus on disclosure and community-level stigma may be needed to reduce racial disparities.

PED0942

FACTORS ASSOCIATED WITH INTERNAL HIV-RELATED STIGMA SCORE AMONG PEOPLE LIVING WITH HIV IN MAURITIUS: RESULTS FROM THE PEOPLE LIVING WITH HIV STIGMA INDEX (2017)

J. Castro Avila[1], V. Villes[1], N. Khodabocus[2,1], A. Ghurbhurrun[2], L. Kalliaperumal[2], N. Ritter[2,1], R. Delabre[1], D. Rojas Castro[1,3], G. Rostom[2,1]
[1]*Coalition PLUS, Community-Based Research Laboratory, Pantin, France,* [2]*PILS (Prévention, Information, Lutte contre le Sida), Port-Louis, Mauritius,* [3]*Aix Marseille University, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France*

BACKGROUND: HIV-related stigma is a major barrier to HIV control and prevention. In Mauritius, the estimated HIV prevalence was 0.8% in 2016; the epidemic is concentrated among key populations such as People Who Inject Drugs (PWIDs). This study aims to identify factors associated with an internal stigma score among People Living With HIV (PLHIV) who responded to the Stigma Index survey Mauritius.

METHODS: The Stigma Index is a cross-sectional survey which recorded the experiences of PLHIV related to external and internal stigma. It was conducted in 2017 by the community-based organisation PILS situated in Mauritius. Participants were recruited via a snowball sampling in National Day Care Center for the Immunosuppressed and Methadone Substitution Sites. We assessed the HIV-related internal stigma with a score (0 to 7), with one point added for each of the seven feelings experienced due to serological status. A negative binomial regression model was used to identify characteristics associated with the internal stigma score.

RESULTS: Among 411 participants, a majority were male (n=265, 64%) and aged 25 to 49 (n=316, 77%). PWIDs (n=267, 65%) were the most represented key population. The unemployment rate was 43% (n=178). Almost two-thirds experienced at least one feeling of internal stigma (n=258, 63%); guilt being the most frequent (n=202, 49%). After adjustment on age, factors significantly associated with an increase in the internal stigma score were: being a woman (aIRR[95%CI]=1.33[1.05;1.68]), being unemployed (1.57[1.20;2.05]), having a part-time employment compared to full time employment (1.61[1.24;2.19]), having lost a job (1.32[1.00;1.75]), being a PWID (1.28[1.03;1.60]), and having experienced at least one indication of stigma in family and community contexts (2.18[1.75;2.72]).

CONCLUSIONS: Factors at the individual, social and structural levels were associated with higher levels of the internal stigma score among PLHIV in Mauritius. These results highlight the need for multi-level community-based interventions which take into account the social determinants of health coupled with intersectional stigma to reduce social and health inequalities. Further investigations are needed to explore the link between gender, access to existing social services, job opportunities and key population membership to develop and implement adapted strategies to address the internal stigma among PLHIV.

PED0943

HIV STIGMA BURDEN AMONG PEOPLE LIVING WITH DIAGNOSED HIV (PLWDH) IN CALIFORNIA: PREVALENCE BY STIGMA TYPE AND HIGH STIGMA SCORE BY DEMOGRAPHIC, BEHAVIORAL, AND CLINICAL CHARACTERISTICS

A.B. Flynn[1], S.L. Williams[1]
[1]*California Department of Public Health Office of AIDS, Sacramento, United States*

BACKGROUND: In general, HIV stigma is associated with lower antiretroviral medication adherence and access to health services. We sought to estimate the prevalence of HIV stigma and evaluate differences in high stigma score by selected characteristics among PLWDH in California.

METHODS: Interview and medical record data were collected in California (excluding Los Angeles and San Francisco) from 2015-2017 as part of the CDC-led, multi-site Medical Monitoring Project (MMP). Of 1,500 adult PLWDH randomly sampled from the Enhanced HIV/AIDS Reporting System (eHARS), 626 participated and 584 (489 men, 91 cisgender women, 4 transgender women) completed the 10-item HIV stigma scale described by Wright et al. (2007). We used SAS 9.4 survey procedures to estimate weighted prevalence of any stigma (response of somewhat agree or strongly agree), overall and by type, and high stigma score (top 75th percentile/score at or above 57.5) by selected characteristics. Gender, race/ethnicity, age group, educational attainment, and characteristics with significant group differences in proportion with high stigma score were included in a logistic regression model.

RESULTS: HIV stigma was ubiquitous, with an estimated 90.0% (95% Confidence Interval (CI) 87.3-92.7) of PLWDH reporting any stigma, 49.1% (CI 44.4-53.7) personalized stigma, 80.7% (CI 77.1-84.3) disclosure stigma, 27.5% (CI 23.4-31.6) negative self-image, and 58.5% (CI 53.9-63.1) public attitudes stigma. In bivariate analyses, high stigma score was associated with a sexual orientation of straight/heterosexual or bisexual, educational attainment less than high school graduation, time since HIV diagnosis of 5-9 years, and unmet ancillary service need. In the adjusted model, group differences in high stigma score remained significant for 3 factors: sexual orientation of bisexual compared to gay/lesbian (odds ratio (OR) 2.2, CI 1.1-4.3), time since HIV diagnosis of 5-9 years compared to 10 or more years (OR 2.7, CI 1.5-4.6), and having unmet need for ancillary services compared to having all service needs met (OR 2.3, CI 1.5-3.8).

CONCLUSIONS: HIV stigma, particularly that pertaining to disclosing HIV status to others, is highly prevalent among PLWDH in California. Efforts to increase viral suppression rates and decrease the number of new HIV infections should include stigma-reduction activities benefitting PLWDH universally and sub-groups with disproportionately high stigma burden.

PED0944

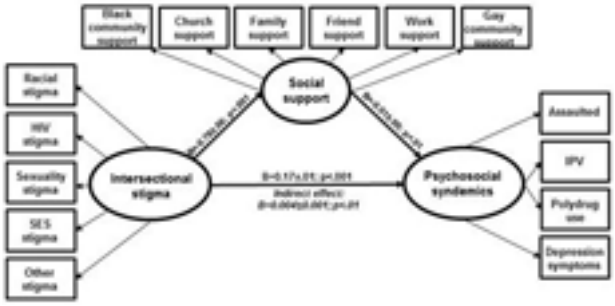
ASSOCIATIONS BETWEEN INTERSECTIONAL STIGMA, RESILIENCY, AND PSYCHOSOCIAL SYNDEMICS IN A MIXED-SEROSTATUS GROUP OF BLACK MSM IN SIX U.S. CITIES

M.R. Friedman[1], L.A. Eaton[2], C.J. Chandler[1], A. Brown, Jr[1], A.C. Tsai[3], D.D. Matthews[4], L.A. Bukowski[1]
[1]*University of Pittsburgh, Pittsburgh, United States,* [2]*University of Connecticut, Hartford, United States,* [3]*Harvard University, Cambridge, United States,* [4]*University of North Carolina, Chapel Hill, United States*

BACKGROUND: Along the HIV continuum of care (CoC), stigma has been associated with implementation gaps. Groups and individuals are stigmatized based on intersecting attributes, including sexuality; race; income; and HIV status. Synergistic psychosocial epidemics (syndemics) are also associated with poor outcomes along the HIV CoC. Resiliencies, including social support, may buffer these outcomes. Few studies have examined relationships between intersectional stigma, resilience, and syndemic, particularly among Black MSM, who experience the highest domestic HIV burden.

METHODS: We recruited Black MSM ≥18 years old (n=4430) from Black Gay Pride events in 6 U.S. cities between 2014—2017. Participants completed surveys via ACASI and undertook onsite HIV testing. We adapted the Experiences of Discrimination Scale to assess past-year stigma that participants attributed to race, sexual minority status, HIV status, socioeconomic status, and "other." We assessed social support via questions quantifying support received from gay communities, Black communities, employment, church, family, and friends. Psychosocial syndemic conditions were assessed via self-report of past-year violence victimization and intimate partner violence (IPV); polydrug use (≥2 substances in past 3 months); and depression symptoms (CES-D-10 ≥10). We constructed a structural equation model to test associations between latent variables of intersectional stigma (predictor), social support (mediator), and psychosocial syndemic (outcome), controlled for sociodemographics and HIV status.

RESULTS: Intersectional stigma was significantly associated with psychosocial syndemic (p<.001). There were significant associations between intersectional stigma and each psychosocial syndemic component (all p-values<.001). Social support was inversely associated with both intersectional stigma (p<.001) and psychosocial syndemic (p<.01), and negatively mediated the relationship between intersectional stigma and psychosocial syndemic (p<.01).



[Figure 1. Structural equation model of total and indirect effects between intersectional stigma (predictor), social support (mediator), and psychosocial syndemics (outcomes) in a mixed-serostatus population of Black MSM in 6 U.S. cities (n=4430), 2014-2017. Model adjusted for city, year, HIV status, ethnicity, income, bisexual behaviour, and age.]

CONCLUSIONS: Our findings show robust associations between intersectional stigma and concurrent psychosocial syndemic, negatively mediated by social support, in a mixed-serostatus population

of Black MSM. We will discuss implications for community-generated stigma reduction and resilience-promoting interventions in the context of HIV prevention and CoC outcomes.

PED0945

HIV-RELATED HEALTH CARE STIGMA AND DISCRIMINATION AND QUALITY OF LIFE AMONG PEOPLE LIVING WITH HIV IN THE UNITED KINGDOM: A LATENT CLASS ANALYSIS

J.M. Wiginton[1], J.L. Maksut[1], S. Murray[1], J. Augustinavicius[1], V. Delpech[2], M. Kall[2], S.D. Baral[1]
[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, United States, [2]Public Health England, London, United Kingdom

BACKGROUND: Development and scale-up of HIV treatment programs have allowed people living with HIV (PLHIV) to live long, healthy lives. However, PLHIV continue to encounter barriers to effectively managing HIV and threats to their quality of life (QoL). Stigma and discrimination in health care settings is a particularly important public health problem, given the extent to which PLHIV interact with health care systems and how these interactions shape overall wellness.

METHODS: Using survey data from Public Health England, we used latent class analysis to identify classes of QoL (problems/no problems across five domains: mobility, self-care activities, usual activities, pain/discomfort, feelings of anxiety/depression) among 4,348 PLHIV engaged in HIV care across the UK. We then used latent class regression to examine relationships between QoL class and a 4-item measure of HIV-related stigma and discrimination in health care.

RESULTS: Four QoL classes emerged: class 1, problems across all domains (18%); class 2, problems with pain/discomfort and feelings of anxiety/depression (18%); class 3, problems with mobility and pain/discomfort (9%); class 4, no problems (55%). Modeling the full scale as the exposure found a one-unit increase in HIV-related stigma and discrimination in health care to be significantly associated with higher odds of membership in class 1 compared to class 4 (OR=1.78; 95% CI=1.54,2.08) and class 2 compared to class 4 (OR=1.60; 95% CI=1.38,1.86), but not class 3 (OR=1.09; 95% CI: 0.83,1.42). Each individual scale item was also significantly associated with higher odds of membership in class 1 compared to class 4 (OR=2.87-5.26) and class 2 compared to class 4 (OR=2.55-3.61). One item, being refused/delayed care due to being HIV-positive, was significantly associated with higher odds of membership in class 3 compared to class 4 (OR=2.00; 95% CI=1.20,3.32).

CONCLUSIONS: The UK is a world leader in the HIV response. However, QoL for PLHIV in the UK varies markedly, with differences emerging across physical and mental health domains. HIV-related stigma and discrimination in health care was associated with differences in QoL, highlighting the continued importance of stigma mitigation interventions for an effective HIV response.

PED0946

EVIDENCE THAT HEALTHY CHOICES, A MOTIVATIONAL INTERVIEWING INTERVENTION, REDUCES HIV-RELATED STIGMA IN YOUTH LIVING WITH HIV: ATN 129

H. Budhwani[1], K. Kolmodin MacDonell[2], T. J. Starks[3], G. Robles[4], V. Dinaj[2], S. Naar[5], *. Adolescent Medicine Trials Network for HIV/AIDS Interventions[6]
[1]University of Alabama at Birmingham School of Public Health, Health Care Organization and Policy, Birmingham, United States, [2]Wayne State University School of Medicine, Family Medicine and Public Health Sciences, Detroit, United States, [3]Hunter College, Psychology, New York, United States, [4]Rutgers, The State University of New Jersey, Social Work, New Brunswick, United States, [5]Florida State University College of Medicine, Center for Translational Behavioral Science, Tallahassee, United States, [6]Adolescent Medicine Trials Network for HIV/AIDS Interventions (ATN), NA, United States

BACKGROUND: HIV-related stigma is a significant barrier to treatment services. Whereas strides have been made to validate interventions to promote testing, adherence, and healthcare engagement, there are few interventions that reduce stigma amongst people living with HIV (PLWH), and to our knowledge -- no validated interventions exist that reduce stigma in youth living with HIV (YLWH). Considering this serious gap, under the auspices of the Adolescent Medicine Trials Network for HIV/AIDS Interventions (ATN), we assessed the effects of Healthy Choices, a Motivational Interviewing intervention, on stigma.

METHODS: We analyzed data from the Healthy Choices (ATN 129) full-scale randomized controlled trial. Participants were randomized to receive intervention in-clinic or in-home; all received the intervention. Thus, all participants are included in this analysis. Recruitment occurred at United States ATN-affiliated clinics (N=183). Participants were aged 16-24, had detectable viral load, reported antiretroviral non-adherence and alcohol use. Stigma was assessed using Berger's Stigma Scale, pre-intervention, 16, 28, and 52 weeks post-intervention. We applied latent growth curve modeling with two linear slopes estimating changes in stigma pre- to post-intervention as well as the trajectory of stigma scores over the follow-up period.

RESULTS: Participant mean age was 21 years; 83% identified as black, and 88% identified as MSM. Expected value for the pre-post-intervention growth factor was statistically significant (B_intercept=2.59; 95% CI:2.36,2.83; p=<.001) as well as differences in the change from baseline to 16-week immediate follow up (B_interceslope1=-0.26; 95% CI:-0.49,-0.03; p=<.026). Expected value of the slope factor measuring growth over the follow-up period was non-significant suggesting that stigma scores were stable from 28 to 52 weeks. There were no differences related to intervention delivery conditions.

CONCLUSIONS: Although there is emerging literature suggesting that Motivational Interviewing can be effective in reducing stigma, this is the first full-scale study to report outcomes longitudinally amongst YLWH. Motivational Interviewing is recommended in standard of care for YLWH and stigma reduction is a high treatment priority; thus, implementation science research to assess barriers to Motivational Interviewing delivery with fidelity is warranted. Behaviorists seeking to improve outcomes in YLWH while addressing stigma, may enhance delivery effects by embedding MI components into their interventions.

PED0947

WHAT ARE THE DETERMINANTS OF SOCIAL SUPPORT IN PERSONS LIVING WITH HIV/AIDS?

N. Sharon Kitibwakye[1,1,1], K. Freddy Eric[1], N. Angella Kigongo[1], E. Laker Odongpinyi[2,2], E. Katana[1,1]
[1]Makerere University, Kampala, Uganda, [2]Infectious Diseases Institute, Kampala, Uganda

BACKGROUND: Social support is known to influence desired health outcomes resulting in decrease in morbidity and mortality. HIV patients with poor social support are at risk of worse health outcomes. Little is known about the determinants of social support in the HIV population in Uganda. This study examined the determinants of social support among HIV patients on Atazanavir-based regimen at the Infectious Disease Institute.

METHODS: We carried out a secondary analysis in a cross-sectional study to determine the prevalence of clinical jaundice among patients on Atazanavir-based second-line therapy which was conducted at Infectious Disease Institute (IDI) from April to May 2019. IDI is a specialist HIV center in Kampala, Uganda with over 7000 patients in care. The study consecutively sample patients on an Atazanavir-based regimen. Social support was assessed by using a 3-item Oslo social scale. We determined the association between social support and age, sex, marital status, education status, religion, other chronic comorbidities, disclosure of HIV status, depression (PHQ 2and 9), drug fatigue, and stigma (stigma scale for chronic illnesses 8-item). We used logistic regression to determine the association.

RESULTS: Data from 236 participants was analysed with the mean age being 40 years (SD;11). The majority were females (66.5%) and 34% were married. Up to 16.5% (n=39) had other comorbidities while only 2 were depressed There was a high level of disclosure of status to either a family member, friend, spouse or children (94%; 221/236). The prevalence of internalized stigma and depression was low (4%; 9/236;) and (2/236; 1%) respectively). Only disclosure of status to others was associated with social support (OR= 4.9, 95% CI 1.1 – 21.3, p-value= 0.038). The association of age, sex, marital status, education status, religion, other chronic comorbidities, depression, drug fatigue, and stigma with social support did not reach statistical significance.

CONCLUSIONS: We found that good / moderate social support was associated with disclosure of HIV status. However, the relationship between social support and disclosure of HIV status warrants further exploration using qualitative research methods.

PREDICTORS OF HIV STATUS DISCLOSURE INTENTIONS TO AN INTIMATE PARTNER AMONG NEWLY DIAGNOSED PATIENTS UNDER SAME-DAY-ART IN JOHANNESBURG, SOUTH AFRICA

T. Sineke[1], L. Hassib[2], S. Kgowedi[3], R.A. Ruiter[2], I. Mokhele[4], D. Onoya[1]
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine. School of Clinical Medicine. Faculty of Health Sciences, Johannesburg, South Africa, [2]Maastricht University, Department of Work and Social Psychology, Maastricht, Netherlands, [3]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [4]Health Economics and Epidemiology Research Office, Office. Department of Internal Medicine. School of Clinical Medicine, Johannesburg, South Africa

BACKGROUND: HIV disclosure is a critical component of HIV prevention and antiretroviral therapy (ART) by facilitating access to social support and engagement in care, improving treatment adherence and HIV prevention behaviour. However, in high stigma and low social support context, it may have adverse consequences. Given the interpersonal risk that comes with HIV disclosure, social relationships are important, particularly among women. Therefore, we aimed to determine important factors to disclosure intention to an intimate partner after diagnosis.

METHODS: We conducted a cohort study among 652 HIV diagnosed adults (≥18 years), enrolled from four primary healthcare clinics in Johannesburg from October 2017 to August 2018. Patients were interviewed immediately after HIV diagnosis. Modified Poisson regression, reporting relative risks (RR) was used to evaluate factors associated with disclosure of HIV status to an intimate partner.

RESULTS: Overall, 60.0% were female and the median age was 33 years (IQR: 28.1-39.3). The majority, 524/652 (80.4%) were in relationships, and only 14.1% were married. A total of 96.3% intended to disclose their HIV result, with 444/499 (88.9%) of those in relationships intending to disclose to a partner. Males (RR 1.1; 95% CI: 1.0-1.2) and those intending not to start treatment if offered (RR 1.1; 95% CI: 1.0-1.2) were more likely to disclose their HIV status to a partner. However, non-married patients (RR 0.9; 95% CI: 0.8-0.9), patients who lived alone (partner/ spouse vs. alone, RR 0.9; 95% CI: 0.7-0.9) and those who lived with family or friends (partner/ spouse vs. alone RR 0.9; 95% CI: 0.8-0.9) were less likely to disclose their status.

CONCLUSIONS: Our results identify important factors that may influence the disclosure of HIV status. While access to ART and uptake have increased with the new guidelines, concealing HIV status to an intimate partner may affect adherence to treatment. access to social support and diminish adherence, retention, and prevention benefits. In light of these findings, there is a need to pay more attention to factors that may inhibit disclosure and to educate patients about the potential implications of concealing HIV status.

PED0949

INVESTING IN COMMUNITY RESPONSES IS CRITICAL IN TACKLING STIGMA, DISCRIMINATION AND VIOLENCE AGAINST KEY POPULATIONS: EVIDENCE FROM PEHCHAN, A STUDY FROM INDIA

G. -[1], V. Arumugam[1], A. Aher[2], B. Ubarhande[1], D.R. Prasad[2]
[1]India HIV/AIDS Alliance, Monitoring and Evaluation, Delhi, India, [2]India HIV/AIDS Alliance, Delhi, India

BACKGROUND: Key populations in many countries face high levels of both perceived and internalized social stigma, discrimination and violence. In India, Men who have sex with men, Transgender and Hijra (MTH) people are subjected to high levels of social stigmatization. India HIV/AIDS Alliance along with consortium partners implemented Pehchan programme (from 2010 to 2015), a Global Fund supported program targeted toward MTH in 18 priority states in India and has reached 436,000 MTH. The program focused around community system strengthening to reduce violence by different sections of the community. 139 crisis management teams were formed to respond to acts of violence or threats of violence. In 2019, India HIV/AIDS Alliance conducted a study to measure the long term impact on this area.

METHODS: Modified CRISP (Community, Resources, Institutional and Processes)methodology was adopted.Multistage sampling (three stages) method was used to select the respondents for the study with mixed method (quantitative and qualitative) data.245 structured interview, 21 FGDs,36 IDI/case studies,82 KIIs were con-

ducted. Descriptive and comparative analyses were carried out using Pehchan endline study as base. CRISP score was also calculated to understand the sustainability of the project.

RESULTS: The proportion of respondents who reported experiencing any type of violence by the police/law enforcement agencies in the previous 6 months increased from the baseline (12%) to end-line (22%) but it has decreased significantly since then and is now at 20%. The CRISP index score is 61.6%, which indicates a high long term impact of Pehchan.MTH respondents who sought support after experiencing violence has consistently increased from the baseline (34%) to 55% at the end of Pehchan, and sustained at high levels (67.4%) four years after the project ended. CRISP index score is 75.6% which indicates a very high long term impact and significant increase in the number of MTH personnel who seek support when they are subjected to violence.

CONCLUSIONS: Community led advocacy resulted in reduction of incidents of violence and increased identification of the same. Marginalized communities need investments that include HIV-related legal services;reforming repressive laws and policies;peer support;legal literacy programs;social inclusion;sensitization of police and law enforcement officers; on stigma and human rights in order to provide an enabling environment to access essential health services.

PED0950

BURDEN OF LIVING WITH HIV IS MOSTLY OVERESTIMATED IN HIV-NEGATIVE MEN WHO HAVE SEX WITH MEN

H. Zimmermann[1], W. van Bilsen[1], A. Boyd[1], U. Davidovich[1,2], HIV Transmission Elimination Team Amsterdam (H-TEAM)
[1]Public Health Service Amsterdam, Department of Infectious Disease Research & Prevention, Amsterdam, Netherlands, [2]Amsterdam University Medical Center, Department of Internal Medicine, Amsterdam Infection & Immunity Institute (AIII), Amsterdam, Netherlands

BACKGROUND: HIV has changed over the past decades from a deadly disease to a relatively easily treatable chronic illness. It is debatable to what extent HIV-negative men who have sex with men (MSM) possess a realistic view of the present burden of living with HIV. Overestimating the burden of HIV could drive HIV-related stigma. We therefore aimed to investigate the anticipated burden of living with HIV among HIV-negative MSM.

METHODS: We conducted a mixed-method study in which in-depth interviews with 18 recently diagnosed MSM were used to generate themes for questionnaire development. The questionnaire consisted of 39 items concerning burden of medicalization of life, HIV-status disclosure, emotional consequences, related stigma, changes in sexual and social behavior, and other practical or formal issues. The questionnaire was distributed via gay (dating) sites/apps among HIV-negative and HIV-positive MSM (diagnosed between 1984-2018). We compared the probability of responding with more negative burden between HIV-negative MSM (as anticipated burden) versus HIV-positive MSM (as actual burden) using finite mixture and logistic regression models.

RESULTS: 1362 MSM completed surveys, of whom 950 (70%) were HIV-negative and 412 (30%) were HIV-positive. Median age was higher for HIV-positive versus HIV-negative MSM (51 years , IQR=41-57 versus 43 years, IQR=30-55, respectively). In comparison to HIV-positive MSM, HIV-negative MSM significantly overestimated the negative impact of living with HIV in 97% (38/39) of the burden-related items. On items measuring general impact, HIV-negative MSM were more likely to anticipate deteriorating quality of life (OR=3.37; 95%CI=2.55-4.45) and feeling bad about having HIV (OR=7.12; 95%CI=5.31-9.55), and were less likely to accept having HIV (OR=4.48; 95%CI=3.28-6.14) compared to HIV-positive MSM.

CONCLUSIONS: HIV-negative MSM largely overestimate the burden of living with HIV as a chronic illness. The overestimation of almost all items suggests ongoing need for knowledge-based and stigma-reducing campaigns. Future analyses should explore whether underestimation of HIV burden on the individual level exists and whether it is associated with risk behaviour among HIV-negative MSM.

PED0951

PEER-LED STIGMA REDUCTION COLLABORATION: TANGIBLE ACTIONS TO REDUCE STIGMA IN CLINICAL SETTINGS

E. Casey[1], T. Forest[2], J. Medina[3], A. Phillips[4], J. Schoep[3], E. Shaw[3], D.E. Tietz[5]
[1]NYC Health + Hospitals, Office of Population Health, New York, United States, [2]NYC Health + Hospitals, MetroPlus, New York, United States, [3]NYC Health + Hospitals, Patient Advocate, Bronx, United States, [4]GMHC, Patient Advocate, New York, United States, [5]NYS Dept of Health, AIDS Institute, Albany, United States

BACKGROUND: NYC Health + Hospitals (NYC H+H) is the largest public hospital system in the United States. The NYC H+H Consumers Council, a committee of HIV peers (patients living with HIV), established a goal of reducing stigma experienced within clinics. To meet this goal, a peer-directed stigma effort was organized between clinic staff and peers to identify recommendations. To address the intersection of stigma, efforts focused on three populations: people living with HIV; individuals that use drugs, and people of trans-experience.

DESCRIPTION: An all-day Stigma Summit was designed as a collaborative problem-solving intervention bringing together representatives from the three focus populations with staff from clinics serving these populations (HIV, substance use, and LGBT), to have an open dialogue on stigma experienced within clinic settings and tangible actions to end such stigma. A Planning Committee was established to ensure balanced representation from focus populations and related clinics. Peers from the focus populations lead planning activities and were the primary facilitators/presenters at the Summit. Attendance was equally divided between patients (48) and clinic staff or issue-area experts (48). Emphasis was placed on dialogue and audience participation was facilitated by technologies allowing for anonymous engagement in discussions.

LESSONS LEARNED: Six Key Themes and 19 Recommended Actions were identified. Themes included a focus on improved involvement and communication between patients and care team members, impacts of stigmatizing structures within electronic medical records (EMR), stigma-reducing roles of clinical and non-clinical staff; and the importance of judgement-free welcoming environments. Recommendations were designed to be specific and actionable, focusing on staffing, training, clinic environment, patient/provider interface, patient supports, referral networks, EMRs, policies, feed-back mechanisms, and staff retention. An implementation framework emerged demonstrating the interconnection between recommendations, different care sites and populations.

CONCLUSIONS/NEXT STEPS: A Summary Report was developed and distributed to all Summit participants, clinical and administrative leaders at NYC H+H, and shared broadly with external partners. Individual clinics were tasked with developing implementation

plans to address care-site issues, and a collaboration between NYC H+H clinic leadership focused on systems-level concerns. The NYC H+H Consumers Council continues to provide oversight and guidance to these efforts.

PED0952

EXPLORING HIV STIGMA AND ITS CORRELATES AMONGST PEOPLE LIVING WITH HIV/AIDS IN A RURAL AREA IN NIGER-DELTA REGION OF NIGERIA

O.N.O. Nwankwo[1], S. Ameh[1], G.I. Nwankwo[2], A. Oku[1], O. Nwankwo[3], I. Elemi Agbo[1], C. Ugwu[4], C.N. Obionu[5]
[1]University of Calabar, Department of Community Medicine, Calabar, Nigeria, [2]University of Calabar, Department of Paediatrics, Calabar, Nigeria, [3]Federal Neuropsychiatry Hospital, Department of Laboratory Sciences, Enugu, Nigeria, [4]WHO Nigeria Office, Awka, Nigeria, [5]University of Nigeria, Department of Community Medicine, Enugu, Nigeria

BACKGROUND: HIV stigma is a strong barrier to the prevention of HIV/AIDS and a major driver of the epidemic. Several studies have shown that people living with HIV in rural areas are more at risk of being vulnerable to HIV stigma and discrimination.Hence there is need for a continuous monitoring of the state of HIV stigma and its correlates amongst such population group. However, there is paucity of data on HIV stigma and its domains from the perspectives of people living with HIV/AIDS (PLWHA) from the rural Niger-delta region of Nigeria. Thus, this study aimed to determine HIV stigma and its correlates amongst PLWHA residing in one of the Niger-delta states.
METHODS: A cross-sectional survey of 367 PLWHA aged above 18 years drawn from a rural health facility was done. Data collection was done through a multi-stage sampling method using a validated,structured interviewer-administered questionnaire adapted from the Berger HIV stigma tool. Descriptive analysis was carried out using frequency/percentages while inferential statistics was carried out using Chi square, Fischers exact test and logistic regression. Analysis was carried out using IBM SPSS version 20.
RESULTS: Majority were females 274(74.7%) with over one-third(41%) aged below 35 years. About half,182(49.6%)were married,248(49.9%) having education below primary school and earning a monthly income below N18,000(US$50)(62.9%).About half,183(50.1%) had an overall presence of stigma.Similarly,there was high experience of the different domains of stigma i.e personalized stigma(enacted stigma)163(44.4%),disclosure concern stigma (anticipated stigma)199 (54.2 %),negative self-image stigma (internalized stigma)185(50.4%) and public attitude stigma(a form of anticipated stigma)168(45.8%).
On bivariate analysis,higher proportion of respondents aged below 35 years had stigma(p=0.03).Those with no forms of depression, perceived they have an overall good quality of life and general adequate social support were less associated with overall experience of stigma(P<0.05).
On logistic regression, those with some form of depression were more likely to be stigmatised OR 3.813(95% CI: 1.113- 13.062).While, respondents with good spiritual domains of quality of life OR 0.406(95% CI: 0.225 - 0.732),good independence domains of quality of life OR 0.411(95% CI: 0.2- 0.846) and good social domains of quality of life OR 0.465(95% CI: 0.239- 0.902) were less likely to be stigmatised.
CONCLUSIONS: There is urgent need for implementing HIV Stigma reduction interventions amongst PLWHA in this region

PED0953

SOCIAL TRANSITION, SUPPORT AND PARTICIPATION AMONG TRANS WOMEN IN NEPAL- IMPLICATIONS FOR HIV RISK AND CARE OUTCOMES

E.C. Wilson[1], H. Xie[1], S. Banik[2], S. Sharma[3], R. Lama[3], A. Rai[3], S. Chhetri[3], J. Lin[1], S. Arayasirikul[1], M. Dhakal[3]
[1]San Francisco Department of Public Health, Trans Research Unit for Equity, San Francisco, United States, [2]Baldwin Wallace University, Public Health and Prevention Science, Berea, United States, [3]Blue Diamond Society, Kathmandu, Nepal

BACKGROUND: Trans women are highly stigmatized around the world. In Nepal, families form the primary social safety net upon which people rely on for income, social support, and care. The consequences of exclusion in low income countries with no social safety net can be dire and have important implications for HIV risk. The goal of this abstract is to examine trans women's experiences of stigma, describe familial social support, examine social participation in Nepal and determine associations of these factors with HIV prevention and care behaviors.
METHODS: Data used for this analysis are from a cross-sectional population-based study of HIV risk among trans women in Nepal. A total of 200 trans women were recruited for the study over a 6-month period. For this analysis, we describe familial social support and reasons why trans women did not socially transition as their true gender. We also examine associations between social transition, support and participation and HIV testing and care engagement to test whether exclusion is associated with poor HIV prevention and care behaviors.
RESULTS: Almost half (41%) of the 200 trans women recruited reported they did not socially transition because of family disapproval of their gender identity. About half reported their primary social support was from a family member, including parents (46%) and siblings (17%). Social support from family was low to moderate (mean score 3.36). Trans women had a participation score of 10.1, indicating moderate to severe restrictions in social participation. Social transition was significantly positively associated with HIV testing (p=0.02) and HIV care engagement (p<0.01), and social support was significantly positively associated with HIV care engagement (p=0.04).
CONCLUSIONS: Our study suggests that trans women with lower stigma may be at less risk for HIV and poor HIV care outcomes. Social transition and support were both positively associated with HIV care engagement, and social transition was positively associated with HIV testing behaviors among trans women in Nepal. Research and interventions to address social integration and support for trans women may improve HIV prevention and care outcomes with this community in Nepal.

PED0954

DISCRIMINATION PERCEIVED BY PEOPLE LIVING WITH HIV/AIDS IN A COHORT IN RIO DE JANEIRO, BRAZIL

A. A. S. Silva[1], D. Chor[1], R. C. Moreira[1], B. Grinsztejn[1], V. G. Veloso[1], M. J. Fonseca[1], R. H. Griep[1], S. W. Cardoso[1], A. G. Pacheco[1]
[1]Fundação Oswaldo Cruz - FIOCRUZ, Rio de Janeiro, Brazil

BACKGROUND: One of the impacts of people living with HIV/Aids (PLWHA) is to face discriminatory experiences that can bring significant damage to quality of life and physical and mental health outcomes. This study aims to characterize the discriminatory experi-

ences perceived by individuals with HIV participating in a Brazilian cohort, regarding context and type of discrimination suffered and to investigate the association of covariates with the perception of discrimination.

METHODS: 649 individuals followed at the INI cohort had extra data collected between 2011 and 2012 following the protocol of ELSA-Brasil study, which included interviews, lab measurements and physical examinations. To measure discrimination, the Lifetime Major Events Scale was used. Besides usual descriptive measurements, logistic regression models were adjusted to study the association of covariates with discrimination. The best final model was selected by a genetic algorithm based on fitness.

RESULTS: 48,6% reported any kind of discrimination, most of them were male (67.5%), with a significant difference observed between genders (p<0.001). Median age among those who perceived discrimination was 42.7 years (IQR=35.8;48.8;p=0.005) and had lower income. The perception of discrimination in public places (22.3%), police approach (19.9%) and the workplace (18.8%) were highlighted. Reasons why participants believed were discriminated included, economic factors (16.7%), physical appearance (14.2%), illness or disability (12.8%) and sexual orientation (12.6%). In the univariate analysis, gender, age, income, number of children and poor health were significantly associated with discrimination. In the final model, gender (OR=1.78;95%CI 0.55-2.22), and age (OR= 0.97;95%CI 0.96-0.99) remained significant, while low CD4 cell counts (OR= 1.73;95%CI 1.28-2.18) was also included by the algorithm.

CONCLUSIONS: The data show that discriminatory attitudes persist highly prevalent among PLWHA, and the associated variables are in consonance with discrimination among PLWHA studies worldwide, which show predominance in males and young adults. Policy and programs should develop approaches to reduce discrimination and ensure a better quality of life for PLWHA.

SOCIOECONOMIC DIFFERENCES: POVERTY, WEALTH AND INCOME INEQUALITIES

PED0955

THE IMPACT OF THE ECONOMIC BURDEN OF SCHOOL FEES ON HEALTH AND HIV RISK IN UGANDA

E.V. Moore[1], N. Nakyanjo[2], R. Nakubulwa[2], E. Spindler[1], A. Deisher[1], J.S. Hirsch[3], F. Nalugoda[2], J.S. Santelli[1]
[1]Columbia University Mailman School of Public Health, Heilbrunn Department of Population and Family Health, New York, United States, [2]Rakai Health Science Program, Kalisizo, Uganda, [3]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States

BACKGROUND: Considerable evidence suggests that staying in school may be protective against HIV in sub-Saharan Africa. Yet the costs of schooling, including "school fees" and the costs of uniforms, transportation, meals, and textbooks, create an economic burden for families. While research at the population level has shown that reducing education costs increases the likelihood that students remain in school, we argue that the total costs of schooling may create adverse household coping mechanisms for income generation, and contribute to sexual risk behaviors and HIV risk.

METHODS: This paper draws from ethnographic research conducted as part of a broader project examining how structural factors shaping the transition to adulthood influence HIV risk among adolescents in Uganda. Data were collected in six sites in the Rakai and Kyotera districts of Uganda: two fishing villages, two trading centers, and two rural villages. Methods included 48 key informant interviews with community leaders, in-depth interviews and focus group discussions with 144 community members (men ages 17-70 and women ages 17-70). Community mapping exercises were used to ascertain students' access to education, including the costs associated with both government and private schools.

RESULTS: We found that the costs of schooling present a considerable economic burden, more than any other household expense, including housing. For example, for a household earning $2/day, the cost of school uniforms, meals, and materials required for just one child to attend an ostensibly "free" government school amounts to 7% of their annual income. Community members suggested that residents are turning to risky transactional sexual relationships in order to afford school fees, for themselves, their children, and their family members.

CONCLUSIONS: These findings suggest that the costs of schooling can result in household coping mechanisms for income generation, including transactional sexual relationships, making the economic burden of school fees a structural factor influencing HIV acquisition among youth in rural Uganda. While most of the current literature assesses the impact of school fees interventions on the student themselves, we argue for a more comprehensive approach to measuring the costs of schooling, including the shifted burden of costs to extended family members.

PED0956

THE IMPACT OF POVERTY AND EXTREME POVERTY IN PEOPLE LIVING WITH HIV ATTENDING TO AN URBAN CLINIC IN GUATEMALA

O. Bonilla[1], L. Aguirre[2], P. Molineros[1], E. Arathoon[1], B. Samayoa[2]
[1]Clínica Familiar Luis Ángel García, Guatemala, Guatemala, [2]Asociación de Salud Integral, Guatemala, Guatemala

BACKGROUND: In Guatemala, 59.3% of the population is poor, and 23.4 is extremely poor. Guatemala has the highest HIV burden in Central America, with 47,000 PLHIV estimated in 2018. Poverty can generate risk behaviors to acquire HIV infection.

The main objective of this study was to analyze PLHIV from a social-economic point of view and determine if being poor influences the time of the diagnosis, retention, and viral load suppression.

METHODS: Socioeconomic programmatic data from 1710 PLHIV linked to a main HIV care and treatment center in Guatemala City from Jan. 2015 to Dec 2019 were analyzed retrospectively. Poverty was determined by income, housing conditions, and other factors through interviews and home visits of the PLHIV.

RESULTS: 57% of the PLHIV linked in the treatment center are poor and 4% extremely poor. 68% of the women and 53% of the men were poor (p<0.05) at the moment of the diagnosis, also Mayan PLHIV have a higher percentage of poverty (69%) than other ethnic groups (p<0.05).

Regarding the time of diagnosis, there is no statistical difference between poor and non-poor PLHIV, 69% had a late diagnosis (baseline CD4 <350). 74% of PLHIV that interrupted ARVs are poor (p<0.05). 77% of viral suppression was reached with no differences between poor and non-poor PLHIV.

CONCLUSIONS: Poverty must be considered in prevention interventions, especially for women and the Mayan population. Retention strategies have to include poverty as a key factor to elaborate pro-

grams for economic and social support. Fortunately, percentages of viral suppression are similar in poor and non-poor PLHIV because ARVs and medical care are free in Guatemala.

BACKGROUND: The objective was to describe intimate partner violence (IPV) perpetrated by men living with HIV (MLHIV), to evaluate its effect on HIV transmission risk, and to identify characteristics of HIV-positive IPV perpetrators in Cameroon.

METHODS: Data from a cross-sectional survey on MLHIV in 19 HIV services were used. IPV scores (psychological and physical IPV (PPV), serious physical IPV (SPV), and sexual IPV (SV), perpetrated in the 12 previous months) were built using principal component analysis on 12 items. Ordinal regression analyses were performed to evaluate the associations of PPV, SPV and SV scores with:
i) being non-stable aviremic (detectable viral load or not receiving antiretroviral therapy for more than 6 months) and at high risk for HIV transmission (non-stable aviremic and inconsistent condom use with at least one of the last two partners of unknown or negative HIV status);
ii) psychosocial, behavioral and dyadic factors.

RESULTS: 28%, 15% and 11% of participants (n=406) were PPV, SPV and SV perpetrators. Proportions of non-stable aviremic participants and high risk for HIV transmission were respectively 44%and 16% and significantly higher in SPV and SV perpetrators.
PPV perpetration was associated with frequent binge drinking (aOR 2.07 [1.08-3.94]), participant's age (0.97 [0.95-1.00] per year) and income (0.98 [0.96-0.99], per 1000 FCFA per household consumption unit). SPV perpetration was associated with participant's age (0.93 [0.89-0.96] per year), not living together with the main partner (0.23 [0.08-0.62]), partner's age younger than 5 years (4.34 [1.63-11.1]), sex with another man in lifetime (7.42 [2.00-27.50]). SV perpetration was associated with inconsistent condom use with at least one of the last two partners (2.9 [1.43-6.39]), not being the household head (2.7 [1.05-5.91]), HIV-related stigma score (1.24 [1.07-1.41] per unit). PPV, SPV and SV were associated with experiencing IPV from partner (respectively 4.5 [2.30-7.62], 4.8 [2.35-9.96] and 4.4 [1.98-8.49]).

CONCLUSIONS: SPV and SV aggravate HIV transmission risk from MLHIV to their female partners. Young age and being older than one's partner, a context of HIV-related stigma, socioeconomic vulnerability and mutual violence, increase IPV perpetration. IPV prevention and detection during counseling of MLHIV could help to reduce HIV transmission risk.

PED0958

MITIGATING THE EFFECT OF EARLY EXPERIENCES WITH PHYSICAL VIOLENCE ON SUBSEQUENT DEPRESSION AMONG ADOLESCENTS AND YOUNG PEOPLE LIVING WITH HIV IN RURAL SOUTH AFRICA

L. Filiatreau[1], D. Giovencco[1], R. Twine[2], N. Haberland[3], X. Gómez-Olivé[2], K. Kahn[2], A. Pettifor[1,2]
[1]University of North Carolina, Epidemiology, Chapel Hill, United States, [2]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit Agincourt, Johannesburg, South Africa, [3]Population Council, New York, United States

BACKGROUND: Experiences of physical violence in early life increases the risk of depression in young people. Depression can subsequently lead to poor HIV care outcomes among adolescents living with HIV (ALHIV). Mitigating the negative effects of early physical violence is crucial in areas such as South Africa where violence remains pervasive and poor mental health and HIV care outcomes persist among ALHIV.

METHODS: We conducted a cross-sectional survey among young people ages 12-24 who were living within the Agincourt Health and socio-Demographic Surveillance System study area in rural South Africa and had a recorded HIV diagnosis in one of two HIV clinical care databases. Participants' history of physical violence perpetuated by intimate partners, family, or acquaintances (ever/never experienced) and current emotional well-being—depression (CES-D), social support (Medical Outcomes Social Support), resilience (CD-RISC), and self-esteem (Rosenberg)— were measured.
We used log binomial regression to estimate the effect of prior lifetime history of physical violence on current depression. Effect measure modification by resilience, social support, and self-esteem was assessed.

RESULTS: Among the 339 study participants included in this analysis, median age was 21 (interquartile range 16-23), 241 (71.1%) were female, 95 (28.0%) had results indicative of depression, and 83 (24.5%) had previously experienced physical violence. Depression was higher among young people with a history of physical violence when compared to those with no history of physical violence (adjusted RR: 2.08; 95% CI 1.48, 2.93). Among those with high social support and self-esteem, the effects of physical violence on depression were lower than among those with low social support and self-esteem (Table 1).

Effect Measure Modifier	Value	aRR (95% CI)	LRT p-value
Social Support (Medical Outcomes Social Support Scale):	High (scores≥38)	1.19 (0.56, 2.56)	p=0.090
	Low (scores<38)	2.13 (1.43, 3.17)	
Self Esteem (Rosenberg Self Esteem Scale):	High (scores≥21)	0.72 (0.30, 1.70)	p=0.002
	Low (scores<21)	2.10 (1.43, 3.08)	
Resilience (Conner Davidson-Resilience Scale):	High (scores≥73)	1.45 (0.80, 2.62)	p=0.240
	Low (scores<73)	2.13 (1.43, 3.17)	

[Table 1.]

CONCLUSIONS: We found that a history of physical violence was associated with current depression among ALHIV in rural South Africa. However, self-esteem and social support appeared to mitigate the impact thus programs to improve self-esteem and social support for ALHIV, along with appropriate depression and trauma treatment, have the potential to improve depression and HIV care outcomes among ALHIV.

PED0959

ENACTED AND ANTICIPATED HIV STIGMA ARE ASSOCIATED WITH INCREASED ODDS OF INTIMATE PARTNER VIOLENCE AMONG FEMALE SEX WORKERS LIVING WITH HIV IN SANTO DOMINGO

A. Rock[1], C. Barrington[1], H.L. McNaughton Reyes[1], V. Fei-Ling Go[1], S. Maman[1], M. Perez[2], Y. Donastorg[2], D. Kerrigan[3]
[1]University of North Carolina, Health Behavior, Chapel Hill, United States, [2]Instituto Dermatológico y Cirugia de Piel Dr. Huberto Bogaert Diaz, HIV Vaccince Research Unit, Santo Domingo, Dominican Republic, [3]Center on Health, Risk & Society, American University, Sociology, Washington DC, United States

BACKGROUND: Female sex workers (FSW) are 13.5-times more likely to be living with HIV than other women in low and middle income countries, and up to 73% have experienced intimate partner violence (IPV) victimization by non-paying partners. IPV is associated with myriad negative outcomes, including suboptimal HIV care and treatment. However, IPV against FSW living with HIV has received little attention. FSW living with HIV contend with multiple forms of HIV and sex work stigma, which theory and empirical studies suggest may erode economic and social resources that are protective against IPV. We examined relationships between HIV stigma and sex work stigma and IPV among FSW living with HIV.

METHODS: We analyzed baseline survey data from an evaluation of Abriendo Puertas (Opening Doors), a multi-level intervention to promote HIV care and prevention within a cohort of 250 FSW living with HIV in Santo Domingo, Dominican Republic (2012-2014). We used multivariate logistic regression to examine relationships between HIV and sex work enacted, anticipated, and internalized stigma and IPV (any physical or sexual violence, last six months).

RESULTS: Participants who reported enacted stigma in the form of HIV workplace discrimination—having lost a job due to HIV—had over six times the odds of IPV compared to those who did not (AOR: 6.68, 95% CI: 2.13, 20.88; p<.001). Regarding anticipated HIV stigma, each increase in the level of fear of being excluded from family activities if one's HIV status were known was associated with a 1.79-fold increase in the odds of IPV (AOR: 1.79, 95% CI: 1.06, 3.02; p=.03). No other stigma/IPV associations were significant.

CONCLUSIONS: Workplace HIV discrimination and fear of family exclusion due to HIV are associated with IPV. Research should examine potential mechanisms of these relationships—workplace discrimination may diminish economic resources, which may hamper leaving abusive relationships or cause stress and conflict in relationships. Fear of family exclusion may undercut social support, which can be protective against IPV. Our findings suggest that to reduce IPV in this population—and stem downstream effects on HIV care and treatment— programs and policies may need to address HIV discrimination and fears of discrimination.

PED0960

MENTAL HEALTH DISPARITIES MEDIATING INCREASED RISKY SEXUAL BEHAVIOR IN SEXUAL MINORITIES: A TWIN APPROACH

O. Oginni[1], P. Jern[2], F. Rijsdijk[3]
[1]Institute of Psychiatry, Psychology and Neuroscience, King's College London, Social, Genetic and Developmental Psychiatry (SGDP) Center, London, United Kingdom, [2]Abo Akademi University, Psychology, Turku, Finland, [3]Institute of Psychiatry, Psychology and Neuroscience, King's College London, Social, Genetic and Developmental Psychiatry, London, United Kingdom

BACKGROUND: Risky sexual behavior is significantly higher in sexual minority (those who identify as lesbian, gay or bisexual - LGB) compared to heterosexual individuals and is a major risk factor for HIV infection among sexual minority men. Risky sexual behavior is associated with mental health problems, however, no population-based studies have investigated the association between mental health and risky sexual behavior disparities in sexual minority individuals. Based on previous evidence of genetic relationships between sexual orientation, mental health and risky sexual behavior; we used the genetically sensitive twin design to determine i. whether mental health disparities in sexual minority individuals mediate the high risky sexual behavior among them, ii. whether this effect was better explained by shared genetic factors, and iii. sex differences in these relationships.

METHODS: Study design was cross-sectional. Participants included 5814 Finnish identical and non-identical twins (mean age = 25 ± 4 years) who were assessed for sexual orientation, mental health indicators (depressive and anxiety symptoms, and substance use) and risky sexual behavior in 2006. Structural equation modelling in OpenMx was used to investigate mental health as a mediator of the increased risky sexual behavior in sexual minority individuals. We adjusted for confounding by common genetic factors using twin modelling and tested for sex differences.

RESULTS: Mental health problems and risky sexual behavior were significantly higher in sexual minority participants and mental health disparities explained 9 and 10% (95% CIs: 2-15% and 7-15% respectively) of the increased risky sexual behaviour among men and women respectively, there were no sex differences. Furthermore,

these relationships were not explained by shared genetic factors, rather each factor had its own unique aetiological influences. In females but not males, environmental factors significantly influenced mental health indicators.

CONCLUSIONS: This is the first population-based study to show that mental health disparities contribute to increased risky sexual behavior in sexual minority men and women and that these relationships are independent of shared genetic factors. Our finding indicates that reducing mental health disparities is a strategy to improving sexual health of sexual minority individuals.

PED0961

MULTILEVEL FACTORS ASSOCIATED WITH FIVE DIFFERENT TYPES OF INTIMATE PARTNER VIOLENCE PERPETRATION AMONG MEN WHO HAVE SEX WITH MEN IN CHINA: AN ECOLOGICAL MODEL INFORMED STUDY

L. Peng[1], D. Wei[1], J. Li[1], W. Cao[2], F. Hou[3], C. Hao[1], J. Gu[1]
[1]Sun Yat-sen University, School of Public Health, Guangzhou, China, [2]Brown University, Center for Evidence Synthesis in Health, School of Public Health, Providence, United States, [3]Kangning Hospital, Department of Public Mental Health, Shenzhen, China

BACKGROUND: In China, intimate partner violence (IPV) among men who have sex with men (MSM) remains less investigated, despite the high prevalence. However, IPV is also an emerging risk factor for HIV infection and transmission among MSM.

METHODS: Informed by the Ecological Model, this cross-sectional study explored multilevel factors (i.e., individual, relationship, community and societal) associated with IPV perpetration among MSM. Participants were recruited from 15 cities of Mainland China, including five cities in East China (Sanya, Fuzhou, Hangzhou, Shenzhen and Qingdao), three cities in Midland China (Taiyuan, Changsha and Hefei), four cities in Northeast China (Changchun, Zhengzhou, Harbin and Urumqi), and three cities in West China (Lanzhou, Nanning and Kunming). Univariate and multivariate regression analysis were conducted.

RESULTS: We found that the prevalence of engaging in physical, sexual, monitoring, controlling and emotional IPV perpetration were 8.6%, 7.1%, 15.2%, 7.6% and 17.1%, respectively. Physical IPV was positively associated with perceived public discrimination and self-stigma toward homosexuality. Sexual IPV was positively associated with involvement in homosexual supporting agency and having more sex partners. Monitoring IPV was positively associated with higher education and perceived stress, but negatively associated with instrumental and emotional support. Controlling IPV was positively associated with drug use during sex and self-stigma, but negatively associated with self-esteem, self-efficacy, and older age of first homosexual sex. Emotional IPV was positively associated with engagement in sex transaction, perceived stress, but negatively associated with resilience.

CONCLUSIONS: IPV perpetration was prevalent in this population. It is necessary to distinguish different types of IPV in future studies and programs, given their differences in prevalence and associated factors.

PED0962

IMPACT OF UNDETECTABLE=UNTRANSMISSIBLE (U=U) KNOWLEDGE ON MENTAL HEALTH OUTCOMES AMONG HIV+ MSM IN THE LATIN-AMERICAN MSM INTERNET SURVEY (LAMIS)

E.M. Reyes-Díaz[1], C.F. Cáceres[1], A.J. Schmidt[2], M. Veras[3], V. Stuardo[4], J. Casabona[5]
[1]UPCH, Centro de Investigación Interdisciplinaria en Sexualidad, Sida y Sociedad, Lima, Peru, [2]London School of Hygiene and Tropical Medicine, Sigma Research, London, United Kingdom, [3]Faculdade de Ciencias Médicas da Santa Casa de São Paulo, São Paulo, Brazil, [4]Universidad de Chile, Escuela de Salud Pública, Santiago, Chile, [5]Centre d'Estudis Epidemiològics Sobre les Infeccions de Transmissió Sexual i Sida de Catalunya, Catalunya, Spain

BACKGROUND: People living with HIV (PLHIV) are at higher risk of poor mental health such as depression and anxiety, partly because of fear of harming others and because of loneliness. Knowledge of not being infectious when having an undetectable viral load ("Undetectable=Untransmissible", or U=U) may have a positive impact on their mental health and quality of life. We sought to estimate the association of Undetectable=Untransmittable (U=U) knowledge and depression/anxiety and Internalized homonegativity among HIV-diagnosed MSM participating in the Latin-American MSM Internet Survey (LAMIS).

METHODS: From January to May of 2018, 64,655 adult MSM from 18 Latin-American countries responded to an on-line questionnaire exploring sociodemographics, mental health metrics, and HIV-related knowledge and behavior. We used adjusted multivariable logistic regression to estimate the association between "Undetectable=Untransmittable (U=U) knowledge" with two outcomes: 1. Presence of anxiety/depression (mild to severe symptoms) in the 4 items from the People Health Questionnaire (PHQ-4); 2. Higher internalized homonegativity, i.e. a score above the median score of the Short Internalized Homonegativity Scale (SIHS). U=U knowledge was assessed with knowing that "a person with HIV who is on effective treatment (called undetectable) cannot transmit the virus to others during sex".

RESULTS: Among all respondents, 10,265 (16%) reported diagnosed HIV. Among those, 74% (7566/10256) reported U=U knowledge; and 60% (4023/10166) had evidence of depression/anxiety (40% mild, 11% moderate, 9% severe). Among the 8824 respondents who answered the questions on IH, there was a median score of 1.14 points in the SIHS. After adjusting for sociodemographics and HIV-care related variables, U=U knowledge was negatively associated with both, presence of anxiety/depression symptoms (PR=0.91; 95%-CI:0.88–0.95) and a higher internalized homonegativity score (PR=0.79; 95%-CI:0.76–0.83).

Outcomes		PR	95% CI	p-value	Adj. PR*	95% CI	p-value
PHQ4	Any anxiety/ depression symptoms vs not	0.93	0.90-0.96	<0.001	0.92	0.89-0.95	<0.001
Internalized Homonegativity	Higher vs lower score	0.75	0.72-0.78	<0.001	0.79	0.76-0.83	<0.001

PHQ4: 4 items Patient Health Questionnaire), PR: Prevalence Ratio, CI: Confidence Interval
*Adjusted PR by demographics (age, educational attainment, employment, born abroad, country of residence, settlement size, sexual identity, relationship status, including partners' HIV status) and HIV care-related characteristics (HIV treatment, Viral load status, Time of HIV diagnosis)

[Table 1. Prevalence ratios of mental health outcomes by U=U knowledge]

CONCLUSIONS: Our findings support that U=U knowledge is one of the factors having a positive impact on mental health outcomes among HIV-diagnosed MSM. Its promotion across Latin-America should be reinforced by HIV health services. Future studies should assess the impact of U=U knowledge on related outcomes such as HIV-stigma perception and quality of life.

PED0963

UNDETECTABLE=UNTRANSMISSIBLE (U=U) KNOWLEDGE AND SEXUAL BEHAVIOR DURING THE MOST RECENT SEXUAL ENCOUNTER WITH NON-STEADY PARTNERS AMONG MSM IN THE LATIN-AMERICAN MSM INTERNET SURVEY (LAMIS)

E.M. Reyes-Diaz[1], C.F. Cáceres[1], A.J. Schmidt[2], M. Veras[3], V. Stuardo[4], J. Casabona[5]
[1]UPCH, Centro de Investigación Interdisciplinaria en Sexualidad, Sida y Sociedad, Lima, Peru, [2]London School of Hygiene and Tropical Medicine, Sigma Research, London, United Kingdom, [3]Faculdade de Ciencias Médicas da Santa Casa de São Paulo, São Paulo, Brazil, [4]Universidad de Chile, Escuela de Salud Pública, Santiago, Chile, [5]Centre d'Estudis Epidemiològics Sobre les Infeccions de Transmissió Sexual i Sida de Catalunya, Catalunya, Spain

BACKGROUND: Among MSM, knowledge about the negligible risk of HIV transmission (untransmissibility) when viral load is undetectable (U=U) may lead to reduction of HIV-stigma and sexual behavior changes. The aim of this analysis is to describe the relationship between U=U knowledge and sexual behavior among MSM participating in the Latin-American Men Internet Survey (LAMIS).

METHODS: From January to May of 2018, 64,655 adult MSM from 18 Latin-American countries responded to an online questionnaire exploring sociodemographics, mental health metrics, sexual behavior, and HIV-related knowledge and behavior. Participants reporting sex with non-steady partners in the last 12 months were included in the analysis. Stratified by self-reported HIV/viral load status, unadjusted prevalence ratios (PR) of sexual behaviors during the last sexual session with a non-steady partner (i.e. number of concurrent partners, type of venue, HIV-status communication, knowledge/assumption of partner's HIV-status, receptive/insertive condomless anal intercourse [CAI]), were assessed in relation to U=U knowledge.

RESULTS: 40,117 (83%) respondents were untested or reported their last HIV test to be negative (NEG), 6,253 (13%) reported HIV diagnosis and undetectable viral load (HIV-UVL); and 1846 (4%) reported HIV diagnosis but detectable/unknown viral load (HIV-DVL). U=U knowledge was associated with: (i) 2+ concurrent non-steady partners among NEG (PR=1.17) and HIV-UVL (PR=1.27) respondents, (ii) having sex at a sex venue among HIV-UVL respondents (PR=0.83), (iii) knowing/assuming to know a partner´s HIV-status among NEG respondents (PR=1.10), (iv) insertive CAI among HIV-UVL respondents (PR=1.15), and receptive CAI among NEG (PR=0.86) and HIV-UVL respondents (PR=1.16). No significant association was observed with communicating HIV status.

	No HIV diagnosis			HIV+ Undetectable			HIV+ No-Undetectable		
	PR	95% CI	p-value	PR	95% CI	p-value	PR	95% CI	p-value
2+ concurrent non-steady sexual partners	1.17	1.12-1.22	<0.001	1.06	0.96-1.16	0.279	1.27	1.08-1.51	0.005
Last sex at sexual venues*	0.99	1.03-1.05	0.748	0.83	0.73-0.95	0.005	1.05	0.82-1.35	0.692
HIV status communication	1.31	0.82-2.12	0.261	1.15	0.99-1.34	0.076	1.02	0.75-1.37	0.920

CAI: Condomless anal intercourse; PR: Prevalence ratio; CI: confidence interval; *sexual venues: Gay sauna, club or backroom of a bar, porn cinema or cruising location. Gray-colored cells indicate p-value<0.05

[Table 1. Sexual behavior outcomes unadjusted prevalence ratio over U=U knowledge stratified by HIV and Viral load status.]

CONCLUSIONS: Our preliminary findings suggest that U=U knowledge has a positive impact on HIV preventive behavior among MSM without HIV (concern about partner's HIV-status and less frequent receptive CAI) and on reducing concern about HIV transmissibility to sexual partners (more frequent CAI) among MSM with HIV but undetectable viral load.

PED0964

EXPERIENCED HOMOPHOBIA AND SUICIDE IN YOUNG GAY, BISEXUAL, AND QUEER MEN: EXPLORING THE MEDIATING ROLE OF DEPRESSIVE SYMPTOMS, SELF-ESTEEM, AND OUTNESS IN THE PINK CARPET Y COHORT STUDY IN SINGAPORE

R.K.J. Tan[1], T. Low[2], D. Le[3], A. Tan[3], A. Tyler[3], C. Tan[3], C. Kwok[3], E. Wong[3], S. Banerjee[3], C.S. Wong[4,5], M.L. Wong[1], M.I.-C. Chen[1,4]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]National University of Singapore, Faculty of Arts and Social Sciences, Singapore, Singapore, [3]Action for AIDS Singapore, Singapore, Singapore, [4]National Centre for Infectious Diseases, Singapore, Singapore, [5]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

BACKGROUND: Gay, bisexual, and queer (GBQ) men are disproportionately affected by HIV and other sexually transmitted infections (STI) in various settings across the world. Studies have shown that young GBQ men are more likely to exhibit suicide-related thoughts and behaviors compared to their heterosexual counterparts, and these have in turn been reported to be associated with HIV/STI risk-related behaviors such as substance use or inconsistent condom use. This study explores the association and mediational pathways between experienced homophobia and suicide ideation or attempts in young GBQ men in Singapore.

METHODS: Results of this study were derived from baseline data of the Pink Carpet Y Cohort Study in Singapore. The Pink Carpet Study is Singapore's first prospective cohort study among young GBQ men, comprising a sample of 570 young GBQ, gender-diverse men aged 18 to 25 years old who were HIV-negative or unsure of their HIV status. Participants were recruited for the baseline between May to September 2019 through social media and a network of community-based groups. Statistical analyses were conducted through descriptive statistics, multivariable Poisson regression, and structural equation modelling techniques.

RESULTS: Of 570 participants, 54.0% (n=308) reported ever contemplating suicide, while 13.3% (n=76) had ever attempted suicide. Controlling for key demographic variables, multivariable Poisson regres-

sion revealed that experienced homophobia was positively associated with ever contemplating suicide (aPR=1.02, 95%CI 1.01-1.03) and ever attempting suicide (aPR=1.04, 95%CI 1.01-1.06), which were analyzed in separate models. Mediation analyses revealed that depression severity, outness (degree of sexual orientation disclosure to others), and self-esteem partially mediated the association between experienced homophobia and suicide ideation, while outness partially mediated the association between experienced homophobia and past suicide attempts. Depression severity fully mediated the association between experienced homophobia and past suicide attempts.

CONCLUSIONS: Experienced homophobia is a key factor driving suicide, and thus likely HIV/STI risk-related behaviors among young GBQ men. Beyond HIV/STI prevention efforts in the GBQ male community, interventions may need to focus on the removal of structures that reproduce such forms of stigma, and empower individuals to buffer the effects of such stigma on self-esteem, depression, and quality of life.

PED0965

OVERLAPPING MINORITY STATUSES AND RISK FOR DEPRESSION, SUICIDE AND EXPERIENCED HOMOPHOBIA AMONG YOUNG GAY, BISEXUAL AND QUEER MEN: INSIGHTS FROM THE PINK CARPET Y COHORT STUDY IN SINGAPORE

D.W.J. Yang[1,2], D. Le[3], A. Tan[3], A. Tyler[3], C. Tan[3], C. Kwok[3], S. Banerjee[3], C.S. Wong[4,5], M.L. Wong[6], M.I.-C. Chen[6,4], R.K.J. Tan[6]
[1]National University of Singapore, Yale-NUS College, Singapore, Singapore, [2]National University of Singapore, Faculty of Law, Singapore, Singapore, [3]Action for AIDS Singapore, Singapore, Singapore, [4]National Centre for Infectious Diseases, Singapore, Singapore, [5]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, [6]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore

BACKGROUND: Gay, bisexual and queer (GBQ) men are disproportionately at risk for mental health disorders relative to their heterosexual counterparts. Minority GBQ men face not only stigma from the general population, but intra-community stigma as well based on their race/ethnicity, body type and/or their gender identity. This study investigates the associations between having these stigmatized minority attributes with various mental health outcomes including depression severity, suicide and experienced homophobia.

METHODS: The study sample was derived from baseline data of the Pink Carpet Y Cohort Study in Singapore comprising a sample of 570 GBQ, gender-diverse men aged 18 to 25 years old who were HIV-negative or unsure of their status upon recruitment. An ordinal variable was constructed to indicate the presence of the number of minority attributes reported by participants, including a non-Chinese race/ethnicity, a body mass index (BMI) of 25 or more, and/or a non-cisgender male gender identity. Statistical analyses were conducted through descriptive statistics and multivariable linear and Poisson regression.

RESULTS: Of the sample, 16.1% (n=92), 16.1% (n=92) and 7.9% (n=45) reported to be non-Chinese, a BMI of 25 or more, and a non-cisgender male gender identity, respectively; 25.6% (n=146) and 7.2% (n=42) reported one, and two or more minority statuses, respectively. Controlling for key demographic variables, being non-Chinese was associated with a past suicide attempt (aPR=1.84, 95%CI 1.13-2.98), depression severity (Beta=1.80, 95%CI 0.26-3.35) and experienced homophobia (Beta=3.51, 95%CI 1.61-5.41); being non-cisgender male was associated with experienced homophobia (Beta=4.04, 95%CI 1.45-6.63); reporting a BMI of 25 or more was associated with depression severity (Beta=1.64, 95%CI 0.11-3.17). Reporting one minority status was associated with depression severity (Beta=1.66, 95%CI 0.35-2.97) and experienced homophobia (Beta=1.79, 95%CI 0.18-3.41), while reporting at least two minority statuses was associated with depression severity (Beta=3.56, 95%CI 1.35-5.77) and experienced homophobia (Beta=6.36, 95%CI 3.64-9.09), as well as a past suicide attempt (aPR=1.27, 95%CI 1.01-1.61), compared to participants without any reported minority statuses.

CONCLUSIONS: Minority GBQ men are more susceptible to depression, suicide and homophobia compared to GBQ men in general, and these risks are compounded with overlapping minority statuses. Interventions are needed to buffer the effects of stigma among minority GBQ men.

PED0966

PSYCHOSOCIAL PROBLEMS MEDIATES THE RELATIONSHIP BETWEEN MINORITY STRESS AND HIV SEXUAL RISK AMONG NIGERIAN GBMSM: ADAPTING THE MINORITY STRESS MODEL

A. Ogunbajo[1], A. Restar[1], S. Iwuagwu[2], R. Williams[3], K. Biello[1], M. Mimiaga[1]
[1]Brown University School of Public Health, Behavioral & Social Sciences, Providence, United States, [2]Centre for Right to Health, Abuja, Nigeria, [3]Equality Triangle for Health and Peoples Development Initiative, Delta, Nigeria

BACKGROUND: Gay, bisexual and other men who have sex with men (GBMSM) in Nigeria bear a disproportionately higher burden of HIV. Meyer's minority stress theory posits that social stress due to the discrimination, violence and stigma experienced by lesbian, gay, and bisexual men and women (LGBs)—because of their sexual orientation and gender identity—may contribute to negative psychosocial outcomes including mental health problems, substance use, and HIV sexual risk We investigated the mediating effects of psychosocial problems, alcohol use, and illicit drug use on the relationship between minority stress and HIV sexual risk taking among a multisite sample of GBMSM in Nigeria.

METHODS: Between June and August 2019, we recruited 406 GBMSM from Abuja, Delta, Lagos, and Plateau to complete a quantitative assessment at local community-based organizations. We utilized structural equation modeling to assess the association and possible mediation between the five constructs: minority stress, psychosocial problems, alcohol use, illicit drug use, and HIV sexual risk behavior.

RESULTS: Overall, minority stress had a statistically significant positive association with HIV sexual risk taking (β=0.57, p=0.000). We found that psychosocial problems mediated the relationship between minority stress and HIV sexual risk taking. Specifically, minority stress was associated with increased psychosocial problems (β=0.64, p=0.000) , which in turn is associated with lower HIV sexual risk taking(β=0.28, p=0.03)The combined estimated indirect effect was statistically significant (β=-0.18, p=0.04). Lastly, psychosocial problems was significantly associated with both alcohol use (β=0.26, p=0.04) and illicit drug use (β=0.20, p=0.05).

CONCLUSIONS: Our findings suggest that experiences of minority stress may result in more HIV sexual risk taking among GBMSM in Nigeria and that relationship may be mediated by psychosocial problems. This is the first known study to investigate whether the constructs within the minority stress model are quantitatively significant among GBMSM in Nigeria. It is important to devise GBMSM-affirming mental health and substance use cessation intervention programs specifically designed by and tailored for GBMSM in Nigeria.

REPRESENTATION AND REGULATION: HOW HOMOSEXUAL MEN ARE POSITIONED IN CHINA'S STATE HIV/AIDS DISCOURSE OVER THE PAST THIRTY YEARS

Z. Sun[1], J. de Wit[1], G. Stevens[1], W. Wei[2]
[1]Utrecht University, Interdisciplinary Social Science, Utrecht, Netherlands, [2]East China Normal University, Social Development, Shanghai, China

BACKGROUND: Previous studies showed that increasing HIV/AIDS risk among homosexual men contributed to the Chinese government to recognize the existence of homosexual men in 2004. Relatedly, it has been suggested that in that same year, China's response to HIV/AIDS shifted from ‚denial' and ‚inactive' to an ‚active' and ‚pragmatic' approach. However, little evidence is available concerning the positioning of homosexual men in official HIV/AIDS discourse before and after 2004. This study explored whether and how China addressed homosexual men in its official HIV/AIDS discourse.

METHODS: This study used a qualitative text analysis method with two types of data representing China's HIV/AIDS discourse: national-level official HIV/AIDS-related documents (including policies, guidelines, regulations; 1987-2019, N=22) and HIV/AIDS and homosexuality-related coverage by the state-run China Central Television (CCTV) (2004-2018, N=12). The text of the media coverage was transcribed verbatim. We analyzed whether and how homosexual men were addressed and interpreted the meaning of the discourse by connecting it to the context.

RESULTS: Three phases could be distinguished within China's official HIV/AIDS-related discourse about homosexual men: 1987-1990; 1991-2001; 2002-present. While homosexual men were explicitly mentioned in phases 1 and 3, they were not addressed explicitly in phase 2, although it is likely that they were included in the category of ‚ugly social phenomenon' that was included. CCTV started to contribute to the public debate on HIV/AIDS and homosexual men as of 2004. The study also identified four aspects of how homosexual men were addressed: managing social and public order; normative awareness-raising and education, which included promoting HIV/AIDS awareness as well as moral conduct and normative sexualities; HIV/AIDS monitoring and testing; and HIV/AIDS epidemiological and behavioral research. Notably, strengthening education on ‚sexual orientation' was included in normative sex education as of 2017.

CONCLUSIONS: In contrast to previous views, this study found that homosexual men were already represented in China's official HIV/AIDS-related documents from 1987 onwards. While China has recently strengthened the HIV/AIDS response among homosexual men population through a behavioral intervention approach, this study found that the persistent focus on normative sex education results in the continued regulation of homosexual men as a result of their non-normative sexuality.

HIV STIGMA, HOMOPHOBIA, COMMUNITY CONNECTEDNESS, AND HIV TESTING AMONG GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN IN KAZAKHSTAN

E.A. Paine[1], Y.G. Lee[2], V. Vinogradov[3], G. Zhakupova[3], T. Hunt[2], S. Primbetova[3], A. Terlikbayeva[3], N. El-Bassel[2], E. Wu[2]
[1]HIV Center for Clinical and Behavioral Studies at Columbia University and New York State Psychiatric Institute, Division of Gender, Sexuality, and Health, New York, United States, [2]Columbia University School of Social Work, Social Intervention Group, New York, United States, [3]Global Health Research Center of Central Asia, Almaty, Kazakhstan

BACKGROUND: HIV prevalence among gay, bisexual, and other men who have sex with men (MSM) in Kazakhstan rose from 1% to 6.1% between 2013 and 2017—yet up to half are estimated to be unaware of their status. HIV testing is key to HIV prevention for MSM in Kazakhstan, yet social factors related to screening are poorly understood. To address this gap, we examine relationships between lifetime HIV testing and internalized HIV stigma, internalized homophobia, and sexual and gender minority (SGM) community connectedness.

METHODS: Data were obtained via structured interviews of 304 MSM in Almaty, Shymkent, and Nur-Sultan in Kazakhstan; this sample represents a cohort of individuals recruited during a NIDA-funded stepped-wedge clinical trial, specifically before implementation of the intervention of interest (August 2018 – February 2019). Respondents were recruited from a variety of physical and online venues. Eligible participants were 18 and over, assigned male, reported at least one incidence of binge drinking or illicit substance use in the past 90 days, and reported sex with a man in the past 12 months. We created composite measures of: internalized HIV stigma (9 items, Cronbach's alpha=0.93; range=0-27); internalized homophobia (9 items, Cronbach's alpha=0.88; range=0-36); and SGM community connectedness (8 items, Cronbach's alpha=0.88; range=0-24). Multivariate logistic regression was used to determine associations between these factors and dichotomized lifetime HIV testing (0=never been tested/1=tested). We report the odds-ratio for each unit increase in predictor variables after adjusting for age, education, employment, income, and sexual orientation.

RESULTS: Approximately 80% of participants reported receiving an HIV test in their lifetime. Analyses revealed a negative association between internalized HIV stigma and past HIV testing (AOR=0.83; CI=0.76-0.91; p<0.001) and a positive association between connectedness to the SGM community and past HIV testing (AOR=1.16; CI=1.05-1.28; p<0.01). Although a negative association was found between internalized homophobia and past HIV testing at the bivariate level (AOR=0.95; CI=0.91-0.99; p<0.05), this association became non-significant after adjusting for covariates.

CONCLUSIONS: Combating HIV-related stigmas and cultivating sexual and gender minority community ties may benefit efforts to increase HIV testing among gay, bisexual, and other men who have sex with men in Kazakhstan.

PED0969

ADDRESSING STIGMA AND DISCRIMINATION AGAINST SEX WORKERS AND MEN WHO HAVE SEX WITH MEN IN PUBLIC HEALTH FACILITIES IN ZIMBABWE

T. Bhatasara[1], G. Ncube[2], R. Dhlamini[3], M. Chipepera[4], P. Zambezi[5], S. Nyamatendedza[6], J. Murungu[7]
[1]Ministry of Health and Child Care, HIV Preventon, Harare, Zimbabwe, [2]Ministry of Health and Child Care, Harare, Zimbabwe, [3]Hands of Hope, Harare, Zimbabwe, [4]PSI, Harare, Zimbabwe, [5]Family AIDS Caring Trust, Harare, Zimbabwe, [6]Gays and Lesbians of Zimbabwe, Harare, Zimbabwe, [7]Pangea Zimbabwe AIDS Trust, Harare, Zimbabwe

BACKGROUND: Zimbabwe remains one of the countries in world with restrictive legislation for Key Populations (KPs) with sex work being criminalised and same sex consensual sex punishable by a jail term. Due to this restrictive legal environment KPs continue to face stigma and discrimination in public health facilities and this has resulted in most KPs shunning public health facilities hence getting HIV infection, untreated STIs and poor retention on Anti-Retroviral treatment.

METHODS: To address stigma and discrimination in public clinics, the Ministry of Health and Child Care together with KP led organizations and community developed a Key Populations Friendly Manual for Health Care Providers, Minimum service Package and Job Aid to train nurses in public health clinics to offer KP friendly services to a diverse of Key Populations in 2018. In 2019, 60 Nurses were trained from 30 selected KP sites, Tapping from KP community knowledge the facilities were linked with KP Community-Based Organizations (CBOs) to revive health centre committees where KPs would be sitting in the committees.

RESULTS: From March to December 2019 a total of 218 KPs accessed services in the identified clinics of 135 were Female Sex Workers and 83 were Men who have Sex with Men. In the same period 87% of the nurses served various Key Populations, 83% of the trained nurses reported to have changed their attitudes towards KPs and would not stigmatize and discriminate against KPs, 65% of the interviewed nurses were able to identify KPs who did not self disclose when they came seeking for services in the facilities, 86 % of the patients who accessed services in the trained clinics reported a positive change of attitude, 13% reported that some nurses still stigmatize and discriminate against KPs. 70% health centre committees revived.

CONCLUSIONS: Training of health care providers in public health facilities on KP friendly service provision substantially addressed stigma and discrimination against KPs. Linking clinics, EPMs, KP CBOs and revival of Health Centre Committees greatly improved the negative attitudes that health care providers had against KPs. KPs have started self-identifying in the clinics due to the training of nurses on KP friendliness.

PED0970

INFORMATION-MOTIVATION-BEHAVIORAL SKILLS (IMB) CORRELATES OF ENGAGEMENT IN HIV CARE AND ART ADHERENCE AMONG YOUNG AFRICAN AMERICAN MSM LIVING WITH HIV

G. Rebchook[1], L. Pollack[1], J. Tan[1], J. Peterson[2], D. Huebner[3], S. Tebbetts[1], S. Kegeles[1]
[1]University of California, Center for AIDS Prevention Studies (CAPS), San Francisco, United States, [2]Georgia State University, Department of Psychology, Atlanta, United States, [3]George Washington University, Milken Institute School of Public Health; Department of Prevention and Community Health, Washington DC, United States

BACKGROUND: Young, African American MSM (YAAMSM) experience HIV-related health disparities. Improving HIV healthcare engagement reduces viral load (VL) preventing HIV-related morbidity and mortality and further transmission. Understanding theory-based behavioral factors associated with HIV care engagement among YAAMSM is essential to design effective care engagement interventions.

METHODS: Using long-chain peer recruitment in two large Texas cities (9/2015 - 7/2016), we enrolled 331 YAAMSM (M_{age}=24.5, range 18-29) living with HIV (confirmed by rapid testing) who completed self-administered surveys on iPads. Self-reported outcomes included: (1) whether participants had an HIV healthcare visit in the past year, and (2) whether last VL test was undetectable while taking at least 90% of ART doses in the past month. T-tests compared mean levels of IMB-relevant psychosocial variables across each dichotomous outcome.

RESULTS: Less than 1/3 of the sample (32.6%; n=108) had received HIV-related healthcare in the previous year; 69.8% (n=183) reported that they were currently taking ART; 53.5% (n=177) reported that their last VL test was undetectable, but only 32.9% (n=109) also reported at least 90% ART adherence in the prior month (Table 1).

	HIV Care in Past Year			Undetectable VL & >90% ART Adherence		
	YES	NO	p	YES	NO	p
INFORMATION VARIABLE						
HIV treatment knowledge	31.55	29.93	<.05	31.92	29.23	<.001
MOTIVATION VARIABLES						
Internalized HIV stigma	15.10	13.75	NS	13.11	14.95	<.05
Healthcare empowerment	17.73	16.57	<.01	17.51	16.63	<.05
Medical mistrust	12.23	13.68	<.05	12.10	13.68	<.05
Internalized heterosexism	11.38	13.42	<.01	11.60	13.22	<.05
HIV discrimination	31.05	34.27	<.10	30.66	34.31	<.05
Treatment optimisiation	12.08	12.34	NS	12.30	12.11	NS
Social support from friends	20.07	20.18	NS	19.26	20.92	NS
Personal responsibility	17.42	16.58	NS	17.36	16.57	NS
Social norm for healthcare	22.66	20.69	<.05	21.67	21.14	NS
BEHAVIORAL SKILL VARIABLES (PROXIES)						
Adherence Self-efficacy resilience	45.57	47.96	<.10	49.29	43.42	<.001
Resilience	74.50	69.23	<.01	74.75	69.14	<.01
*Participants originally diagnosed in last 3 months are not included in analyses						

[Table 1. Correlates of HIV care engagement at baseline]*

We combined adherence and self-reported VL into one outcome because the date of the last VL test was unknown and relying only on self-reported VL would overestimate the proportion who were actually undetectable.

CONCLUSIONS: Multiple information, motivation, and behavioral skill variables were associated with HIV care engagement and reporting an undetectable VL. HIV healthcare engagement interventions for YAAMSM living with HIV should consider strategies to in-

crease knowledge of HIV treatments (information), as well as ART adherence self-efficacy and personal resilience (behavioral skills). To address motivations associated with seeking HIV care and/or being undetectable, programs should help YAAMSM: (1) reduce internalized HIV stigma, medical mistrust, internalized heterosexism, and concerns about HIV discrimination; (2) increase healthcare empowerment; and (3) reinforce social norms that support engagement in HIV care.

PED0971

APPROACHES TO IDENTIFY UNKNOWN HIV POSITIVE MEN WHO HAVE SEX WITH MEN

M. Nyaga[1]

[1]University of Washington, Public Health/Global Health, Seattle, United States

BACKGROUND: Identifying unknown HIV-positive persons is critical for effective HIV treatment and prevention. Traditional approaches may be ineffective for stigmatized groups, especially in countries where homosexuality is criminalized. Several studies in the USA have demonstrated that peer recruitment, termed social and sexual network index testing (SSNIT), has improved identification of undiagnosed MSM and sex workers. This has not previously been tested in countries where homosexuality is illegal, however. This study compared the efficacy of SSNIT and VCT for identifying undiagnosed HIV+ MSM in Nairobi, Kenya.

METHODS: Four clinical sites in Nairobi offering HIV prevention, screening and linkage to care services and were registered with the government were randomly selected for this study. Two implemented SSNIT protocols and two offered traditional VTC methods. In each site, participants were tested, filled a survey and were compensated (US$3). In the SSNIT sites, individuals who tested positive or engaged in high risk activities were offered the opportunity to become peer recruiters and receive US$5 for each associate whom they referred and who came in for testing.

RESULTS: 497 participants completed the survey and HIV testing, n=258 (52%) at the SSNIT clinics and n=239 at the VCT clinics. Participants in the experimental and control sites did not significantly differ in any sociodemographic variables. Peer recruiters for the SSNIT strategy recruited between 13 and 51 participants (mean 30). The percentage of newly identified HIV-positive participants (24.4%) was greater at the SSNIT sites than at VTC sites (6.3%). Clinic-level positivity trends in the previous 6 months prior to the study were similar (10.1% and 12.2% respectively). Clinics that used the SSNIT strategy had higher incidence rates of new HIV diagnoses than control clinics (Incidence Rate Ratio =3.98, p<0.001).

CONCLUSIONS: These findings suggest that SSNIT can increase the identification of undiagnosed HIV-positive MSM in a resource-constrained country where homosexuality is criminalized. We recommend additional studies to confirm these findings but also rollout of this approach to help address the challenge of providing effective treatment and prevention of HIV for MSM's in countries such as Kenya.

THE STIGMATIZING EFFECT OF "TARGETING" US BLACK MEN WHO HAVE SEX WITH MEN IN THE SOCIAL MARKETING OF PREP: A MIXED METHODS STUDY

S.K. Calabrese[1], J.F. Dovidio[2], V.V. Patel[3], D. Modrakovic[1], C.A. Boone[1], R.W. Galvao[4], S. Rao[1], D. Kalwicz[1,5], B.C. Wilbourn[1], M. Kharfen[6], M. Magnus[1], M.C. Zea[1]

[1]George Washington University, Washington, United States, [2]Yale University, New Haven, United States, [3]Albert Einstein College of Medicine, Bronx, United States, [4]University of Pennsylvania, Philadelphia, United States, [5]American University, Washington, United States, [6]District of Columbia Department of Health, Washington, United States

BACKGROUND: Racial disparities in PrEP awareness and uptake suggest a need to prioritize black men who have sex with men (BMSM) in PrEP social marketing initiatives. However, images linking BMSM to sex and HIV may inadvertently reinforce existing stigma. We evaluated the acceptability of targeted PrEP advertisements among BMSM using mixed methods.

METHODS: Our exploratory concurrent mixed methods design included an experimental online survey (n=96) and four focus groups (n=18) with sexually active, HIV-negative/status-unknown, PrEP-inexperienced BMSM (2018-2019). Participants were recruited in East Coast US cities via dating apps, social media, and participant referral. Survey participants were randomly assigned to view 1 of 12 visual advertisements, which systematically varied by level of sexualization (low/medium/high) and couple composition (BMSM couple/Black heterosexual couple/multiple diverse couples/no couples) according to a 3x4 factorial design. The "multiple diverse couples" advertisements featured 4 couples of differing races, genders, and sexual orientations. The "no couples" (control) advertisements included only text. Participants rated 16 dimensions of acceptability (e.g., pleasant, stigmatizing). Sexualization, couple composition, and interaction effects were tested using MANOVA (p<.05). Focus group participants reported advertising preferences and responded to the same 12 advertisements, displayed simultaneously. Transcripts were thematically analyzed.

RESULTS: Survey participants ranged in age from 19-72 years (M(SD)=32(10.7)). Most reported being gay (78.1%) and employed full-time (67.7%). There were significant couple composition effects on advertisement acceptability, but no significant sexualization or interaction effects. Pairwise comparisons revealed that advertisements featuring BMSM exclusively were perceived as more stigmatizing than advertisements featuring multiple diverse couples or no couples; 40.0% of participants viewing such advertisements rated them as "very" or "extremely" stigmatizing. Advertisements with diverse couples vs. no couples were considered more eye-catching, relatable, and memorable. Focus group participants corroborated concerns related to the stigmatization of BMSM, suggesting advertisements featuring BMSM couples could be alienating and fuel PrEP conspiracy theories.

CONCLUSIONS: PrEP social marketing initiatives must consider the historical stigmatization of BMSM when designing visual content to place within advertisements. Displaying diversity within a single advertisement–including BMSM and people of other races, genders, and sexual orientations–could enhance relatability and reach, ultimately supporting the US Ending the HIV Epidemic initiative and similar initiatives worldwide.

IMPACT OF UGANDA'S PROPOSED ANTI-HOMOSEXUALITY BILL ON ACCESS TO HEALTH SERVICES BY MEN WHO HAVE SEX WITH MEN IN THE LANGO SUB-REGION IN NORTHERN UGANDA

G.E. Sangadi[1], S. Maher[2], P. Donggo[1], S. Bauman[3], N. Brady[4], A. Austin[3], M. Makumbi[5]
[1]USAID RHITES North Lango Project/John Snow Inc, Programs - Care and Treatment, Lira, Uganda, [2]John Snow Inc, Programs - Key Populations Programing, Boston, United States, [3]John Snow Inc, Programs - Monitoring and Evaluation, Boston, United States, [4]John Snow Inc, Programs, Boston, United States, [5]USAID RHITES North Lango Project/John Snow Inc, Lira, Uganda

BACKGROUND: In February 2014, the Anti-Homosexuality Act was passed by Uganda's Parliament and officially signed into law. Although annulled due to a technicality, it caused spikes in anti-homosexual behavior and discrimination. Public speculation around the reintroduction of this bill in October 2019 led to an increase in violence and arrests against LGBT communities in Uganda. In the Lango sub-region, approximately 260 men-who-have-sex-with-men (MSM) have avoided essential HIV prevention, care, and treatment services due to perceived stigma and discrimination (S&D) against the LGBTQ community. The reintroduction of the Anti-Homosexuality Act would re-inforce and sanction continued S&D against LGBT populations, and potentially further threaten health-seeking behavior. This evaluation examines MSM's experiences of S&D and knowledge of this bill.
METHODS: Programmatic data from the JSI-led USAID RHITES-N, Lango project and qualitative data from focus group discussions (FGD) with 33 MSM and key informant interviews with 7 peer leaders were used to document S&D experienced across the sub-region. Participants were asked to identify ways to improve MSM health service delivery in the event that the bill was reintroduced and approved.
RESULTS: Between October 2018 and September 2019, peer-led hot spot mapping and profiling exercise identified 260 MSM. However, only 57 MSM received services; one new positive MSM started antiretroviral therapy; 21 started PrEP but only 17 are adherent on PrEP despite a sustained risk for HIV infection. Peer leaders expressed fear of being arrested and reported an increased suspicion of clients' activities from health care workers. "I feel like everybody knows or suspects me, I rather keep indoors." "I cannot easily discuss all my medical concerns with health care providers." "I am comfortable here and I would rather receive my care from the community provided by other peers if possible." "I keep moving and shifting my residence for my safety." MSM preferred community-based approaches to care through Drop-in Centers, routine camps, peers, and already identified KP-friendly health care providers.
CONCLUSIONS: This work shows a high level of S&D experienced by MSM seeking health services. The Anti-Homosexuality Bill, if passed, will increase institutional barriers to accessing health care services for the LGBTQ population.

PED0975

HEALTH CARE SEEKING BEHAVIOURS AND CHALLENGES IN ACCESSING HIV SERVICES IN MEN WHO HAVE SEX WITH MEN IN RURAL RAKAI, UGANDA

L. NAKIGANDA[1], B. Bavinton[1], D. Serwadda[2], R. Nakubulwa[3], M. Poynten[1], A. Grulich[1]
[1]University of New South Wales, HIV Epidemiology and Prevention, Kirby Institute, Sydney, Australia, [2]Makerere University, Makerere University School of Public Health, Kampala, Uganda, [3]Rakai Health Sciences Program, Kalisizo, Uganda

BACKGROUND: HIV prevalence among men who have sex with men (MSM) in Uganda is approximately 13.7%. Accessible HIV prevention services are crucial to reduce the increasing new HIV infections. However, in Uganda, same-sex sexual behaviour is criminalised. High levels of stigma and discrimination, and a restrictive and hostile environment for MSM makes it difficult to seek diagnosis and access timely and adequate HIV care treatment. This study sought to understand the health seeking behaviours of MSM and explore the barriers to access HIV health care services in a rural setting in Rakai, Uganda.
METHODS: A qualitative study of 16 MSM in rural rakai, Uganda was conducted targeting men aged 18 years or older who reported at least one episode of sex with another man in the preceding 3 months. Semi structured in-depth interviews were conducted, and snowball sampling was used to identify participants. Audio data was transcribed verbatim, coded using nvivo10 software and analyzed using content analysis approach.
RESULTS: Different challenges and experiences were discussed by MSM as they accessed services, including:
(i) discriminatory practices by health workers at hospitals which leads to concealing sexual identity in order to access any treatment,
(ii) Challenging government health policies like partner notifications,
(iii) limited knowledge and skills by health care providers about MSM- specific services
(iv) negative perceptions from fellow clients who seek health care at facilities
(v) lack of confidentiality and privacy disclosure concerns
(vi) harassment and mistreatment by health care providers including inappropriate reactions like anger, irritation and intrusive questioning by health workers (vii) being denied health services with unnecessary referrals and
(viii) HIV related stigma.
CONCLUSIONS: This study highlights the gaps in provision and access of HIV prevention services among this vulnerable and high-risk group. Concerns in relation to access to services, health care provider relationships and the legal environment arise. Interventions should be designed that target both MSM, health care providers and a safe, legal and friendly environment for access of any HIV services. We recommend a close collaboration between government, health care providers and MSM themselves to create a socially and culturally tolerant environment for a comprehensive HIV care system.

PED0976

EXPERIENCED HOMOPREJUDICED VIOLENCE AND HIV SELF-TESTING UPTAKE AMONG MEN WHO HAVE SEX WITH MEN IN GUANGZHOU, CHINA

D. Wu[1], E. Yang[2], B. Hall[3], S. Baral[4], W. Huang[5], W. Tang[2], J. Tucker[2]
[1]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [2]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [3]Macau University, Macau, Macao, SAR of China, [4]Johns Hopkins School of Public Health, Baltimore, United States, [5]Emory University, Georgia, United States

BACKGROUND: Homoprejudiced violence is defined as physical, verbal, psychological and cyber aggression against others because of their actual or perceived sexual orientation. It may lead to fear of coming out and prevent men who have sex with men (MSM) from seeking facility-based HIV testing services. Because HIV self-testing (HIVST) is convenient and protects privacy, it may provide a unique opportunity for the sub-group to test for HIV in a safer environment. This analysis examined the association between homoprejudiced violence experience and HIVST among MSM in China.

METHODS: MSM in Guangzhou completed an online survey in September 2018. Survey participants were born biologically male, 16 years old or above, ever had sex with another man, and were prior facility-based HIV testers. Data drawn from these surveys included 12 items asking homoprejudiced violence experiences of physical assaults, verbal aggression, psychological abuse, and cyber violence, as well as lifetime HIV self-testing. A summative item was generated by combining the 12 violence experience items. Univariate and multivariable binary logistic regressions were used to examine the associations between reported homoprejudiced violence and HIVST.

RESULTS: A total of 718 eligible men were included. Roughly two-thirds (63.0%) of the men were under the age of thirty, and more than half (57.4%) had a university education or above. Three-hundred-seventy-nine men (52.8%) experienced homoprejudiced violence, and most (538. 74.9%) had disclosed their same-sex behaviors to others. Two thirds (484, 67.4%) ever self-tested for HIV. Our regression model showed that men who had disclosed their sexual orientation (AOR=4.93, 95% CI:2.95-8.24) and those who had experienced homoprejudiced violence (AOR=3.05, 1.61-5.77) were more likely to have self-tested for HIV. An interaction effect was identified for sexual orientation disclosure and homoprejudiced violence experience on HIVST uptake. Among MSM who had not disclosed their sexual orientation, those who had experienced homoprejudiced violence were more likely than those who had not to have done HIVST whereas there was no association between the two variables among those who disclosed sexual orientation.

CONCLUSIONS: HIV self-testing can be a good alternative HIV testing choice for those who experienced homoprejudiced violence and did not disclose their sexual orientation.

PED0977

PEER-LED COMMUNITY-BASED INTERVENTIONS ARE EFFECTIVE IN ENSURING HIV-POSITIVE MEN WHO HAVE SEX WITH MEN AND TRANSGENDER PEOPLE ACHIEVE VIRAL SUPPRESSION: EVIDENCE FROM MALAWI

M. Gondwe[1], L. Masankha Banda[2], E. Mpunga[2], M. Reberintwari[2], C. Akolo[3], M. Nguluwe[4], W. Masuku[4], D. Chilongozi[2]
[1]FHI 360, Public Health Division, Lilongwe, Malawi, [2]FHI 360, Public Health, Lilongwe, Malawi, [3]FHI 360, Public Health, Washington, United States, [4]CEDEP, Public Health, Lilongwe, Malawi

BACKGROUND: Achieving the third 90 - 90% of people on antiretroviral therapy (ART) virally suppressed - especially among key populations (KP), including men who have sex with men (MSM) and transgender people (TG), remains a major challenge across countries pursuing epidemic control. Between October 2018 and September 2019, the USAID/PEPFAR-supported LINKAGES project, in collaboration with local partner CEDEP, implemented community-led interventions in four districts of Malawi to support HIV-positive MSM and TG to achieve viral suppression.

DESCRIPTION: LINKAGES introduced a combination of strategies, including peer navigation and community-led support groups, to improve support for ART adherence and generate demand for viral load (VL) testing. Trained MSM and TG peer navigators (PNs) – medication-adherent role models living with HIV –provided enhanced support to HIV-positive peers through follow-up visits at their homes and 'safe spaces'. During the visits, PNs conducted motivational counseling sessions on the importance of ART adherence and benefits of VL testing. Eleven support groups were established to clients' literacy on VL, and drop-in centres (DICs) provided reminders to clients who were due for VL testing. Whole blood samples were collected from DICs and transported to laboratories for processing. Clients accessed results at DICs during routine subsequent visits. VL suppression was defined as <1000 copies/ml.

LESSONS LEARNED: A total of 653 (570 MSM and 83 TG) records of KPs living with HIV were reviewed to monitor VL suppression trends over 12 months. Of these, 556 (85%) were on ART and 249 (44.7%) were due for VL monitoring. VL samples were collected and analyzed for 202 clients (81%) [176 MSM and 26 TG], and results were returned for 176 [150 MSM and 26 TG]. Of the 176 with recorded results, 171 (96.6%) [145 MSM and 26 TG] were virally suppressed, representing 96% and 100% suppression rates among MSM and TG, respectively.

CONCLUSIONS/NEXT STEPS: We achieved high rates of viral suppression among MSM and TG people with community-led adherence support and VL demand generation interventions, underscoring the importance of community-led approaches to achieving the 'third 90'. Based on these results, LINKAGES will scale-up these approaches across the entire program in Malawi.

PED0978

PREVALENCE AND CORRELATES OF HIV INFECTION AND UNKNOWN HIV INFECTION AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN KAZAKHSTAN: EVIDENCE FOR A BREWING SYNDEMIC FROM A MULTI-CITY STUDY

E. Wu[1], Y.G. Lee[1], G. Zhakupova[2], V. Vinogradov[2], S. Primbetova[2], A. Terlikbayeva[2], N. El-Bassel[1], T. Hunt[1], G. Mergenova[2]
[1]Columbia University School of Social Work, Social Intervention Group, New York, United States, [2]Global Health Research Center of Central Asia, Almaty, Kazakhstan

BACKGROUND: HIV prevalence among MSM in Kazakhstan has reportedly increased from 1.2% in 2011 to 6.2% in 2017. This far outpaces the increase in overall HIV prevalence in Kazakhstan, but there is concern that HIV among MSM in Kazakhstan is underestimated. Using a multi-city sample, we examined correlates of HIV infection—including unknown infection—among MSM from three Kazakhstan cities.

METHODS: MSM from Almaty, Nur-Sultan, and Shymkent are participating in an ongoing NIDA-funded stepped-wedge clinical trial. Analyses utilized data when all sites were in the pre-implementation phase (August 2018- February 2019, *N*=304). Structured interviews elicited self-reported sociodemographics (age, sexual orientation, education, employment, income, city), HIV status, sexual behaviors, substance use, and psychological distress (DASS, Lovibond & Lovibond, 1995) and internalized homophobia (IH scale by Herek *et al.*, 1998). Biologically confirmed HIV status utilized rapid oral tests followed by confirmatory blood Western blot. Mutlivariate logistic regression identified correlates of biologically-confirmed HIV infection. This was followed by exploratory (due to small numbers) analyses to identify correlates of incorrect self-reported HIV status.

RESULTS: Sixty-seven (22%) participants were confirmed as living with HIV. After covariance adjustment for sociodemographics, the following were significantly associated with HIV infection: greater number of male sexual partners (*AOR*=1.4, *95%CI*=1.1-1.8, *p*=.03); binge drinking (*AOR*=2.4, *95%CI*=1.0-5.9, *p*=.04) and illicit substance use (*AOR*=2.6, *95%CI*=1.3-5.0, *p*<.01) in the past 90 days; and greater psychological distress (*AOR*=1.1, *95%CI*=1.0-1.1, *p*=.04). Among the 67 confirmed positives, only 28 (47%) self-reported living with HIV. Bivariate analyses indicated that those who incorrectly knew/reported their HIV status were significantly younger (*p*=.01); had greater psychological distress (*p*=.04) and internalized homophobia (*p*=.02); and more likely to binge drink in the past 90 days (*p*<.01).

CONCLUSIONS: The high prevalence of HIV correlated with substance use and psychological distress among this multi-city sample of MSM in Kazakhstan. Originally developed for MSM in the United States, the syndemic framework—which posits substance use, psychological distress, and HIV are interacting epidemics—may also apply in Kazakhstan. Approaches such as self-testing, drug treatment as prevention, and anti-stigma interventions may be particularly valuable to decrease HIV transmission and unknown infection among MSM in Kazakhstan.

PED0979

AGE, SUBSTANCE USE, AND THEIR RELATIONSHIP TO SEXUAL RISK BEHAVIORS AMONG BLACK MEN WHO HAVE SEX WITH MEN IN NEW YORK CITY

C. Aivadyan[1], Y.G. Lee[1], N. El-Bassel[1], E. Wu[1]
[1]Columbia University School of Social Work, Social Intervention Group, New York, United States

BACKGROUND: In the United States, Black young men who have sex with men (YMSM) aged 18 to 24 bear the largest burden of HIV among young people in general, and among YMSM in particular. Substance use is associated with sexual risk behavior among men who have sex with men (MSM) and YMSM, yet substance use and sexual risk behavior do not explain higher rates of HIV among Black MSM. Little is known about the association between substance use and sexual risk behavior among Black YMSM.

METHODS: To examine the association between substance use and sexual risk behavior among Black YMSM, we analyzed screening data (*N*=1,009) from an efficacy trial of a couples-based behavioral HIV intervention for Black MSM in New York City. Descriptive statistics and hierarchical linear regression were used to evaluate the relationship between substance use and age (18-24 vs. 25+) on number of sexual partners and acts of condomless anal sex (CAS) in the past 3 months. To examine the impact of age, we used an interaction term of substance use and age. All models controlled for HIV seropositivity.

RESULTS: Of 185 Black YMSM, 33.0% self-identified as HIV-positive, 83.2% reported binge drinking or drug use, 83.8% reported CAS (*M*=20.3, *SD*=27.2), and 60.5% reported concurrent sexual partners (*M*=10.7, *SD*=19.1). Of 824 Black MSM, 65.5% self-identified as HIV-positive, 81.2% reported binge drinking or drug use, 73.9% reported CAS (*M*=13.5, *SD*=21.6), and 56.8% reported concurrent sexual partners (*M*=4.0, *SD*=7.8). Statistically significant interactions were found between age and binge drinking or drug use (*p*<.05), binge drinking (*p*<.01), and marijuana use (*p*<.01) on number of sexual partners. Statistically significant interactions were found between age and cocaine use (*p*<.05) and illicit prescription drug use (*p*<.01) on number of acts of CAS.

CONCLUSIONS: Substance use and sexual risk behavior do not explain higher rates of HIV among Black MSM, but findings from this sample suggest that they may contribute to the disproportionate impact of HIV among Black YMSM. To meet the needs of Black YMSM, HIV prevention interventions for Black MSM may benefit from being tailored to developmental level and addressing substance use and sexual risk concurrently.

PED0980

PARENTING INTENTIONS AMONG YOUNG GAY MEN LIVING WITH HIV IN MEXICO CITY, MEXICO

D. Camp[1], S. Hussen[1], M. Hernández Leyva[2], A. Piñeirúa-Menéndez[3]
[1]Emory University Rollins School of Public Health, Hubert Department of Global Health, Atlanta, United States, [2]Universidad Nacional Autónoma de México, Facultad de Medicina, Mexico City, Mexico, [3]Clínica Especializada Condesa Iztapalapa, Mexico City, Mexico

BACKGROUND: Young gay and other men who have sex with men (YGMSM) are disproportionately affected by HIV in Mexico. Men in Mexico typically start thinking about fatherhood in late adolescence; however, little is known about Mexican YGMSM's thoughts about childbearing. This issue is complicated by both their sexual identity and their HIV serostatus; however, reproductive justice theory holds

that individuals – regardless of gender or sexual orientation – have a right to bear and raise healthy children. Within this framework, we sought to explore conceptualizations of fatherhood and parenting desires among YGMSM living with HIV in Mexico City.

METHODS: We conducted 16 in-depth qualitative interviews with YGMSM living with HIV in Mexico City. Participants were recruited from two large HIV clinics. Domains of the questionnaire included: (1) parenting desires, (2) preferences about different methods (e.g., adoption, in-vitro fertilization), and (3) perceived barriers. A modified grounded theory approach was used for coding and qualitative analysis.

RESULTS: Participants ranged in age from 18 to 21 (mean 19.4) years, and had been diagnosed with HIV for an average of 17 months (range: 15 days to 6 years). Most participants expressed a desire to have a child in the future, but were uninformed as to their options for doing so. Participants largely preferred adoption as a mechanism for fathering a child, citing a perceived risk of HIV transmission as a deterrent to artificial insemination and other assisted reproductive technologies. However, some participants expressed a desire to have a child that was genetically their own, but shared doubts as to whether this would be feasible. The majority of participants stated that the topic of childbearing had never come up during the course of their routine HIV care.

CONCLUSIONS: YGMSM living with HIV in Mexico City are interested in having children. Our findings suggest a role for future interventions, both to inform YGMSM living with HIV about potential avenues for pursuing parenthood, as well as with to support HIV care providers to initiate discussions about future parenting with their YGMSM patients.

PED0981

PREP USE AND HIV AWARENESS AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN TURKEY: PRELIMINARY RESULTS OF A HORNET SURVEY

A. Nazli Zeka[1], A. Garner[2], D. Gokengin[3]
[1]Dokuz Eylul University Medical Faculty, Infectious Diseases and Clinical Microbiology, Izmir, Turkey, [2]Hornet Gay Social Network, California, United States, [3]Ege University Medical Faculty, Infectious Diseases and Clinical Microbiology Department, Izmir, Turkey

BACKGROUND: Turkey is a low HIV prevalence country. However, the number of new diagnoses has been increasing significantly for the last decade especially among men who have sex with men (MSM). Evidence shows that pre-exposure prophylaxis (PrEP) reduces HIV incidence. Although PrEP is not licensed in Turkey, interest around it is high among MSM. This survey aims to define HIV and PrEP awareness and question current and willingness for future PrEP use among Hornet users.

METHODS: Turkish Hornet Gay Social Network sent out an online survey including 20 questions on PrEp and HIV to Hornet users in Turkey on December 22nd, 2019. Descriptive statistics were used for proportions, and Chi-square and Mann Whitney- U tests to compare variables associated with PrEP use. The survey is still open for responders.

RESULTS: A total of 5853 responses were received; 39% was from the largest metropolitan city, Istanbul. The mean age was 30.6 years [Standard deviation (SD) 9.2; min-max 13-78]; 12.5% were living with HIV and 31.6% did not know their status. Among HIV negative/untested men, 86.9% had heard PrEP from the internet (34.8%), friends (20%), and physicians (15.1%); 23.3% was currently using PrEP. Access to drugs was through physicians (40%), friends (27.9%) or the internet (20.3%) and 82.1% did not inform their physicians about PrEP use. Compared to non-PrEP users, current users had tested for sexually transmitted infections (STIs) more frequently in the last 12 months [odds ratio (OR) 1.3 95% confidence interval (CI) 1,15-1,569], had been involved in chemsex more frequently within the last 3 months (OR 1.6, 95%CI 1,2- 2,1) and had a more satisfactory sex life (OR=2.36, 95%CI 1.96, 2.84). A high proportion (61.5%) of HIV negative or untested men and current non-PrEP users reported that they would consider using it in the following six months.

CONCLUSIONS: The majority of HIV-negative MSM are interested to take PrEP and some are already using PrEP without any medical follow-up. PrEP rollout seems to be an urgent need in Turkey and use of online social networks for education, policy change among drug providers and increased community engagement is critical in this sense.

PED0982

CORRELATES OF VIRAL LOAD TRAJECTORIES IN A DIVERSE COMMUNITY SAMPLE OF HIV-POSITIVE MSM ENROLLED IN AN MHEALTH STUDY

S. Lammert[1], O. Shalhav[2], A. Talan[2], H.J. Rendina[2], K.J. Horvath[1,3]
[1]University of Minnesota School of Public Health, Division of Epidemiology & Community Health, Minneapolis, United States, [2]Hunter College of the City University of New York (CUNY), Department of Psychology, New York City, United States, [3]San Diego State University, Department of Psychology, San Diego, United States

BACKGROUND: We assessed correlates of viral load (VL) trajectories over a 17-month period among a diverse community sample of HIV-positive MSM residing in New York City and participating in an mHealth antiretroviral (ART) adherence intervention, Thrive with Me (TWM).

METHODS: Demographic, sexual behavior, psychosocial factors, urinalysis for recent drug-use, and VL were collected at baseline and during follow-up (Month-5, Month-11, and Month-17). Level of detection for VL was defined as <20 copies. Participants were classified based on their VL status during the 17-month intervention:
1) Always Undetectable (AUVL);
2) Always Detectable (ADVL); and
3) Variable (VVL;
undetectable and detectable VLs). Differences in baseline demographic, sexual behavior, psychosocial factors, and drug-use toxicology were calculated between the three groups using ANOVA for numeric variables and chi-square for categorical variables. Pair-wise post-hoc comparisons were conducted for significant variables.

RESULTS: 401 participants were recruited for the TWM intervention. Participants, on average, were 39 years old (IQR=30–48). More than three-quarters of participants were racial or ethnic minorities, including 57% African American and 27% Hispanic/Latino. Frequency of participants with detectable VL were found at each of the following time points: Baseline (n=154; 38.5%); Month-5 (n=142; 40.1%); Month-11 (n=127; 39.1%); Month-17 (n=139; 43.7%). During the intervention, 33% and 20% of participants were in the AUVL (n=135) and ADVL (n=82) groups, respectively. Nearly half (n=184; 45.9%) of participants were in the VVL group. Differences were found between the groups in 30-day adherence (p<0.001), life chaos (p=0.02), and a positive toxicology for marijuana (p=0.04), methamphetamine (p<0.001), and amphetamine (p<0.001) use. Pairwise differences in 30-day adherence (AUVL: 92.1 vs VVL: 87.4 vs ADVL: 80.9) and methamphetamine-use (AUVL: 5.2% vs VVL: 15.5% vs ADVL: 28.8%) were significant for all compari-

sons. Differences between the AUVL and ADVL groups were found in marijuana use (33.6% vs 50.0%) and life chaos (15.0 vs 16.8). Amphetamine use differed between AUVL (2.2%) and both VVL (13.3%) and ADVL (22.5%) groups.

CONCLUSIONS: Trajectories of VL this community sample of HIV-positive MSM was associated with different adherence, drug-use, and life chaos profiles. In particular, a positive toxicology screens for marijuana, methamphetamine, and amphetamines are associated with having a persistent detectable VL.

PED0983

DOUBLE BARREL STIGMA: A QUALITATIVE STUDY OF HIV POSITIVE MEN WHO HAVE SEX WITH MEN IN ACCRA, GHANA

R. Musah[1], G. Dzansi[1], E. Asampong[2]
[1]University of Ghana, Department of Adult Health, School of Nursing and Midwifery, Accra, Ghana, [2]University of Ghana, School of Public Health, Accra, Ghana

BACKGROUND: Men who have sex with men (MSM) suffer a disproportionate burden of stigma and discrimination associated with their sexuality and HIV status. HIV stigma is believed to be associated with negative psychosocial consequences that affect treatment outcomes. The burden is doubled for MSM living with HIV in countries such as Ghana where there is a legal restriction on their sexual expression. This study sought to explore the experience of stigma among MSM living with HIV using the socio-ecological model. The model explores stigma from four levels: individual, family/peer, community and structural.

METHODS: A qualitative interpretive descriptive which involved obtaining in-depth information from participants about their experiences of stigma was done. Coding interview transcript, categorizing and grouping the narratives, establishing the meaning and forming concrete constructs and themes was undertaken. Verbatim quotations and contextual meanings were reported. The snowballing sampling technique was used to select fifteen (15) participants from a municipal polyclinic, in Accra, Ghana. A face-to-face interview was conducted with a semi-structured interview guide. The interviews were audiotaped, transcribed verbatim and analyzed deductively using thematic content analysis.

RESULTS: The main themes were: adjusting to life as MSM living with HIV, dealing with family/peer acceptance and rejection, facing community abuse and discrimination and seeking institutional support. Individual adjustment was associated with depression and suicidal ideation. Family and peer relationships were broken with some MSM being ejected from home because of disclosing their sexual orientation and HIV status. Participants noted their personal features exposed them to abuse and exclusion from participating in community activities. Efforts at seeking institutional support were inundated with negative attitudes of health workers, inadequate resources for care and the structure of services. Protection and secrecy expected by MSM living with HIV within the care cascade were denied and the MSM were not resilient in openly declaring their identity as MSM and HIV positive.

CONCLUSIONS: The stigma associated with sexual orientation and HIV status impacts the life of MSM living with HIV. Resilience training will enhance the psychosocial wellbeing of MSM living with HIV. Integrating information technology and taking health care services to the 'MSM community' will also improve access to care.

PED0984

CORRELATES OF BEING UNTESTED FOR HIV AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN KAZAKHSTAN

Y.G. Lee[1], G. Zhakupova[2], V. Vinogradov[2], E.A. Paine[3], T. Hunt[1], S. Primbetova[2], A. Terlikebayeva[2], N. El-Bassel[1], E. Wu[1]
[1]Columbia University School of Social Work, Social Intervention Group, New York, United States, [2]Global Health Research Center of Central Asia, Almaty, Kazakhstan, [3]HIV Center for Clinical and Behavioral Studies, New York, United States

BACKGROUND: Experiencing a drastic increase in HIV prevalence—from 1.2% in 2013 to 6.2% in 2017, MSM in Kazakhstan are disproportionately affected by the HIV epidemic. HIV testing is a critical point of entry into the continuum of care and treatment services; yet, little is known about potential barriers to HIV testing uptake among MSM in Kazakhstan. To enhance efforts of increasing MSM's engagement in the HIV care continuum, we examined factors associated with being untested for HIV in a sample of Kazakhstan-based MSM who are participating in a NIDA-funded stepped-wedge clinical trial.

METHODS: Recruitment took place in Almaty, Nur-Sultan, and Shymkent at physical as well as digital venues frequented by MSM. Eligibility requirements included: ≥18 years old; residing in a study city; ever identifying as man and/or being assigned male at birth; recent history (past 90 days) of binge drinking or illicitly using a substance; and recent history (past 12 months) of sex with another man. For this study, baseline data, collected from 304 MSM during the pre-implementation phase (July 2018–February 2019), were analyzed. Univariate analysis described the sample's sociodemographic characteristics, sexual behaviors, substance use, and lifetime HIV testing history. Multivariate logistic regression identified sociodemographic and behavioral correlates of being untested for HIV in the sample.

RESULTS: Approximately 20% of participants reported being untested for HIV in lifetime. Among sociodemographic factors, younger age (AOR=0.9, 95%CI=0.9-1.0, p<.01) and bisexual identity (AOR=2.2, 95%CI=1.1-4.3, p=.03) were significantly associated with being untested for HIV. Additionally, having sex under the influence with a male sex partner in the past 90 days (AOR=3.1, 95%CI=1.6-6.3, p<.01) and a decreasing number of substances illicitly used in lifetime (AOR=0.6, 95%CI=0.5-0.8, p=<.01) were significantly associated with being untested for HIV.

CONCLUSIONS: Results highlight the need for facilitating HIV testing uptake among MSM in this sample, particularly those who are younger, and identifying as bisexual. One valuable approach may be through substance use treatment; another may be encouraging those with previous HIV testing experience to engage and/or encourage other MSM to get tested.

PED0985

NEIGHBORHOOD SOCIAL COHESION AND SEXUAL RISK BEHAVIORS AMONG BLACK MEN WHO HAVE SEX WITH MEN IN THE SOUTHERN UNITED STATES: FINDINGS FROM THE MARI STUDY

D. Duncan[1], S.H. Park[1], I. Kawachi[2], Y. Ransome[3], C. Branas[1], Y.A. Al-Ajlouni[1], J. Knox[1], D. Hickson[4]

[1]Columbia University, Epidemiology, New York, United States, [2]Harvard T.H. Chan School of Public Health, Department of Social and Behavioral Sciences, Boston, United States, [3]Yale School of Public Health, Department of Social and Behavioral Sciences, New Haven, United States, [4]Us Helping Us, Inc., Washington D.C., United States

BACKGROUND: HIV prevention remains a public health priority among Black MSM, especially in the southern US. No studies have examined associations between neighborhood social cohesion and sexual risk behaviors among Black MSM in the southern US. The current study examines associations between neighborhood social cohesion and sexual risk behaviors among Black MSM in the southern US.

METHODS: Data came from the MARI Study of Black MSM ages 18-66 years recruited from the Jackson, MS and Atlanta, GA metropolitan areas (n=354). Participants completed questions about neighborhood social cohesion and sexual behaviors, and underwent STI and HIV testing. Neighborhood social cohesion was assessed with a 5-item scale: 1) This is a close knit neighborhood; 2) People around here are willing to help their neighbors; 3) People in this neighborhood generally don't get along with each other; 4) People in this neighborhood can be trusted; and 5) People in this neighborhood do not share the same values. The sum of the scores were categorized into low (5-12), medium (13-14) and high (15-20), based on tertiles. We conducted multivariable logistic regression analyses to examine the association between neighborhood social cohesion with multiple sexual risk behaviors (e.g., condomless sex and drug use before or during sex), controlling for age, Latino ethnicity, sexual orientation, level of education, employment status, annual household income, annual income level, history of incarceration, HIV status, and city fixed effects.

RESULTS: Low compared to highest neighborhood social cohesion was associated with increased odds of alcohol use in the context of sex (aOR=2.65; 95% CI=1.46-4.81) and condomless anal sex with casual partners (aOR=2.07; 1.12-3.84). No association was found between neighborhood social cohesion and drug use in the context of sex, having six or more casual sex partners, group sex or asking the partners HIV status.

CONCLUSIONS: Low neighborhood social cohesion was associated with increased odds of alcohol use in the context of sex and condomless anal sex with casual partners among Black MSM in the southern US. Social cohesion should be considered in interventions that focus on alcohol use and condomless sex as a strategy for HIV prevention among MSM.

PED0986

DIFFERENCES IN PREVALENCES OF PREP USE AND NON-USE BY SEXUAL AGREEMENT TYPE AND COUPLE-SEROSTATUS AMONG GAY MALE COUPLES

L. Darbes[1], D. Chakravarty[2], T. Neilands[3], C. Hoff[2]

[1]University of Michigan, Department of Health Behavior and Biological Sciences, Ann Arbor, United States, [2]San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States, [3]University of California, Division of Prevention Sciences, Center for AIDS Prevention Studies, San Francisco, United States

BACKGROUND: PrEP use is increasing among gay men. However, relationship status is not often considered while examining rates of uptake. Early findings on attitudes towards PrEP among men in relationships were mixed – along with approval of the potential benefits, concerns emerged about how reduced fears of HIV infection might impact sexual agreements, the disclosure (or non-disclosure) to primary partners of potentially risky sexual episodes with outside partners, and the ensuing influence on relationship trust and communication.

METHODS: We recruited male couples (N=280; 560 individuals) – 80% concordant HIV-negative, 20% serodiscordant – between July 2017 and November 2019 for an HIV prevention intervention trial in the San Francisco Bay Area using active and passive strategies. We present select frequencies related to PrEP use among the HIV-negative participants (N=502) in the baseline assessment by couple-serostatus and agreement type.

RESULTS: The median age was 34 years (SD: 11.5) and median relationship length was 4 years (SD: 7.5). 22% reported monogamous agreements. Overall, 62% reported ever using PrEP.

Couple HIV-status	PrEP use status in the previous 3 months	Total n (%)	Monogamous agreement n (%)	Non-monogamous agreement n (%)
Concordant HIV-negative (n=444)	Did not use PrEP	223 (50%)	86 (39%)	137 (61%)
	Used PrEP	221 (50%)	18 (8%)	203 (92%)
HIV Serodiscordant (n=58)	Did not use PrEP	23 (40%)	7 (30%)	16 (70%)
	Used PrEP	35 (60%)	2 (6%)	33 (94%)

[Table 1: Prevalence of PrEP use among HIV-negative men (N=502) in Concordant Negative and Serodiscordant relationships by Sexual Agreement type]

CONCLUSIONS: Only 50% of HIV-negative men in concordant and 60% in serodiscordant relationships used PrEP, demonstrating a continuing need to increase uptake. As is understandable, the prevalence of PrEP use varies vastly by agreement type with over 90% of those using PrEP reporting non-monogamous agreements. Of note, however, is that across both couple-serostatus groups, among those who did not use PrEP, roughly two-thirds reported non-monogamous agreements. This may indicate the declining role of sexual agreements as "safety agreements". Further, compared to earlier samples from the same location, the proportion of monogamous agreements decreased (from 50% to 22%) suggesting that PrEP may be influencing the type of sexual agreements being formed. These findings speak to the need for partners to incorporate PrEP use explicitly into discussions of sexual agreements in order to better address male couples' unique prevention and relationship needs in the ever-evolving HIV prevention landscape.

BACKGROUND: While PrEP is highly effective in preventing HIV, PrEP awareness and use is lower in some MSM populations. We sought to understand the impact of stigma, sexual identity, disclosure of sexual orientation and LGBTQ community engagement on PrEP awareness and use.
