METHODS: HPTN 078 screened 1305 MSM in Boston, Baltimore, Atlanta and Birmingham between 2016-2017 through deep-chain respondent driven sampling. At screening, participants were asked about sociodemographic and behavioral factors, along with PrEP awareness and use. Univariate and multivariate multinomial logistic regression models were used to determine the factors associated with PrEP awareness, nonuse (i.e., PrEP aware) and PrEP awareness and use (i.e., PrEP use) versus non-awareness of PrEP. A mediation analysis was used to further assess the influence of covariates on PrEP awareness and use.

RESULTS: Among 335 HIV-negative men, most were non-white (42.4% African American; 19.7% other race); less than 35 years of age (57.3%); insured (78.9%); and reported some college education (59.1%). The majority of the sample were aware of PrEP (68.3%); of those 52.5% had never taken PrEP. In univariate analyses, internalized stigma decreased the odds of being PrEP aware (0.61; 0.47-0.79) and PrEP use (0.34; 0.22-0.53); community stigma decreased the odds of PrEP use (0.28; 0.12-0.68); homosexual compared to bisexual identity increased the odds of being PrEP aware (4.93; 2.86-8.50) and PrEP use (9.67; 3.74-25.0); disclosure of sex identity increased the odds of being PrEP aware (2.80; 1.42-5.50) and PrEP use (6.19; 2.70-14.2); and LGBTQ engagement increased the odds of being PrEP aware (2.80; 1.42-5.50) and PrEP use (1.85; 1.38-2.47). In an adjusted model, only homosexual vs bisexual identity increased the odds of being PrEP aware (6.28; 2.38-16.6) and PrEP use (15.3; 1.62-144). The mediation analysis indicated that 25-33% of the effect of sexual identity on PrEP awareness and PrEP use is mediated through internalized stigma.

CONCLUSIONS: In this sample, comfort with being homosexual increased PrEP awareness and use, a finding partly mediated through internalized stigma. Given the lower use in minority MSM, stigma interventions that address comfort with bisexual identity may yield greater PrEP uptake.

PED0988

STRUCTURAL VIOLENCE HINDERS AND RESILIENCY ENABLES ACCESS TO SEXUAL HEALTH SERVICES FOR GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN WORLDWIDE

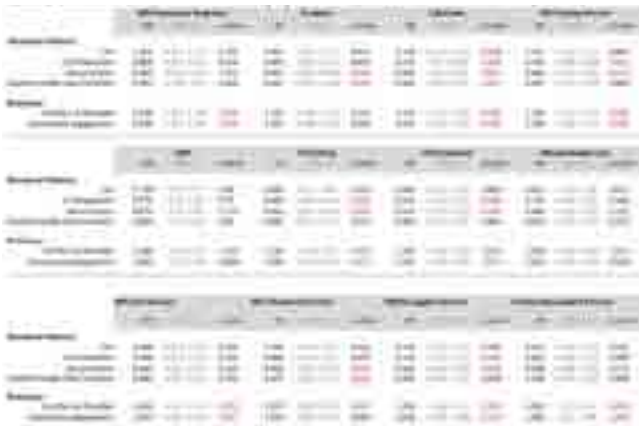
S. Arreola[1], T. Doan Thanh[2], D. Solares[3], J. Walimbwa[4], G. Ayala[5]
[1]MPact Global, Research, Oakland, United States, [2]Lighthouse Social Enterprise, Ha Noi, Vietnam, [3]Consultant for MPact, Hong Kong, Hong Kong, SAR of China, [4]ISHTAR, Nairobi, Kenya, [5]MPact Global, Oakland, United States

BACKGROUND: Gay, bisexual and other men who have sex with men GBMSM continue to be disproportionately impacted by HIV. Scale up of sexual health services is urgently needed to ameliorate the HIV pandemic. Structural violence SV impedes access to services. We examined impacts of SV, Childhood Sexual Abuse [CSA], Criminalization of Homosexuality, Sexual Stigma [AKA homophobia], Health Provider Discrimination, Comfort w/ Provider, and Community Engagement and Resiliency Comfort with Provider and Community Engagement, on access to sexual health services among GBMSM worldwide.

METHODS: Using global convenience sampling data from the 2019-20 Gay Men's Health and Rights online survey, in ten languages, we evaluated associations between SV/resiliency, and accessibility of 12 sexual health services. We fitted GEE logistic regression models with robust standard errors, accounting for clustering by country among 2,172 GBMSM.

RESULTS: Structural Violence: Poor access to all 12 services were significantly associated with greater sexual-stigma. Additionally, poor access to condoms, lubricants, and HIV-treatment services were associated with more provider-stigma; and poor access to lubricants, HIV-testing, PrEP, STI-testing, STI-treatment, and PWUD-support services were associated with criminalization.

Resiliency: Good access to all 12 services were associated with having comfort with providers. In addition; good access to HIV-prevention, lubricants, HIV-testing, PrEP, STI-testing, STI-treatment, HIV-care, PWUD-support, and community-support services were associated with community engagement.



[Table 1. Structural violence and resiliency by sexual health services for GBMSM worldwide]

CONCLUSIONS: Although poor access to all services had been found to be associated with CSA in previous bivariate analyses, no significant associations were found in current multivariable analyses. This may result from CSA being a distal determinant of outcome variables, relative to the others which occurred within last 6-months. Findings indicate that efforts to prevent and treat HIV among GBMSM should be coupled with structural interventions to reduce sexual stigma

generally and specifically among health providers, overturn homosexuality criminalization policies, and support community engagement activities among GBMSM.

PED0989

PREFERENCE FOR PRE-EXPOSURE PROPHYLAXIS (PREP) AND USE OF POST-EXPOSURE PROPHYLAXIS (PEP) AMONG MSM IN SHENZHEN, CHINA

G. Shen[1], H. Lu[2], Y. Xiong[1], L. Wei[3], J. Zhao[3], W. Tang[1]
[1]SESH Global, Guangzhou, China, [2]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [3]Shenzhen Center for Disease Control and Prevention, Shenzhen, China

BACKGROUND: Both pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP) are recommended by the WHO to prevent HIV infections. In China, PrEP has yet to be adopted by the national guidelines but there is an estimated increasing demand for PrEP, even PEP has been widely used. This study aims to explore MSMs' acceptance of PrEP and factors associated with use of PEP.

METHODS: A venue-based cross-sectional study was conducted among men who have sex with men (MSM) in Shenzhen, China, in 2018. A total of 1,542 participants completed questions on both PrEP and PEP. Descriptive statistics were used to analyze the willingness to take PrEP and previous use of PEP. Univariate and multivariable logistic regression analyses were performed to examine factors associated with previous use of PEP.

RESULTS: Overall, 67.1% (1035/1542) of the participants were willing to take oral pills or injection of PrEP. Among those who were interested in taking PrEP, the majority (828/1035, 80%) preferred oral pills over injection. Event-driven PrEP (710/896, 79.2%) was slightly more favored than daily-basis PrEP (696/896, 77.7%). In addition, for those who had taken PEP (53/1542, 3.4%), 86.8% (46/53) had taken at least a 28-day full course regimen of PEP; still, over half of them (30/53, 56.6%) had at least once failed to take the full regimen. Multivariable logistic regression analyses showed that previous use of PEP is associated with inconsistent condom use in oral sex (AOR=2.42, 95% CI: 1.01-7.16) and in anal sex (AOR=1.51, 95% CI: 0.77-3.13) in the past 6 months and having HIV testing previously (AOR=3.01, 95% CI 1.41-7.46). Having missed doses of PEP is associated with self-identifying as gay (AOR=39.7, 95% CI: 1.91-2086.0) and bisexual (AOR=54.4, 95% CI=1.94-3737.7), and inconsistent condom use in anal sex (AOR=8.40, 95% CI: 1.45-73.6).

CONCLUSIONS: The level of willingness to take PrEP observed in the present study is high and consistent with the existing literature conducted in China. Sexual behaviors and HIV testing history may be correlated with previous uptake of PEP. Concerning the high interest in PrEP and poor adherence to PEP prescriptions, future HIV prevention programs can provide MSM with necessary information on taking PrEP and PEP.

PED0990

ANALYSIS OF MULTI MEDIA INTERVENTIONS FOR TESTING, PREP, PEP AND OTHER PREVENTION STRATEGY AWARENESS, REACHING KEY POPULATIONS IN THAILAND

P. Phiphatkhunarnon[1], T. Sowaprux[1]
[1]Love Foundation, Chiang Mai, Thailand

BACKGROUND: Men who have sex with men (MSM) remain the population most affected by HIV infection in THAILAND, and pre-exposure prophylaxis (PrEP) had not been implemented until 2016. The purpose of this study was to study the effectiveness of multimedia campaigns in reaching hard to reach populations through using Facebook, YouTube, and Instagram videos.

DESCRIPTION: The Love Foundation created the Speak OUT campaign and promoted this campaign across social media channels like Facebook, YouTube and others from March 2019 to December 2019. A survey was conducted between November 22nd and December 22nd, 2019. The survey included 9 questions regarding age, residence, HIV serostatus, PrEP-related indications, PrEP awareness, willingness and current use (confirm adjust). Users were invited to take the survey by responding to app inbox messages via Hornet. Responses from the same IP address were excluded. We used latent class analysis to group individuals with similar patterns of HIV risk behaviors to determine which groups would be currently using PrEP and most willing to use PrEP as well as testing other novel HIV awareness messages such as U=U.

LESSONS LEARNED: There were a total of 3,009 responses, of which 1,335 reported HIV-negative or unaware of one's serostatus and were eligible for this analysis. The best-fitting latent class analysis model described three distinct classes: (1) Traditional Safer Sex (53%), those who mostly use condoms and has lowest HIV risk; (2) Newly Sexually Active (20%), those who are much younger, mostly untested for HIV, and unaware of post-exposure prophylaxis (PEP) or PrEP; and (3) Current Style (27%), those who practice condomless anal intercourse. PrEP was the most effective message, with 67% reporting successfully understanding the campaign. However, messages relating to understanding U=U (40.1%) and HIV testing (59.8%) were not as well received.

CONCLUSIONS/NEXT STEPS: Our research has identified three distinct patterns, which may help care providers and policy makers develop tailored strategies that facilitate the uptake of PrEP by such key population appropriately. More research is needed to understand the challenges to population struggles in understanding U=U, an important concept to improve HIV prevention, and lowering stigma.

PED0991

CHANGES IN HIV RISK AND PREVENTION BEHAVIORS AMONG MEN WHO HAVE SEX WITH MEN IN CHINA OVER TIME FROM 2012-2018

D. Yang[1], J. Li[1], J. Gu[1], C. Hao[1]
[1]Sun Yat-sen University, School of Public Health, Guangzhou, China

BACKGROUND: Men who have sex with men (MSM) have a disproportionate burden of HIV infection and high rates of risky HIV-related behaviors.

This study aimed to explore the changes of the characteristics in HIV risk and prevention behaviors in China over time from 2012-2018 among MSM.

METHODS: The data were collected (n=22,532) in Chengdu city between 2012 and 2018 through standardized face-to-face interviews. The participants were recruited among MSM who received voluntary counselling and testing services (VCT) provided by the largest local nongovernmental organizations (NGOs). We used Chi square test to explore trends in behavioral changes and run logistic regression models to determine risk factors associated with HIV-related risk behaviors.

RESULTS: Of all the 22,532 MSM, 92% aged 18-45; 64.1% attended college or university; 75.1% were single. MSM who aged 46-72 with low-level education is more likely to engage in anal sex without condoms. Results reveal significant changes in sexual risk and prevention behavior over time, including an increase in the rate of sexual prevention activities including life-time HIV testing rate and consistent condom use rate, but also an increase in rate of some sexual risk behavior, such as having multiple sexual partners. The prevalence of condomless sex rate decreased from 58.8% in 2012 to 39.4% in 2018 and prevalence of life-time HIV testing increased from 51.7% in 2014 to 75.5% in 2018). Significant increase was found in the number of sexual partners in the past six months (the prevalence of having more than 5 sexual partners increased from 7.3% at 2014 to 11.6% at 2018). In addition, significant changes in the modes of partner-seeking: the percentage of MSM who seek partners through online social media increased from 43.7% in 2014 to 70.3% in 2018).

CONCLUSIONS: We found significant improvement for condom use and HIV testing among MSM over time. Besides, the number of sexual partners over time was significant , which may due to that gay apps and online platforms have rapidly expanded their partner-seeking opportunities. Future research is warranted to investigate risk factors and behaviors associated with gay app use as well as explore potential sexual health interventions via these apps.

PED0992

HIV SELF-TESTING TECHNOLOGIES AND THE IMPORTANCE OF "THE RELATIONAL": THE PERSPECTIVES OF MEN WHO HAVE SEX WITH MEN ON ORAQUICK KITS IN KENYA

B. Kina Kombo[1], M. Thomann[2], H. Musyoki[3], K. Olango[4], S. Kuria[5], M. Kyana[6], J. Musimbi[1], M. Mugambi[7], P. Bhattacharjee[8], R. Lorway[8]
[1]Partners for Health and Development in Africa, Key Populations, Nairobi, Kenya, [2]University of Memphis, Department of Anthropology, Memphis, United States, [3]National AIDS and STI Control Programme, Ministry of Health, Key Populations, Nairobi, Kenya, [4]Men Against AIDS Youth Group (MAAYGO), Programs, Kisumu, Kenya, [5]Mambo Leo Peer Empowerment Group (MPEG), Kiambu, Kenya, [6]HIV & AIDS People's Alliance of Kenya (HAPA Kenya), Mombasa, Kenya, [7]National AIDS and STI Control Programme, Ministry of Health, HIV Testing, Nairobi, Kenya, [8]University of Manitoba, Community Health Sciences, Winnipeg, Canada

BACKGROUND: Men how have sex with men (MSM) in Africa are highly vulnerable to HIV infection, owing to individual, socio-environmental and structural risk factors. These factors continue to influence access to HIV services, including HIV testing. HIV self-testing (HIVST) technologies are not only convenient but may also address access barriers related to stigmatization, which inhibits HIV testing. Our qualitative study aimed to examine the feasibility of introducing HIVST as part of a larger intervention focus on MSM. The goal was to generate evidence to inform program planning to reach, earlier, the undiagnosed segment of MSM populations.

METHODS: Following a community-based approach, we conducted an exploratory qualitative study in three counties in Kenya— Kisumu, Mombasa and Kiambu—working in close collaboration with community-led organizations. In total, 72 MSM agreed to enroll in the prospective qualitative cohort, to be followed over a one-year period, and to participate in open-ended, semi-structured interviews at three time points. We report on the first time point. We trained community researchers to design and use an interview guide that examined participants' reactions to and perceptions of a sample HIVST testing kit provided to them. Data were analyzed using a participatory approach that involved community researchers and their supervisors. Ethical clearance was gained through Kenyatta National Hospital and the University of Manitoba.

RESULTS: Participants' generally reacted favorably when given the kits to examine. In individualistic terms, they thought the technology was convenient to use, the directions clear, and the users would have control over the time and space for testing. Participants envisioned problems with the kits, however, in relational terms. Some participants anticipated HIV status disclosures during the kit's disposal, worrying that neighbors or partners might find the kits. Although some participants felt the technology could discreetly fit into a bag, others commented that the kits were not "pocket friendly" for sex work.

CONCLUSIONS: HIVST holds considerable potential for reaching undiagnosed MSM by increasing testing uptake. However, policy makers and program planners need to consider the relational concerns of MSM living in crowded contexts (such as informal settlements, where privacy is not easily afforded) and doing sex work.

PED0993

COMMUNITY MSM-LED SERVICE DELIVERY: HIV POSITIVITY RATES AND TARGETED TESTING TOWARDS HTS EFFICIENCIES AMONG 10,000 MSM IN SOUTH AFRICA

D. Nel[1], P. Botha[1], M. Rifkin[2], R. Ogle[1], D. Smith[2], N. Tsoeu[1]
[1]OUT LGBT Wellbeing, Pretoria, South Africa, [2]CareWorks, Newlands, South Africa

BACKGROUND: While constitutionally protected, MSM in South Africa remain stigmatized and marginalized from health services. Bisexual MSM are a bridging population between MSM and the general population. OUT is an MSM-led South African LGBT NGO with 25+ years of experience. With funding from USAID, OUT established the Engage Men's Health (EMH) program to improve HIV case finding, ART and PrEP coverage for MSM in South Africa.

DESCRIPTION: EMH began services in April 2019 and offers HTS, ART and PrEP. A drop-in-center and five outreach teams operate in Johannesburg, and a team in each Nelson Mandela Bay and Buffalo City. During HTS, clients provide demographic and behavioral information to promote data-use towards a client-centric approach. 10,263 clients were provided HTS during start-up (April – September 2019). 87% self-identifying as bisexual, gay or MSM, though nearly 60% indicated sex with both men and women. Overall 489 positives (140 known and 349 new) were identified (4.76%). 33.4% of those accessing HTS were first time testers, which accounted for 32% (110/349) of new positives. Highest positivity rates were seen among MSM age 40-44 years (8.62%, 67/710), followed by those 45-49 years (7.66%, 35/421). Higher positivity rates were seen among MSM reporting sex with men only (7.64%, 210/2534), than among MSM reporting sex with men and women (3.22%, 190/5,715).

LESSONS LEARNED: Leveraging the reputation of a local and recognized peer-led MSM organization resulted in client trust and HTS uptake. Behavioral data aligned to HTS results, in that predictors of

positivity included older MSM, gay/MSM-identified, sex with men only, and receptive anal sex. Skilled peer outreach workers and on-the-ground management is required to actively identify high-risk and older MSM rather than passive presence within social venues.

CONCLUSIONS/NEXT STEPS: Programs should transition from strategies that reach and identify MSM at friendly social venues, to broader outreach coverage to more effectively reach older and first-time testers. High levels of bisexuality suggest MSM should also be considered a bridging population, with increased effort made to identify and provide HTS to female partners of MSM. To reach all MSM, programs should include non-gay branding and market services as male SRH services.

PED0994

USE OF DRUGS, CHEMSEX AND RISK OF HIV AND OTHER SEXUALLY TRANSMITTED INFECTIONS AMONG MSM IN MOSCOW REGION

V. Alliluev[1], T. Kazantseva[1], A. Beloglazov[1], D. Zakharchenko[1]
[1]*Charitable Foundation "For Support of Social Initiatives and Public Health", Program, Moscow, Russian Federation*

BACKGROUND: There is a lack of integrated HIV-prevention and Harm Reduction services aimed at MSM in Russia. Community-Based VCT (CBVCT) MSM clients informally report use of different types of drugs. Between July 2018 and June 2019, a quantitative survey was conducted to define the risk profile of MSM drug users, monitor the HIV/Hepatitis C prevalence and find appropriate ways of introducing drug use risk reduction counselling into CBVCT activities.

METHODS: All clients of the LaSky Community Service Center completed the survey about use of psychoactive substances, incl. Chemsex, sexual behavior, sociodemographic characteristics and rapid testing results. In total, 1348 MSM giving their information consent were interviewed. Differences between MSM drug users and non-users with respect to risks of HIV/Hepatitis C contraction were studied.

RESULTS: 27,3% of MSM reported use of psychoactive substances: 26,7% - non-injectable and 3,3% injectable ones. 12% of Chemsex-users were HIV-positive. Stimulants are the most frequent type of drugs: 52,7% of MSM non-injectors used mephedrone, ecstasy, amphetamines, GHL/GBL, cocaine, crystal methamphetamine and ketamine. 59,5% of users took drugs to make sex feelings longer and intensive. Compared to non-users, MSM drug users (predominantly non-injectors) were more likely to be young men aged 21-30 and 'internal' Russian migrants. In the last twelve months, users were more likely to be engaged in penetrative sex with PWUDs (54,1% and 17,3%, p.<0,01) and HIV-positive men whose HIV-status they were aware of (47,4% and 32,7%, p.<0,1).No differences were found between users and non-users with respect to condom use (60,6% and 61,7%), prevalence of HIV (11,8% and 11,4%) and Hepatitis C (2,8% and 1,4%, respectively).

CONCLUSIONS: Most MSM drug users are vulnerable to HIV and STIs due to younger age and migration status. High level of STIs and absence of difference in HIV-prevalence between users and non-users can be explained by the facts that overwhelming majority of users takes non-injecting substances and about half of users consume substances associated with Chemsex. Existing CBVCT services are preferable place to engage drug using MSM and extend integration of Harm Reduction services into HIV/STI prevention programs for MSM.

PED0995

REACHING HIGH CLASS MEN-WHO-HAVE SEX WITH MEN (MSM) THROUGH SOCIAL MEDIA: A TOOL FOR IMPROVING ACCESS TO HIV SERVICES FOR HARD-TO-REACH MSM

L. Asomaning Obeng[1], P. Nartey[2], C. Asamoah-Adu[3], R. Afari Asare[3], K. Mawuena Diaba[4]
[1]*Ghana West Africa Program to Combat AIDS &STI, Monitoring and Evaluation, Accra, Ghana,* [2]*Centre for Popular Education and Human Rights Ghana, Programmes, Koforidua, Ghana,* [3]*Ghana West Africa Program to Combat AIDS &STI, Programmes, Accra, Ghana,* [4]*Ghana West Africa Program to Combat AIDS &STI, Programmes and M&E, Accra, Ghana*

BACKGROUND: The conventional peer education approach to reach men-who-have sex with men (MSM) usually leaves out high profile MSM, who are very discrete with their sexuality and mostly do not participate in community-level HIV programs. However, most civil society organizations in Ghana implementing MSM programs are yet to fully understand and utilize social media as an intervention tool for reaching high-class MSM. Under the New Funding Model II Key Population (KP) HIV program being led by West-Africa Program to Combat AIDS & STI (WAPCAS) in collaboration with CEPEHRG, a Sub-recipient implementing part of the MSM program, the use of social media was piloted to reach this category of MSM and refer them for services.

DESCRIPTION: The program adopted the use of social media handles including Facebook, WhatsApp, Grinder and Planet Romeo targeting high-class MSM. A dedicated desk was set up solely to identify high profile MSM online. Clients reached through social media apps were referred to KP-friendly nurses from Ghana Health Service to access HIV testing services through an appointment-based system. Clients were provided the option of choosing the health facility they would like to visit due to several factors including proximity, fear of stigma, etc. MSM reached had physical contact with only healthcare providers without having direct contact with peer educators due to the issue of trust and their wish for unanimity.

LESSONS LEARNED: In 2019, this approach reached 62 MSM and referred same for HIV testing services (HTS). All the clients referred tested for HIV with no positive yield. However, the counseling sessions revealed that most of them were engaged in high-risk sexual behaviors hence the need to scale-up interventions for this sub-population.

CONCLUSIONS/NEXT STEPS: Follow-up this cohort of high-profile MSM and their sexual networks for index HIV testing, reach them with risk reduction messages, condoms and lubricants to ensure they remain negative. Pilot this strategy with high-class female sex workers for HIV and other reproductive health services.

PED0996

COMMUNITY SYSTEMS STRENGTHENING IS KEY FOR SUSTAINABLE HIV RESPONSE AMONG MSM AND TGH. EVIDENCE OF LONG TERM IMPACT FROM THE PEHCHAN PROGRAMME IN INDIA

V. Arumugam[1], A. Aher[1], G. Gunjan[1], R. Prasad[1,1]
[1]*India HIV/AIDS Alliance, New Delhi, India*

BACKGROUND: India HIV/AIDS Alliance along with consortium partners implemented Pehchan programme (from 2010 to 2015), a Global Fund supported program targeted toward MSM Transgender, and Hijra populations (MTH) in 18 priority states in India and has reached 436,000 MTH with value added services. The program fo-

cused around community system strengthening, capacity building of the 200 community based organizations, and creating evidences for policy changes related to MTH. India HIV/AIDS Alliance conducted a study to measure the long term impact of the program on the community and prgoramme outcome areas.

METHODS: Modified CRISP (Community, Resources, Institutional and Processes) methodology was adopted. Multistage sampling (three stages) method was used to select the respondents for the study with mixed method (quantitative and qualitative) data. 245 structured interview, 21 FGDs, 36 IDI/case studies, 82 KIIs were conducted. Descriptive and comparative analyses were carried out using Pehchan endline study as base. CRISP score was also calculated to understand the sustainability of the project.

RESULTS: 116 CBOs were functional at the time of closure of the project in 2015 in the study states. Findings showed that in 2019, four years after the program had ended, 85 (73%) of CBOs were still in existence of which 55 were implementing HIV services projects, 30 were existence but not having any projects. Community mobilization and collectivization continued upward after Pehchan ended (from 67% in 2015 to 83% 2019) as more community members being registered with local CBOs/networks. CRISP score for the Community Pillar was 69% which suggests that the impact of Pehchan on community-related aspects has been high. The CRISP consolidated score of availing HIV services was 86% which informed a very high long - term impact.

CONCLUSIONS: Evidence from this study suggests that community involvement, its rights-based collectivization, and mobilisation of MTH community members continued to have an impact after the program ended. Together these results show that investments in community systems are sustainable and can effectively complement formal health systems in expanding the reach to marginalised populations. More Investments on CBOs will lead more inclusive HIV response in long term achievement.

PED0997

ASK AND TELL: FACTORS ASSOCIATED WITH HIV SEROSTATUS DISCLOSURE AMONG 711 MEN WHO HAVE SEX WITH MEN IN CHINA

W. Cao[1], J. Li[2,3], S. Sun[4], L. Peng[2], J. Gu[2,5], C. Hao[2,3], F. Hou[3,6], J. Li[7], D. Wei[2], X. You[2], Y. Deng[2], A.M. Ekström[8,9]
[1]Brown University, Center for Evidence Synthesis in Health, School of Public Health, Providence, United States, [2]Sun Yat-Sen University, School of Public Health, Guangzhou, China, [3]Sun Yat-sen University, Sun Yat-sen Global Health Institute, Guangzhou, China, [4]Boston University, School of Public Health, Bsoton, United States, [5]Sun Yat-sen University, Sun Yat-sen Global Health Institut, Guangzhou, China, [6]Kangning Hospital, Public Mental Health, Shenzhen, China, [7]Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Department of Clinical Research, Guangzhou, China, [8]Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden, [9]Karolinska University Hospital, Department of Infectious Diseases, Huddinge, Sweden

BACKGROUND: HIV disclosure has been researched for years among men who have sex with men (MSM). However, majorities of the literature focused on HIV-positive MSM but ignored HIV-negative or unknown MSM, who are expected to present different knowledges, concerns, and behaviors. The aim of this study was to investigate multilevel factors associated with HIV disclosure among MSM with various status in China.

METHODS: A cross-sectional survey was conducted among 711 MSM who were recruited through 15 gay-friendly non-governmental organizations located in 15 cities of China during 2018-2019. Inclusion criteria were male older than age 18 years old and self-reported anal intercourse with at least one man in the last six months. We collected information on participants' HIV serostatus disclosure behaviors (ask and tell) and potential multilevel correlates using a structured questionnaire. Individual level correlates included self-reported HIV status, HIV specific health literacy, HIV testing history, and risk perception for HIV infection. Interpersonal level correlates included sex with different types of partners, inconsistent condom use, drug use during sex, venue to look for partners, and the role in the sexual intercourse. Validated scales were used for these measurements. Univariate and multivariate logistic regression were used for data analyses.

RESULTS: Of the 711 participants, 41.4% told all partners their HIV status all the time while 30.4% asked all partners about their HIV status all the time. Participants were more likely to tell partners HIV status if they reported themselves as HIV-negative (AOR=1.41; 95% CI: 1.01-2.11), presented high HIV literacy (AOR=1.10; 95% CI: 1.01-1.19), and had sex with regular partners (AOR=1.52; 95% CI: 1.05-2.28). However, participants were less likely to tell HIV status if they perceived lower risk of HIV infection (AOR=0.65; 95% CI: 0.47-0.88) and had receptive sex only (AOR=0.61; 95% CI: 0.42-0.89). Similar results were found for participants' asking behavior.

CONCLUSIONS: The overall HIV serostatus disclosure was low among this urban representative sample of Chinese MSM. Programs aiming to promote HIV serostatus disclosure should support HIV testing, increase health literacy, and inform risk for HIV infection. Subgroups who were less likely to ask/tell HIV status should be identified to provide additional support.

PED0998

SOCIAL COHESION, STIGMA, AND HIV RISK AMONG MEN WHO HAVE SEX WITH MEN, TRANSGENDER WOMEN AND GENDERQUEER INDIVIDUALS IN TWO CITIES IN ZIMBABWE

S. Miller[1], J. Mantell[2], L.E. Parmley[1], G. Musuka[1], I. Chingombe[1], M. Mapingure[1], J.H. Rogers[3], Y. Wu[1], A. Hakim[4], O. Mugurungi[5], T.G. Harris[1]
[1]ICAP at Columbia University, New York, United States, [2]New York State Psychiatric Institute and Columbia University Irving Medical Center, HIV Center for Clinical and Behavioral Studies, Department of Psychiatry, Division of Gender, Sexuality and Health, New York, United States, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Harare, Zimbabwe, [4]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Atlanta, United States, [5]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe

BACKGROUND: Stigma and social cohesion may be associated with HIV risk. However, little data describing these associations are available among men who have sex with men (MSM) and transgender women/genderqueer (TGW/GQ) individuals in Zimbabwe.

METHODS: MSM and TGW/GQ individuals aged 18 years and older were recruited in Harare and Bulawayo for a bio-behavioral survey using respondent-driven sampling (RDS). Consenting participants (n=1511) completed questionnaires and received HIV testing. Sexual orientation and gender identity stigma was assessed with no/yes items inquiring about enacted discrimination in healthcare and community settings. Exploratory factor analysis was used to determine an internally consistent, Likert-type social cohesion scale (Cronbach's alpha=0.83). Measures were quantified by dichotomizing summed responses at the median. Multiple logistic regression models were used to assess associations of stigma and social cohesion with HIV risk adjusting for age and gender identity. Estimates are RDS-unadjusted as the sample did not reach convergence for HIV.

RESULTS: Prevalence of stigma above the median was 63.9% in Harare and 59.7% in Bulawayo. Stigma was associated with testing HIV positive in Harare [adjusted odds ratio (aOR)=2.00, 95% confidence interval (CI)=1.31-3.06] and Bulawayo (aOR=1.68, 95% CI=1.16-2.45). Stigma was not associated with condom use at last sex with a casual or main male partner or HIV testing. Prevalence of social cohesion above the median was 37.2% in Harare and 72.0% in Bulawayo. Social cohesion was associated with decreased condom use at last sex with a casual male partner in Harare (aOR=0.54, 95% CI=0.32-0.91) and Bulawayo (aOR=0.43, 95% CI=0.21-0.88), and was not associated with other outcomes (Table).

	Social Cohesion (high vs. low)		Stigma (high vs. low)	
Outcome Variable[1]	Harare	Bulawayo	Harare	Bulawayo
	aOR (95% CI)	aOR (95% CI)	aOR (95% CI)	aOR (95% CI)
HIV positive	0.76 (0.51, 1.13)	0.70 (0.48, 1.02)	2.00 (1.31, 3.06)	1.68 (1.16, 2.45)
Used condom at last sex (main partner)	1.00 (0.72, 1.39)	0.88 (0.62, 1.24)	0.73 (0.52, 1.02)	1.10 (0.80, 1.51)
Used condom at last sex (casual partner)[2]	0.54 (0.32, 0.91)	0.43 (0.21, 0.88)	1.25 (0.73, 2.13)	0.67 (0.37, 1.21)
Ever tested for HIV	0.69 (0.43, 1.10)	1.03 (0.68, 1.55)	0.96 (0.59, 1.56)	1.16 (0.80, 1.68)

[1]All models were adjusted for age and gender identity [2]Models restricted to those with ≥1 casual sexual partner in last 6 months (Harare: n=362, Bulawayo: n=319)

[Table. Association of social cohesion and stigma with HIV-related outcomes and behaviors among MSM and TGW/GQ individuals in Harare and Bulawayo, Zimbabwe, 2019]

CONCLUSIONS: Findings suggest the need to address stigma among MSM and TGW/GQ individuals in Harare and Bulawayo. Decreased condom use with casual partners among those with high social cohesion suggests that trust between MSM and TGW/GQ individuals may influence HIV risk perception. Interventions should promote condom use among MSM and TGW/GQ individuals in Zimbabwe.

PED0999

INDEPENDENT ASSOCIATIONS OF STRUCTURAL DISADVANTAGE AND DISTRESS TOLERANCE WITH CONDOMLESS ANAL SEX IN A SAMPLE OF MEN WHO HAVE SEX WITH MEN WITH HISTORIES OF CHILDHOOD SEXUAL ABUSE

C. Fitch[1], J. Najarro[2], C. O'Cleirigh[1]
[1]Massachusetts General Hospital, Boston, United States, [2]Fenway Community Health, Boston, United States

BACKGROUND: Men who have sex with men (MSM) are at disproportionate risk for HIV/STI transmission through condomless anal sex. MSM with histories of childhood sexual abuse (CSA) are at more elevated risk for HIV/STI infection compared to those without such histories. Previous research has highlighted both psychological and structural correlates as risk factors associated with frequency of condomless anal sex. Few studies have focused on resiliency factors, which may buffer these associations. This analysis sought to examine the association of distress tolerance with condomless anal sex over and above the effect of psychological and structural risk factors.
METHODS: MSM with histories of childhood sexual abuse (CSA; N=108) completed informed consent, clinician-administered and self-report assessments. Hierarchical ordinary least squares regression was used to test associations between psychological risk factors (Post-traumatic stress disorder (PTSD) symptomology and crystal methamphetamine use), number of structural barriers (i.e., government-sponsored income, unstable housing, and neighborhood crime), and distress tolerance with number of condomless anal sex episodes in the past three months. All procedures were approved by Institutional Review Boards at Massachusetts General Hospital, Fenway Community Health, and University of Miami.
RESULTS: PTSD symptomology (B = 0.010, SE = 0.006, p = .086) and crystal methamphetamine use (B = 0.993, SE = 0.559, p = .079) were marginally associated with more episodes of condomless anal sex. When number of structural barriers and distress tolerance were added to the model, more structural barriers endorsed was associated with more episodes of condomless anal sex (B = 0.432, SE = .146, p < .01). Higher distress tolerance was associated with fewer episodes of condomless anal sex (B = -0.380, SE = 0.156, p <.05). The R2 value in the final model was 0.183.
CONCLUSIONS: Distress tolerance and structural disadvantage have independent associations with condomless anal sex in high risk MSM. Interventions among populations at high risk for HIV should be multilevel, considering both integration of existing evidence-based strategies (e.g., Dialectical Behavior Therapy) to improve distress tolerance as well as structural interventions (e.g., case management) to ameliorate structural disadvantage.

PED1000

LOW HIV TESTING AMONG MEN WHO HAVE SEX MEN IN GHANA: IMPLICATIONS FOR ACHIEVING THE FIRST 90 TREATMENT TARGET

D. Abbey[1], E.O. Ankrah[1]
[1]Ghana AIDS Commission, Accra, Ghana

BACKGROUND: HIV testing remains the cornerstone of any HIV prevention effort. Reduction of HIV infection among Key Populations (KP) is one of the key priorities of the current National HIV and AIDS Strategic Plan (2016-2020). HIV impacts key populations such as men who have sex with men (MSM) disproportionately. The Prevalence of HIV among MSM is 18.1% which is 11 time higher than that of the general population.
METHODS: This study used secondary data of the 2017 Bio-Behavioural Survey (BBS) among MSM in Ghana. The inclusion criteria for MSM to participate in the BBS were if they were; biologically male; aged 18 years or older; consensual sex with another man in the last 12 months (self-reported) and if they lived/worked/socialized in either one of the study regions in Ghana. Response driven sampling was used to recruit 4,095 participants. Data was analysed using STATA 10.0, statistical significance was performed with significant level of 0.05.
RESULTS: HIV testing estimates across study regions and the number of HIV positive on treatment was found to be relatively low, only 24.3% of participants reported having accessed HIV testing in the last 12 months.
It was found that HIV testing estimates differed per study region. The highest testing prevalence was found in the Eastern region. 69.2% of the study sample in the Eastern Region reported ever having tested for HIV and received their results. The lowest testing prevalence were recorded for participants in Northern Ghana, where 24.1% of the study sample reported ever having tested and receiving their test results.
Region specific estimates also showed that those who have never tested for HIV constitute 72.5% of MSM sampled in Northern Ghana whilst 30.8% of MSM sampled in the Eastern region reported to have never tested for HIV.

CONCLUSIONS: To achieve the first 90 in Ghana by 2020, a targeted effort is required to reach MSM. This can be done making health facilities friendly for MSM community and promoting index testing.

PED1001

WELL-BEING OF LGBTI+ PEOPLE AS AN ESSENTIAL ELEMENT OF THE GLOBAL HIV RESPONSE

E. Lamontagne[1,2], S. Howell[3,4,5], A. Yakusik[2]
[1]Aix-Marseille University, CNRS, EHESS, Centrale Marseille, AMSE, Les Milles, Marseille, France, [2]UNAIDS, Strategic Information Department, Geneva, Switzerland, [3]LGBT Foundation, San Francisco, United States, [4]Hornet, San Francisco, United States, [5]Johns Hopkins University, Centre for Public Health and Human Rights, Baltimore, United States

BACKGROUND: Social, economic and structural factors can contribute to the higher transmission of HIV in sexual minorities, dissuade them from seeking treatment, and fuel mental health issues. Unfortunately, data about these factors are lacking in many low- and middle-income countries, hampering the HIV response among the community that needs it the most.
A global Lesbian, Gay, Bisexual, Transgender, Intersex and plus (LGBTI+) happiness survey was conducted to examine how various demographic, economic, socioecological, homophobic, psychosocial, attitudinal and behavioural variables potentiate HIV risk behaviour.
METHODS: We used a socioecological approach to identify the relevant variables, selecting established instruments with validated questions and scores.
Members of the LGBTI+ community were involved in each step of the survey, i.e. protocol development, pilot tests, implementation and analysis.
This anonymous survey was accessible in 30 languages from May to December 2019 through a secure encrypted internet link.
It was broadcasted worldwide through LGBTI+ social networks and social media. The survey was also promoted at country-level thanks to the support of national LGBTI+ organisations, activists, and development partners.
RESULTS: Responses were collected from a convenience sample of 115.644 LGBTI+ participants from 197 countries and territories. Our initial findings indicate that stigma and discrimination is keeping 34% of the participants away from accessing health care facilities for their sexual health or for HIV-related services. Moreover, 26.7% never had a HIV test. Globally, self-reported HIV prevalence is 10.6% among participants and 11% of those who report that they are living with HIV are not accessing treatment. Among those accessing treatment, 20.4% are not virally suppressed. Data show significant disparities between countries. The majority (55%) of LGBTI+ living with HIV are additionally confronted with HIV stigma, leading most (77.6%) of them to disclosure concerns. A large share (14%) of participants report severe psychological distress.
CONCLUSIONS: The survey brings new data on discrimination, inequalities, mental health and well-being of LGBTI+ population from 197 countries and territories. It additionally provides data on HIV-related behaviour, access to HIV services and HIV-related stigma. Forthcoming analysis of the relationships between these socioecological variables and the vulnerability to HIV infection could help shaping a better tailored HIV response.

PED1002

A MIXED METHODS STUDY TO EXAMINE DISCONTINUATION OF PREP AMONG YOUNG MEN OF COLOR WHO HAVE SEX WITH MEN (YMSM)

K. Kubicek[1], A. Bolton[1], S. Wu[1], M. Kipke[1]
[1]Children's Hospital Los Angeles, Los Angeles, United States

BACKGROUND: While pre-exposure prophylaxis (PrEP) is an effective HIV prevention method, uptake among some of the most at-risk populations is slow. Young men of color who have sex with men (YMSM) are one of these populations; while awareness of PrEP is high among this group, uptake remains low. One area in which little has been reported are reasons for discontinuation of PrEP within this population.
METHODS: Data described here are a part of the Healthy Young Men's Cohort Study (HYM), a mixed-method study focused on the HIV prevention and care continua among YMSM of color (N=448). Using an explanatory, participant selection mixed-method design, we conducted analysis with four waves of survey data (representing two years) and one-on-one qualitative interviews (n=22) with YMSM who reported past and/or current PrEP use to better understand reasons for discontinuing PrEP use among YMSM of color.
RESULTS: Of the 82 YMSM who reported any PrEP use (22% of those eligible from cohort), 50 (61%) reported consistent PrEP and the remainder discontinued and/or were inconsistent. Quantitative analysis found that consistent users were more likely than those who discontinued use to have a partner on PrEP (p > .001), have a doctor who asked about their sexual activity (p>.001), have a higher number of sex partners (p > .01), and report recent use of poppers (p > .01). Qualitative data identified two primary reasons for discontinuing PrEP. First, changes in insurance status forced some YMSM to stop filling their PrEP prescriptions. These changes were related to aging out of the ACA mandates and as well as frequent changes in employment, which often translated into changes in insurance . Second, participants described conducting a risk assessment of their behavior, often concluding that they are not "high risk" and therefore do not need PrEP.
CONCLUSIONS: Risk profiles of YMSM are dynamic and their use of PrEP may change based on their own assessment of risk. Initiating PrEP use requires both access to providers through consistent insurance as well as providers who are willing to prescribe; discussions about YMSM's sexual behavior can help initiate discussions about PrEP and encourage YMSM to be adherent.

PED1003

REPRODUCTIVE INTENTIONS AMONG GAY AND BISEXUAL MEN INITIATING PREP IN THE SUSTAINABLE HEALTH CENTER IMPLEMENTATION PREP PILOT STUDY, UNITED STATES, 2014-2016

J.T. Jones[1], D.K. Smith[1], K.W. Hoover[1], SHIPP Study Group
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

BACKGROUND: The use of HIV pre-exposure prophylaxis (PrEP) by a partner without HIV can reduce the risk of sexual HIV transmission. PrEP use does not adversely affect male fertility or pregnancy outcomes, and a man's reproductive intentions might influence PrEP use during condomless sex while attempting conception with a partner who has HIV. Studies have assessed PrEP use and reproduc-

tive intentions among HIV-negative women. Few studies have examined the reproductive intentions of HIV-negative gay and bisexual men (GBM) . We assessed reproductive intentions and associated correlates among GBM enrolled in the Sustainable Health Center Implementation PrEP Pilot (SHIPP) study.

METHODS: We analyzed baseline data from men who self-identified as gay or bisexual (n=1,275) who participated in the SHIPP study. SHIPP was a prospective cohort study of PrEP implementation in five community health centers in Chicago, Jackson, Philadelphia, and Washington, D.C. conducted from 2014 through 2016. Participants completed audio computer-assisted self-interviews that queried intentions to have a child in the future, sexual orientation, whether they previously fathered a child, marital status, HIV status of their sexual partner(s), and condom use. We estimated the association between GBM's reproductive intentions and their characteristics using Poisson regression models and calculated unadjusted and adjusted prevalence ratios (aPR) with 95% confidence intervals (CI).

RESULTS: Approximately 46.6% (n=594) of GBM indicated their intentions to have a child in the future. Black/non-Hispanic (aPR =1.40; 95% CI: 1.10, 1.78) and other/non-Hispanic GBM of color (aPR=1.40; 95% CI: 1.01, 1.93) were more likely to report intentions to have a child in the future. Respondents were less likely to report intentions to have a child in the future as age increased (30-39 years, aPR=0.80, 95% CI: 0.64, 0.99; 40-49 years, aPR=0.49, 95% CI: 0.33, 0.72; 50+ years, aPR=0.07, 95% CI: 0.02, 0.21).

CONCLUSIONS: Nearly half of respondents reported intentions to have a child in the future. GBM of color were more likely to report intentions to have a child in the future. Health care providers offering PrEP to GBM of color at increased risk for HIV acquisition should assess their reproductive intentions and incorporate family planning counseling into their healthcare when indicated.

PED1004

PARTNERSHIP TYPE AND SEXUAL PARTNER SEROCONCORDANCE ARE ASSOCIATED WITH CONDOMLESS ANAL INTERCOURSE AMONG MSM SEXUAL PARTNERSHIPS IN SAN FRANCISCO

J.M. Ikeda[1], C. Rowe[1], V. McMahan[1], G.-M. Santos[1]
[1]San Francisco Department of Public Health, Center on Substance Use and Health, San Francisco, United States

BACKGROUND: 60% of newly diagnosed HIV cases disproportionately affect cis-gender men who have sex with men (MSM) in San Francisco, CA. Most studies focus on individual-level characteristics for reducing high risk sexual behavior rather than understanding partnership-level characteristics. We conducted this analysis to examine if there is an association between condomless anal intercourse and partner type, partner disclosure of HIV status, and sexual partner seroconcordance.

METHODS: We conducted a secondary analysis of sexual partnerships (up to three most recent partners) from a cross-sectional MSM study in San Francisco, CA from March 2015 to July 2017. We conducted bivariate analysis among exposure variables of interest. We used Student-Newman's coefficient to evaluate whether the partners were similar across MSM networks by partner type (primary vs casual), HIV status, partner disclosure of HIV status and sexual partner seroconcordance. The variables that were similar (above p>.20) were placed in a multi-variate analysis. Multivariable generalized estimating equation logistic regression model was used to evaluate association between condomless anal sexual intercourse with partner type, HIV status, sexual partner seroconcordance, where they met the partner, receptive anal sex, and partner disclosure of HIV positivity.

RESULTS: This analysis is from 227 MSM with 535 of their most recent sexual partnerships in the past 6 months. 154 (37%) of the partners were HIV positive, of whom 44 engaged in condomless anal intercourse with detectable viral loads (n=36, $\lambda 2$ =58.6, p=.00). Of the HIV negative partners, only 27% were taking PrEP and engaged in condomless anal intercourse (n=86, $\lambda 2$ =13.3 p=.00). In partnerships of known HIV status, 76% of the MSM were in sexual relationships with their same known serostatus (n=44, $\lambda 2$ =24.3 p=.00). In multi-variate analysis, condomless anal intercourse was significantly associated with casual or primary partner (aOR=0.896, 95% CI =0.834- 0.956, p=.00) and partner seroconcordance (aOR = 0.753, 95% CL=0.656-0.865, p=.00) were associated with lower odds of condomless anal sex.

CONCLUSIONS: Partner type and sexual partner seroconcordance are protective exposures for condomless anal intercourse among MSM. These finding suggest that partner-level interventions should be taken into account when developing HIV prevention interventions.

PED1005

SOCIAL AND DATING ONLINE PLATFORMS AS AN OPPORTUNITY TO REACH NIGERIAN MSM WITH HIV SERVICES. THE EXPERIENCE OF THE LAGOS COMMUNITY HEALTH CENTRE

D. Okonkwo[1], E.E. Akom[2,3], F. Azeez[4], E. Shoyemi[4], Y. Adamu[5], S. Adebajo[4], L. Chittenden[5], E. Lee[3]
[1]HJF Medical Research International, Abuja, Nigeria, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, IHPT, Bethesda, United States, [3]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [4]Population Council, Abuja, Nigeria, [5]US Army Medical Research Directorate - Africa, Abuja, Nigeria

BACKGROUND: Provision of HIV prevention, care and treatment services for key populations (KPs) is priority for achieving 95-95-95 targets and epidemic control in Nigeria. The DOD HIV Walter Reed Program in Nigeria and HJF Medical Research International collaborate with Population Council Nigeria in deploying a One Stop Shop (OSS) model that actively engages KP influencers as trained peer educators and service providers in the seamless integration of HIV services provided at the OSS community health center and though mobile Community ART teams (CART). In 2019 the OSS identified social and online dating MSM sites as emerging "hotspots" for providing HIV information and linkage to services.

DESCRIPTION: Five trained MSM peer influencers and mentors were selected amongst existing MSM peers, based on communication skills, use of social and dating platforms, and influence on peers. The intervention included mapping of top Nigerian MSM online social and dating sites and the development of a list and schedule of "hot-topics" information (OSS services, clinic information and contact information of peers). This information is visible on dating status page and basic tracking systems identify OSS/CART service users who were reached in chat rooms and on dating platforms.

LESSONS LEARNED: Based on utilization, WhatsApp chat rooms and Grindr were selected for the intervention. Since implementation started in January 2019, WhatsApp and Grindr were referenced by 1,958 MSMs who showed up at the OSS and at mobile CARTs, by 196 MSM who accessed first time HIV testing, and by 60 MSM newly diagnosed with HIV. An important segment of the MSM who were reached through social media were male sex workers, representing 10% of the 19,582 MSM reached by the program as of October 2019.

CONCLUSIONS/NEXT STEPS: The utilization of existing online MSM social and dating platforms presents an opportunity to scale up the reach of different MSM typologies and their partners with HIV information, escorted referrals and linkages to the OSS and mobile CART team HIV and STI services. This especially important, in societies characterized by the strong presence of stigma and discrimination, human rights abuse and weak community and social support.

PED1006

DEPRESSION, HIV RISK BEHAVIORS, AND PERCEPTIONS OF RISK AMONG YOUNG BLACK MEN WHO HAVE SEX WITH MEN (YBMSM) IN LOS ANGELES COUNTY, CALIFORNIA

J. Doxey[1], L. D'Anna[1], J. Owens[1], J. Wood[1], C. Canjura[1], T.A. Washington[2]
[1]California State University, Center for Health Equity Research, Long Beach, United States, [2]California State University, School of Social Work, Long Beach, United States

BACKGROUND: YBMSM continue to experience higher rates of new HIV infections compared to other population groups within the United States. Depression has been associated with high-risk sexual behavior and injection drug use. Thus, we sought to understand the relationship between depression and HIV behavior and perceptions of HIV risk among YBMSM in Los Angeles County.

METHODS: Between November 2016 and September 2018 peer health educators recruited YBMSM (n=250) aged 18-24 years from public venues and partner organizations for the PPOWER project. PPOWER explored the influence of peer support on HIV protective behaviors among marginalized YBMSM. Interviewer-assisted questionnaires included measures of sexual risk behaviors, depression symptoms (CES-D), sexual self-efficacy, substance use, and perceptions of HIV risk.T-tests and Spearman correlations were utilized to analyze the quantitative data.

RESULTS: At baseline, 40.0% reported exchanging resources (drugs, money, or shelter) for unprotected sex, 29.6% had unprotected sex with a partner known/suspected to have HIV/STI, 21.2% had unprotected sex with a partner known/suspected to inject drugs, 63.4% had sex under the influence of drugs/alcohol. Higher mean depression scores (n=249) were associated with all four high-risk sexual behaviors as follows: 1) Exchanging unprotected sex for resources (t(246)= 5.392, p<.001), 2) Unprotected sex with a partner known/suspected to have HIV/STI (t(247)= 2.883, p<.001), 3) Unprotected sex with a partner known/suspected of injecting drugs (t(245)= 7.314, p<.001), and 4) Sex under the influence of drugs/alcohol (t(246)=3.177, p<.01). Higher mean depression scores were also associated with lower sexual self-efficacy with non-main sexual partners (rs=-.211, p<.05), lower perception of risk of harm related to sharing unsanitized needles (rs=-.315, p<.001) and lower perception of risk of sex without a condom or dental dam (rs=-.137, p<.05).

CONCLUSIONS: Depression among YBMSM is associated with high-risk sexual behaviors, lowered sexual self-efficacy, and low perception of risk for HIV risk behaviors, which can result in adverse health outcomes including HIV/STIs. These findings point to the need for innovative interventions to address mental health issues, perceptions of HIV risk, and strategies for reducing sexual risk behaviors. A collective commitment to improve mental health and quality of life among YBMSM is required to decrease current HIV seroconversion rates among YBMSM.

PED1007

ANTICIPATED AND ACTUAL EXPERIENCES OF DISCONTINUING PREP REFLECT THE 'IMAGINED FUTURES' AND EVERYDAY CONCERNS OF GAY AND BISEXUAL MEN, RATHER THAN HIV RISK: IMPLICATIONS FOR SERVICE PROVISION AND HEALTH PROMOTION

D.A. Murphy[1,2], J. Ellard[3], K. Ryan[4,5], M. Holt[6], J.B.F. de Wit[7,6], E. Wright[4,5,8]
[1]University of New South Wales, Kirby Institute, Sydney, Australia, [2]University of Sydney, Department of Gender and Cultural Studies, Sydney, Australia, [3]Australian Federation of AIDS Organisations, Sydney, Australia, [4]Alfred Health, Department of Infectious Disease, Melbourne, Australia, [5]Burnet Institute, Melbourne, Australia, [6]University of New South Wales, Centre for Social Research in Health, Sydney, Australia, [7]Utrecht University, Department of Interdisciplinary Social Science, Utrecht, Netherlands, [8]University of Melbourne, Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia

BACKGROUND: Now that many barriers to accessing pre-exposure prophylaxis (PrEP) in Australia have been removed, there is increasing interest in the reasons people discontinue PrEP. While clinical guidance documents for prescribers recommend discussing PrEP discontinuation with patients, these documents generally focus on HIV risk, and adherence to the dosing requirements, rather than on contextual factors that may be more pertinent to PrEP users.

METHODS: In-depth interviews were conducted with 59 participants from two PrEP demonstration projects conducted between 2014 and 2018 in Victoria, Australia. Of these participants, 42 also took part in follow-up interviews approximately 18 months later. Participants were asked to anticipate reasons why they might stop taking PrEP in the future, and to describe any experiences of taking a break from, or discontinuing, PrEP. Interviews were digitally recorded and transcribed. NVivo12 software was used to manage and code these data, and the material was examined using a Critical Discourse Analysis (CDA) approach.

RESULTS: All 59 participants were gay or bisexual men, including 2 trans men. Anticipated reasons for discontinuing PrEP were framed in terms of participants' everyday concerns or 'imagined futures', rather than being explicitly related to HIV. Entering a new relationship was cited as a potential reason for discontinuing PrEP, although usually framed in terms of 'love' or 'monogamy' rather than HIV risk. Similarly, re-evaluations of personal HIV risk were framed in terms of imagined futures that included decreased sexual activity due to ageing and/or decreased sexual desirability; and worries about side-effects and/or toxicity were related to body image concerns, as well as beliefs about pharmaceuticals and HIV antiretrovirals. Some participants anticipated being able to stop PrEP only when they were in a better state emotionally, with PrEP representing control that extended beyond HIV. Among participants who actually discontinued PrEP due to entering a relationship, this discontinuation symbolised the meaningfulness of the relationship to one or both partners (with HIV risk de-emphasised).

CONCLUSIONS: These findings provide useful insights for service provision and health promotion interventions. Reframing PrEP in ways that correspond to the actual concerns of users is vital in supporting patients/clients to anticipate discontinuation, and to prevent unintentional breaks.

PED1008

LINKING KENYA HOUSING POLICY, HIV PREVENTION AND QUALITY OF LIFE AMONG QUEER REFUGEES: A STUDY OF RONGAI, KAJIANDO-BASED REFUGEE SHELTER, 2017-2019

R. Kisige[1], T. Muyunga-Mukasa[2]
[1]Team No Sleep Foundation, Health Education, Nairobi, Kenya, [2]Advocacy Network Africa, Advocacy, Mobilisation and Education, Nairobi, Kenya

BACKGROUND: An LGBTIQQ identity, non-citizen status and social status provide problem contexts affecting housing stability. Kenya has an ambivalent refugee policy, legal dispensation and policy strategies targeting refugees help reduce housing dispossession and health-related morbidity. The aim of the study was to highlight the link between housing policy and Queer refugee housing stability.
METHODS: Research design N-48; research methods were Key Informant, questionnaire administering, checklist analysis, eligibility testing (48 eligible out of 59). Only respondents who had lived in Kenya since 2017 were eligible.
RESULTS: In the last 1 year, rent, utilities and food were paid for. All respondents reported that both a refugee and LGBTIQQ identity could lead to eviction or dispossession without recourse to courts of law for compensation. 6 respondents living with HIV stated that housing and nutrition provided through Shelter programmes were crucial for ARV Adherence and viral suppression. The Civil Servants (Housing Scheme Fund) Regulations, 2004, bars refugees from benefitting from equity release clauses, they can't own homes and cannot benefit from the „affordable housing scheme". This affects one's social mobility and stable housing. Lacking right documentations and not earning the required salary caps disqualify refugees from accessing social services including access to home loans or housing units under the Kenya housing schemes programme.
CONCLUSIONS: There is a link between identity, financial, political, religious, social, cultural and legal status. These not only affect housing stability but can lead to other vulnerabilities such as poor ARV adherence for those living with HIV. Ensuring proper documentation enhances one's eligibility for social support but for Queer refugees this means seeking safer spaces too.

PED1009

PRACTICAL STRATEGIES TO IDENTIFY TRANSGENDER, GAY AND MEN WHO HAVE SEX WITH MEN AND LINK TO HIV SERVICES: EXPERIENCE FROM RWANDA

S. Muhirwa[1]
[1]Health Development Initiative, Key Populations, Kicukiro, Rwanda

BACKGROUND: The risk of HIV acquisition in 2018 globally was estimated to be 28 times higher among men who have sex with men (MSM) as compared to heterosexual men (UNAIDS special analysis, 2018). In Rwanda the prevalence of HIV among adults aged 15- 49 is approximately 3% and among MSM is estimated to be 4%. Although homosexuality is not criminalized in Rwanda, MSM face extensive stigmatization and systematic discrimination. This in turn leads to poor health seeking behaviors and a reluctance to disclose their status as MSM and affect services tailored to this population.
DESCRIPTION: Numerous strategies and steps have been used to reach isolated MSM and refer them to HIV services in Kigali City and three districts of Southern Province over a period of five years (2015-2019). Those include: Engaging leaders of existing LGBTIs associations-- Involving MSM peer educators-- Organizing MSM community events to target influential MSM who may not be involved in associations/groups-- MSM Key informants-- Recruitment of MSM Community Health Workers-- Training of Health Care Providers-- Use of Technologies (social media including watsapp groups etc.)-- Index partners and partner notification for those diagnosed HIV positive-- Selection of locations for MSM services delivery sites by measuring the neighboring community behaviors towards the MSM lifestyle—Educating/sensitizing surrounding community and law enforcers to reduce stigma--Regular supply of MSM products (water-based lubricants and condoms).
LESSONS LEARNED: Over the course of the five years of this program, over 2500 new MSM in Kigali City and three districts of Southern Province were reached with over 160 HIV positive diagnosed and high achievable linkage to treatment. Which is the highest figure in whole country for programs implemented targeting transgender, Gay and MSM. Implementing stated innovative strategies, proved a highly effective way of reaching more MSM.
CONCLUSIONS/NEXT STEPS: Engagement and training of service providers and the general community need to continue to encourage integration of this marginalized and often vulnerable population. In order to curb the spread of HIV and improve heath seeking behaviors, especially among MSM, innovative strategies for integration and access to services specifically tailored to MSM are vital.

PED1010

KNOWLEDGE, ATTITUDES AND PRACTICES OF POLICE OFFICERS TOWARDS KEY POPULATIONS IN ZIMBABWE

F. Dube[1], A. Mpofu[1], M. Katumba[2], L. Munangaidzwa[3], T. Mhaka[3], R. Yekeye[3]
[1]National AIDS Council, Harare, Zimbabwe, [2]COC Netherlands, Johannesburg, South Africa, [3]NAC, Harare, Zimbabwe

BACKGROUND: Among other reasons, the high HIV prevalence among key populations has been related to abuse and stigma from police officers. To understand the Zimbabwean situation better, we conducted a study to assess the knowledge, attitudes and actions of police officers towards sex workers and men who have sex with men. The study also sought to identify advocacy and capacity issues for improving police officers attitudes and practices towards KPs.
METHODS: A descriptive cross sectional study design was used. Quantitative and qualitative data was collected from police officers, sex workers and organisations that deal with MSM. 424 police officers were interviewed through Interviewer administered questionnaires, 20 focus group discussions were conducted with sex workers and five key informants were interviewed. Epi Info version 3.5.3 statistical package was used to analyse quantitative data. Thematic content analysis was carried out for the focus group discussions.
RESULTS: 75.6% of the study participants had limited knowledge of HIV prevention methods whilst 6% had no knowledge. Regarding KPs vulnerability to HIV, 10% (95%CI: 7.3%-13.3%) of study participants agreed with the statement that all key population are HIV positive with 90% (95% CI: 86.7%-92.7%) disagreeing. 60% of the study participants had arrested FSW, 14.3% had arrested MSM in the past two years. 269 police officers(64%) expressed their willingness to build collaboration with key populations in their work. Only 10 (2.4%) disagreed on building collaboration with key populations. The majority 68% of the study participants were of the attitude that they can help in eliminating unequal treatment of key populations. The majority

(63.6%) of the study participants would accept their relative or colleague if they belong to any of the key population subgroups and are willing to be reoriented (90.1%) to improve the policing of key populations. However they were some study participants (36.4%) who responded that they will not accept either a relative or colleague identifying as KPs.

CONCLUSIONS: Most of the police officers have limited knowledge on HIV prevention methods and had limited knowledge on groups that constitute key populations. The majority of the officers have arrested sex workers while the minority had arrested MSM for various reasons.

PED1011

DO I TELL MY DOCTOR? FACTORS ASSOCIATED WITH MSM SEXUAL ORIENTATION DISCLOSURE IN HEALTH CARE, RESULTS FROM THE LATIN AMERICAN MSM INTERNET SURVEY (LAMIS)

A. Borges Moreira da Rocha[1], I. Prado Generoso[1], A. J. Schmidt[2], T. Thiago Felix Pinheiro[1], J.L. Gomez[1], M.A. Veras[1]
[1]Santa Casa de São Paulo Medical School, Collective Health Department, São Paulo, Brazil, [2]London School of Hygiene and Tropical Medicine, Sigma Research, London, United Kingdom

BACKGROUND: In most Latin American countries, stigma related to non-heteronormative sexualities impacts health policies and the personal relation with health care providers. In some countries/societies, disclosure of same-sex sexual behavior in health care settings is associated with access to prevention strategies. This study aimed to examine factors associated with disclosure in health care in Latin America (LA).

METHODS: LAMIS was a cross-sectional online survey responded by 64,655 adult MSM in Latin America, from January to May of 2018, assessing demographics, sexual behavior, mental health, HIV and other STI data. For this analysis, the outcome "Disclosure in health care" was defined based on reporting that the health care professional (HCP) at the most recent STI test (in the last 12 months), "definitely knew" they had sex with men. A multivariable Poisson regression model adjusted by country was used to measure associations between this outcome and demographic variables, including sexual identity, "outness" towards family and friends, and HIV status. We used data from 18 Latin American countries, excluding participants with discrepant answers.

RESULTS: In total, 25.482 participants had an STI test in the last 12 months, of which 14.486 (56.85%) reported disclosure of same-sex sexual contacts towards the HCP, with proportions ranging from 28% on Venezuela to 63% in Mexico and 87% in Guatemala. Compared to men aged 18-24, all older age strata had a lower adjusted prevalence ratio of disclosure in health care. Living in cities larger than 500.00 inhabitants were positively associated with disclosure (aPR:1.07;95%CI:1.03-1.11). Overall outness was positively associated with disclosure (aPR:2.12;95%CI:1.91-2.35 for "out" to all vs. "out" to none), so as diagnosed HIV (aPR:1.30,95%CI:1.28-1.33).

CONCLUSIONS: Even with the disparities between Latin American countries, more than half of the sample reported disclosure of sexual orientation to their HCP. Living in larger cities, coming out to family and friends and diagnosed HIV are social experiences that could facilitate the expression of sexuality at health services. A societal climate allowing for general outness, particularly in smaller settlements, might facilitate disclosure and therefore better health care access in LA.

PED1012

PREVALENCE OF CHEMSEX AMONG MSM IN INDONESIA AND ITS ASSOCIATIONS TO HIV RISK BEHAVIOURS

I. Praptoraharjo[1,1], L. Nevendorff[1], E. Sindunata[1], W. Reswana[2], M. Al[2]
[1]Atma Jaya Catholic University Jakarta, HIV AIDS Research Center, Jakarta, Indonesia, [2]GWL-INA, Jakarta, Indonesia

BACKGROUND: A bulk of evidence from previous research inform that chemical use during sexual encounter (Chensex) among MSM has been a significant risk factor to HIV transmission among MSM. HIV prevalence among MSM is 25% in 2015, the highest among key affected populations in Indonesia. No data available for this phenomenon and as a consequence, no programmatic effort has been developed. This study aims to estimate prevalence of chemsex among MSM and to identify its associated factors.

METHODS: A cross-sectional web survey using adapted questionnaire from European MSM Survey (EMIS) was used to collect the data from 1881 respondents across 32 out of 33 provinces in Indonesia. A descriptive statistic was used to provide the prevalence of the chemsex and logistic regression was used to determine the associations between chemsex and independent variables.

RESULTS: About one out of three MSM reported chemsex in the last 12 months. Almost all (91percent used poppers as the main substance. Only 14,63 percent reported crystal methamphetamine in the chemsex in the same period. MSM who practice chemsex were more likely having commercial sex, sexual partners, HIV positive, STI experience and mental health problems than MSM who do not practice chemsex.

CONCLUSIONS: MSM who practice chemsex are at the higher risk of HIV acquisition due to the high prevalence of HIV among MSM in general. Therefore it is a mandatory for the HIV program in Indonesia to integrate harm reduction approach targeting MSM who practice chemsex into the existing MSM program.

INTERSECTIONAL IDENTITIES AND MULTIPLE VULNERABILITIES TO HIV AND CO-INFECTIONS

PED1013

MULTILEVEL PREDICTORS OF PREP USE AMONG MEN OF COLOR WHO HAVE SEX WITH MEN IN THE UNITED STATES

K. Rodriguez[1], K. Wyka[1], C. Grov[2,1], K. Meyers[3], D. Nash[1,2], E. Kelvin[1,2]
[1]CUNY Graduate School of Public Health and Health Policy, Department of Epidemiology and Biostatistics, New York, United States, [2]CUNY Institute for Implementation Science in Population Health, New York, United States, [3]Aaron Diamond AIDS Research Center/Rockefeller University, New York, United States

BACKGROUND: Men who have sex with men (MSM) of color in the United States (US) are at disproportionate risk for HIV, and despite its availability, Blacks and Latinos account for the smallest percentage of PrEP prescriptions. Furthermore, although >50% of HIV diagnoses in 2017 occurred in the South, residents of this region only just accounted for 25% of PrEP users. The data suggests that minority identity as well as regional factors may be important drivers of PrEP uptake.

METHODS: May 2015-March 2016, we conducted a cross-sectional survey among a geographically diverse sample of MSM in the US. Based on participant residential zip code, the survey data was linked

to publicly available state-level data, including state-level LBGTQ+ and racial equality measures. Multilevel logistic regression was used to explore the association of variables at the individual, social, and state-level with current PrEP use.

RESULTS: Of 1,465 HIV-negative participants, 13.6% were currently taking PrEP. In the adjusted regression model, residents of states with high LGBTQ+ equality had significantly higher odds of taking PrEP compared to those in low equality states (aOR=2.0, P=0.03). In addition, those who did not identify as gay (i.e. MSM who identified as heterosexual, bisexual, or other) (aOR=0.5, P=0.01) and those who identified as Hispanic (aOR=0.7, P=0.05) or Asian (aOR=0.5, P=0.02) had lower odds of PrEP use compared to those identifying as gay and Black respectively.

Those of middle age had higher odds of PrEP use (30-39 years: aOR=1.5, p=0.04) compared to the youngest group (<29 years). Social measures such as having a main partner who was HIV+ (aOR=3.6, p=0.001) or HIV-negative and on PrEP (aOR=12.8, p<0.0001) was associated with a higher odds of PrEP use, as was having a higher number of partners in the past 3 months (2-5 partners: aOR=3.9, p=0.0005; >5 partners: aOR=6.7, p<0.0001 versus 0 partners) and a recent STI diagnosis (aOR=2.6 P<0.0001).

CONCLUSIONS: Several individual and social-level factors were associated with PrEP use among MSM of color. In addition, state-level LGBTQ+ equality may facilitate PrEP uptake. Implementation of policies that reduce equality may hinder expansion of PrEP in this high-risk group and impact our ability to end the epidemic.

PED1014

MEETING THE NEEDS OF PEOPLE LIVING WITH HIV/AIDS AND EXPERIENCING HOMELESSNESS IN SAN FRANCISCO THROUGH INTERAGENCY PARTNERSHIP AND MOBILE MULTI-DISCIPLINARY MEDICAL ENGAGEMENT

D. Borne[1], J. Sakowitz[2], J. Fox[1], R. Arnold[3], P. Denehy[1], D. Carter[3], D. Ganiyev[3]

[1]SF Department of Public Health, San Francisco, United States, [2]San Francisco Homeless Outreach Team, San Francisco, United States, [3]San Francisco Community Health Clinic, San Francisco, United States

BACKGROUND:

HHOME takes a mobile, multi-disciplinary approach to meeting the needs of PLWHA experiencing homelessness. It targets PLWHA not engaged in HIV treatment, with low CD4 count, detectable viral load, high emergency department/hospital utilization, no primary care, substance use disorders, severe mental illness, and homelessness. Program goals include offering low-barrier, client-centered medical, psychiatric, and addiction treatment outside of clinics, offering medication adherence support, increasing access to shelter and supportive housing, decreasing emergency department/hospital utilization, and strengthening citywide coordination of care.

DESCRIPTION: The HHOME team comes from four city agencies and consists of a physician, nursing staff, a housing case manager, a medical case manager, and two peer navigators. The staff work in mobile dyads at shelters, streets, encampments, hospitals, and treatment programs, and operate two weekly drop-in clinics. The team engages clients with a harm-reduction approach. HIV medications are started as soon as possible; otherwise, treatment begins with options including vitamins, psychiatric/addiction medication, and prophylaxis. The team links clients to shelter and permanent housing. To locate disengaged clients, the team uses persistent outreach. Once clients have two appointments in a clinic, are stably housed, have benefits, and are at a lower acuity, they transition to less-intensive case management.

LESSONS LEARNED: Since 2014, the HHOME program served over 160 individuals, of which 61 participants were enrolled in a longitudinal study from 2014 to 2017. At 12 months after enrollment, 83.6% had two HIV primary care appointments, 60% were virally suppressed, 83.6% transitioned to stable placement, and 73.8% entered supportive housing. The authors will review and summarize long-term data now available, including death rate, disengagement from care, and eviction, to update these findings. Multi-disciplinarity, mobility, and system re-organization are key elements in HHOME's success. Team collaboration facilitates close linkages between clients' primary care, HIV treatment, and housing process.

CONCLUSIONS/NEXT STEPS: HHOME is a successful model for treating medically acute and socially complex clients. It offers lessons that can be applied to other locations and populations. This upstream investment in system reorganization and mobile, high-intensity, and client-driven care improves community viral suppression and leads to cost savings by increasing care efficiency and reducing utilization of emergency services.

PED1015

AMANDA SELFIE, A TRANSGENDER CHATBOT: INNOVATIONS TO IMPROVE ACCESS TO HIV INFORMATION AND PREP SERVICES AMONG ADOLESCENT MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN IN BRAZIL

P. Massa[1], D. Ferraz[2], I. Dourado[3], L. Magno[4], G. Vendramini[1], M. Greco[5], A.P. Silva[5], A. Grangeiro[1]

[1]Universidade de São Paulo, São Paulo, Brazil, [2]Fundação Oswaldo Cruz, Brasilia, Brazil, [3]Universidade Federal da Bahia, Salvador, Brazil, [4]Universidade do Estado da Bahia, Salvador, Brazil, [5]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

BACKGROUND: HIV infection has increased among adolescent men who have sex with men (AMSM) and transgender women (ATGW) in Brazil. Pre-exposure prophylaxis (PrEP) may contributed to reduce HIV incidence in these groups. Nevertheless, two main challenges are to be overcome: scaling-up information about PrEP and linking AMSM and ATGW to healthcare facilities. Aiming to respond to these challenges, we have developed an artificial intelligence chatbot (AIC).

DESCRIPTION: The AIC, named "Amanda Selfie", is part of PrEP1519, a demonstration study among AMSM and ATGW aged 15-19 years, ongoing in three Brazilian cities: Salvador, Belo Horizonte and São Paulo. Amanda was developed with the participation of AMSM and ATGW and conceived to be a transgender robot. Available 24/7 on Facebook Messenger, it emulates chat-based conversations on sensitive subjects: STI, PrEP and combination prevention (CP). Through an on-line quiz, it can identify those in high risk for HIV, inform about CP and schedule appointments to PrEP1519 clinics.

LESSONS LEARNED: As part of Amanda's development, an experimental phase took place between June-December 2019. 747 people accessed the chatbot and 63 (8.4%) were AMSM and ATGW 15-19 yo; among those, 73% reported HIV risk practices. Most frequently asked topics were PrEP, HIV/AIDS and PEP. Doubts related to sexual experience, sexual orientation and gender identity were frequent. 20% of those accessing Amanda and belonging to the target groups (n=13) scheduled appointments to PrEP1519 clinics and 10% showed up to consultations.

CONCLUSIONS/NEXT STEPS: Frequently asked topics show a high demand for information on HIV/AIDS and Amanda's potential to improve AMSM and ATGW information on CP. Questions on sexuality indicate Amanda was seen as a reliable space to talk about personal experiences. Its capacity to reach the target group is still limited and might be due to: being hosted in a new page, unknown by adolescents beforehand; being linked to a single social network (Facebook); and depending on user's initiative. The low number of adolescents scheduling appointments through Amanda may be due to its limited conversation flow. Next steps include linking Amanda to existing applications, pages, and groups used by AMSM and ATGW. Also, implementing a shorter, multiple-ended dialogue flow.

PED1016

WALKING A FINE LINE: UNDERSTANDING THE OVERLAP OF SEX WORK AND YOUNG WOMEN IN SOUTH AFRICA

M. Milovanovic[1], K. Hlongwane[1], M. Jaffer[1], M. Matuludi[1], V. Mboweni[1], P. Ndlovu[1], F. Abdullah[2], L. Vanleeuw[2], N. Slinger[2], K. Otwombe[1], G. Gray[2], R. Jewkes[2], J. Coetzee[1]
[1]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [2]South African Medical Research Council, Pretoria, South Africa

BACKGROUND: Adolescent girls and young women (AGYW) account for a disproportionate number of new HIV infections globally. In South Africa, as many as 25% of AGYW engage in intergenerational, transactional relationships for material gain. These are often driven by socioeconomic factors. Thus, the sex for money transaction becomes a viable survival mechanism. Studies from across South Africa have shown that HIV prevalence amongst sex workers ranges from 40-90%, and that 30-40% of sex workers are under 25 years of age, with an elevated HIV risk profile. Thus, understanding the overlap of AGYW and sex work is becoming a central tenet to epidemic control in South Africa, especially within the context of highly targeted funding mechanisms which may inadvertently overlook high risk AGYW, or younger Sex Workers.

METHODS: A cross-sectional national survey of Female Sex Workers (FSWs), using a chain referral sampling method, was conducted across 12 sites in South Africa between February-July 2019. Study procedures included a questionnaire component: assessing demographics, past and current sexual behaviour, substance use, HIV testing and treatment history, and a clinical component HIV rapid testing and laboratory testing for viral load.

RESULTS: Preliminary findings show that 13.2% (398/3005) of our sample were aged 18-24 years, with a median age of first coitus being 16 (IQR:14-17) years and 6.3% (25/396) entering into sex work before 16 years, with the primary reason being economic sustainability. More than half (67.7%, 268/396) had been pregnant and a quarter (25.4%, 101/397) report having used drugs within the last year. HIV prevalence was 39.2% (156/398), with 17.9% (28/156) of AGYW FSWs being recently infected. Of the 127 known positives, 95.2% (101/106) were on treatment and 57.1% (56/98) of those on treatment were virally supressed. Though not significant, HIV prevalence was higher in those who started selling sex before 16 than after 16 years (44.0% vs. 38.5%; p=0.5881).

CONCLUSIONS: Our data has the ability to retrospectively model the continuum of vulnerability that AGYW experience, thus outlining the drivers of entry into sex work and also understanding which interventions should be developed and implemented with the goal of increased HIV prevention, viral suppression and linkages to care.

PED1017

LESBIAN, BISEXUAL AND TRANSGENDER WOMEN FROM BRAZIL: WOMEN'S LIVES MATTER?

M. Seixas[1], B. Benevides[2], A. Baptista[3], M. Malta[4]
[1]Brazilian Lesbian Association, Rio de Janeiro, Brazil, [2]Brazilian National Transgender Association - ANTRA, Rio de Janeiro, Brazil, [3]Oswaldo Cruz Foundation, Human Rights & Health Department (ENSP/DDHS), Rio de Janeiro, Brazil, [4]University of Toronto, Department of Psychiatry, Faculty of Medicine, Toronto, Canada

BACKGROUND: In Brazil, a woman is raped every 11 minutes and 12 women are killed daily. Lesbian, bisexual and transgender (LBT) women are disproportionately affected by sexual and gender-based violence (SGBV). Brazil registers more than 50,000 rapes/year, less than 30% of rapes are reported, and less than 2% of criminals prosecuted. Since 2008, Brazil has had the highest worldwide rate of homicide among LBT women. LBT women are more likely to experience SGBV, under-report crimes and not receive appropriate care and legal support, including HIV PEP (post-exposure prophylaxis) and post-rape care. Mental disorders are highly prevalent among LBT women experiencing SGBV. There is a lack of accessible and LBT friendly interventions in the country.

DESCRIPTION: The Brazilian National Lesbian Association, in partnership with other LGBTQ+ associations the Brazilian Ministry of Health and international donors, is collaborating with the development of a mobile health intervention to SGBV against LBT women in Brazil. The "Rainbow Resistance" will facilitate SGBV online reporting, map risky areas and LBT friendly services. It is our major goal to improve crime reporting, access

LESSONS LEARNED: Community-based participatory research (CBPR) fostered a close and productive collaboration between researchers, health professionals and LBT activists from Brazil. CBPR is a key methodology allowing this intervention to be developed 'for and by LBT women', in synch with a key motto for successful interventions targeting marginalized groups: "Nothing About Us Without Us!". The "Rainbow Resistance" strategy was launched in December 2019, and our app reached more than 1,000 downloads in the first weeks.

CONCLUSIONS/NEXT STEPS: Our intervention was developed to facilitate LBT survivors of SGBV an quickly connection with the support they need. This link include referral to free legal support, shelters for those experiencing domestic violence, suicide crisis support 24/7, referral to health and mental care, including post-rape care (HIV testing, PEP etc). Our next steps include the evaluation of Rainbow Resistance feasibility and acceptability, and it's impact on SGBV reporting and access to health services among survivors.

PED1018

CONTEXTUALIZING HIV RISK: EXPLORING RELATIONSHIPS BETWEEN MARIJUANA, POLYSUBSTANCE USE, MENTAL HEALTH, AND SEXUAL RISK BEHAVIORS AMONG YOUNG BLACK MEN WHO HAVE SEX WITH MEN (YBMSM) IN LOS ANGELES COUNTY, CA

L. D'Anna[1], J. Wood[1], J. Owens[1], C. Canjura[1], T.A. Washington[2]
[1]California State University, Center for Health Equity Research, Long Beach, United States, [2]California State University, School of Social Work, Long Beach, United States

BACKGROUND: Marijuana, alcohol, and polysubstance use are HIV risk factors for YBMSM in urban settings where structural and social stressors prevail. They experience elevated rates of condomless sex, STIs, and higher numbers of sex partners. Marijuana use can precede and influence other substance use. Cognitive impairment with marijuana use can result in risky sexual behaviors amplified by other drugs. The legalization of recreational marijuana necessitates a better understanding of marijuana use and risk within groups disproportionately burdened by HIV.

METHODS: The PPOWER Project examined problem marijuana, alcohol, and other drug use and sexual risk among 250 YBMSM ages 18-24 in Los Angeles County from November 2016 through September 2018. Baseline data are reported.

RESULTS: Eighty percent reported marijuana use. Self-reported 30-day substance use included: marijuana (59.2%), alcohol (70%), other drugs (26%), marijuana and alcohol (32.4%), and marijuana, alcohol, and other drugs (19.6%). Risk behaviors included: sex while high (62.4%), trading unprotected sex for shelter/drugs (40.0%), no previous condom experience (12.4%), no condom/barrier during last sex (55.2%), and unprotected sex with someone known/suspected to have HIV/STI (29.6%). Almost half (48.4%) did not consider sex without a condom/barrier, or while high (59.2%), to be a harmful risk. The majority (87.3%) reported no prior use of either PrEP/PEP, 26.4% reported no previous HIV test, and 22 (8.8%) self-reported HIV-positive-status. Problem marijuana use was correlated with each HIV risk behavior measured. However, problem marijuana use was also correlated with problem use of alcohol ($r(248)=0.48$, $p<0.01$) and other drugs ($r(249)=0.48$, $p<0.01$). In the final analysis, variance in sexual risk variables were largely accounted for by problem alcohol use. Notably, higher 30-day CES-D depression score and emotional problems caused by alcohol/drugs remained significantly correlated across our models.

CONCLUSIONS: Findings emphasize specific HIV risk factors for YBMSM and point to the importance of investigating relationships between social contexts, polysubstance use, and sexual behavior. Marijuana was the pervasive drug of choice, but was frequently used with alcohol, a known sexual health risk factor. Ameliorating the public health injustices evidenced by HIV inequalities requires concerted efforts to address contextual environments and to support YBMSM in developing and sustaining positive mental health.

PED1019

INTEGRATING RESILIENCY INTO MEDICATION ADHERENCE MESSAGING FOR BLACK MSM LIVING WITH HIV IN THE URBAN U.S. THROUGH PHOTOVOICE AND DOCUMENTARY FILM

M. Teti[1], M. Reese[2], S. Epping[3]
[1]The University of Missouri, Public Health, Columbia, United States, [2]KC Care, Kansas City, United States, [3]University of Missouri, Journalism, Columbia, United States

BACKGROUND: Black men who have sex with men (BMSM) in the U.S. report low HIV medication adherence compared to other groups with HIV. Current adherence messaging stresses the RISKS of non-adherence, which may not resonate with BMSM. We asked BMSM to describe their medication adherence challenges AND strengths, and consider ways to include BMSM's resiliency in adherence messaging.

METHODS: We engaged men in a community-based research process. We used Photovoice to allow men to depict their experiences through images and group and individual interviews. Thematic analysis captured patterns in the photos and interviews. Upon presenting the themes to the participants, they requested an additional set of video interviews, to create a documentary that used their stories to educate emerging health professionals about their challenges and strengths. They believed the documentary was important to help translate their experiences to action, a key component of community-based research.

RESULTS: On average, participants' (N=19) were 34 years old and were living with HIV for five years. Via photos and discussions, men reported four adherence challenges: traumatic medical care experiences, incarceration fears (re HIV disclosure), intersectional stigma (HIV/racism/ heterosexism), and community/familial isolation (Black church, father figure). Adherence facilitators/strengths were: persistence, chosen families, self-love, and taking control over HIV. Video interviews expanded on these themes to create a 20-minute documentary that included footage of men discussing the themes to explain BMSM's resources, challenges, and needed support to adhere to treatment. We presented the documentary to 100 college-level health professional students.

CONCLUSIONS: BMSM face notable socio-structural challenges but do possess individual strengths. When applied to HIV medication adherence messaging, men suggested messages should highlight men's self-care abilities and persistence; that men deserve love; and that men can control/survive HIV. Participants said that HIV policies against incarceration for sex while positive and supportive HIV testing/treatment programs would help BMSM openly disclose their HIV status and access treatment. Participants believed that mechanisms like the documentary they created were essential to expose men's challenges; show BMSM with HIV as complex, resilient and able to overcome challenges; decrease stigma; and increase support in communities and in medicine for treatment adherence.

PED1020

BARRIERS TO HEPATITIS C TREATMENT AMONG PEOPLE LIVING WITH HIV/HCV COINFECTION IN THE PRE- AND POST-DAA ERAS

M. Urry, MPH[1], S. Olender, MD, MS[1], M. Scherer, MD[1], M. Gonzalez, MPH[2], R. Mathu, MPH[2], R. Schnall, RN, MS[3], J. Zucker, MD[1], K. Marks, MD, MS[4], P. Gordon, MD[1]
[1]New York-Presbyterian Hospital at Columbia University Irving Medical Center, Department of Medicine, New York, United States, [2]New York-Presbyterian Hospital at Columbia University Irving Medical Center, Division of Community and Population Health, New York, United States, [3]Columbia University School of Nursing, New York, United States, [4]Weill Cornell Medical College, New York, United States

BACKGROUND: Treatment of Hepatitis C virus (HCV) has evolved from interferon (IFN)-based treatments with low cure rates to more efficacious direct-acting antiviral (DAAs) regimens, yet barriers to cure persist amongst HIV/HCV coinfected populations. We sought to better understand these barriers among patients and providers in the DAA era at our academic urban medical center via the mixed methods CHANGE (A Proposal to Cure HCV and Guide Engagement among People Living with HIV) study. Of 1,948 patients living with HIV, there were still 61 patients with untreated chronic active HCV infection at the initiation of the study.

Characteristic	2013 n = 18	2019 n = 12
Gender	Male: 12 (75%) Female: 4 (25%)	Male: 8 (67%) Female: 3 (25%) Transgender: 1 (8%)
Age (median, range)	59 (33-68)	49 (35-69)
Race/Ethnicity	African-American: 12 (69%) Hispanic/Latino: 3 (17%) White: 1 (5%) >1 Race/Ethnicity: 2 (11%)	African-American: 6 (50%) Hispanic/Latino: 4 (34%) White: 1 (8%) >1 Race/Ethnicity: 1 (8%)
Social History	Self-Reported History of Injection Drug Use: 11 (61%) History of Incarceration: 9 (50%)	Self-Reported History of Injection Drug Use: 10 (83%) History of Incarceration: 7 (58%)
Years since HCV Diagnosis (median, IQR)	11 (6-16)	6.5 (2-5)
Years since HIV Diagnosis (median, IQR)	18 (12-25)	17 (12-24)

[Table 1. Patient Demographics]

METHODS: As a part of broader study activities, we conducted and thematically analyzed 21 in-depth interviews with PLWHIV and untreated HCV and their providers. An organizational assessment was also conducted. We compared emerging themes with previously collected site data from 2013, including 26 in-depth interviews with providers and coinfected patients.

RESULTS: Many barriers prevalent prior to the release of DAAs continue to impact accessibility to treatment, including substance use; housing instability; incarceration; lack of social support throughout therapy; and finally, comorbidities being prioritized over treating HCV.

Systemic barriers also persist across both generations of HCV treatment, including burdensome insurance policies and prior authorizations. Provider hesitancy to prescribe to those with unstable HIV and/or complex psychosocial needs due to the prohibitive cost of and difficulty in re-authorizing repeat prescriptions of DAAs has also proven to be a new deterrent to treatment.

HCV treatment and cure is more widely understood now than in 2013. The evolution of infectious disease physicians, rather than hepatologists, as HCV treatment providers is also a stark difference between the two time points.

Characteristic	2013 n = 8	2019 n = 9
Credentials	7 MDs (4 ID, 2 HIV-trained, 1 internist) 1 NP	6 MDs (5 ID, 1 HIV-trained) 3 NPs
Experience	Median 14 years experience (range 3-36 years) Providers' Coinfected Patient Panel Size: <3 patients: 16 providers 5 patients: 1 provider 25-30 patients: 1 provider	Years' Experience treating HIV: <5 years: 4 providers 5-15 years: 2 providers <15 years: 3 providers Years' experience treating HCV: 1-2 years: 2 2-5 years: 3 5-15 years: 2 >15 years: 1

[Table 2. Provider Demographics]

CONCLUSIONS: Despite ease of treatment and cure with DAAs, multidisciplinary case management and behavioral health care remain essential to successfully treat HIV/HCV coinfected individuals. These findings also demonstrate successful de-specialization of HCV treatment.

PED1021

INTIMATE PARTNER VIOLENCE AMONG YOUNG BLACK GAY AND BISEXUAL MEN: AN UNDEREXPLORED RISK FACTOR FOR HIV

D. Brooks[1], D. Celentano[1], R. Arrington-Sanders[1], N. Galai[1], A. Wirtz[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

BACKGROUND: Young Black Gay and Bisexual Men (YBGBM) are disproportionately impacted by HIV in the U.S. Emerging data suggests that Intimate Partner Violence (IPV) may play a role in HIV acquisition and also prevent survivors from achieving viral suppression. The majority of IPV research has traditionally focused on heterosexual women. Limited research has established the rate or types of IPV experiences YBGBM face. Therefore, we quantitatively examined the types of IPV experienced by YBGBM.

METHODS: Young BGBM 15-24 years old in Baltimore, Washington DC, and Philadelphia were recruited utilizing several methods including clinics, social media, community-based outreach, and respondent driven sampling. Eligibility included: self-identified as Black, cisgender, with a history of oral or anal intercourse within the last 12 months with another man. Participants were asked to complete a rapid HIV-1 antibody test and a self-administered 45-minute electronic socio-behavioral health survey (eg.HIV risk perceptions, PrEP utilization, sexual partner matrix). IPV was measured (eg: recent IPV experience within the last 3 months), using a recently developed and validated measure for MSM. Data was analyzed using Stata.16.

RESULTS: N= 349 participants identified as Black/African-American with a mean age 20.7 years (SD=2.46). Approximately 23% reported that arguments escalated to physical violence within the previous three months. Additionally, 11% were forced or pressured to perform sexual activities, 11% reported being pressured to have sex without a condom after asking the sexual partner to use a condom, 17% report-

ed being insulted or threatened, 9% was prevented from communicating with family or friends, and 9% reported that they felt afraid within their relationship. Collectively, 34% of YBGBM experienced any form of recent IPV.

CONCLUSIONS: To achieve 95-95-95 treatment and prevention goals, a deeper understanding of how IPV impacts YBGBM is imperative. Our findings suggest that in urban cities, YBGBM experience IPV at levels similar to women globally. However, there is a dearth of research and services available to support YBGBM who experience IPV. Additional Information regarding the social and cultural drivers of IPV among this population, its relationship to HIV risk, and how to ensure that experiences of IPV do not accelerate HIV transmission among this population is key.

OTHER POPULATIONS VULNERABLE IN SPECIFIC CONTEXTS

PED1022

ACCESS OF YOUNG PEOPLE, SEX WORKERS AND MEN WHO HAVE SEX WITH MEN TO COMBINED HIV PREVENTION SERVICES IN A VERY REPRESSIVE CULTURAL AND RELIGIOUS CONTEXT, IN MAURITANIA

A. Diop[1]
[1]*Association des Gestionnaires Pour le Développement, Management, Nouakchott, Mauritania*

BACKGROUND: In Mauritania 44.4% of men who have sex with men and 4.4% of sex workers are infected with HIV. Because of the law that condemns sex work to prison terms and same-sex sex to the death penalty, MSM had no access to HIV care. Unmarried young people do not have access to services because of social and religious constraints. With funding from Amplifychange in early 2019, we have set up a service center adapted to this population in Nouakchott.

DESCRIPTION: Our strategy, in partnership with the national AIDS program and others stakeholder, first identified group leaders and mobilized them as peer educators. These people made it possible, through focus groups, to define the activity package suited to their needs. These people have been of great help in building trust. The main actions carried out are screening services, treatment of transmissible sexual infections and a legal clinic with discussion groups. We also offer continuous condom distribution and therapeutic education for people living with HIV among the group.

LESSONS LEARNED: In seven mouth, 217 female sex workers, 174 men who have sex with men, 386 adolescent girls and 34 migrants are tested for HIV for the first time. 82% of the group had wanted to take the test for months, but never had the ideal setting to do it. Test results since the center's launch are 3.71% positive among sex workers, 26.33 among MSM and 1.8% among migrants. In addition, 157 cases of sexually transmitted infections were treated, 16 legal consultation sessions, 138,880 condoms were distributed.

CONCLUSIONS/NEXT STEPS: For a better impact of the fight against the epidemic, intervention with key populations is imperative. It is possible to intervene with men who have sex with other men and sex workers, as well as adolescents in a difficult context, provided that you identify group leaders and involve them in everything. This practice deserves to be extended in the country and in similar contexts and encourage better involvement of civil society in the response to HIV.

PED1023

ONLINE/OFFLINE – AN IMPORTANT INTERFACE FOR THE PROVISION OF LOCAL AND RESPONSIVE CONTRACEPTIVE EDUCATION AND SEXUAL HEALTH EDUCATION FOR YOUNG PEOPLE IN MTWARA, TANZANIA

I. Grant[1], Y. Mohamed[1], O. Lohay[1]
[1]*Mtwara Clinical Officer Training College, Medical, Mtwara, Tanzania, United Republic of*

BACKGROUND: Young people in Tanzania need better information on contraception and sexual health. Sixty-seven percent of unmarried, sexually active women aged 15-19 are using a modern method of contraception but only 10% of these who had recent contact with a health care professional had discussed contraception and HIV/AIDS with them (Tanzanian DHS, 2015-16).

The 'COTC club' is a student-led, voluntary organisation based at the Clinical Officer Training College (COTC) in Mtwara, Tanzania that has provided interactive and informal contraceptive education and comprehensive sexual health education in schools for 10 years. The club visits 10 local schools/colleges per year to reach 2000 young people, linking COTC to its local community. They offer small group teaching by knowledgeable and well-respected 'near-peers'.

Good information on contraception and sexual health is available online and 78% of Tanzanian households have a mobile phone (TDHS, 2015-17). However, effective use of this resource requires private internet access, the ability to find suitable websites, skills to assess the quality of the information provided and links to local providers.

DESCRIPTION: We developed and piloted an intervention based on the value of linked online/offline support. The intervention adds support to classroom based contraceptive and sexual health education sessions by providing a phone number for young people to send anonymous questions by text message and posting these anonymised questions with answers a Facebook page "Tuongee Uzazi wa Mpango" (contraceptives conversations).

LESSONS LEARNED: The phone number received more than 87 sexual health questions which were answered and posted on the Facebook page which gained 2000 followers and stimulated an additional 23 questions. here are some of the questions.

Myths and misconceptions	2	No	
What is the best method of contraception?	3	Yes	How contraceptives work Natural family planning Best contraceptives for new couples Best contraception method for lactating mothers
Fertility	10	Yes	When to have sex to get a male baby
Menstrual problems	4	No	
Sexual health/HIV	4	Yes	Can masturbation cause infertility? Does family planning increase rate of HIV/AIDS infection.
Total	87		23

CONCLUSIONS/NEXT STEPS: Linking traditional contraceptive and sexual health education in schools and colleges with an online resource to provide opportunities for additional questions and continuing support is a feasible strategy for increasing access to contraceptive information and information on HIV/AIDS.

PED1024

INFORMAL / UN-ORGANIZED SECTOR LABOR - NEEDS ASSESSMENT STUDY TO DESIGN A MULTI-PRONGED STI/HIV/TB PREVENTION STRATEGY

U. Jogendra[1], P. Pankaj[1], S. Baqar[2]
[1]GAP-ISRCDE, Care and Support, Ahmadabad, India, [2]International Labor Organization, HIV/TB, Delhi, India

BACKGROUND: The Informal/unorganized sector labor is a humongous workforce in India. The National AIDS Control Program (NACP), so far covers migrant labor in the industrial sector, but there are many groups of informal and unorganized labor such as construction workers, small scale industries, catering services, garment sector workers are left out. The GAP NGO conducted a needs assessment surveys in three districts of Gujarat State India, supported by an international labor organization (ILO) to understand the vulnerabilities of such workforce to STIs, HIV, and TB develop a multi-pronged HIV prevention strategy.

METHODS: GAP conducted a mapping exercise in all the three districts of Gujarat State. GAP team including PLHIV prepared survey questionnaires and subsequently collected data from 1200 informal through face to face interviews. The data collection and analysis process continued from August to December 2019. Some of the key findings are as follows.

RESULTS:

- The mobile lifestyle increases their vulnerability to STIs and HIV.
- About 20.36% of people responded that they have had unprotected sex with more than one sex partner in the last one month.
- The survey revealed a number of hidden female sex workers and MSM.
- As high as 91% of the laborers had inadequate to no knowledge about STIs/HIV and AIDS. Though there were aware of TB.
- Condoms were not available in work-places or in their residential areas.
- ANC women laborers were not covered for the HIV test.
- About 78% of the respondents were agreeable to voluntarily HIV tests in their workplace, provided it was free of cost. Similarly, they were willing to TB screening.

CONCLUSIONS: There is an urgent need to engage with key stakeholders of this large constituency of un-organized labor, who cannot be ignored if 90:90:90 targets for HIV and sustainable development goals have to be realized.

PED1025

REPRODUCTIVE ASPIRATIONS, CONTRACEPTION USE AND DUAL PROTECTION AMONG ADOLESCENT MOTHERS LIVING WITH HIV

E. Toska[1,2,3], L. Cluver[2,4], C. Laurenzi[5], C. Wittesaele[2,6], L. Sherr[7], S. Zhou[1,8], N. Langwenya[1], HEY BABY cohort study
[1]University of Cape Town, Centre for Social Science Research, Cape Town, South Africa, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]University of Cape Town, Department of Sociology, Cape Town, South Africa, [4]University of Cape Town, Department of Child and Adolescent Psychiatry, Cape Town, South Africa, [5]Stellenbosch University, Institute for Life Course Health Research, Department of Global Health, Stellenbosch, South Africa, [6]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [7]University College London, Institute for Global Health, London, United Kingdom, [8]University of Cape Town, Department of Statistics, Cape Town, South Africa

BACKGROUND: Recently, adolescent mothers living with HIV (AMLHIV) are a group of increasing interest to policymakers and program implementers. To better shape services and health outcomes, we need evidence on reproductive aspirations and contraception use in this high-risk group.

METHODS: Between March 2018-July 2019, interviews were conducted with 1,712 adolescent girls and young women: 293 AMLHIV, 497 nulliparous adolescent girls living with HIV (ALHIV), 734 HIV-negative adolescent mothers (control adolescent mothers), and 188 HIV-negative nulliparous adolescent girls (nulliparous controls), in a mixed rural-urban district in South Africa. Standardized questionnaires included socio-demographic measures, reproductive health and contraception experiences. Ethical approvals were obtained from Universities of Oxford, Cape Town and Departments of Health and Education. Multivariate logistic regression and marginal effects models in STATA 15 were used to test associations between HIV status, adolescent motherhood and outcomes of reproductive aspirations, contraception use, and dual protection, controlling for covariates.

RESULTS: Nearly 95% of all adolescent mothers reported that their first childbearing pregnancies were unintended. Irrespective of HIV-status and motherhood, over two-thirds of all participants wanted multiple children. Hormonal contraception, condom use and dual protection were low across all groups. In multivariate regression modelling, ALHIV (mothers or nulliparous) were less likely to report dual protection (OR0.68 95%CI 0.51-0.92 p=0.013) and more likely to report no protection at last sex (OR2.99 95%CI 2.15-4.16 p≤0.001. In marginal effects modelling, adolescent mothers were least likely to report condom use at last sex. Despite higher probabilities of using hormonal contraception, rates of dual protection were low: 16.9% among control adolescent mothers and 16.3% among AMLHIV. Adolescents mothers had the highest probabilities of not being protected with any method: 28.6% among control adolescent mothers and 23.5% among AMLHIV.

CONCLUSIONS: Among adolescent girls and young women living in HIV-endemic communities, reproductive aspirations and contraceptive practices closely overlap with HIV risk and infection. Tailored service provision must account for their reproductive aspirations and contraception use and support them to practice dual protection. Adolescent-responsive health services could help young women to plan their pregnancies for when they are healthy and well-supported, as well as help interrupt the cycle of HIV transmission.

PED1026

ADVANCING THE 1ST AND 2ND 90 HIV/ AIDS GOALS THROUGH SURGE WITHIN THE OVC CONTEXT - A CASE STUDY OF 13 DISTRICTS IN WESTERN AND CENTRAL UGANDA

A. Dennis[1]
[1]*Catholic Relief Services, Kampala, Uganda*

BACKGROUND: In 2015, Uganda committed to ensure that 90% of all people living with HIV know their HIV status, of those 90% will receive sustained ART, and 90% of those on ART will be virally suppressed by 2020. Uganda has approximately 95,000 children <15 yrs living with HIV, 65,000 are on ART. HIV incidence declined to 50,000 infections per year while HIV related mortality declined to 20,000 in 2017 (UPHIA 2016-2017).

By end of 2017, results showed Uganda was not reaching its targets, with a deficit of 300,000 HIV Positives, this was attributed to the fact that Evidence-based strategies for some national guideline areas were not being rolled out uniformly, especially index/APN testing and same day initiation.

Uganda through guidance from PEPFAR adopted the SURGE Strategy which aimed at rapidly identifying individuals living with HIV and initiating them into ART. The USAID supported Sustainable Outcomes for Children and Youth (SOCY) project implemented by CRS aims at contributing to achievement of the global 90:90:90 targets through adopting SURGE Approach across all its implementing districts within the OVC context.

DESCRIPTION: SOCY used the surge Approach to identify new positives and link them into care within the OVC context. These key strategies include

Ø Establishment of district-based SURGE teams
Ø Development of District based SURGE Strategies/ SOPs
Ø Clients with unknown HIV status were identified as index
Ø Conducting HIV Risk assessment
Ø Collaboration with clinical partners to provide testing and weekly reporting to track progress and support same day linkage and ART initiation
Ø Targeted testing Approaches
Ø Application of short learning cycles and rapidly adopting other strategies

LESSONS LEARNED: SOCY implemented SURGE from April 2018 to December 2018 in 13 districts. 1,546 children 0-17 years were at risk and were tested. 35 tested HIV Positive (New) representing 2.3% HIV Yield and all the 35 (100%) children were linked to care. By end of 2018, Uganda had met the 1st 90 and 2nd 90 a remarkable achievement that SOCY is proud to have contributed too.

CONCLUSIONS/NEXT STEPS: SURGE within OVC Context has played a critical role in propelling Uganda towards the path of achieving the 90:90:90 global targets

PED1027

EDUCATION, HEALTH AND SOCIAL SECURITY FOR ORPHAN AND VULNERABLE CHILDREN:INDIA'S RESPONSE TO HIV PREVENTION

s. walia[1], D.R. Rana[1], D.N. Goel[1], N. Rawat[1]
[1]*National AIDS Control Organisation, New Delhi, India*

BACKGROUND: In India 42% of new HIV infection is among children, the prevalence is even higher in orphan and vulnerable children. This encouraged the Indian government to device programme for welfare of vulnerable children.

There is a consistent pattern of unsafe health care practices and lack of attention to HIV/AIDS amongst children in health policy. Therefore, it was pertinent to provide nutrition, stigma-free education and comprehensive care for vulnerable children.

The objective of the project was to reduce vulnerability of children of KPs by improving their access to health, education and social protection and to improve parental capacity to meet children's needs.

DESCRIPTION: The project was implemented in five states with highest HIV prevalence i.e. Andhra Pradesh (East Godavari, Guntur, Krishna), Maharashtra (Mumbai, Thane, and Pune), Manipur (Imphal East & West), Mizoram (Aizawl) and Nagaland (Dimapur).

In each district, NGOs were hired to identify children of key populations and conduct activities in structured manner.

Semi-structured interviews were conducted for key population and their children, and caregivers to assess their understanding of health, nutrition, education, psychosocial support, and social protection needs.

District specific activities were then conducted through ToTs, workshops, seminars and awareness camps on health & hygiene, HIV prevention and sexual violence, life skill education, interpersonal skills and Parenting Education on Child needs.

LESSONS LEARNED: During one year of intervention from October 2018 to September 2019, approx. 28977 children of KPs were identified of which 25173 (86.88%) children were assessed. 15575 (61.87) children were linked to various services like health need, education, social protection etc. Besides, 5338 caregivers were linked to services. Out of all the children screened for HIV, 1116 children were tested. 91 children were found positive and 81 children initiated on treatment. The focus was laid on strategies to enhance identification, assessment and service delivery to these children.

CONCLUSIONS/NEXT STEPS: Project has been quite successful in terms of mapping of children of KP and extension of security assuring them safe and HIV free life. Key findings from Phase-I of this project was disseminated through National Workshop and project was scaled up to other states during Phase II.

PED1028

TARGETED COMMUNITY-BASED SCREENING IN HIGH PREVALENCE POCKETS INCREASE THE IDENTIFICATION OF NEW POPULATION GROUPS AT-RISK FOR HIV AND UNREACHED KEY POPULATIONS IN INDIA

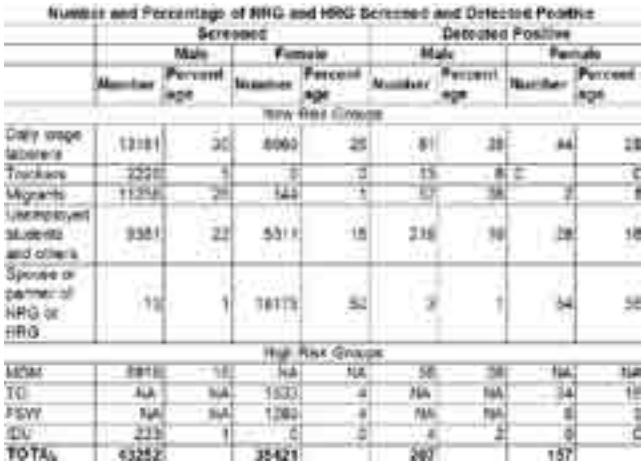
R. Chandramaulika[1], A. Bose[1], A. Hazra[1], A. Puri[2], R. Sindhu[2], L. Ganguly[1], A. Kumar[3], S. Solanki[4], A. Kushwah[5], S. Chakraborty[1], L. Ramakrishnan[1], S. Raghavan[1]
[1]SAATHII, New Delhi, India, [2]NACO, New Delhi, India, [3]Jan Vikas Samiti, Varanasi, India, [4]RCDSSS, Ajmer, India, [5]Badlaav Samiti, Indore, India

BACKGROUND: India has a concentrated epidemic with high prevalence among high-risk groups (HRG), and ANC prevalence of 0.22%. However 30% of the HRG are not reached with prevention interventions. Recent surveillance reported new epidemic trends, with 84% of the new infections occurring among New Risk Groups (NRG). Towards helping detect new HIV cases among NRG and unreached HRG, SAATHII, in collaboration with National AIDS Control Organisation, seven grass-root organizations (GRO) and support from MAC AIDS Fund, scaled-up community-based screening (CBS) in 35 districts of seven states between November 2017- December 2019.

DESCRIPTION: High prevalence and low-coverage geographies were selected for the intervention. Subsequently, GRO staff sensitized the local stakeholders and organized 1,510 CBS camps in collaboration with the government for unreached migrants, truckers, FSW, MSM/TG, construction factory and farm-workers, students, and unemployed. Camps entailed counseling, collection of data on demographics, HIV-related vulnerabilities and history of testing, and screening for HIV. Those screened positive were accompanied to the government facilities for confirmation and treatment.

LESSONS LEARNED: Over 28 months, 78,773 individuals were counseled and screened for HIV and 95% of these have never been tested before. Among these 42,962 were men, 34,276 women, and 1,535 trans-women. NRG comprised 87% of the screened with 0.40% positivity and HRG 13% with 0.91%. The new risk groups identified included daily wage laborers and unemployed and their spouses (Refer to Table 1 for details).

The location and timing of the camps held as per the convenience of the beneficiaries helped reach large populations and the family-based approach helped screen large numbers of women. The program detected 364 new HIV+ individuals and 91% of these were linked to treatment services.



[Table]

CONCLUSIONS/NEXT STEPS: Targeted community-based testing is a cost-effective strategy for reaching emerging At-Risk populations, unreached high-risk populations, and their female partners and family members.

PED1029

ASSOCIATION OF ALCOHOL USE WITH HIV AMONG MEN & WOMEN IN HOIMA DISTRICT, MID-WESTERN UGANDA

C. Baleke[1], A. Miller[2], R. Bulamba Malyabe[3], S. Mugamba[4], E. Kyasanku[1], G. Nakigozi[1], G. Kigozi[1], G. Kigozi[1], S. Watya[1], F. Nalugoda[1], J. Nkale[1]
[1]Africa Medical and Behavioral Sciences Organisation (AMBSO)-URO CARE, Population Health Survailence (PHS), Kampala, Uganda, [2]University of California, School of Medicine, California, United States, [3]Africa Medical and Behavioral Sciences Organisation (AMBSO)-URO CARE, DATA, Kampala, Uganda, [4]Makerere University Walter Reed Project (MUWRP), Community Mobilisation, Kampala, Uganda

BACKGROUND: Alcohol is the most commonly used psychoactive substance worldwide and is linked to engagement in risky sexual practices (such as unprotected sexual intercourse and multiple sex partners) that increase risk of HIV. We present findings of association between alcohol use, HIV risk behaviors and HIV prevalence among men & women in Hoima, an oil mining district in Uganda.

METHODS: We analyzed cross-sectional data of 2,291 men and women (13-80 years) participating in the Africa Medical and Behavioral Sciences Organization's (AMBSO) Population Health Surveillance study. Participants were recruited between February and April 2019. Alcohol use and HIV risk behavior in the past year were documented. Blood samples were tested for HIV using standard Ministry of Health testing algorithm. Chi square test was used to determine association between alcohol use, risky sexual behaviors and HIV among the participants. Multivariable regression was used to adjust for potential confounders including gender, age, marital status, level of education, number of sex partners and condom use.

RESULTS: Thirty one percent (31%) of participants reported alcohol use in the past year. Women were disproportionately burdened by HIV compared to men (9.3% vs 4.5%: p<0.05). HIV positive participants were more likely to drink alcohol daily or weekly compared to HIV negatives (among females: 10% vs 5%:p=0.004; among men 56% vs 38%;p=0.037). Women and men who drank daily/weekly were more likely to be HIV positive than those who don't drink alcohol (women: 17.9% vs 8.1%; p<0.05; Men 6.4% vs 3.5%; p<0.05). HIV positive participants were more likely to take alcohol before sex compared to HIV negatives (24% vs 15%: P<0.013). After adjustment, alcohol use was associated with high HIV prevalence (p=0.035).

CONCLUSIONS: This research confirms a positive association between alcohol use and HIV status. Interventions to reduce alcohol use need to be designed for this community.

PED1030

CHALLENGES OF DEAFNESS OVERSHADOW THE CHALLENGES OF AGING WITH HIV IN PALM SPRINGS, CALIFORNIA

A. Cabral[1], M. Dideiro[2,3], P. Rubin[4], C. Christenson[4], J. Taylor[4], P. Kushalnagar[5], B. Brown[6]

[1]University of California, Community Health Sciences, Los Angeles, United States, [2]David Geffen School of Medicine, University of California, Los Angeles, United States, [3]London School of Hygiene and Tropical Medicine, Public Health, London, United Kingdom, [4]HIV and Aging Research Project-Palm Springs, Palm Springs, United States, [5]Gallaudet University, Psychology, Washington D.C., United States, [6]Center for Healthy Communities, School of Medicine, University of California, Riverside, United States

BACKGROUND: Deaf individuals face language barriers that cause limitations in access to health services. Lack of understanding of Deaf culture from providers further exacerbates social marginalization that the community faces. To date, there is little to no research that ascertains the challenges of aging with HIV while Deaf.

METHODS: In Spring of 2019 we conducted an American Sign Language (ASL) focus group of self-identified Deaf older (55+) people living with HIV (PLWH) and their caregivers in Palm Springs, California. A community advisory board of PLWH (including older Deaf persons), determined the focus group questions. Deaf participants and their caregivers were asked about three topics: major health issues experienced by older PLWH, resiliencies allowing people to age successfully with HIV, and priority research topics regarding HIV and aging. Focus group facilitators were Deaf and one was living with HIV. The session was video-recorded, then interpreted and transcribed into written English by Deaf researchers. The rigorous and accelerated data reduction (RADaR) technique was used for systematic analysis of the written transcripts.

RESULTS: The focus group consisted of 3 Deaf PLWH and 4 caregivers of deaf PLWH. Of the participants with HIV, all were white with a mean age of 68 years. The central concern was the lack of access to health care due to communication barriers, such as scarcity of visual aids and information available in ASL, exacerbating lower levels of health literacy. Participants stated a need for improved standards for ASL interpreters in medical settings and a dire need for health care providers with knowledge of medical ASL. Social isolation and HIV-related stigma were also an important concern. When asked about resiliencies for aging with HIV, participants mentioned social support, medication adherence, and health information videos in ASL.

CONCLUSIONS: This study highlights gaps in knowledge about the priorities of the Deaf community living with HIV, particularly in the setting of health care research. The study revealed that the Deaf community needs improved support when accessing healthcare, irrespective of HIV care. This study emphasizes how the intersectional identities of PLWH must be kept in mind as other identities may greatly impact aspects of living with HIV.

PED1031

PREDICTORS OF HOSPITALIZATIONS DUE TO MENTAL HEALTH AMONG VULNERABLE YOUTH AT RISK FOR HIV: IMPLICATIONS FOR HIV PREVENTION

S.-J. Lee[1], P.H. Rezvan[1], R. Rezai[1], C. Goldbeck[1], M.J. Rotheram[1], _. ATN_CARES[1]

[1]University of California, Psychiatry and Biobehavioral Sciences, Los Angeles, United States

BACKGROUND: Tremendous advancements in HIV prevention have led to aspirational efforts to end the HIV epidemic. However, this goal will not be achieved without addressing the significant mental health and other risks among youth vulnerable to acquiring HIV. Among vulnerable youth, mental health impairments increase risk for HIV acquisition and lead to negative health outcomes at each step in the HIV prevention continuum. We assessed the prevalence of hospitalization due to mental health and various vulnerability indicators among youth recruited from a large prospective Adolescent Medicine Trials Network (ATN) CARES study.

METHODS: As part of the ATN CARES Study, 469 cis-heterosexual men (n=259) and women (n=120) and non-heterosexual female (n=89) youth aged 12-24 years old were recruited through social service agencies, homeless shelters, HIV care clinics, and by clinic referral in Los Angeles (n=218) and New Orleans (n=251). Hospitalization for Mental Health (HMH) was defined by participants reporting whether they have ever stayed overnight in a hospital for mental health problems in their lifetime. Vulnerability Composite Score (VCS) was derived by summing across the following indicators: moderate to severe anxiety, moderate to severe depression, homelessness, incarceration, intimate partner violence, sex exchange, suicide attempt, sexual abuse and four trauma-related indicators, alcohol abuse, illicit drug use, marijuana use, and lack of physical activity.

RESULTS: The median age at the time of enrollment was 21 years, range [14-24]. The majority of the sample were African-American (74.9%), followed by Latino (13.1%), White (7.5%), and others 5%. More than a third (40.1%) were hospitalized due to mental health in their lifetime. The mean VCS was 7.3 (SD=3.2; range [1-15]). The findings show evidence of 25% increase in the odds of HMH for a one-unit increase in VCS (aOR: 1.25, 95% CI (1.16, 1.34)), adjusting for demographic characteristics.

CONCLUSIONS: We observed a high rate of HMH and presence of multiple vulnerability risk indicators among our youth. The findings from this study underscore the importance of addressing multiple vulnerabilities negatively impacting youth at risk for HIV. Optimizing HIV prevention among vulnerable youth would require an integrated response to address mental health challenges and other risks facing youth.

PEOPLE WHO USE DRUGS (INCLUDING BY INJECTION)

PED1032

DENIAL OF PAIN MEDICATION POSITIVELY ASSOCIATED WITH ATTEMPTED SUICIDE AMONG A COHORT OF PEOPLE LIVING WITH HIV WHO USE ILLICIT DRUGS

J. Loh[1,2], S. Nolan[1,3], C. Grant[1], M.-J. Milloy[1,3]
[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [3]University of British Columbia, Department of Medicine, Vancouver, Canada

BACKGROUND: A global public health concern, chronic pain is prevalent among people living with HIV (PLWHA), and people who use illicit drugs (PWUD), especially illicit opioids. Recently, chronic pain's role as a contributing factor to the ongoing opioid overdose crisis has garnered attention, however, the consequences of denial of pain medication remain largely unexplored, especially among PLWHA who use illicit drugs living with chronic pain. Thus, we sought to measure the prevalence of being denied pain medication among PLWHA who use illicit drugs. We also sought to investigate correlates of pain medication denial among this population.

METHODS: Data were derived from the ACCESS study, an ongoing prospective cohort study of people living with HIV who use illicit drugs in Vancouver, Canada. At baseline and biannually, participants complete an interviewer-administered questionnaire eliciting information on sociodemographic characteristics, behaviours (including illicit drug use patterns, healthcare access and social/structural exposures. We used generalized estimating equations (GEE) to identify correlates of being denied pain medication among participants reporting chronic pain.

RESULTS: Between December 2011 and May 2016, 506 individuals were recruited and contributed 1950 interviews. At baseline, 49 (10.49%) individuals reported being denied pain medication in the previous six months. Over the study period, 214 individuals (11.89%) reported being denied pain medication in the past six months. In a multivariable GEE model, we found that being denied pain medication in the last six months was significantly and positively associated with self-management of pain (adjusted odds ratio [AOR] = 4.86, 95% CI: 3.16 – 7.47), and attempted suicide in the previous six months (AOR = 3.41, 95% CI: 1.77 – 6.58).

CONCLUSIONS: In our sample of PLWHA who use illicit drugs living with chronic pain, being refused pain medication was associated with self-management of pain and attempted suicide. These findings suggest that limiting access to pain medications among vulnerable populations may increase risks associated with exposure to illicit opioids through self-medication of chronic pain and elevate the risk of suicide. Future research should investigate the complexity of chronic pain, clinical responses, and policies around access to prescription analgesics among people living with HIV who use illicit drugs.

PED1033

EXPANDING ACCESS TO HIV TESTING AND DIAGNOSIS AMONG PEOPLE WHO INJECT DRUGS IN HIGH HIV BURDEN AREAS OF THE RURAL UNITED STATES

H. Surratt[1], M. Staton[1], N. Vundi[2]
[1]University of Kentucky, Behavioral Science, Lexington, United States, [2]University of Kentucky, Center for Health Services Research, Lexington, United States

BACKGROUND: HIV is increasingly impacting rural areas in the United States, tied to the ongoing opioid epidemic, growing stimulant use, and widespread drug injection. Kentucky is among states with the heaviest rural HIV burden and increasing rates of new diagnoses; in 2017, 36% of women had IDU as a transmission factor, as did 9.5% of men. Availability of HIV testing, as well as infrastructure to deliver PrEP and HIV care is limited in many rural areas of the state. However, syringe service programs (SSPs) have been implemented widely since 2015, following an HIV outbreak among injectors in southern Indiana. Many of these SSPs are located in rural communities experiencing disparities in services for people who inject drugs (PWID). This presentation examines uptake of HIV testing by PWID in 3 Appalachian Kentucky counties.

METHODS: Data is from an ongoing NIDA-funded epidemiologic study enrolling 350 PWID to examine drivers of SSP uptake. Eligible participants have injected drugs at least once in the past month and are 18+ years of age, recruited using Respondent-Driven Sampling. Enrollment occurs in health department SSPs and community-based locations serving PWID, and includes eligibility screening, informed consent and a structured interview using validated instruments.

RESULTS: 324 PWID enrolled between February 2018 and October 2019. The sample is 50.0% female and largely White (90.7%); 4 (1.2%) reported being HIV+. A majority were utilizers of SSPs (58.3%). The most frequently injected drug was methamphetamine (52.2%). Just 31.5% reported HIV testing in the prior six months. Recent HIV testing was associated with having a regular source of healthcare, having been in SUD treatment within the past year, being currently prescribed suboxone, and reported worry or concern about health behaviors. Although 48 individuals reported discussing HIV testing at the SSP, only 19 received HIV testing in these venues.

CONCLUSIONS: We observed suboptimal uptake of HIV testing among PWID in Appalachian Kentucky, including within SSPs. Increasing availability and accessibility of testing for at-risk PWID is of critical importance to stem the growth in rural HIV diagnoses. HIV self-testing has potential to decrease concerns around stigma and confidentiality in rural areas.

PED1034

COMMUNITY AFFILIATION AND ITS ASSOCIATION WITH METHAMPHETAMINE INITIATION IN YOUNG GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN: THE PINK CARPET Y COHORT STUDY

C.A. O'Hara[1], W.L. Koh[2], D. Le[3], A. Tan[3], A. Tyler[3], C. Tan[3], C. Kwok[3], S. Banerjee[3], C.S. Wong[4,1], M.L. Wong[2], M.I.-C. Chen[2,4], R.K.J. Tan[2]
[1]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, [2]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [3]Action for AIDS Singapore, Singapore, Singapore, [4]National Centre for Infectious Diseases, Singapore, Singapore

BACKGROUND: Young gay, bisexual and other men who have sex with men (YMSM) are especially vulnerable to the risks associated with substance use, including HIV and other sexually transmitted infection (STI) acquisition. The use of amphetamine-type substances such as methamphetamine among YMSM in sexual contexts has been established as a major risk factor for HIV/STI acquisition, however less work has explored how varying measures of community affiliation may simultaneously be associated with substance use. This study explores the association between community connectedness, outness, and age of sexual debut with methamphetamine initiation among a sample of YMSM in Singapore.

METHODS: Results of this study were derived from baseline data of the Pink Carpet Y Cohort Study in Singapore. The Pink Carpet Study is Singapore's first prospective cohort study among YMSM, comprising a sample of 570 non-heterosexual, gender-diverse men aged 18 to 25 years old who were HIV-negative or unsure of their HIV status upon recruitment. Participants were recruited for the baseline between May to September 2019 through social media and a network of community-based groups. Statistical analyses were conducted through descriptive statistics and multivariable Poisson regression.

RESULTS: Among 570 participants who comprised the baseline sample of the cohort, 4.9% (n=28) of the sample reported ever using methamphetamine. The mean age of sexual debut was 17.7 years (SD=3.08). Multivariable analyses revealed that community connectedness (aPR=0.92, 95%CI 0.84-1.00) and an older age of sexual debut (aPR=0.86, 95%CI 0.79-0.94) were negatively associated, while ever having suicide ideation (aPR=3.81, 95%CI 1.50-9.70) and outness to family (aPR=1.28, 95%CI 1.00-1.64) were positively associated with ever using methamphetamine.

CONCLUSIONS: Results suggest that a younger age of sexual debut, or being exposed to sexual networks at a younger age, as well as other psychosocial risks associated with suicide ideation and being out to one's family were associated with methamphetamine initiation in this sample of YMSM. Future interventions should consider developing harm reduction interventions addressing the potential risks associated with methamphetamine use, and psychosocial interventions to YMSM who are sexually active or more out at an earlier age.

PED1035

RELIGION AND INTERNALIZED STIGMA AMONG HIV-POSITIVE PEOPLE WHO INJECT DRUGS (PWID) IN KAZAKHSTAN

T. McCrimmon[1], L. Gilbert[1], M. Darisheva[2], M. Chang[1], T. Hunt[1], A. Terlikbayeva[2], S. Primbetova[2], E. Wu[1], N. El-Bassel[1]
[1]Columbia University, Global Health Research Center of Central Asia, New York, United States, [2]Global Health Research Center of Central Asia, Almaty, Kazakhstan

BACKGROUND: Kazakhstan's HIV epidemic is concentrated primarily among people who inject drugs (PWID). Internalized or self-stigma among HIV-positive PWID can hinder both disclosure of HIV status and treatment-seeking behaviors, thereby perpetuating the spread of the virus. Despite this, there has been little regional research on the structural drivers of internalized stigma, including social and cultural determinants such as religion. This study seeks to explore the association between religion and internalized stigma among HIV-positive PWID in Kazakhstan.

METHODS: We recruited and enrolled 616 HIV-positive PWID between 2017 and 2019 in four cities in Kazakhstan. Participants completed a computerized self-assessment, which included questions on religion's influence in their lives and religious service attendance. It also included the PLHIV Stigma Index, which has a 15-item subscale for internalized stigma. We used descriptive statistics and multiple regression analyses to describe and examine the association between religious affiliations and internalized stigma.

RESULTS: Participants were mostly male (n=450, 73.1%) and of Russian ethnicity (n=360, 58%). The majority (n=413, 67.1%) identified as Christian. When asked how much influence religion had on their life, 182 (32.2%) reported no influence, 238 (42.0%) reported some influence, and 146 (25.8%) reported a large influence. Participants of all religious backgrounds reported experiencing internalized stigma. More than half reported that they felt guilty (n=364, 59.1%), or blamed themselves (n=367, 59.6%) for their HIV status. Many reported self-stigmatizing avoidance behaviors in response to their HIV status, the most common being deciding not to marry (n=130, 21.1%) or have more children (n=167, 27.1%). Multiple regression showed that both an increase in the influence of religion (b=.117, 95% CI: 0.121, 0.729) and increased frequency of church attendance (b=.126, 95% CI: 0.069, 0.318) were significantly associated (p<.01) with a higher number of affirmative responses on the internalized stigma subscale.

CONCLUSIONS: HIV-positive PWID in Kazakhstan exhibit high level of internalized stigma, which may present barriers to testing and treatment among this key population. Our results suggest that stronger religious affiliation is associated with increased experience of internalized stigma. This suggests the importance of including faith leaders and faith-based communities in stigma reduction efforts in the region.

PED1036

PUBLIC OR PRIVATE - WHICH WAY TO GO? A QUALITATIVE STUDY OF HIV-POSITIVE PATIENTS' NAVIGATION OF ADDICTION CARE IN SAINT PETERSBURG, RUSSIA

M. Vetrova[1,2], O. Toussova[1], E. Blokhina[1], N. Bushara[1], B. Idrisov[3,4], S. Bendiks[2], S. Rossi[2], J.H. Samet[2,5,6], E. Krupitsky[1,7], D. Lioznov[1,8], K. Lunze[2,6]

[1]Pavlov University, St. Petersburg, Russian Federation, [2]Boston Medical Center, Boston, United States, [3]Bashkir State Medical University, Ufa, Russian Federation, [4]Federal Research Institute for Health Organization and Informatics of Ministry of Health of the Russian Federation, Moscow, Russian Federation, [5]Boston University School of Public Health, Boston, United States, [6]Boston University School of Medicine, Boston, United States, [7]National Medical Research Center of Psychiatry and Neurology, St. Petersburg, Russian Federation, [8]Smorodintsev Research Institute of Influenza, St. Petersburg, Russian Federation

BACKGROUND: Less than a quarter of HIV-positive people who inject drugs (PWID) in Russia utilize addiction care. This qualitative study explored experiences of HIV-positive PWID navigating addiction care at private and public facilities.

METHODS: We conducted 41 qualitative in-depth interviews with healthcare providers (n=26: 13 physicians at addiction, HIV, TB, general care clinics and prisons; 6 social workers and 7 psychologists; median age 36 years, 58% female) and patients (n=15, median age 35 years, 33% female) from medical facilities and nongovernmental organizations in St. Petersburg, Russia. Purposive sampling aimed to recruit those most insightful about care organization and navigation in clinical settings. Thematic data analyses using NVivo 11 were guided by a socio-ecological healthcare model considering policy, institution, care team, and patient level factors of care in the public and private sectors.

RESULTS: Perspectives of providers and patients were consistent for policy, institution, and care team barriers; those included: the bureaucratic burden of registration as a PWID, which is required for free addiction care at public settings and limits citizen rights, raising confidentiality concerns; high care costs in the private sector; the lack of an ineffective use of resources for sufficient delivery of rehabilitation programs; ineffective communication between providers and patients; in consideration for patients' health literacy; and failure to use motivational approaches with patients. Providers reported that private addiction clinics lacked preventive HIV services and linkage to community organizations with HIV clinical services. On a patient-level, the providers perceived patients as demanding and unmotivated, while patients perceived treatment as ineffective. Patients in both settings felt powerless and hesitated accessing addiction care due to previous negative experiences.

CONCLUSIONS: Registration policy is the public sector's major barrier for care utilization, while the private sector lacks HIV prevention and linkage to rehabilitation. Healthcare providers in both sectors should be offered motivational training, while patients should be offered empowering interventions to help access and navigate addiction healthcare.

PED1037

ENACTED DRUG USE STIGMA AS A BARRIER TO HIV VIRAL SUPPRESSION AMONG PEOPLE WHO INJECT DRUGS IN INDIA

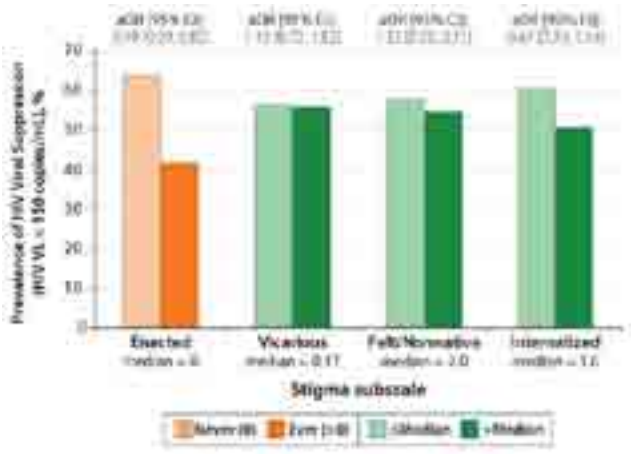
E.U. Patel[1], S.S. Solomon[1,2,3], A.M. McFall[1], N. Prata Menezes[1], A.K. Srikrishnan[3], M.S. Kumar[3], S. Anand[3], D.D. Celentano[1], G.M. Lucas[2], S.H. Mehta[1]

[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, [3]YR Gaitonde Centre for AIDS Research and Education, Chennai, India

BACKGROUND: HIV viral suppression among PWID in most low-and-middle-income settings is well below the UNAIDS 2030 target. In the era of universal ART, it is critical to understand residual barriers to viral suppression among PWID. Despite the pervasiveness of drug-related stigma, limited data exist regarding its association with viral suppression.

METHODS: A cross-sectional sample of 11,721 PWID was recruited from 12 Indian cities using respondent-driven sampling (8/2016-5/2017). Participants had to be ³18 years and report injection drug use (IDU) in the past 2 years. Surveys captured data on four domains of drug use stigma: enacted, vicarious, felt/normative, and internalized (5-6 items/domain). Each subscale had a range of 0-3 (Cronbach's a >0.85 for all). For each item and subscale, multilevel logistic regression examined associations with viral suppression (VL<150 copies/mL) among previously diagnosed HIV-infected participants who were ART-eligible according to concurrent national treatment guidelines. Analyses used RDS-II weights.

RESULTS: Of 2,517 HIV-infected PWID, 987 were diagnosed and ART-eligible (81% male; median age, 38 years) of whom 56.1% were virally suppressed. The median scores for vicarious, felt/normative and internalized stigma were 0.17, 2.0, and 1.6, respectively; 34.8% reported enacted stigma. After adjustment for age, sex, education, alcohol use, active IDU, and region, those who reported any experience of enacted stigma had half the odds of viral suppression (aOR=0.49 [95%CI=0.29-0.82]) (Figure). Of the individual items, those who had ever received a threat of physical harm because of their drug use were less likely to be virally suppressed (aOR=0.46 [95%CI=0.33-0.64]), as were individuals who felt that they use drugs because they are paying for their karma or sins (aOR=0.49 [95%CI=0.29-0.82]).



[Figure]

CONCLUSIONS: Among PWID in India who were aware of their HIV status and should have been on ART, experiences of stigma related to drug use, not necessarily just within healthcare settings, were a significant barrier to viral suppression.

PED1038

PERCEPTIONS OF OPIOID SUBSTITUTION THERAPY AMONG PEOPLE WITH HIV WHO INJECT DRUGS AND THEIR INTIMATE PARTNERS IN KAZAKHSTAN

S. Landers[1], T. Nussinov[1], G. Mergenova[2], L. Sarsembayeva[2], V. Gulyaev[2], S. Primbetova[2], A. Terlikbayeva[2], A. Davis[1]
[1]Columbia University School of Social Work, New York, United States, [2]Columbia University Global Health Research Center of Central Asia, Almaty, Kazakhstan

BACKGROUND: Eastern Europe and Central Asia is the only region globally in which rates of incident HIV infections continue to rise, primarily due to injection drug use. Opioid substitution therapy (OST) may help individuals overcome drug dependency and increase adherence to antiretroviral therapy, but such programs are not yet widely available. In Kazakhstan, pilot methadone programs have been implemented in several cities, but the government must decide whether to expand or reduce them. To provide insight, this study examines perceptions of OST among HIV-positive people who inject drugs (PWID) and their intimate partners in Kazakhstan.

METHODS: Interviews were conducted with 20 HIV-positive PWID and 18 of their intimate partners as part of a couple-based study in Almaty, Kazakhstan. Interviews were conducted in Russian, transcribed verbatim, and then translated into English. Transcripts were coded using thematic analysis.

RESULTS: Many participants expressed negative perceptions of OST that stemmed from mistrust or misperceptions about methadone. Participants reported concerns that methadone was more harmful than illegal narcotics and was only another addictive substance. Other concerns included the time-intensive nature of the treatment, potential legal problems registering with a narcotics center, and apprehensions that the government could revoke the program and leave people to suffer without treatment. Some participants recounted anecdotes from the media about detrimental effects of methadone. Fewer participants expressed positive perceptions of methadone; perceived benefits included improved quality of life (work, relationships), positive effects on health, and reduced legal concerns because it is a decriminalized substance. All three participants currently using methadone reported feeling satisfied with the treatment, appreciated its health benefits, and were grateful for an improved quality of life. The two participants who previously used methadone but stopped treatment reported experiencing negative physical and psychological effects.

CONCLUSIONS: Many PWID and their partners in Kazakhstan express negative perceptions of methadone. Misperceptions about OST may stem from media campaigns in neighboring countries that have strict bans on OST. If OST programs are to continue in Kazakhstan, a concerted effort should be made to combat misperceptions to increase uptake. Additionally, introducing new OST methods that are not susceptible to abuse, such as buprenorphine, could benefit this population.

PED1039

SELF-STIGMA FACED BY PEOPLE WHO INJECT DRUGS IN KACHIN STATE, MYANMAR

P.T. Chit[1], Y.M. Thaung[1], R. Whelan[2], H.T. Thwin[1], K.P. Naing[1], Y. Htoon[3]
[1]Community Partners International, USAID HIV/AIDS Flagship Project (UHF), Yangon, Myanmar, [2]Community Partners International, Research Department, Yangon, Myanmar, [3]Metta Develpment Foundation, Yangon, Myanmar

BACKGROUND: Injecting drugs is one of the main drivers of HIV/AIDS in Myanmar, especially in northern Kachin State. The 47% prevalence of HIV/AIDS among people who inject drugs (PWID) in Kachin is significantly higher than the already high (35%) national prevalence of HIV/AIDS among PWID. The compounded stigma against HIV/AIDS and PWID can present a major obstacle in care-seeking, and therefore prevention and control of HIV/AIDS at local, national, and global levels. In Kachin, organizations like Metta Development Foundation combat stigma against HIV/AIDS and PWID through community education and mobilization to encourage social reintegration. This study aimed to characterize the level of self-stigma that PWID in Kachin State experience.

METHODS: From May-July 2019, a survey was conducted in four townships in Kachin state where Metta implements HIV/AIDS prevention programs. Snowball sampling was used to interview PWID who had received HIV/AIDS- and/or methadone-related health services. The 40-item Substance Abuse Self-Stigma Scale (Luoma et al.) with a 5-point Likert scale was translated into local languages to assess self-devaluation, fear of enacted stigma, stigma avoidance, and values disengagement.

RESULTS: Among 222 participants (Mean age 31.8, SD±7.7), all were male (98%) and used heroin (99%) but poly-use was common (61%). Participants having monthly income <US$64 were significantly associated with higher self-stigma and higher value disengagement compared to those who had monthly income >US$64 ($p<0.05$). Respondents who were widowed or divorced experienced more self-devaluation than those who were single ($p<0.05$). Prior arrest for drug use was associated with higher fear of enacted stigma ($p=0.04$).

CONCLUSIONS: PWID reported experiencing multiple dimensions of self-stigma, and factors like marital status, income, and prior arrest for drug use increased the level of self-stigma for specific domains. Planning social integration and support of PWID as part of HIV/AIDS-related service delivery should take these factors into consideration. While the drug use epidemic in Myanmar is concentrated in men, the study sample reflects the challenges of reaching the "hidden population" of female PWID. A Substance Abuse Self-Stigma Scale that is culturally adapted for the local context in Myanmar should be developed and validated for future studies.

PED1040

SYPHILIS INFECTION AMONG PEOPLE WHO USE DRUGS AND INJECT DRUGS IN CAMBODIA: FINDINGS FROM A NATIONAL SURVEY USING RESPONDENT DRIVEN SAMPLING METHOD

P. Chhoun[1], K. Prem[2], N. Chann[3], S. Tuot[1], S. Eng[1], P. Mun[3], G. Mburu[4], S. Yi[1,2,5]

[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [3]National Center for HIV/AIDS, Dermatiology and STD, Surveillance Unit, Phnom Penh, Cambodia, [4]Lancaster University, Division of Health Research, Lancaster, United Kingdom, [5]Touro University California, Center for Global Health Research, Vallejo, United States

BACKGROUND: Globally, syphilis is a cause of significant health burden, and one of the four most frequent curable sexually transmitted infections (STIs). Although STI control is recommended as part of harm reduction and HIV programs, research and services devoted to syphilis among people who use and inject drugs (PWUD/PWID) remain limited, particularly in low- and middle-income countries. We conducted this cross-sectional study to explore the prevalence and correlates of syphilis infection among people who use and inject drugs (PWUD/PWID) in Cambodia.

METHODS: This national survey was conducted in 2017 among PWUD/PWID recruited from the capital city and 11 major provinces using the Respondent Driven Sampling method. We used a structured questionnaire for face-to-face interviews, and syphilis was diagnosed using SD Bioline HIV/Syphilis Duo test. A multivariable logistic regression model was constructed to identify independent risk factors associated with syphilis infection. The National Ethics Committee for Health Research (NECHR) of the Ministry of Health, Cambodia (No. 193 NECHR) approved this study.

RESULTS: After excluding 62 participants who did not meet the eligibility criteria, this study included 1677 PWUD/PWID, with a mean age of 28.7 (SD= 7.9). The prevalence of syphilis among PWUD in the study was 3.4% (95% CI= 2.4-4.6). After adjustment, syphilis infection was positively associated with being female (AOR= 2.97, 95% CI= 1.26-7.01), living on the street (AOR= 3.44, 95% CI= 1.27-9.32), having an average monthly income in the past 6 months of <US$300 (AOR= 2.25, 95% CI= 1.05-4.82), having transactional sex in the past three months (AOR= 2.40, 95% CI= 1.25-4.61), and having been to a rehabilitation center in the past 12 months (AOR= 2.54, 95% CI= 1.01-6.57). Syphilis infection was negatively associated with having attained at least high school level of formal education (AOR= 0.28, 95% CI= 0.08-0.98).

CONCLUSIONS: This study identified several socio-demographic, behavioral, and structural factors that may determine syphilis infection among PWUD/PWID in Cambodia. We suggest that harm reduction policy should incorporate training of harm reduction staff on STI screening and education and strengthening the availability of point of care test using dual HIV/syphilis test, particularly for marginalized PWUD/PWID.

PED1041

SOCIO-COGNITIVE FACTORS INFLUENCING ACCESS TO HIV PREVENTION SERVICES AMONG PEOPLE WHO INJECT DRUGS IN DAR ES SALAAM, TANZANIA

S. Likindikoki[1], D. Meyrowitsch[2], G. Leyna[1,3], M. Leshabari[1], M. Mizinduko[1], A. Mwijage[1], N. Makyao[4], B. Tersbøl[2], T. Lange[2], K. Moen[5], E.J. Mmbaga[1,5]

[1]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of, [2]University of Copenhagen, Copenhagen, Denmark, [3]Tanzania Food and Nutrition Centre, Dar es Salaam, Tanzania, United Republic of, [4]Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, United Republic of, [5]University of Oslo, Oslo, Norway

BACKGROUND: Globally, People Who Inject Drugs (PWID) have limited access to health services. There is a paucity of data on factors influencing access to Comprehensive HIV Intervention Package (CHIP) in Tanzania. We assessed socio-cognitive factors affecting access to different HIV prevention services among PWID in Dar es salaam, Tanzania.

METHODS: A cross-sectional survey using respondent driven-methodology was performed among PWID aged 18 and above living in Dar es Salaam. Data on access to HIV services and socio-cognitive factors were collected through face-to-face interviews. Weighted logistic regression analyses were used to measure associations between socio-cognitive factors and access to HIV prevention services. Adjusted Odds Ratio (aOR) and corresponding 95% confidence Interval (CI) were reported. All the analyses were two tailed and significance level was set at 5%.

RESULTS: A total 611 participants (94%=male) with a median 34 years (IQR 29-38) were recruited. High perceived risk of HIV was significantly associated with decreased odds of access to; HIV testing services (HTS) [aOR=0.3; CI95%: 0.1-0.5], condom [aOR=0.1; 95%CI: 0.02-0.5], use condom [aOR=0.2; 95%CI: 0.2-0.8], peer educator service [aOR=0.4; 95%CI: 0.2-0.8], clean needle [aOR=0.1; 95%CI: 0.1-0.3]. Being employed [aOR=4.9; 95%CI: 1.3-18.5] was associated with increased access to HTS. Being a female, [aOR=8.3; 95%CI: 1.3-54.3], having completed primary education [aOR=1.8; 95%CI: 1.1-3.2] and having correct comprehensive HIV knowledge (CCHK) [aOR=1.8; 95%CI: 1.1-2.9] were associated with increased condom use. Internalized stigma (aOR=2.9; 95%CI: 1.3-6.2] and exposure to physical and sexual violence (aOR=4.4; 95%CI: 1.3-15.3) were associated with higher odds of utilization of peer education services. Exposure to sexual violence was associated with decreased odds of accessing clean needle (aOR=0.4; 95%CI: 0.1-0.9).

CONCLUSIONS: The results suggest that socio-cognitive factors play a major role in influencing access to different HIV prevention services among PWID. There is an urgent need for health education interventions to strengthen CCHK and impacting HIV risk perception. Addressing both physical and sexual violence as well as stigma and discrimination will go a long way in promoting access to health services. These results will inform ongoing efforts to "closing the tap" and realize the 90-90-90 targets in Tanzania.

PED1042

HIV PREVALENCE AND TREATMENT CASCADE AMONG OPIOID-USING PROBATIONERS IN THREE CITIES, UKRAINE

N. Saichuk[1], S. Dvoriak[1], K. Dumchev[1], E. Gryshayev[1], O. Chernova[1], J. Rozanova[2], F. Altice[2]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Yale University School of Medicine and School of Public Health, New Haven, United States

BACKGROUND: In Ukraine, many offenders sentenced for drug-related crime are not incarcerated, but are put on probation and reside in the community. They are living with or are at risk of HIV transmission due to high prevalence of injecting drug use. Access to HIV prevention and treatment for drug users and probationers is limited due to high level of stigma and multiple systemic barriers. The objectives of this study is linking probationers to Opioid Agonist Treatment (OAT), an evidence-based method of opioid dependence treatment and HIV risk reduction.

METHODS: We used baseline data from project MATLINK, studying an intervention for OAT enrollment for probationers. Potential participants were referred by officers to interviewers for study screening during regular probation visits. The eligibility criteria included being registered in probation in the study catchment area, meeting criteria for opioid dependence and not receiving OAT for at least 15 days. Eligible participants completed baseline assessment including an HIV test and a structured interview. History of incarceration was analysed as predictor of access to services using multivariate logistic regression.

RESULTS: We screened 1298 people in three cities of Ukraine; 182 met the eligibility criteria. 129 (70%) of them consented to participate and completed baseline assessment. 111 (86%) were males, mean age 36 years old. HIV prevalence was 44% (95%CI: 35.3%-52.7%), significantly higher among participants with incarceration history compared to those without (53.2% versus 27.9%, OR=2.9, 95%CI:1.3-6.5). In all sample, 74.6% were tested previously and were aware of their HIV status; this proportion was higher among those with incarceration history (93.6% vs 74.4%, OR=5.0, 95% CI:1.6-15.6). Among HIV-positive participants, 74.1% (95%CI:63.0%-86.1%) knew their status; proportion registered in care was 61.8% (95%CI:49.0%-74.7%), proportion receiving ART was 41.8% (95%CI: 28.8%-54.9%), with no signficiant difference by incarceration history.

CONCLUSIONS: We found that HIV prevalence in this population is high - almost double of that among drug injectors in other studies. History of incarceration increases the odds of being HIV-infected. Access to HIV testing among probationers is quite high, however access to treatment for HIV-positive is far from reaching the universal coverage goals, calling for additional programmatic efforts for this priority population.

PED1043

HOW 'INVISIBLE' WOMEN WHO USE DRUGS (WWUDS) IN COASTAL KENYA BECAME 'VISIBLE' IN ACCESSING HEALTH, SRHR THROUGH THE EFFORTS OF MUSLIM EDUCATION AND WELFARE ASSOCIATION (MEWA) WORKING WITH COMMUNITY LEADERS

A. Badhrus[1], F. Jeneby[1], R. Said[1], M. Handule[2], N. Noor[1]
[1]Muslim Education and Welfare Association, Health and Harm Reduction, Mombasa, Kenya, [2]Mainline Foundation, Harm Reduction, Amsterdam, Netherlands

BACKGROUND: WWUDs in Mombasa have been silently suffering while trapped in addiction, crippled by culturally-entrenched stigma and discrimination; and exposed to HIV and other infectious diseases. They have been regular victims of GBV, from both Police and the community. Cultural taboos and religious restrictions have had adverse effect, forcing them to be 'invisible'. Programs and interventions that mainly targeted men exposed WWUDs to further exploitation and marginalisation.

High HIV prevalence rate was evident as risky sexual behaviours with multiple sex partners was widespread.

DESCRIPTION: MEWA a local NGO partnership with Mainline Foundation delivers harm reduction services for PWUDs since 2012. MEWA's 2016 early client records indicated that approximately 1% of their clientele at the drop-in centres (DICs) was female accessing health and rights care. However, observations indicated a high number of WWUDs were not accessing services.

MEWA pioneered intervention programs targeting WWUDs by providing a variety of services from outreach to free detox, addiction treatment, clinical services, nutritional support and clothing. Working with law enforcers, religious leaders and the general community overcome their resistance to programs.

LESSONS LEARNED: Mapping undertaken by MEWA identified WWUDs in isolated dens. MEWA introduced daily meals in 'drug dens' followed by NSP and residential rehabilitation services for opioid withdrawal. Residential adherence services for HIV/TB/Methadone enabled compliance with the 90-90-90 UN HIV cascade.

WWUDs are open to SRHS when integrated within the DICs. Uptake of family planning and condoms remains low because WWUDs want to have children and those engaging in sex work are paid more when having unprotected sex.

CONCLUSIONS/NEXT STEPS: MEWA services achieved sustained viral load suppression at 83% and 100% TB cure rates among WWUDs. Additionally, disclosure and partner risk tracing has been established in the 'drug dens' for women who test positive for STIs. The introduction of special 'female space' at the DICs Increased uptake of services. Messages on GBV were developed leading to increased reporting of cases. Male involvement in programming increased as we opened up spaces that supported effective communication and improved parenting skills for couples and spouses. A final aspect of our program with WWUDs is entrepreneurship training and mentorship programs to build resilience.

PED1044

THE ROLE OF CANNABIS IN INFLUENCING ADHERENCE TO ANTIRETROVIRAL THERAPY AMONG PEOPLE LIVING WITH HIV WHO USE ILLICIT DRUGS: A QUALITATIVE STUDY

K.L. Chayama[1,2], T. Kerr[1,2], C. Ng[2], M.-J. Milloy[1,2], W. Small[2,3], R. McNeil[1,2,4]
[1]University of British Columbia, Department of Medicine, Vancouver, Canada, [2]British Columbia Centre on Substance Use, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [4]Yale University, Department of Internal Medicine, New Haven, United States

BACKGROUND: Achieving optimal adherence to antiretroviral therapy (ART) remains a challenge for many structurally vulnerable people living with HIV (PLHIV) who use illicit drugs. Given the high prevalence of cannabis use among PLHIV and evidence to support the efficacy of cannabis use in ameliorating HIV-related symptoms and co-morbidities, previous studies have sought to assess the relationship between cannabis use and adherence to ART. However, further research is needed to better understand this dynamic. This qualitative study examines how cannabis use influences ART adherence among PLHIV who use illicit drugs.

METHODS: From September 2018 to April 2019, we conducted in-depth interviews with 25 PLHIV who use illicit drugs (ages 35-64, 15 women, 10 men) in Vancouver, Canada, focusing on experiences with cannabis. All participants were ART-exposed and regularly used cannabis as well as illicit drugs. Interviews were audio-recorded, transcribed, and coded. Salient themes were identified using inductive and deductive approaches.

RESULTS: While several participants reported that cannabis had no to minimal impacts on ART adherence, others reported that cannabis use facilitated ART adherence by: (1) improving mood and motivation; (2) alleviating ART-related side effects (e.g., nausea, insomnia); and (3) improving daily functioning through management of co-morbidities (e.g., depression, chronic pain). While participants indicated a preference for cannabis over prescription (e.g., dimenhydrinate for nausea) or illicit (e.g., heroin) drugs to achieve these results, access to cannabis through medical providers was limited, and most participants continued to obtain cannabis from alternate sources (e.g., illicit market, compassion club), even after the legalization of recreational cannabis use. Illegal sources provided participants with access to their preferred cannabis strains, as well as cannabis that was free or affordable. For some participants, the closure of multiple unlicensed dispensaries after cannabis legalization posed a new challenge to cannabis access.

CONCLUSIONS: Cannabis use may improve adherence to ART for some PLHIV who use illicit drugs. Our findings offer further evidence to support the therapeutic role of cannabis in the context of HIV treatment, and suggest the need for concrete efforts to ensure equitable access to cannabis, including medical education that supports its authorization by healthcare providers, for enhanced HIV treatment and care.

PED1045

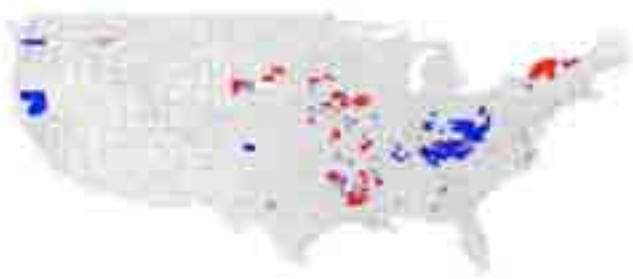
A SPATIAL ANALYSIS OF RETAIL OPIOID PRESCRIPTIONS IN U.S. COUNTIES, 2010 - 2017

A. Martinez[1]
[1]San Francisco State University, Sociology and Sexuality Studies, San Francisco, United States

BACKGROUND: Examining spatial dimensions of the opioid crisis can yield important insights for identifying local geographies of risks for HIV and Hepatitis C virus (HCV). This analysis seeks to identify spatial patterns of changes in rates of retail opioid prescriptions between 2010 and 2017 in the United States.

METHODS: This analysis utilizes geographic information systems (GIS) software to generate statistically significant clusters (hotspots, coldspots, and spatial outliers) of changes in rates of retail opioid prescriptions per 100 persons. Rates of retail opioid prescriptions per 100 persons are publicly available at the state and county level, through the Centers for Disease Control and Prevention (CDC). Clustered and non-clustered counties are compared using American Community Survey variables including poverty, race, and rural geography.

RESULTS: There are 2,734 counties in the U.S. with data points for both 2010 and 2017. 83.8% of all counties experienced a decrease in rates of retail opioid prescriptions per 100 persons. The median rate change in retail opioid prescriptions decreased by 58 prescriptions per 100 persons. Spatial analysis shows 57 high-high clusters (in red), 105 low-low clusters (in blue), 30 low-high spatial outliers (in light blue), and 18 high-low spatial outliers (in light red) (Figure 1). Clusters of counties with above average decreases in rates of retail opioid prescriptions were concentrated in the Appalachian region of the U.S.. County residents in low-low clusters, which represent counties with above average rate decreases, were 92.6% white compared to 79.8% of residents in non-clustered counties ($p<0.05$).



[Figure 1.]

CONCLUSIONS: Public health professionals can utilize opioid-related spatial data and spatial statistics to identify local geographies at elevated risks for opioid-related HIV transmission. Street-acquired opioid use could increase in counties that experience a decrease in rates of retail opioid prescriptions without an increase in availability of government subsidized drug treatment programs or syringe exchange programs.

PED1046

"TREAT THEM WHERE THEY'RE AT:" MEDICATION LOCKERS AS A MODEL FOR HIV AND HCV TREATMENT AND MEDICATION ADHERENCE AMONG PEOPLE WHO INJECT DRUGS EXPERIENCING HOMELESSNESS

R. Giuliano[1], A. Reynolds[1]
[1]*San Francisco AIDS Foundation, Syringe Access Services, San Francisco, United States*

BACKGROUND: People who inject drugs (PWID) experiencing homelessness are underserved in traditional models of medical care and experience significant health disparities, notably in HIV/HCV infection. While HCV can be cured and HIV managed successfully with daily medication, people experiencing homelessness in San Francisco can struggle with medication adherence since they lack a stable, consistent place to store and keep medications. In addition, displacement by police sweeps create significant challenges for securing belongings, including medications. In SF, only 33% of HIV-positive homeless PWID are virally suppressed compared to 74% of HIV-positive individuals overall, and 68% of active HCV infections are among PWID who comprise less than 3% of the city's population. To address these issues, San Francisco AIDS Foundation (SFAF) developed a medication locker program to improve medication adherence.

DESCRIPTION: SFAF's Harm Reduction Center is a warm and welcoming space providing injection equipment, overdose prevention, HIV/HCV/STD testing, on-site HCV and STI treatment, linkage to HIV care, health education, medical care, and the "Luv Your Liver Lounge," an HCV treatment program. Since approximately 80% of people accessing services at the Harm Reduction Center are people experiencing homelessness or unstably housed, we make available 144 medication lockers to individuals who need a safe and secure place to store HIV, HCV, PrEP or other medications. From February, 2016 to December, 2018, our HCV treatment program achieved a completion rate of 85%, with 105 of the 124 individuals who initiated HCV treatment achieving a cure.

LESSONS LEARNED: With accessible systems of care and support, PWID experiencing homelessness can successfully adhere to treatment, achieve an HCV cure, and create opportunities for increased positive health outcomes.

CONCLUSIONS/NEXT STEPS: Integrating HCV care at syringe access sites is a crucial part of addressing HCV cure rates among PWID and providing access to lockers is a model for HIV medication adherence and PrEP with this population. Building on these successes, SFAF is expanding to mobile syringe access sites with an outreach van staffed with medical providers, HCV program staff and medication storage lockers to engage individuals beyond the Harm Reduction Center.

PED1047

AMPHETAMINE-TYPE STIMULANT USE AND HIV RISKS AMONG TRANSGENDER WOMEN IN CAMBODIA: A NATIONAL SURVEY USING RESPONDENT DRIVEN SAMPLING METHOD

S. Eng[1], S. Tuot[1], P. Mun[2], P. Chhoun[1], N. Chann[2], G. Mburu[3], S. Yi[1,4,5]
[1]*KHANA Center for Population Health Research, Phnom Penh, Cambodia,* [2]*National Center for HIV/AIDS, Dermatiology and STD, Surveillance Unit, Phnom Penh, Cambodia,* [3]*Lancaster University, Division of Health Research, Lancaster, United Kingdom,* [4]*National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore,* [5]*Touro University California, Center for Global Health Research, Vallejo, United States*

BACKGROUND: Globally, transgender women are among the most vulnerable to HIV. The use of amphetamine-type stimulants (ATS) is prevalent and associated with increases in HIV infections and several other negative health outcomes in HIV key populations. However, studies on ATS use among transgender women, particularly in low- and middle-income countries have been scant. In this study, we identified the prevalence and factors associated with ATS use among transgender women in Cambodia.

METHODS: In 2016, we collected data from 1375 transgender women recruited from 13 provinces for the National Integrated Biological and Behavioral Survey using the Respondent-Driven Sampling method. We collected information on demographic characteristics, sexual behaviors, substance use, depressive symptoms, stigmatization and social support, gender-based violence, and adverse childhood experiences. Weighted multivariable logistic regression analysis was conducted to identify independent correlates of recent ATS use. This study was approved by the National Ethics Committee for Health Research (No. 420 NECHR).

RESULTS: Overall, 10.4% of the survey participants reported ATS use in the past three months. After controlling for potential confounders, recent ATS use remained negatively associated with living in rural areas (AOR= 0.47, 95% CI= 0.26-0.84) and having higher level of formal education (AOR= 0.34, 95% CI= 0.13-0.88). For HIV risks, recent ATS use remained positively associated with involvement in transactional sex in the past three months (AOR= 2.70, 95% CI= 1.83-3.98). Recent ATS use also remained positively associated with other substance use including higher frequency of binge drinking (AOR= 5.37, 95% CI= 2.77-10.42) in the past three months. Regarding mental health problems, recent ATS use remained negatively associated with a feeling that co-workers or classmates were supportive regarding their transgender identity (AOR= 0.49, 95% CI= 0.30-0.78) and positively associated with having depressive symptoms (AOR= 1.80, 95% CI= 1.21-2.66) and experiences of emotional abuse during childhood (AOR= 2.12, 95% CI= 1.33-3.39).

CONCLUSIONS: ATS was the most common illicit drugs among transgender women in Cambodia. Our findings suggest that developing and implementing additional harm reduction strategies tailored to ATS use among transgender women are needed. Integration of HIV and mental health interventions into harm reduction programs should be more focused.

PED1048

PREVALENCE AND RISK FACTORS OF HIV INFECTION AMONG PEOPLE WHO INJECT DRUGS IN CAMBODIA: FINDINGS FROM A NATIONAL SURVEY USING RESPONDENT DRIVEN SAMPLING METHOD

S. Eng[1], P. Chhoun[1], N. Chann[2], S. Tuot[1], P. Mun[2], G. Mburu[3], S. Yi[1,4,5]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]National Center for HIV/AIDS, Dermatiology and STD, Surveillance Unit, Phnom Penh, Cambodia, [3]Lancaster University, Division of Health Research, Lancaster, United Kingdom, [4]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [5]Touro University California, Center for Global Health Research, Vallejo, United States

BACKGROUND: People who inject drugs (PWID) continue to be among the most vulnerable populations to acquire HIV and hepatitis C virus (HCV) infection globally. Despite increasing program implementations, scientific data related to this key population in developing countries remain scarcely available. This study explores the prevalence of HIV and factors associated with HIV infection among PWID in Cambodia.

METHODS: This national biological and behavioral survey was conducted in 2017. Participants were recruited from 12 major provinces nationally using the Respondent Driven Sampling method. Face-to-face interviews were conducted using a structured questionnaire, and blood samples were collected for HIV, syphilis, and HCV testing. Multivariable logistic regression analysis was conducted to identify risk factors for HIV infection. All analyses were estimated with sampling weights that corrected for non-response and sample design. This study was approved by the National Ethics Committee for Health Research (No. 193 NECHR).

RESULTS: This study included 310 PWID with a mean age of 31.8 (SD= 7.8) years. The prevalence of HIV was 15.2%. Almost two-thirds (61.4%) of the HIV-positive PWID were co-infected with HCV, and 44.7% were not aware of their HIV status prior to this study. After controlling for potential confounding factors, HIV infection remained positively associated with being female (AOR= 1.88, 95% CI= 1.03-4.04), being in an older age group of ≥35 (AOR= 2.99, 95% CI= 1.33-9.22), being widowed/divorced/separated (AOR= 2.57, 95% CI= 1.04-6.67), living on the streets (AOR= 2.86, 95% CI= 1.24-4.37), and having HCV infection (AOR= 3.89, 95% CI= 1.86-8.15). On the other hand, having completed at least 10 years of formal education (AOR= 0.44, 95% CI= 0.13-0.83) and higher monthly income of ≥US$200 (AOR= 0.20, 95% CI= 0.05-0.74) reduced the odds of HIV infection.

CONCLUSIONS: The prevalence of HIV among PWID in Cambodia remains high, but is reducing compared with the 24.8% reported in the 2012 national survey. Findings from this study provide critical information for stratifying and developing HIV risk profiles for PWID and tailoring interventions based on identified vulnerabilities and risk factors for HIV. In addition, the findings underline the importance of social structural factors in HIV epidemiology among PWID, which require mitigation.

PED1049

RISK PROFILE AND ATTITUDES OF FILIPINO CISGENDER MEN WHO HAVE SEX WITH MEN TOWARD SEXUALIZED DRUG USE ('CHEMSEX') AND ACCESS TO QUALITY SEXUAL HEALTH SERVICES IN THE PHILIPPINES

R. Olete[1,2], O. Lermet[1], S. Marquez[1], K. Peters[3], L. Ocampo[4], M. Milliam[5]
[1]UNODC, Mandaluyong City, Philippines, [2]Sustained Health Initiatives of the Philippines, Mandaluyong City, Philippines, [3]UNODC- Southeast Asia and the Pacific, Bangkok, Thailand, [4]UNAIDS-Philippines, Mandaluyong City, Philippines, [5]Gabay sa Pulang Laso, Caloocan City, Philippines

BACKGROUND: As of December 2018, there are 49,078 men who have sex with men diagnosed with HIV yet condom use among this population remains below ideal (32%). Moreover, limited access to sexual health services among the subpopulation of cisgender MSM engaged in sexualized drug use (cMSM-SDU) presents a gap in HIV treatment cascade that should be addressed. This study aimed to determine the risk profile, perception, and needs of cMSM-SDU in accessing sexual health services in the country.

METHODS: A cross-sectional, online survey via social media was conducted among cMSM who use drugs from August to November 2019. A 5-point Likert scale (Cronbach's alpha=0.65) was used to determine their perception toward SDU and sexual health. Descriptive and regression analyses were used to summarize quantitative data.

RESULTS: A total of 126 cMSM who use drugs participated in the online survey (average age=33, SD=7.3). More than half were HIV positive (52.4%), 90/126 (71.4%) were engaged in SDU, 22/126 (17.5%) were injecting drug users, and 16/126 (12.7%) shared needles. Methamphetamine ('Shabu') and nalbuphine (Nubain) were the most common drugs used (19.8% and 8.7% respectively). Regression analysis found that cMSM who use drugs were twice more likely to have condomless sex (OR=2.333, 95%CI=1.055–5.161, p=0.036) and almost three times at risk for HIV (OR=2.766, 95%CI=1.193–6.415, p=0.018). There were 112/126 (88.9%) who did not have any idea where to access health services on Chemsex in the country, and 77/126 (61%) prefers to access Chemsex-related health information online. Likert scale results from 90 cMSM-SDU showed that majority agreed or strongly agreed that they knew how to safely use drugs and should get tested for HIV and other STIs because of their Chemsex behavior (67.8% and 82.4% respectively).

CONCLUSIONS: Filipino cMSM-SDU are at higher risk of HIV infection. Despite knowing their needs in accessing Chemsex-related health services, actual harm reduction programs remain inaccessible in the country. Thus, access to evidence-based sexual health information and services for cMSM-SDU should be widened through online-based outreach programs. Moreover, combined prevention strategies such as increased pre-/post-exposure prophylaxis intake and intensified condom campaigns are necessary to augment the risks associated with SDU.

PED1050

OCCASIONAL INJECTION DRUG USE AMONG RESPONDENTS TO THE GLOBAL DRUG SURVEY 2019

L.J. Maier[1], M.J. Barratt[2], J.A. Ferris[3], A.R. Winstock[4]
[1]UCSF, Clinical Pharmacy, San Francisco, United States, [2]RMIT University, Social and Global Studies Centre, Melbourne, Australia, [3]University of Queensland, Centre for Health Services Research, Brisbane, Australia, [4]University College London, Institute of Epidemiology and Health Care, London, United Kingdom

BACKGROUND: Injection drug use is associated with increased risk for HIV and Hepatitis C infections. It is usually assumed that people who inject drugs do this daily and that syringe access programs and supervised consumption facilities are the best way to prevent harm related to the practice or actual substance use. However, there are also people who inject drugs occasionally and little is known about their polysubstance use behavior that may increase the risk for HIV infections.

METHODS: Data from the Global Drug Survey (GDS) 2019, the largest anonymous web survey on drug use, were analyzed to explore substance use behavior and overdoses among people who recently injected drugs. In addition, all respondents were asked to indicate whether they think that supervised consumption facilities are an effective strategy to reduce the risks of injection drug use.

RESULTS: Of 112,246 respondents who answered the question on supervised consumption sites, only 83.4% agreed that this was an effective strategy to reduce the risks from injection drug use. Of the sample, 7.1% reported ever having injected a drug, only some of them used heroin, less than half injected in the last 30 days (2.9% on average, highest in the U.S. with 6.9%) and the median number of days injected in the last 30 days was 7. Only 120 people reported overdosing on heroin and one third was administered naloxone. Recent heroin use was associated with self-reported depression and psychosis (p<.001).

CONCLUSIONS: This is the first multinational analysis that analyzed substance use patterns of people who inject drugs mostly occasionally. In addition to providing harm reduction services to prevent HIV and Hepatitis C people who inject drugs occasionally may also benefit from mental health treatment and open dialogues that help reduce stigma related to injection drug use.

PED1051

IMPACT OF RECREATIONAL DRUG USE ON CLINICAL OUTCOMES, EMOTIONAL WELL-BEING AND HEALTH-RELATED QUALITY OF LIFE IN PEOPLE LIVING WITH HIV: A MULTICENTER OBSERVATIONAL RETROSPECTIVE COHORT STUDY

M.J. Fuster-Ruiz de Apodaca[1], V. Castro-Granell[2,3], A. Jaen[4], J. Casado[5], N. Garin[6], L. Leal[7], S. Cenoz[8]
[1]Sociedad Española Interdisciplinaria del SIDA (SEISIDA), Madrid, Spain, [2]Hospital Marina Baixa, Villajoyosa, Spain, [3]Programa de Farmacia de la Universidad de Granada, Granada, Spain, [4]Fundació Recerca i Docència Mutua Terrassa, Barcelona, Spain, [5]Hospital Ramón y Cajal, Madrid, Spain, [6]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [7]Hospital Clínico, Barcelona, Spain, [8]ViiV Healthcare, Madrid, Spain

BACKGROUND: This study analyzed the impact of recreational drug use (RDU) on clinical outcomes, emotional well-being, and health-related quality of life (HRQoL) in people living with HIV (PLHIV) in Spain.

METHODS: Two cohorts of PLHIV taking antiretroviral therapy (ART) for at least one year were recruited between April 2017 and May 2018 according to their RDU: frequent RDU (consumption ≥1 drug ≥10 times a year, excluding the use of methadone, morphine, and cannabis as a single drug) vs. no-RDU. We collected the following retrospective last 12-month clinical data from clinical records: ART adherence (pharmacy refill), CD4, CD4/CD8 ratio, viral load, resistance to and adverse effects of ART, previous clinical conditions, and use of health services. ART adherence, HRQoL, and psychological well-being were measured through validated tools (CEAT-VIH, WHO-QoL-HIV-BREF, and GHQ-12). These variables and self-reported sexually transmitted infections (STIs) were collected at the inclusion visit through a cross-sectional survey. Differences between groups were analyzed through Chi-square, Student T for independent samples, and mixed analysis of variance (ANOVA) using SPSS v.22.

RESULTS: A total of 275 PLHIV were included; 12 were excluded by protocol deviation. The final sample was composed of 51.3% RDU and 48.7% non-RDU. Most participants were male (93.5%) with an average age of 45.8±10.8 years. RDU patients presented lower scores of ART adherence (p=.017, and p=.006, for multi-interval adherence and self-reported adherence respectively), more visits to the emergency unit (p=.046), and marginally more non-AIDS related events (p=.061) but fewer visits to their specialist physician (p=.059). ANOVA results showed that there were significant interactions both between the group membership and the change between the first determination vs. the last in the percentage of CD8 and the CD4/CD8 ratio (p=.020, and p=.024 respectively) during the follow-up year. While the percentage of CD8 decreased among non-RDU, it remained stable among RDU; and while the CD4/CD8 ratio increased among non-RDU, it decreased among RDU. RDU presented lower scores in HRQoL (p< .0001) and emotional well-being than non-RDU (p< .0001).

CONCLUSIONS: This observational retrospective cohort study shows evidence that recreational drug use could worsen PLHIV health outcomes.

PED1052

INJECTION BEHAVIOR AMONG PWID RECRUITED BY PEER DRIVEN INTERVENTION

M. Gogia[1], T. Kasrashvili[1], T. Zurashvili[1], G. Jikia[1]
[1]Georgian Harm Reduction Network, HIV and HCV Prevention, Tbilisi, Georgia

BACKGROUND: HIV epidemic is concentrated among key populations, specifically among PWID and MSM population in Georgia. Among all HIV registered cases IDU associated transmission is 38.1%. Needle and syringe program operating in Georgia since 2001 have a strong positive impact on individual and community health. Only 62% of PWID population are covered by harm reduction program, significant part remains hidden and their behavior not assessed.

METHODS: Peer-driven intervention including cross sectional study design and snowball/Respondent Driven sampling was applied to reach hidden population. HIV risky behavior and knowledge were assessed by standardized instrument Risk Assessment Battery (RAB) among PWID that were never covered by harm reduction program before. Overall 1820 PWID were recruited for the study during 9 month in 2018-2019 in 11 cities of Georgia. Uni and bi-variation analysis was performed by SPSS v.21.

RESULTS: Study results showed that 53% participants are sharing injecting paraphernalia (bottle, spoon, boiling pan/glass/container, cotton/filter) and 34% only syringe during last 6 months. Paraphernalia sharing practice is more common is small cities. 73.2% of participants reported injection in a big group (up to 3 members). 30% of respondents say that they are cleaning the used syringes by: boiled water

(57%), soapy water (27%). Few people use chlorine, alcohol, soda and urine for syringe cleaning. Main source for syringes (80%) is Needle and Syringe programs, 33% got syringes at drug cooking places or from drug dealers, 11 persons used syringes that were found in the street. A quarter of respondents indicate to use not sterile cotton for drug filtering. Knowledge of HIV transmission among study participants is rather satisfactory, 80% of them answered all 5 questions correctly; In total RAB index is 0.6 (max rate is 1).

CONCLUSIONS: The study results show that using non-sterile equipment is more common among PWID that don't use harm reduction services. Use of paraphernalia is more frequent that using needles/syringes. Increased efforts should be done to educate PWID on safer injection practice, paying attention on using sterile injection tools and discuss the disadvantages of widespread syringe rinsing practices; and motivate them to be involved in existing harm reduction programs.

PED1053

PROMOTING A "ONE-STOP-SHOP HARM REDUCTION MODEL" FOR WOMEN WHO USE DRUGS IN HARD TO REACH SETTINGS – FINDINGS FROM A DEMONSTRATION PROJECT IN INDIA

B. Ubarhande[1], V. Arumugam[1], K. Kishor[2], R. Prasad[2]
[1]Alliance India, Strategic Information, Delhi, India, [2]Alliance India, Program, New Delhi, India

BACKGROUND: In India, an estimated 177000 people who inject drugs (PWID) and HIV prevalence among the PWID is 9.9%. Women injecting drug users in India is estimated around 30,000. Women face more severe consequences because their drug use may severely transgress gender roles and social norms. In India, harm reduction services for women are available scarcely and are not comprehensively implemented in line with WHO recommendations. India HIV/AIDS Alliance is the Principle Recipient of the Global Fund Regional Harm Reduction Advocacy grant (2017-2020) across seven Asian countries (HR Asia) and implements a women-centric harm reduction services to demonstrate effectiveness and feasibility of the same in the project countries leading to 90-90-90 in India.

DESCRIPTION: India HIV/AIDS Alliance developed an integrated harm reduction strategy building on a 2 pronged approach i.e., a) community mobilization and outreach and b) a one-stop-shop women-friendly comprehensive model that directly provides all 9 WHO recommended harm reduction services at one location. As a result, 150 WWIDs are registered till date and are receiving a one-stop-shop woman-friendly comprehensive harm reduction services at one location. The initial findings from the first 9 months of implementation led to HIV testing (98%), Hepatitis C testing (89%), initiated on OST (51%), 33% of women are tested for TB, 11% of women received NSP services and 83% (n=12) of HIV positive clients initiated ARV treatment.

LESSONS LEARNED: Integration of HIV and harm reduction services in one place needs convergence and mainstreaming of different ministries. Providing all harm reduction services at one location may be cost-effective, feasible and replicable. Integration of community approach and providing comprehensive services at one place increases the accessibility for harm reduction services among WWUDs.

CONCLUSIONS/NEXT STEPS: Replicate the one-stop-shop women-friendly comprehensive harm reduction model at the sub-national, national and regional in Asia based on the cost-effectiveness, feasibility etc.

PED1054

TRANSACTIONAL SEX AS A PATHWAY FOR HIV AND RISING SEXUALLY TRANSMITTED INFECTIONS AMIDST THE OPIOID EPIDEMIC

M. Ellis[1], S. Scroggins[1], Z. Kasper[2], T. Cicero[2], E. Shacham[1]
[1]Saint Louis University, College for Public Health and Social Justice, Saint Louis, United States, [2]Washington University in St. Louis, Saint Louis, United States

BACKGROUND: Recently, the United States has experienced increases in associated human immunodeficiency virus (HIV), sexually transmitted infections (STIs) and opioid use disorder. Discussion of HIV/STIs in association with the opioid epidemic typically center on injection drug use and needle-sharing. However, there are other pathways of infection associated with substance use, in particular the exchange of oral, anal or vaginal sex for drugs (i.e., transactional sex). The purpose of this study was to examine the prevalence and associated factors of transactional sex among a sample of chronic opioid users.

METHODS: Individuals entering one of 91 treatment centers across the United States for opioid use disorder (N=1,594) in 2018-2019 were surveyed on sociodemographic variables, opioid use patterns, the trading of sex (e.g., oral, anal or vaginal) for drugs, and history of HIV/STI diagnosis/treatment.

RESULTS: Transactional sex was endorsed by 24.0% of treatment-seeking opioid users. Sexual minorities had exceptionally high rates compared to heterosexuals (56.0% vs. 18.8%, p<0.001), as did females compared to males (41.7% vs. 13.5%, p<0.001) and opioid injectors compared to non-injectors (31.8% vs. 18.1%, p<0.001). In terms of HIV/STI history, those who exchanged sex for drugs were significantly more likely than those who have not to have been diagnosed with HIV (3.7% vs. 1.3%, p=0.002). In addition, transactional sex was associated with a greater prevalence of least one STI (59.7% vs. 27.6%), syphilis (16.1% vs. 1.8%), genital herpes (24.2% vs. 5.3%) chlamydia (30.1% vs. 11.9%) and gonorrhea (32.3% vs. 11.4%).

CONCLUSIONS: The exchange of sex for drugs was endorsed by a significant proportion of chronic opioid users and associated with higher rates of HIV/STIs, notably syphilis. While transactional sex was higher among females and opioid injectors, what was most striking is the high engagement of this behavior among sexual minorities. Opioid users, in particular sexual minorities, should receive increased engagement with prevention and intervention programs designed to mitigate potential infection from transactional sex.

PED1055

WHERE WE CAN FIND UNDIAGNOSED HIV-POSITIVE PEOPLE WHO INJECT DRUGS TO IMPROVE TREATMENT CASCADE? EXPERIENCE FROM UKRAINE

T. Saliuk[1], Y. Sazonova[1]
[1]ICF "International HIV/AIDS Alliance in Ukraine", M&E, Kiev, Ukraine

BACKGROUND: People who inject drugs (PWIDs) in Ukraine is the largest of the key population groups with HIV prevalence of 23%. The recent treatment cascade among MSM is 59%-90%-80%. We investigated where we should look to improve HIV case finding in this population.

METHODS: Data from the integrated bio-behavioural survey conducted in 2018 [Sample size 10076 PWIDs, and 2261 HIV positive cases diagnosed during the survey] were analysed using descriptive sta-

tistic and multilevel logistic regression model. The regression model assessed associations between unknowing the HIV positive status before being tested during the survey (previously not detected HIV case) as outcome and various socio-demographic and behavioural characteristics. Not knowing HIV positive status included those who self-reported before testing either being negative or never tested before. For the programmatic purposes we also used oblast/city level PWIDs size estimation data to see where the biggest numbers of undiagnosed HIV cases are located.

RESULTS: Quarter of PWIDs was never tested for HIV. To be not previously detected were more likely those aged between 35 and 44 y.o. (odds ratio [OR] 5.4, 95% confidence interval [95%CI]: 3.5-8.5), male sex (OR 1.9, 95%CI 1.6-2.3), were previously incarcerated (OR 1.7, 95%CI 1.5-2.2), single (OR 1.2, 95%CI 1.1-1.4), those who were not exposed to prevention services (OR 2.1, 95%CI 1.9-2.6). Majority of 21 000 undiagnosed HIV cases among PWIDs located in biggest four sites: Kyiv, Dnipro and Kryviy Rig cities, and Odessa region (64% of all undiagnosed cases). Five more cities will contribute to the detection of 80% of remaining cases.

CONCLUSIONS: Knowing the profile of those who are more likely to be HIV positive but yet not detected is important to prioritize the HIV case detection services. To improve the case detection among PWIDs, focus should be paid to males injecting drugs, single people, those who are not yet a client of prevention services, and those who are at older age. Focus cities level approach should be used to prioritize program efforts. Additional factors could be further accessed.

PED1056

ARE NEW LONG ACTING MEDICATIONS FOR OPIOID USE DISORDER (OUD) ACCEPTABLE? A DISCRETE CHOICE EXPERIMENT TO INFORM IMPLEMENTATION STRATEGIES FOR OUD TREATMENT AND HIV/HCV PREVENTION

D. Muthulingam[1], L.M. Madden[2,3], T. Hassett[2], L. Fraenkel[2], F.L. Altice[2,3]
[1]Washington University, St. Louis, United States, [2]Yale University, New Haven, United States, [3]APT Foundation, New Haven, United States

BACKGROUND: A central component of HIV/HCV prevention are medications for opioid use disorder (MOUD), which now include new long-acting injectable and implantable formulations. These are especially favored in the highly-vulnerable correctional settings and can potentially pair with long-acting HIV PrEP and treatment. However, we know little about patient preferences to inform scale-up and retention.

METHODS: Discrete choice experiments present hypothetical medication profiles measuring trade-offs and estimating patient preferences. In 12 choice-tasks, participants selected between 2 hypothetical medications or "none." Each profile included 5 attributes: initiation process; location/administration route; mortality reduction; side effects; and withdrawal symptoms from discontinuing. We surveyed participants with OUD initiating care July 2018 – July 2019 at the APT Foundation, a not-for-profit community treatment center in Connecticut.

RESULTS: We surveyed 530 patients survey, with 59% of participants men, 72% with any history of incarceration, 27% incarcerated in last 30 days (3 days median since release), and 36% were court-ordered to care. 56% of selections were driven by location and route of MAT administration. Fewer were concerned about withdrawal (21%), initiation (18%), even fewer about side effects (2%) and risk of death (3%). Expectedly, patients preferred medications with the most comfortable induction process (average utility 40.7), maximum mortality benefit (13.2), and no withdrawal (38.0). The most acceptable side effects were headaches and sleep changes (14.0, associated with buprenorphine) more than those associated with methadone (-13.7, sleepiness, weight gain, constipation, sexual problems) or those associated with injection/ implant (-0.4,irritation at the site of administration). Less expectedly, patients strongly preferred oral route of administration – preferring to pick up oral tabs from a pharmacy monthly (37.2) and even daily supervised dosing (19.7) over receiving a monthly injection (-24.8) or twice-yearly surgical implant (-32.2).

CONCLUSIONS: Although novel long acting formulations may seem appealing for less frequent visits and dosing, the required injection and surgical implant routes of administration were less popular than oral medications, especially buprenorphine. Scaling up MOUD is critical for addressing the HIV and HCV epidemics driven by the opioid crisis. Although there is progress in increasing availability and options for MOUD, accounting for patients' preferences will be critical for program strategy, uptake, and retention.

THE INTERSECTION OF EXCHANGE SEX AND HIV: EXAMINING THE WAYS IN WHICH WOMEN FIND EXCHANGE SEX PARTNERS

C. Agnew-Brune[1], D. Broz[1], A. Rivera[2], S. Glick[3], A. Jimenez[4], Z. Lopez[5], P. Wermuth[6], E. Higgins[7], C. Wejnert[1], NHBS Study Group
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]NYC Department of Health and Mental Hygiene, HIV and AIDS Office, New York City, United States, [3]University of Washington, School of Medicine, Seattle, United States, [4]University of Illinois, Community Health, Chicago, United States, [5]Houston Department of Public Health, Houston, United States, [6]University of Texas, Houston, United States, [7]Michigan Department of Health and Human Services, Detroit, United States

BACKGROUND: Globally, exchanging sex for money or drugs plays an important role in HIV transmission. Studies estimate that HIV prevalence among women who exchange sex in the US is between 0.3% and 30%. HIV risk may vary by the ways in which women find men or other partners to exchange sex with (referred to here as modalities). A better understanding of modalities is needed to inform HIV prevention efforts, but data on modalities in the US are sparse. Using qualitative data, we documented modalities of exchange sex among women from 5 US cities.

METHODS: During the 2016 National HIV Behavioral Surveillance (NHBS), five cities (Chicago, Detroit, Houston, New York City, and Seattle) conducted semi-structured in-depth interviews and focus groups with self-identified women who exchange sex for money or drugs. Women were asked open-ended questions about their own experiences and their perceptions of modalities. Written notes and quotes were summarized by interview staff at each site and these data were analyzed using a directed content analysis approach.

RESULTS: In total, 105 women were interviewed (43 in one-on-one interviews, 62 in 12 focus groups). While most women interviewed (65%) reported primarily finding exchange sex partners through walking the street or "stroll", additional modalities were commonly identified and described including massage parlor or brothel, es-

cort service, exotic venues or strip clubs, online, drug dealer or drug house, and boyfriend or husband/friends/family/neighbors. The majority of women also reported using multiple modalities. Engaging in high-risk practices, including drug use practices that may increase risk for HIV, and fear of violence, were frequently mentioned and varied by modality reported.

CONCLUSIONS: In this study women who exchange sex reported variations in modalities used to find exchange sex partners including using multiple modalities. Our findings also suggest that risk and safety concerns may vary across modalities. Additional research is needed to improve our understanding of how HIV risk may vary by modality, how to categorize modality meaningfully in subsequent quantitative surveys (particularly when multiple modalities are used), and how to best tailor prevention efforts toward the different contexts of exchange sex to most effectively reach different women.

PED1058

EVOLUTION OF CONDOM USE WITH CLIENTS AND STEADY PARTNERS OF FEMALE SEX WORKERS IN ZAMBIA

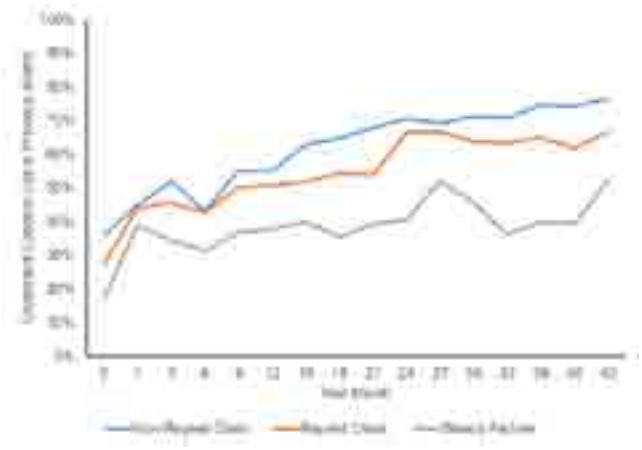
K. Malama[1,2], M. Price[3,4], L. Sagaon-Teyssier[1,2], A. Tichacek[5], R. Parker[5], W. Kilembe[6], M. Inambao[6], B. Spire[1,2], S. Allen[5]
[1]Aix-Marseille University, Marseille, France, [2]INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]International AIDS Vaccine Initiative, New York, United States, [4]University of California at San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [5]Rwanda Zambia HIV Research Group, Emory University, Pathology & Laboratory Medicine, School of Medicine, Atlanta, United States, [6]Rwanda Zambia HIV Research Group, Zambia-Emory HIV Research Project, Lusaka, Zambia

BACKGROUND: With pre-exposure prophylaxis in its infancy, consistent condom use remains a pillar of HIV prevention in sub-Saharan Africa. Female sex workers (FSW) have multiple concurrent partners with whom condom use is inconsistent, but it is unclear how participating in observational studies affects condom use by FSW over time. We studied condom use trends with clients and steady partners of Zambian FSW in an HIV incidence cohort.

METHODS: HIV-negative FSW in Lusaka and Ndola participated in an incidence cohort from September 2012 to September 2017. Follow-up occurred at Month 1 and every three months thereafter. In face-to-face interviews at each visit, nurses asked FSW how many times they had sex with/without a condom with their steady partners, repeat clients, and non-repeat clients in the previous month. FSW received HIV and family planning counselling with free condoms during visits.

Our outcome was consistent (100%) condom use during vaginal, oral or anal sex. To measure the evolution and differences in consistent condom use by partner type, we used generalised estimation equations with sociodemographic adjusted odds ratios (AOR) and 95% confidence intervals (CI).

RESULTS: Our sample included 389 FSW who had at least one follow-up visit. Median study duration was 33.5 months (Interquartile range: 30.1-42.7). Consistent condom use at baseline was 17% with steady partners, 28% with repeat clients and 36% with non-repeat clients. Compared to steady partners, FSW were over twice as likely to use condoms with repeat clients (AOR: 2.40, 95% CI: 1.85-3.13), and non-repeat clients (AOR: 2.66, 95% CI: 2.00-3.53) throughout the study.



[Figure.]

CONCLUSIONS: In a non-interventional FSW cohort, consistent condom use increased as the study progressed. This suggests the importance of sexual and reproductive health counselling with condoms for high-risk populations enrolled in observational studies. Future HIV prevention interventions should account for differential condom use between clients and steady partners of FSW.

PED1059

PERCEIVED CHALLENGES AND FACILITATORS TO ART INITIATION, ADHERENCE AND TASP AWARENESS AMONG FEMALE SEX WORKERS AND KEY INFORMANTS IN ETHEKWINI, SOUTH AFRICA

J. Smit[1], C. Milford[1], M. Beksinska[1], N. Mosery[1], K. Sithole[1], J. Mantell[2]
[1]MRU, University of the Witwatersrand, MatCH Research Unit (MRU), Durban, South Africa, [2]HIV Center for Clinical & Behavioral Studies, New York State Psychiatric Institute & Columbia University Irving Medical Center, New York, United States

BACKGROUND: Antiretroviral therapy (ART) to suppress viral load in people living with HIV (Treatment as Prevention [TasP]) is a key strategy to decrease new HIV infections. In 2015, only 25.6% of HIV-positive female sex workers (FSW) in eThekwini were accessing ART, far below the national average.

METHODS: We explored perceived challenges and facilitators to ART initiation, adherence and TasP awareness with 53 FSW ≥18 years, via 7 focus group discussions (3 with HIV-positive FSW, 4 with HIV-negative FSW) and in-depth interviews with 4 FSW (unknown HIV status), working in 5 hotels; and 29 key informant interviews (managers, bouncers, healthcare providers [HCPs], policymakers) in eThekwini, South Africa. Data analysis, using inductive and deductive approaches, was facilitated with NVivo.

RESULTS: While FSW described numerous reasons for not wanting to initiate ART: feeling healthy, high CD4 counts, denial of being sick, fear of stigma/rejection, resignation to death ("...I am already dying, what's the use"?), some had positive attitudes: staying healthy for their children's sake, knowing people who had done well on treatment. Participants in all cadres believed that TasP and ART increased life expectancy of HIV+ people, keeping them healthy and reduced chances of transmitting HIV to partners. However, few FSW understood the TasP rationale ("they suppress AIDS in your blood"). Challenges impacting ART adherence included side effects: body shape changes, weight gain, drowsiness, nightmares, nausea, and rashes; dislike and duration of taking pills regularly; judgement by others; forgetfulness ("you will ... see yourself high [on drugs] and ... just for-

get"); and belief that alcohol and ART cannot be mixed. Reminding each other, sharing pills with those who ran out, support ("You will gain power through me; when I take mine, she will also be taking hers…") were strategies noted by FSW to foster adherence. Some hotel staff and HCP suggested that access to ART in mobile clinics or workplace would fit FSW' lifestyle.

CONCLUSIONS: Attitudes to ART initiation were mixed and interventions to improve understanding of TasP and facilitate access to ART in the workplace are needed and should incorporate strategies proposed by FSW to support adherence.

PED1060

SEXUAL VIOLENCE EXPERIENCED BY FEMALE SEX WORKERS IN IRAN: A CROSS-SECTIONAL STUDY OF 13 CITIES

S. Hosseini Hooshyar[1,2], A. Mirzazadeh[1,3], M. Karamouzian[1,4], H. Sharifi[1], A.A. Haghdoost[1,5], R. Khajehkazemi[1], M. Shokoohi[1,6]
[1]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [2]The Kirby Institute, UNSW Sydney, Sydney, Australia, [3]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]School of Population and Public Health, Faculty of Medicine, University of British Columbia, Vancouver, Canada, [5]Social Determinants of Health Research Centre, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [6]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada

BACKGROUND: Female sex workers (FSWs), the second most vulnerable population to HIV in Iran, are at a high-risk of physical, sexual and emotional violence. Little is known about the magnitude and correlates of sexual violence against FSWs in Iran. This study aimed to measure the prevalence of lifetime and recent (last-year) sexual violence, and examine the individual, interpersonal, and environmental factors associated with sexual violence among Iranian FSWs.

METHODS: Our analysis used data from the 2015 national bio-behavioral survey of FSWs that was collected in one-on-one interviews using a standard risk-assessment questionnaire across 13 cities in Iran. Sexual violence was defined as having experienced any act of forced/threatened sexual contact from a paid/unpaid sexual partner. Poisson regression models were built to investigate factors associated with recent sexual violence among FSWs. Adjusted prevalence ratios (aPR) along 95% confidence intervals (CIs) were reported.

RESULTS: A total of 1,335 FSWs (mean age [SD]:35.3 [8.8] years) responded to the sexual violence queries. Lifetime and recent sexual violence were reported by 40.1% (95% CI: 33.9, 46.6) and 16.9% (95% CI: 13.1, 21.6), respectively. Factors associated with recent sexual violence included lifetime substance use (aPR 1.63, 95% CI: 1.01, 2.62), last-year group sex (aPR 1.75, 95% CI: 1.25, 2.44), lifetime anal sex (aPR 1.89, 95%CI: 1.42, 2.50), last-month frequent number of clients (i.e. ≥5) (aPR 1.43, 95%CI: 1.06, 1.92), current unstable housing (aPR 1.75, 95% CI: 1.25, 2.46), and last-year incarceration (aPR 1.73, 95% CI: 1.23, 2.45).

CONCLUSIONS: Our findings indicated that sexual violence was prevalent among Iranian FSWs, particularly among those who reported substance use and high-risk sexual behaviors and who experienced structural vulnerabilities such as unstable housing or incarceration. Therefore, it underscores the need for community-empowerment interventions to address violence and its associated harms among FSWs, a population experiencing high levels of violence in Iran.

PED1061

HIV RISK BEHAVIOR AND HEALTH CARE SERVICE AVAILABILITY AMONG FEMALE SEX WORKERS IN YANGON, MYANMAR

L. Htet[1], T. Myint[2], Y.M. Thaung[1], H.T. Thwin[1], K.P. Naing[1], T.S. Aung[1]
[1]Community Partners International, USAID HIV/AIDS Flagship Project, Yangon, Myanmar, [2]STI Myanmar University, Department of Public Health, Yangon, Myanmar

BACKGROUND: Myanmar is one of the 35 countries which accounts for 90% of global new HIV infection. HIV prevalence among FSW in Yangon is the second-highest in the Asia Pacific Region. Sex work in Myanmar is illegal and stigma and discrimination against FSW in the community and health care setting cause hindering them access to HIV services. The study was conducted to explore risk behaviors and availability of health care services related to HIV among Female Sex Workers in Yangon Myanmar.

METHODS: The study was was a cross-sectional analytical study with non-probability, targeted snowball sampling methods using quantitative questionnaires conducted from July 2018 until October 2018. The study included 220 participants of the FSW population residing in Yangon, Myanmar. Data collection was done with FSW peer outreach workers and analyzed with SPSS Version 23.

RESULTS: Consistent condom use among FSW was 20% with non-client partners and 30% with the clients. Less than 50% of participants used condoms at last sex with their non-client partners and 71% of FSW used condoms at last sex with the clients. HIV positive rate was 18.8% among FSW who did not use the condom at last sex with the clients compared to only 7.1% positivity among those who used condoms at last sex with the clients. There was a significant association between condom use at last sex with the clients and HIV status (Pearson Chi-Square: value 4.337, df 1, p-value 0.037). 92% of respondents received condoms from outreach and knew the place to go for HIV testing. 74% of the respondents tested HIV within one year and received results.

CONCLUSIONS: Condom use at last sex with paying clients has a significant association with HIV status and the practice of condom use is lower among female sex workers with regular or non-client partners. Most of the female sex workers usually went to key population service centers or NGO clinics for HIV services including HIV testing and treatment, STI treatment and prevention interventions. Providing key population friendly services and comprehensive continuum of prevention, HIV testing, treatment and retention in care as a free of charge, one-stop service should be promoted.

PED1062

ACCEPTABILITY AND WILLINGNESS TO USE HIV SELF-TESTING AMONG FEMALE SEX WORKERS IN ZAMBIA: IMPLICATIONS FOR DIFFERENTIATED TESTING MODALITIES IN HIV PROGRAMMING

C. Brander[1], J.G. Rosen[1], N. Choka[1], M. Mbizvo[1], W. Tun[2]
[1]Population Council Zambia, Lusaka, Zambia, [2]Population Council, Washington, United States

BACKGROUND: Efforts to bring routine HIV testing services (HTS) to scale have been compromised by access, financing, and implementation challenges. HIV self-testing (HIVST) promises to close these gaps, particularly in settings with generalized HIV epidemics like Zambia (adult prevalence: 12%) where marginalized and stigmatized subgroups – including female sex workers (FSWs) – are poorly

reached by existing HTS. To determine acceptability and identify appropriate strategies for scaling HIVST in Zambia, this study measured factors associated with willingness to use oral-fluid HIVST among FSWs in Livingstone, Lusaka, Ndola, and Solwezi districts.

METHODS: In March–July 2017, women 18yrs and older reporting exchanging sex for money in the past six months were recruited via respondent-driven sampling for a bio-behavioral survey. "Very willing" and "somewhat willing" responses to a single, five-point item were dichotomized as a proxy for HIVST acceptability. Responses were weighted using population size estimations to be representative of the study population. Bi- and multivariate logistic regression was used to identify socio-demographic, behavioral, and service use correlates of HIVST acceptability among FSWs who self-reported negative or unknown HIV status (n=1,312).

RESULTS: The median age of the sample was 25yrs (sd=6.14yrs) and most were never married (61.1%). The majority (80.1%) had an HIV test before, but few had heard of or used HIVST (23.2% and 4.7% respectively). Over half (57.5%) expressed willingness to use HIVST. FSWs currently married and who completed secondary school or higher reported willingness to self-test at significantly higher proportions than FSWs never-married (79.4% vs. 54.9%, p=0.005) and who never completed primary school (69.8% vs. 33.8%, p<0.001), respectively. In multivariate analysis, any prior HIV testing (Adjusted Odds Ratio [AOR]=1.75, 95% Confidence Interval [CI]: 1.15–2.66), previous HIVST use(AOR= 3.47, CI: 1.42-8.47), and current family planning (FP) use (AOR=1.61, CI: 1.01-2.56) were significantly associated with HIVST willingness. Sexual risk behaviors (e.g., condom use inconsistency, number of sexual partners) were not associated with HIVST.

CONCLUSIONS: Any prior HIV testing, prior HIVST, and current FP use surfaced as factors significantly associated with future willingness to use HIVST, which was moderately accepted. Findings highlight the role existing facility-based HTS and FP services could play in promoting HIVST for FSWs.

PED1063

ASSESSING STIGMA AND KNOWLEDGE OF HIV STATUS AMONGST FEMALE SEX WORKERS IN ZAMBIA: IMPLICATIONS FOR ACHIEVING 'THE FIRST 95'

C. Brander[1], J.G. Rosen[1], N. Choka[1], M. Mbizvo[1], W. Tun[2]
[1]Population Council Zambia, Lusaka, Zambia, [2]Population Council, Washington, United States

BACKGROUND: Female sex workers (FSW) are at high risk of HIV acquisition and transmission and face numerous barriers in accessing HIV services, with stigma and discrimination being a major barrier. This has important implications for reaching the UNAIDS 95-95-95 targets, particularly 'the first 95' (95% of HIV-positive individuals know their status). This study measured the association of sex work-related stigma on knowledge of HIV status amongst FSWs in Livingstone, Lusaka, Ndola, and Solwezi districts in Zambia.

METHODS: In March–July 2017, women 18yrs and older reporting exchanging sex for money in the past six months were recruited via respondent-driven sampling to participate in a bio-behavioral survey including HIV testing. Stigma was self-reported as experiencing at least one of the following as a result of being a sex worker in the past 12 months: denial of healthcare, employment, church/religious services, restaurant/bar services, housing, and police assistance. Amongst the 970 FSW who tested positive for HIV, the primary outcome was determined among those incorrectly identifying their serostatus or denying knowledge of their status prior to testing. Responses were weighted using population size estimations to be representative of the study population. A multivariate logistic regression model controlling for socio-demographic characteristics tested for an association between stigma and knowledge of HIV status.

RESULTS: The median age of the study population was 30yrs (standard deviation=6.48yrs). Only 44% of FSW who tested positive knew their status. Few had been refused healthcare (2.58%), restaurant/bar (1.55%), or religious services (2.58%), while refusal of employment (7.32%), police assistance (10.21%), and housing (18.76%) were more common. Over half (61.1%) of FSW reported experiencing at least one form of stigma. In multivariate analysis, stigma lowered the odds of knowing HIV status by 0.71 (p=0.026, 95% CI=0.53-0.96).

CONCLUSIONS: The alarmingly low rate of HIV positive FSW in Zambia that were aware of their status falls far below the UNAIDS 95-95-95 targets. The findings point to the importance of advocacy efforts to combat stigma against FSW in the community, and suggests that stigma mitigation efforts are needed to improve accessibility of HIV testing amongst FSW and improve the first 95-95-95 target.

PED1064

SOCIAL NETWORKING AND ICT USE AMONG YOUNG FEMALE SEX WORKERS IN KAMPALA, UGANDA: A BASELINE SURVEY OF A RANDOMIZED CONTROLLED TRIAL

F.X. Kasujja[1,2], E. Muhanguzi[1], R. Namugumya[1], D. Bagiire[1], H. Mutabazi[1], M. Mirembe[1], J. Seeley[3,1], R. King[4]
[1]The MRC/UVRI & LSHTM Uganda Research Unit, Social Aspects of Health across the Life Course, Entebbe, Uganda, [2]Makerere University School of Public Health, Epidemiology and Biostatistics, Kampala, Uganda, [3]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [4]University of California, Global Health Sciences, San Francisco, United States

BACKGROUND: Young female sex workers (YFS) are at high risk for HIV-infection in Uganda. About 2 in 5 YFS in Kampala, Uganda, aged 15-24 years, are living with HIV. Social networking and ICT provide a potential avenue for HIV prevention and management interventions in this population. We conducted a baseline survey to determine the level of social networking and ICT use among YFS.

METHODS: Data were collected from January 2017 to July 2019 using audio-computer assisted self-interviews from 236 HIV-negative YFS in Kampala as part of an RCT to test a combination structural and cognitive-behavioral prevention intervention.

RESULTS: About 23.3% (55) of the participants had completed at least 11 years of formal education (Ordinary Level of Secondary Education). About 67.4% (159) of the participants had mobile phones. However, only 4.2% (10) owned a computer or tablet. About 40.7%(96) reported having at least some computer use experience. Internet access was 30.8% (72); 4.8% (11) reported being very confident with using the internet with most participants relying on the use of SMS (64.2%). Internet was mostly used to access Facebook (51.4%) and Whatsapp (32.4%).

About half reported accessing Facebook at least once a week; the corresponding proportion for Whatsapp was 63.4%. The proportion of participants with at least some experience using Microsoft software packages was 21.1% (49) for Word, 4.7% (11) for PowerPoint and 3.9% (9) for Microsoft Excel.

		n(%)	95% confidence interval
Has a mobile phone		159(67.4)	61.1-73.1
Uses SMS		131(64.2)	57.4-70.5
At least some computer use experience		96(40.7)	34.5-47.1
Access the internet on the phone, tablet or computer		72(30.8)	25.2-37.0
Reasons for accessing the internet			
	Whatsapp	34(32.4)	23.6-42.2
	Facebook	54(51.4)	41.4-61.3

[Table: Social networking and ICT use among YFS in Kampala, Uganda]

CONCLUSIONS: YFS in Kampala have access to mobile phones; however, internet access is low. SMS is the most frequent means of telecommunication. Social networking and computer skills are low. Low-tech mobile phone solutions are the most viable vehicle for ICT Interventions in the HIV response for this population.

PED1065

IMPROVING HIV CASE FINDING AND TREATMENT INITIATION AMONG FEMALE SEX WORKERS IN MOZAMBIQUE: RESULTS FROM A PROJECT IN NIASSA, GAZA AND ZAMBEZIA PROVINCES

B. Mbulo[1]
[1]*ADPP Mozambique, Program, Maputo, Mozambique*

BACKGROUND: Mozambican Female sex workers (FSW) are up to four times more likely to be living with HIV than general population women of reproductive age. HIV prevalence among Mozambican FSW has been measured at between 17.8% and 31.2%, depending on location. As a sub-recipient on the FHI360's USAID-funded PASSOS project, ADPP Mozambique is responsible for increasing access to and uptake of HIV services for FSW in 3 Provinces, especially HIV testing and treatment initiation.

DESCRIPTION: Since 2017, ADPP has been working in hotspots across three provinces providing HIV testing and treatment referrals for FSW. In 2019, to increase the positivity rate on its HIV testing component, ADPP introduced a tailored risk assessment tool used prior to testing to help identify FSW most at risk of HIV. The tool elicited information from FSW on risk factors such as condom use, drug use, and numbers of clients. In addition, bar/hotel owners in the targeted districts were asked to identify additional hotspots for HIV testing where they suspected undetected cases of HIV might be found. FSW found to be HIV+ were provided with additional support, such as being accompanied to clinics and weekly home visits during the first three months, to help ensure treatment initiation and adherence.

LESSONS LEARNED: Prior to introducing the new HIV testing tools and additional support for treatment initiation, the project's HIV testing component had a positivity rate of 12% (in 2017) and 6% (in 2018) and a treatment initiation rate of 65% (in 2017) and 77% (in 2018) among FSW found to be HIV+. In 2019, with the introduction of the additional measures, the project's positivity rate increased to 18% and treatment initiation rate increased to 82%.

CONCLUSIONS/NEXT STEPS: FSW are a highly heterogeneous group with a wide range of behaviors, risk profiles, and levels of access to and utilization of services. Outcomes on HIV testing among FSW can be improved by utilizing simple tools and methods to help ensure precious project resources are focused on those most at risk and by additional efforts tailored to the local context to ensure treatment initiation for all of those found to be HIV+.

PED1066

THE IMPLEMENTATION OF PEER EDUCATION AT COMMUNITY LEVEL TO IMPROVED KNOWLEDGE, ACCEPTANCE AND UTILIZATION OF FEMALE CONDOMS AMONG SEX WORKERS IN INDONESIA

R.A. Setyani[1], M.A. Fathoni[2,2]
[1]*Respati University of Yogyakarta, Midwifery Profession Education, Yogyakarta, Indonesia,* [2]*Regional Development Planning Agency of Yogyakarta, Yogyakarta, Indonesia*

BACKGROUND: The utilization of condoms for HIV AIDS prevention in Indonesia is only in male condoms. In fact, there are many women at risk of sexual intercourse because men do not want to use condoms. This research aimed to explain the effectiveness of peer education at community level strategy among female sex workers (FSWs) to their knowledge, acceptance and utilization of female condom in Indonesia.

METHODS: The study applied an explanatory sequential mixed methods study in Indonesia during January – December 2019. The quantitative study component used a quasi-experimental design to test the implementation of peer education at community level strategy among 550 FSWs. The control group was 600 FSWs without peer education. We used Mann-Whitney u test for the data analysis.

RESULTS: FSWs in the intervention perceived higher awareness about the risk of HIV (86%), therefore even though they felt inconvenient to use the female condom, their acceptance (80%) and utilization (77%) is higher than the control group. The data findings revealed a significant better acceptance and utilization of FSWs to female condom in the intervention group to the control group ($p<0.001$).

CONCLUSIONS: Implementation strategies of peer education at community level among female sex workers improved utilization and acceptance of female condom. It could be an empowerment woman program which suggested to Ministry of Health for HIV AIDS prevention.

PED1067

PREVALENCE AND FACTORS ASSOCIATED WITH HIV INFECTION AMONG FEMALE ENTERTAINMENT WORKERS IN CAMBODIA: FINDINGS FROM A NATIONAL SURVEY

S. Tuot[1], P. Mun[2], N. Chann[2], S. Eng[1], P. Chhoun[1], G. Mburu[3], S. Yi[1,4,5]
[1]*KHANA Center for Population Health Research, Phnom Penh, Cambodia,* [2]*National Center for HIV/AIDS, Dermatiology and STD, Surveillance Unit, Phnom Penh, Cambodia,* [3]*Lancaster University, Division of Health Research, Lancaster, United Kingdom,* [4]*National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore,* [5]*Touro University California, Center for Global Health Research, Vallejo, United States*

BACKGROUND: Cambodia has made tremendous progresses in the fight against HIV epidemic. However, the country continues to face challenges in eliminating HIV among key populations, including female entertainment workers (FEWs). This study explored the prevalence of HIV and factors associated with HIV infection among FEWs in Cambodia.

METHODS: The National Integrated Biological and Behavioral Survey among FEWs was conducted in 2016 in the capital city and 17 other provinces with a large FEW population size and high burden of HIV. The study sample included 3,151 FEWs aged 18 years or older, recruited using a two-stage cluster sampling method. A multivariable logistic regression model was constructed to explore factors associated with HIV infection. This study was approved by the National Ethics Committee for Health Research (Ref: 297NECHR).

RESULTS: The mean age of the participants was 26.2 (SD= 5.7) years. The prevalence of HIV among FEWs in this study was 3.2% (95% CI= 1.76-5.75). After controlling for potential confounders, the risk of HIV infection was significantly higher in women older than 30 (AOR= 2.72, 95% CI= 1.36-8.25), women who were not married but living with a partner (AOR= 3.00, 95% CI= 1.16-7.79), women who reported using illicit drugs in the past three months (AOR= 3.28, 95% CI= 1.20-4.27), and women who reported having genital ulcers or sores (AOR=2.06, 95% CI= 1.09-3.17), genital warts (AOR= 2.89, 95% CI= 1.44-6.33), and abnormal vaginal discharge (AOR= 3.51, 95% CI= 1.12-9.01) in the past three months. The risk was significantly lower in women who had attained at least 10 years of formal education (AOR= 0.32, 95% CI= 0.17-0.83) and women working in a karaoke bar (AOR= 0.26, 95% CI= 0.14-0.50) and beer garden (AOR= 0.17, 95% CI= 0.09-0.54).

CONCLUSIONS: This study suggests that to reduce the prevalence of HIV among FEWs, priorities should be geared towards older women and FEWs working as freelance sex workers. While outreach interventions among venue-based FEWs remain essential, online and mobile-based programs should be tailored towards promoting consistent condom use, especially in non-commercial relationships, regular HIV testing, early screening and management of STIs, and reducing the harmful use of alcohol and illicit drugs.

PED1068

FACILITATORS AND BARRIERS TO TREATMENT ENGAGEMENT AND RETENTION AMONG FEMALE SEX WORKERS LIVING WITH IN INDONESIA: A COMMUNITY-LED STUDY

L. Andriyani[1], A. Arina[1], A. Widihastuti[2], A. Nugroho[3]
[1]OPSI, the National Network of Indonesian Sex Workers, Jakarta, Indonesia, [2]UNFPA Indonesia, Jakarta, Indonesia, [3]Universitas Lambung Mangkurat, School of Public Health, Faculty of Medicine, Banjarbaru, Indonesia

BACKGROUND: Over the past few years, HIV response for female sex workers (FSWs) population in Indonesia has been employing a so-called 'new outreach model'. Despite its successes on reach and test, the approach seemed to fell short in adequately putting and retaining HIV-positive FSWs in care and treatment. This study aimed to explore barriers and facilitating factors associated with HIV treatment access and retention among HIV-positive FSWs in Indonesia.

METHODS: This is a community-led study performed by OPSI, the national network of Indonesian sex workers. We applied a mixed-method study design and collected quantitative and qualitative data from 80 HIV-positive FSWs and nine key informants in four cities of Indonesia.

RESULTS: Of all participants, over a third HIV-positive FSWs (34%) delayed their ART treatment if not started at all. The reasons of treatment delay were because they had high CD4 count (26%), worried of getting side-effects (22%), and felt healthy or had no symptom of opportunistic infections (22%). Our qualitative findings also highlighted that complicated referral system, have no legal identity, and not understanding treatment procedures were among the structural barriers that often occurred. Of those ever-started ART, 65 (86%) reported consistently taking their treatment. We found self-acceptance towards their HIV-positive status, family support, tailored ART service, and peer support were facilitating HIV-positive FSWs to stay on treatment. We also noted that complicated flow of ART services, treatment fatigue, feared of getting stigma, and felt ART worsening their condition were among factors caused some FSWs stopped their treatment. The qualitative findings revealed that self-acceptance towards HIV status, experienced any side-effect at the early days of treatment, rejections from family, and lured by the myth of herbal cure were among factors that had discouraged FSWs from staying on treatment. Moreover, participants with a history of treatment drop out revealed that having their condition worsened, persistence support from their peers, and having a 'treatment role model' were factors that have driven them back on treatment.

CONCLUSIONS: To ensure HIV-positive FSWs remain engaged across the HIV care continuum, attention should be paid to increase treatment literacy, guarantee social support, and reduce stigma and discrimination faced by FSWs.

PED1069

INCREASE IN RISK BEHAVIOR ALONGSIDE INCREASED ART COVERAGE AMONG FEMALE SEX WORKERS IN BOTSWANA: EVIDENCE FROM 2012 AND 2017 BIOLOGICAL AND BEHAVIORAL SURVEILLANCE SURVEYS

L. Okui[1], W. Dikobe[1], M. Gilbert[1], J. Ngidi[2], S. Chishala[2], D. Kanyenvu[2], O. Kemotere[1], R. Kereng[1], K. Kusi[2], J. Bolebantswe[2], B. Ntwayagae[2], B. Nkomo[2], C. Petlo[2], M. Mine[2], M. Merrigan[3]
[1]FHI360 Botswana, LINKAGES, Gaborone, Botswana, [2]Ministry of Health and Wellness, Gaborone, Botswana, [3]FHI 360, LINKAGES, Washington DC, United States

BACKGROUND: Because female sex workers (FSWs) have multiple sex partners and face barriers to consistent condom use, they are highly susceptible to HIV. Under the USAID/PEPFAR-funded LINKAGES project, we compared data from the 2012 and 2017 Behavioral and Biological Surveillance Survey (BBSS) to examine trends in HIV prevalence, risk behaviors, and ART coverage among FSWs in Botswana.

METHODS: In both 2012 and 2017, eligible FSWs were recruited using time-location sampling at hot spot venues where face-to-face interviews and collection of biological samples were conducted. Percent changes and p values were calculated for comparisons between 2012 and 2017. Data analysis incorporated sampling weights and adjustments to standard errors for clustering on day-time sampling events.

RESULTS: FSWs continue to be highly affected by HIV in Botswana. The study found a nonsignificant decline in overall HIV prevalence (61.9% vs. 51.3%, p=0.19). However, this decline was statistically significant in Francistown from 53.5% to 37% (p=0.007). Consistent condom use declined with all partner types, most significantly among cohabiting partners (21.4% vs 78.3%, p=0.02). This lower condom use can be triangulated with a significant increase in syphilis prevalence among FSWs (6.7% vs 3.5%, p=0.07). Condom fatigue may be the reason; 7.3% of FSWs reported "not liking" condoms as one of the main reasons they are not used consistently compared to 0.8% in 2012 p=0.000). In 2017, FSWs appear to be more likely to accept more money for not using condoms in commercial sex compared to 2012 (56.1% vs 49.3%, p=0.00). Finally, ART coverage among HIV-positive FSWs improved significantly between 2012 and 2017 (87.8% vs. 24.9%, p=0.000).

CONCLUSIONS: There has been good progress since 2012 among FSWs in accessing HIV testing and treatment services, but in contrast, consistent condom use has declined, resulting in an increase in some STIs. Programs need to enhance combination prevention strategies to address this issue.

PED1070

COMMUNITY-BASED INDEX CASE TESTING (ICT) AMONG FEMALE SEX WORKERS AND THEIR SEXUAL PARTNERS IN ETHIOPIA: EFFECTIVE STRATEGIES FOR OVERCOMING BARRIERS

I. Hailu[1], R. Ritzenthaler[1], E. Tilahun[2], M. Ketema[3], M. Addisu[3]
[1]Population Services International, TB/HIV, Addis Abeba, Ethiopia, [2]Population International, CR, Addis Abeba, Ethiopia, [3]Population Services International, IFI Manager, Bahirdar, Ethiopia

BACKGROUND: Female sex workers (FSWs) in Ethiopia are disproportionately affected by HIV, with an estimated prevalence of 23% (national MARPs Survey, 2013, EPHI), compared to a national prevalence of 0.9% (EDHS, 2016). While index case testing and assisted partner notification (ICT/PNS) is recognized as an essential component of the HIV response, it has until recently been considered less feasible among FSWs, because there is a perception that their sexual networks are unstable and that FSWs are reluctant to disclose their partners names. PSI, under the USAID-funded MULU Activity, has developed successful approaches for ICT/PNS with FSW in two of the highest burden regions in Ethiopia: Addis Ababa and Amhara.
DESCRIPTION: MULU launched community ICT/PNS as its key HIV case finding modality in July 2018. The project applied various techniques to overcome barriers to disclosure and HIV testing uptake included: use of skilled nurses both to elicit contacts from FSW and to reach out to clients , reaching out to clients with a non-sensitive setting , and planning for repeated contacts with partners. the program utilized anonymous and disguised testing techniques for elicited contacts. Nurses have been trained to use a daily micro planning tool on number index clients counseled, number contacts elicited, number contacted and tested. Standard operating procedure by all community level staff for effective interpersonal communication between client and health provider was implemented.
LESSONS LEARNED: In FY19, 3,471 individuals (FSWs and their sexual partners) were tested through ICT/PNS, with 721 new HIV positives identified (20.8% yield). This significantly exceeded HIV case finding through other modalities: VCT (2.9% yield); mobile (3.6%) and PITC (2.8%). Nurse counslors screen index clients for risk of intimate partner violence (IPV), and then check if the client is comfortable disclosing HIV status to her partners. An average of 3 contacts per index client were elicited.Effective interpersonal communication by skilled health providers, fidelity to daily micro planning tool , as well as teamwork, has paved the way for active tracing of elicited contacts.
CONCLUSIONS/NEXT STEPS: ICT/PNS is the most effective and efficient case finding modality among key populations to be scaled up at all high impact HIV hot spots.

PED1071

RISK COMPENSATION AND RISK OF TRANSMISSION AND REINFECTION OF HIV AMONG HIV+ FEMALE SEX WORKERS USING MODERN CONTRACEPTIVE IN ZAMBIA

N. Choka[1], M. Mbizvo[1], W. Tun[2], C. Brander[3]
[1]Population Council, Reproductive Health, Lusaka, Zambia, [2]Population Council, Washington DC, United States, [3]Population Council, Lusaka, Zambia

BACKGROUND: Preventing pregnancy is often a greater concern to sexually active unmarried women in Zambia than preventing HIV/STIs. This is of particular concern among HIV+ Female Sex Workers (FSWs) who are at high risk of HIV reinfection and transmission. Using modern contraceptives helps HIV+ female sex workers to prevent pregnancy, but puts them at greater risk of HIV reinfection and transmission. This analysis assessed risk compensation and risk of reinfection/transmission of HIV/STI among HIV+ female sex workers using modern contraceptive in Zambia.
METHODS: In March–July 2017, women 18 years and older reporting exchanging sex for money in the past six months were recruited via respondent-driven sampling to participate in an integrated bio-behavioral survey—administered in Lusaka, Livingstone, Ndola and Solwezi Districts. Low condom use was defined as using condoms in less than half of their sexual encounters in the past 12 months. Among the 965 HIV+ female sex workers, bivariate chi-square, logistic regression and treatment effect analysis were conducted to assess the causal effect of modern contraceptives on condom use.
RESULTS: The median age of the sample was 30 years. Almost half (45%) were formally cohabiting with a male partner and 35% had a primary school education. Modern contraceptive use was moderately prevalent (54%) and among those, 17% had low condom use. Injectable contraceptive use accounted for 20% and bivariate analysis shows that injectable contraceptive use was significantly associated with STIs (p=0.004). After controlling for sociodemographic variables female sex workers using injectables had higher odds (AOR=1.6, CI=[1.02-2.41]) of low condom use . Average condom use fall by an estimated 6% when every woman is on injectable contraceptive relative when no woman is on injectable contraceptive.
CONCLUSIONS: Female sex workers who are HIV+, and at risk of HIV transmission or reinfection, are less likely to use a condom, in particular when they are already using an injectable contraceptive method for pregnancy prevention. Therefore, modern contraceptives should be provided to female populations at higher risk of HIV and STIs complimentarily with condoms.

PED1072

REDUCING STIGMA AND DISCRIMINATION IN HEALTH FACILITIES TO INCREASE SERVICE UPTAKE AMONG KP AND PLHIV. A CASE STUDY FROM 15 SELECTED HEALTH FACILITIES IN GHANA

R. Ofori-Atta[1], C. Asamoah-Adu[2], K. Mawuena Diaba[3]
[1]Ghana West Africa Program to Combat AIDS &STI, Programmes (Human Rights), Accra, Ghana, [2]Ghana West Africa Program to Combat AIDS &STI, Programmes, Accra, Ghana, [3]Ghana West Africa Program to Combat AIDS &STI, Programmes and M&E, Accra, Ghana

BACKGROUND: In 2017 Ghana conducted an assessment on human rights (HR) and access to health care services. The findings indicated stigma and discrimination (S&D) was a major barrier to access health care services, critical was the mention of stigma in health facilities

(HF). The findings of the assessment became the basis for developing a HR intervention for Ghana to complement existing HIV/TB interventions for maximum impact.

DESCRIPTION: The HR intervention funded by the Global Fund (2018-2020) is implemented by WAPCAS.

One of the key activities under the HR intervention is the training of health care providers from selected facilities to reduce S&D. The current intervention focuses on 15 Ghana Health Service (GHS) facilities with the objective of training facility staff to provide quality services in a stigma-free environment.

The 15 facilities were grouped into 2; the first 7 and the second batch of 8 facilities. The consent and approval were sought from the Director-General of the GHS for the rollout of the intervention.

The intervention was structured into phases; the trainer of trainers (ToT) for each facility with not less than 5 persons including a PLIHV, using the ToTs to step down the training of 70% of the facility staff, identification of a S&D Champion team in each facility after training, Champion Team identifying specific interventions to reduce S&D in the HF, develop a work plan on the rollout of the identified interventions, and then roll out the intervention.

LESSONS LEARNED: In all 3,500 staff from 15 HF have been trained and sensitized on HR and stigma reduction. HF have learnt to treat all patients equally irrespective of their condition and sexual orientation. It has enhanced health care delivery and helped eliminate cultural stereotypes of KP. A clients' exit survey shows quality of service is high in over 80% of the facilities.

CONCLUSIONS/NEXT STEPS: We will continue to assess S&D status of facilities post-intervention period.

PED1073

DIFFERENCES IN FEMALE SEX WORKERS NETWORKS: DATA FROM A LARGE RDS STUDY IN 12 BRAZILIAN CITIES, 2016

L. Penna Braga[1], G. Nogueira Damacena[2], C. Landmann Szwarcwald[2], The Brazilian FSW Group
[1]National School of Public Health Sergio Arouca, Oswaldo Cruz Foundation (ENSP/Fiocruz), Rio de Janeiro, Brazil, [2]Institute of Scientific and Technological Communication and Information in Health, Oswaldo Cruz Foundation (ICICT/Fiocruz), Rio de Janeiro, Brazil

BACKGROUND: Female Sex Workers (FSW) are one of the key-populations for HIV in Brazil. Respondent-Driven Sampling (RDS) is an important tool to reach hidden populations, such as FSW. However, the applicability of RDS in multicenter studies is a challenge. This study aims to investigate diferences in socio-demographic, sexual behavior and sex work characteristcs among FSW in the 2nd Biological and Behaviour Surveillance Survey in Brazil.

METHODS: Cross-sectional study conducted in 12 brazilian cities in 2016 among FSW recruited by RDS. The eligibility criteria were: be at least 18 years old; to have had at least one sexual intercourse in exchange for money in the past four months in one of the study cities; and to present a valid cupon to participate. For each city, the sample was at least 350 interviews (estabilished by the Ministry of Health) and 6-8 seeds were chosen qualitatively. It was offered rapid tests for HIV, syphilis, hepatitis B and C.To explain differences in HIV prevalence, the main factors associated of HIV infection were described for FSW network reached in each city.

RESULTS: Salvador had the highest prevalence of both HIV and syphilis, 18.2% and 18.5%, while Campo Grande had the lowest prevalence, 0.2% HIV and 3.3% syphilis. In Recife was observed the highest proportion of FSW working at street venues (84.4%), followed by São Paulo (75.3%), and Salvador (61.0%). The proportion of FSW who would waive the use of condom for any reason ranged from 14.9% in Manaus to 61.3% in Porto Alegre. The cities with the highest frequencies of illicit drug use were São Paulo (29.7%), Salvador (22.7%), and Rio de Janeiro (22.7%), while Belo Horizonte had the lowest (5.1%).

CONCLUSIONS: It was observed important differences between cities in the FSW network composition and development. RDS multicenter studies are important to target national HIV response. However, the differences between cities strengthen the importance to discuss the limitations to report RDS data separately by site in multicentric studies, since the networks formed do not represent the entire population, especially in studies with small sample sizes in each center, and limited time to execute the research.

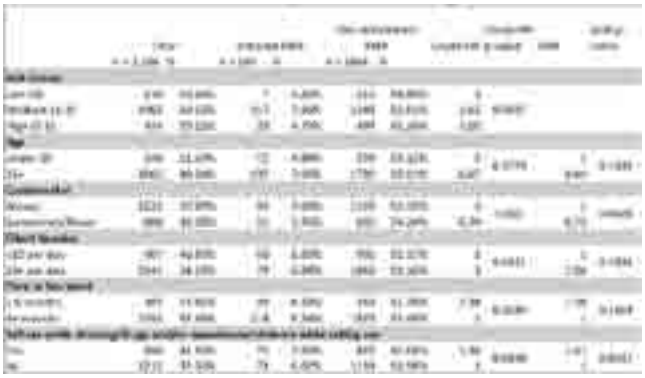
PED1074

RETROSPECTIVE COHORT STUDY TO DETERMINE THE CORRELATION BETWEEN HIV RISK PROFILE AND UPTAKE OF ORAL PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG SEX WORKERS IN JOHANNESBURG, SOUTH AFRICA

C. O'Connor[1,2,3], R. Bothma[1], R. Hendricks[1], S. Moyo[1], N. Hill[1], G. Maimela[1]
[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]Sustained Health Initiatives of the Philippines (SHIP), Manila, Philippines, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: Among South Africa's 112,000 female sex workers (FSWs), approximately 54% are living with HIV, and the annual incidence of 7% among FSWs significantly exceeds that of the general population, making pre-exposure prophylaxis (PrEP) an essential intervention. Wits RHI has one of the largest and longest running sex worker programmes globally, which reached more than 30,000 sex workers in 2018 and was an early implementer of daily oral pre-exposure prophylaxis (PrEP) in South Africa.

METHODS: A retrospective cohort study included sex workers in Johannesburg receiving services between January 2018 – January 2019. Peer educators conducted risk assessments with the variables: age, condom use, client number, time in sex work, and drinking/drugs/violence while working. A risk score of 0-5 was generated. Risk assessment data were matched with PrEP initiation records. Univariate and multivariate regression models were conducted to determine the association between risk factors and PrEP uptake.



[Table 1. Association between HIV risk factors and PrEP uptake for FSWs in Johannesburg, South Africa]

RESULTS: 2,108 FSWs who completed the risk assessment, 144 (6.83%) initiated PrEP. FSW's with a "Medium" risk score were most likely to take PrEP (OR=2.62) followed by the "High" risk group (OR=1.50, p=0.0027). PrEP was slightly more likely to be taken by FSWs who

were younger, newer to sex work, and who used substances and/or experienced violence. Inconsistent condom use and higher client number was not associated with PrEP uptake.

CONCLUSIONS: This analysis is limited by the nature of the routine programme data, in which risk analysis data was available for only a small subset of PrEP patients and did not distinguish known HIV positive clients.

For PrEP to be effective in interrupting transmissions and contribute towards reaching epidemic control, it is imperative that PrEP be taken by those at highest risk of HIV infection. In key populations, the PrEP promotion strategy should be tailored to better reach those FSWs in the highest risk group.

PED1075

"WOULD YOU RAPE WHEN SEX WORKERS ARE AVAILABLE?": EXAMINING THE MEANINGS AND VALUE FEMALE SEX WORKERS (FSW) AND THEIR MALE CUSTOMERS ATTACHED TO SEX WORK IN EASTERN UGANDA

S. Parikh[1], T. Nyoni[2]
[1]Washington University in Saint Louis, Department of African and African American Studies Department, St. Louis, United States, [2]Washington University in Saint Louis, Brown School of Social Work, St. Louis, United States

BACKGROUND: Evidence points to inconsistent condom use among FSWs in Uganda. However, little is known about the motivations and situations associated with the selling and buying of unprotected sex. This qualitative ethnographic study aims to (1) explore the meanings and value FSWs and their male customers attach to selling and buying of sex, (2) to establish ways in which sex trade interactions and exchanges could promote unprotected sex.

METHODS: In-depth interviews were conducted with 59 female sex workers (ages 18-40) and male customers (ages 20-45) in truck stops along the Trans-Africa Highway and fishing communities in and around Lake Victoria. Interviews elicited participants' life history narratives, including childhood experiences, circumstances under which participants came to sell or buy sex, unprotected sex, and the value and meaning derived from buying. The interpretive analysis was conducted using open and focused thematic coding.

RESULTS: Findings show that sex work remains a risky form of labor; FSWs face social stigma and shame around selling sex, forcing them to conceal their source of income from their families. Moreover, although was safer sex was preferred and enforced by most FSWs, male customers often financially incentivized unprotected sex to maximize sexual pleasure. Due to poverty and despite knowledge of risks, FSWs did occasionally sell in unprotected sex to maximize financial income or material benefits to support their families. However, both FSWs and male customers perceive sex work to be a vital community service. They further explained that sex work provides sexual relief to men who cannot afford normal relationships, helps reduce cases of physical and sexual violence, as well as rape against women and girls while generating income to educate children and supports families.

CONCLUSIONS: Findings suggest that most FSWs engaged in unprotected sex as a rational choice that places the social risk of failing to provide for children and family as more significant and immediate than the biological risk of STI/HIV infection, which is considered not immediately life-threatening. Efforts to promote safer sexual practices within sex work must be linked to income and livelihood interventions. More public education to promote safer sex and reduce stigma around sex work is needed.

PED1076

STRUCTURAL BARRIERS INFORMING IMPLEMENTATION STRATEGIES FOR ANTIRETROVIRAL THERAPY AMONG FEMALE SEX WORKERS LIVING WITH HIV IN DURBAN, SOUTH AFRICA

C. Comins[1], V. Guddera [2], K. Young[2], M. Mcingana[2], N. Mulumba[2], S. Mishra[3,4], D. Phetlhu[5], H. Hausler[2], S. Baral[1], S. Schwartz[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]TB HIV Care, Durban, South Africa, [3]University of Toronto, Medicine, Toronto, Canada, [4]Li Ka Shing Knowledge Institute and St. Michael's Hospital, Toronto, Canada, [5]University of Western Cape, Cape Town, South Africa

BACKGROUND: HIV treatment strategies for female sex workers (FSW) have focused on individual barriers to antiretroviral therapy (ART). However, across South Africa, nearly two-thirds of all FSW are living with HIV, of whom 40% are virally suppressed. We aim to study structural determinants affecting ART use and viral suppression (VS) among FSW living with HIV.

METHODS: Data represent baseline data from an adaptive randomized intervention trial (Siyaphambili) in Durban, South Africa. FSW were eligible if >18 years, selling sex as their main source of income, and diagnosed with HIV ≥6 months. Engagement in ART was self-reported, and viral load assessed and defined as <50 copies/mL. The associations between structural determinants – inclusive of work environments, intersecting stigmas, and violence – and baseline ART use and VS were assessed with multivariable robust Poisson regression, controlling for age and education.

RESULTS: A total of 1,207 FSW living with HIV were enrolled. Overall, 87.7% (n=1,0578/1,207) had initiated treatment, 66.6% (n=804/1,207) were currently on ART, and 38.3% (n=466/1,207) were VS. Additionally, 27.8% (n=336/1,207) reported homelessness, 63.5% (n=767/1,207) had a history of physical or sexual violence, and 81.4% (n=982/1,207) experienced anticipated, perceived, enacted, or internalized stigma. Compared to stable housing, homelessness or living in a shelter decreased associated ART use (aPR=0.78, 95% CI 0.68-0.90, p=0.001) and VS (aPR=0.71, 95% CI 0.56-0.92, p=0.008). A history of sexual or physical violence, anticipated stigma, and enacted stigma each decreased associated ART use, and anticipated stigma also decreased VS (Table 1). Venue type, perceived stigma, and internalized stigma were not associated with either outcome.

	On ART		Virally suppressed	
	aPR	955 CI	aPR	95% CI
Venue type				
Indoor[a]	REF	REF	REF	REF
Outdoor[b]	0.95	0.85-1.06	1.04	0.86-1.25
Living situation, prior 6 months

Anticipated stigma	0.86	0.78-0.95**	0.83	0.69-0.99*
Perceived stigma	1.01	0.91-1.13	1.00	0.81-1.22
Enacted stigma	1.14	1.03-1.27*	1.18	0.97-1.44
Internalized stigma	1.03	0.94-1.14	1.03	0.86-1.24

*p value<0.05
**p value<0.01
***p value<0.001
[a]Indoor includes private home, brothel, bar, private party, hotel or guest house
[b]Outdoor venues include street, park, public garden, beach, cemetery or private vehicle
[c]Stable housing includes as owning a place, staying with friends, family or boyfriend, student housing
[d]Other includes brothel, hostel, refusal or missing

[Table 1. Correlates of engagement in antiretroviral therapy and viral suppression among female sex workers in Durban, South Africa]

CONCLUSIONS: Structural barriers were common among this population and associated with decreased ART use and VS. These findings highlight the complex treatment needs of FSW and that further integration of structural determinants within current treatment programs is critical to optimizing treatment outcomes and impacting the HIV epidemic.

PED1077

HIV SELF-TESTING REACHES PREVIOUSLY UNREACHED KEY AND VULNERABLE POPULATIONS IN DEMOCRATIC REPUBLIC OF THE CONGO (DRC)

M. DiCarlo[1], M. Cheron[2], P. Mabanza[2], F. Mbuta[2], V. Ranebennur[3], H.R.S. Rodriguez Sherman[1], D. Ngoie[2]
[1]FHI 360, Washington, United States, [2]FHI 360, Lubumbashi, Congo, Democratic Republic of the, [3]FHI 360, Mumbai, India

BACKGROUND: HIV self-testing (HIVST) helps countries expand access to HIV testing services, reach those at high risk who may not otherwise get tested, and achieve the first 95 of UNAIDS' 95-95-95 targets, that 95 percent of all people living with HIV should know their status. Among key population (KP) members, who have low uptake of other testing options, reported benefits include privacy, convenience, pain-free testing, and ease of use.

DESCRIPTION: In DRC, HIVST was implemented by the LINKAGES project in Kinshasa, Haut Katanga, and Lualaba for female sex workers (FSWs), men who have sex with men (MSM), and FSW clients from October 1, 2018, to September 30, 2019. Peer educators (PEs) were trained to offer OraQuick HIVST kits only to peers who, based on a risk assessment, had never tested before and who had refused testing by any other means (mobile, drop-in center [DIC], facility). First-time testers were also prioritized for mobile and DIC testing. HIVST was assisted and was done in the presence of the PE. Peers with reactive tests were referred or accompanied to confirmatory testing and antiretroviral therapy (ART) initiation.

LESSONS LEARNED: FSWs, MSM, and FSW clients who self-tested were between two and five times as likely to have an HIV-positive result compared to those testing at DICs and mobile units (Table 1). The percent of first-time testers ranged from 91% to 100% for all populations and testing modalities. Lastly, the ART initiation rate following HIVST was higher than mobile or DIC testing for FSWs and MSM, but slightly lower for FSW clients.

	Indicators	FSWs	MSM	FSW Clients	Total
Self-testing	Case finding via HIVST	46% (N=498)	20% (N=347)	31% (N=68)	35% (N=913)
	% KP/PP initiated on ART	95%	94%	86%	94%
	% KP/PP who tested with self-testing kit who were first-time testers	100%	100%	100%	100%
Mobile testing	Case finding from mobile testing	10% (11,902)	7% (N=2,791)	7% (N=2,776)	9% (N=17,469)
	% KP/PP testing positive at mobile testing initiated on ART	83%	75%	88%	82%
	% KP/PP who were first-time testers among all tested in mobile testing	94%	91%	96%	94%
Drop-in Center (DIC)	Case finding at DICs	13% (N=2,286)	10% (N=1,931)	7% (N=306)	11% (N=4,523)
	% KP/PP testing positive at DICs initiated on ART	92%	87%	90%	90%
	% KP/PP who were first-time testers among all who tested at DICs	99%	99%	100%	99%

[Table 1]

CONCLUSIONS/NEXT STEPS: HIVST is critical to reaching undiagnosed HIV-positive key and priority population members who have refused to attend HIV testing at mobile, DIC, and facility sites. Assisted HIVST may also lead to high ART initiation rates when done through PEs.

PED1078

CONTRIBUTORS TO RESILIENCE FOR HIV PREVENTION AMONG FEMALE SEX WORKERS IN PATTAYA THAILAND

J. Sherwood[1], D. Phuengsamran[2], N. Darawuttimaprakorn[2], S. Janyam[3], M. Decker[4]
[1]amfAR, The Foundation for AIDS Research, Washington DC, United States, [2]Mahidol University, Institute for Population and Social Research, Salaya, Thailand, [3]Service Workers in Group Foundation (SWING), Bangkok, Thailand, [4]Johns Hopkins School of Public Health, Population Family & Reproductive Health, Baltimore, United States

BACKGROUND: Resilience is an understudied intrapersonal factor which has been associated with reduced HIV risk behaviors for some key populations including men who have sex with men. Resilience may hold equal promise for female sex workers (FSW) who also experience high rates of HIV, trauma, and adversity. We explore contributing factors to resilience among FSW in Pattaya Thailand with implications for preventing HIV and improving population health.

METHODS: 401 venue-based FSW were recruited via proportional-to-size venue-based sampling in Pattaya Thailand for an in-person survey (May, 2017). Consenting participants were asked questions on depressive symptoms, self-efficacy, experience in the sex trade, health access, feelings of community acceptance, safety, and resilience. Multivariable generalized linear regression was used to examine correlates of resilience from three domains; individual-level factors, venue/work factors, and community-level factors. Hierarchical regression models were built to examine the contribution of each domain of factors separately and in conjunction.

RESULTS: FSW resilience scores averaged 31.72 (range 13-40). In the multivariable model including factors from all three domains, FSW resilience was correlated with several individual-level factors including non-depression (β 2.55, 95% CI 1.07, 4.03), higher self-efficacy for condom use (β 1.64, 95% CI .66, 2.63), and lower self-efficacy for safety (β -.67, 95% CI -1.20, -.13). At the community-level, FSW resilience was associated with feelings of increased community acceptance of sex work (β .65, 95% CI .22, 1.20). No venue/work factors were found to be statistically associated with resilience, however FSW who reported higher levels of venue manager support had higher resilience scores (β .70, 95% CI -.26, 1.67).

CONCLUSIONS: FSW resilience scores from this sample are higher than those from previous samples of FSW in Asia, but lower than many general population estimates from high-income settings. In this context resilience may be an important HIV prevention factor for FSW with implications for improving condom use and mental health. Resilience-building interventions which have shown promise could be adapted for FSW in low and middle-income setting to improve HIV outcomes beyond what may be possible with risk-reduction interventions alone.

PED1079

HIV RISK PATTERNS AMONG WOMEN WHO USE DRUGS ON THE U.S.-MEXICO BORDER: A COMPARISON BY SEX WORK STATUS

G. Perez[1], J. Lechuga[2], S. Beachy[3], S. Lopez[2], A. Varela[2], O. Beltran[4], R. Ramos[1], M.E. Ramos[4]
[1]Alliance of Border Collaboratives, El Paso, United States, [2]The University of Texas at El Paso, Public Health, El Paso, United States, [3]Lehigh University, Counseling Psychology, Bethlehem, United States, [4]Programa Compañeros, Ciudad Juarez, Mexico

BACKGROUND: HIV research among female substance users residing on the U.S.-Mexico border has focused almost exclusively on female sex workers (FSWs). We analyzed the HIV risk factors of women who use drugs in the El Paso-Juarez U.S.-Mexico border region by sex work status.

METHODS: We analyzed data from a cross-sectional survey of females who use drugs. A total of 100 females substance users (30% who were sex workers) were recruited using respondent driven sampling. Data analysis included independent sample t-tests and chi-square tests to explore differences between FSWs and non-FSWs across different risk factors (i.e. demographics, substance use, STIs, HIV testing, sexual risk behaviors, and violence).

RESULTS: FSWs were younger (M = 34.83, SD = 6.72) vs non-FSWs (M = 40.24, SD = 11.67) (t = 2.26, p < .05). A significant difference was found in the amount of crack used with FSWs reporting a higher mean quantity of crack used 6.25 rocks (SD = 3.04) vs a mean of 2.64 rocks (SD = 5.36) for non-FSWs, (t = -2.25, p < .05). No significant differences were found in number or type of STI diagnoses or mean months elapsed since the last HIV test. Regarding sexual risk behaviors, FSWs reported a higher mean number of condomless sex acts in the last 30 days (M = 19.08, SD = 24.44) vs non-FSWs (M = 9.06, SD = 11.85) (t = -2.25, p < .05). However, non-FSWs reported a higher mean number of exchanges of sex for crack without a condom in the last 30 days (M = 7.06, SD = 16.86) than FSWs (M = 1, SD = 4.32) (t = 2.62, p < .05). Regarding violence victimization, a greater percentage of female sex workers (66.7%) than non-FSWs (18.6%) reported human rights violations by law enforcement, ($\chi 2$ = 15.67, p < .05).

CONCLUSIONS: Our findings indicate that different HIV risk patterns afflict women who use drugs depending on whether they are employed in the sex trade. Understanding the diverse needs of women substance users can increase the preventive services available for them and inform the development of tailored interventions.

PED1080

THE METHODOLOGICAL ASPECTS OF DESIGNING A FEMALE SEX WORKER-LED COMMUNITY INTERVENTION TO IMPROVE PRE-EXPOSURE PROPHYLAXIS UPTAKE AND RETENTION IN SOUTH AFRICA; AN INTERVENTION MAPPING APPROACH

N.F. Makhakhe[1], A. Meyer-Weitz[1], Y. Sliep[1]
[1]University of KwaZulu-Natal, Psychology (Health Promotion), Durban, South Africa

BACKGROUND: In 2016 the South African government approved PrEP distribution among high risk groups to reduce new HIV infections. Sex workers were targeted with PrEP as part of combination prevention. Research by the department of health showed that from June 2016-May 2018, 87% of FSWs tested negative, 66% were offered PrEP however only 13% were initiated. The reasons for low uptake have been concerns about side effects, lack of knowledge, as well as the social stigma and inability to adhere because of mobility. Due to these challenges, it was important to engage FSWs in the design of a FSW led community intervention to promote PrEP and address challenges pertaining to uptake, adherence and retention.

METHODS: From May-November 2018, we conducted a needs analysis with 30 individual interviews with FSWs, a researcher and a nurse and focus groups with nine FSWs. Data from the needs analysis informed the development of an intervention. The intervention was co-created starting September-November 2019, following a six step mapping process with eight FSW peer educators and a researcher, who held six meetings to discuss and formulate intervention determinants, change objectives, theory based methods, intervention program as well as identifying implementing partners and an evaluation plan.

RESULTS: All the participants interviewed appreciated the role of PrEP as an additional prevention tool, however recognised that the current strategies were not person-centred. The FSW-led intervention highlights the development of agency, power, self-efficacy and hope among FSWs. The proposed intervention destigmatizes PrEP through positive messaging, equipping FSWs with the ability to differentiate PrEP from ARVs given to people living with HIV. Suggestions are given on how to manage pill supply and side effects as well as equipping participants to be ambassadors for PrEP.

CONCLUSIONS: Improving uptake of PrEP among FSWs will require dedicated efforts in designing FSW acceptable interventions that address their individual and social needs. Meaningful involvement of FSWs in the design and implementation of PrEP services encourages uptake, and creates a sense of ownership to ensure sustainability of programs.

PED1081

PERPETUATING INEQUITY: DISPARITIES IN HIV-RELATED RISK AMONG TRANS WOMEN SEX WORKERS AND EFFECTS OF A TARGETED, ANTI-SEX-TRAFFICKING POLICY

C.M. Turner[1], S. Arayasirikul[2], E.C. Wilson[3]
[1]San Francisco Department of Public Health, Trans Research Unit for Equity (TRUE), University of California, Doctoral Program in Epidemiology & Translational Science, San Francisco, United States, [2]San Francisco Department of Public Health, Trans Research Unit for Equity (TRUE), University of California, Department of Pediatrics, School of Medicine, San Francisco, United States, [3]San Francisco Department of Public Health, Trans Research Unit for Equity (TRUE), University of California, Department of Epidemiology and Statistics, San Francisco, United States

BACKGROUND: Sex work is a means of survival for many trans women (TW) and presents numerous risks, including criminalization, institutionalization, trauma and contracting HIV. We assessed longitudinal disparities in HIV-related risk outcomes among trans women who do sex work (TWSW), and evaluated these risks for TWSW compared to TW not engaged in sex work from pre- and post-implementation of the US 2018 "Allow States and Victims to Fight Online Sex Trafficking Act" and "Stop Enabling Sex Traffickers Act" (FOSTA-SESTA).

METHODS: We analyzed 428 HIV-negative, adult TW from the Trans*National cohort study (2016-2019). Generalized estimating equations (GEE) characterized longitudinal differences in socioeconomic outcomes, transphobic hate crimes, discrimination from the police or courts, sexual partner meeting places, engagement in condomless anal intercourse, and incarceration for TWSW compared

to TW not engaged in sex work after adjusting for social transition and race/ethnicity. Finally, we compared the adjusted, pre-to-post law changes in the aforementioned outcomes for TWSW versus TW not engaged in sex work using difference-in-differences GEE regression analyses.

RESULTS: Over 18 months, TWSW had higher adjusted odds of being unstably housed, having illicit income sources, experiencing transphobic hate crimes, experiencing discrimination from police/courts, meeting sex partners in the street/public settings, meeting sex partners on Craigslist or other online forums (except dating apps), engaging in condomless anal intercourse, or being recently incarcerated ($p<0.01$ for all comparisons); TWSW also had a higher mean number of income sources ($p=0.03$). One difference-in-differences analysis showed additive interaction: the adjusted mean number of income sources reported by TWSW compared to those not engaged in sex work decreased from pre- to post-FOSTA-SESTA (from 1.81 to 1.54 for TWSW and from 1.48 to 1.45 for TW not engaged in sex work; $p=0.050$).

CONCLUSIONS: Numerous disparities in HIV-related risk exist for TWSW in San Francisco. Preliminary findings show that FOSTA-SESTA may not exacerbate some of these disparities; however, these analyses are likely underpowered and require more post-law follow-up data with a larger number of TWSW. This highlights the urgent need for comprehensive, long-term follow-up data of TW to accurately analyze policy effects, especially given the recent enactment of a number of other policies targeting TW.

PED1082

COMMUNITY BASED DISTRIBUTION OF HIV SELF-TEST REACHES MORE UNDIAGNOSED FEMALE SEX WORKERS IN TANZANIA

P. Urasa[1], N. Makyao[1], L. Subi[2], A. Ramadhani[3], M. Kagashe[4], B. Mutayoba[3], Neema Makyao
[1]National AIDS Control Programme, Prevention Unit, Dodoma, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, Directorate of Prevention Services, Dodoma, Tanzania, United Republic of, [3]Ministry of Health, Community Development, Gender, Elderly and Children, Prevention Services, Dodoma, Tanzania, United Republic of, [4]Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, United Republic of

BACKGROUND: Tanzania has made remarkable progress in reaching the 90-90-90 goals by 2020. Multiple HIV Testing Services (HTS) delivery are being implemented including Provider-Initiated HIV Testing and Counseling in health facilities or various community-based services . Trained peer educators are engaged to work in community settings and hotspots where Key and Vulnerable (KVP) beneficiaries gather, to deliver risk reduction counselling and facilitate linkage to HTS. Despite multiple approaches to ensure no one is left behind, testing gap exist among KVPs . HIV Self-Test has the potential to reach untested persons in Tanzania, link them to HIV care and treatment, to support the achievement of 909090 goals.

DESCRIPTION: The pilot was implemented from May 2018 to March 2019,aim to generating data on implementation models, uptake and acceptability of HIV self-testing among Key and Vulnerable Population so as to inform programming and policy shift. Various HIVST kits delivery points were established in Facility and Community through HIVST kits distributors. Providers were trained to provide information on HIVST kits usage. Direct and Secondary distribution models of kits were used in both setting. All KVP clients reached were given the opportunity to use a self-test (direct distribution), and take additional tests to their partners and/or peers (secondary distribution). Secondary distribution was intended to serve hardest-to-reach populations who could not access conventional HIV testing approaches with the KVP beneficiaries serving as distributors.

LESSONS LEARNED: A total of 20,632 kits were distributed to 17,252 clients. 84% were primary client who contacted the provider while 16.4 % kits were distributed as secondary. Majority 89.2% kits were distributed via community outreach settings and onsite 63.3%. Most clients were female Sex Workers as Primary client, and 76.4% aged 20-29 years and lowest were People Who Use Drugs 0.2%. 78.5% clients who received HIVST returned their results, and 4.1% were diagnosed HIV positive.

CONCLUSIONS/NEXT STEPS: Demand for HIV self Testing Services is high. Community based HIVST kits distribution Model is the best for reaching undiagnosed KVP Living with HIV in Tanzania. HIVST project contributed significantly to strengthen networks of KVP groups and promoted use of HIV preventive services.

PED1083

DETERMINANTS OF CONDOM BREAKAGE AMONG FEMALE SEX WORKERS IN NIGERIA

A. Adeyemi[1], C.E. Osakwe[2], E. Abatta[3], J. Halliday[1], O. Fakunle[2]
[1]Center for Infectious Diseases Research and Evaluation, Abuja, Nigeria, [2]Healthmatch International, Abuja, Nigeria, [3]Federal Ministry of Health, Abuja, Nigeria

BACKGROUND: The 2014 Nigeria Integrated Biological and Behavioral Surveillance Survey (IBBSS) estimated HIV prevalence at 19.4% for brothel-based Female Sex Workers (FSW) and 8.6% for non-brothel based FSW which was above the national average of 1.3%. Evidence has shown that FSWs were sometimes more likely to be consistent in condom use than regular partners, boy/girlfriends, and casual partners. Condoms are effective against the spread of HIV infection if they are correctly used without breakage during sexual intercourse. Condom breakages and slippages have been associated with commercial sex activities. This study assessed the determinants of condom breakage among FSW in Nigeria.

METHODS: The 2014 IBBSS data on female sex workers were analyzed. This was a cross-sectional study that involved cluster and time-location sampling techniques in brothels and non-brothels. The study was conducted in 13 Nigerian states and Federal Capital with a structured questionnaire collecting information on sexual and reproductive health. A negative binomial regression model was used to assess the determinants of condom breakage in the last one month.

RESULTS: The average age of FSW was 27.1±6.2years with an average age at first sex being 17.0±2.8years. The average number of clients/day was 4.4. The mean condom breakage was 1.1±3.2times. About 36.1% were currently married, 38.8% had sex with men that were 10years older, 55.0% completed at least secondary education, and 72.6% had HIV/STI information in the last 12 months. About 91.8% used condoms at last sex and consistent condom use was 29.1%. The percentage of condom breakage was 40.3% in the last month prior to the survey. Determinants of condom breakage were lack of condom lubrication incidence rate ratio (IRR)=3.6 95%CI 2.2-4.1, improper use of condom IRR=2.1 95%CI 1.5-3.9 and had sex with men that were 10years older IRR=1.9 95%CI 1.3-3.2.

CONCLUSIONS: Availability of condom lubricants is important in reducing the incidence of breakage of condoms. Although condom use at last sex was high but consistent condom use was low. Also,

improper use of condom is a determinant. Consistent, proper and effective use of condoms needs to be promoted among FSWs. Additionally, HIV/STI information should contain key information on effective condom use.

PED1084

A PILOT RANDOMIZED TRIAL OF A THEORY-INFORMED MHEALTH INTERVENTION TO SUPPORT ANTIRETROVIRAL THERAPY ADHERENCE IN HIV-POSITIVE HIGH-RISK WOMEN IN MOMBASA, KENYA

F.M. Aunon[1], G. Wanje[2], B. Richardson[1], L. Masese[1], T.A. Odeny[1], J. Kinuthia[3], K. Mandaliya[1], W. Jaoko[2], J.M. Simoni[1], R.S. McClelland[1]
[1]University of Washington, Seattle, United States, [2]University of Nairobi, Nairobi, Kenya, [3]Kenyatta National Hospital, Nairobi, Kenya

BACKGROUND: Women in sub-Saharan Africa have a higher prevalence of HIV compared to men, and women who engage in transactional sex are particularly affected. Mobile health (mHealth) interventions have shown promise in improving treatment outcomes in people living with HIV. This pilot randomized controlled trial (RCT) evaluated preliminary efficacy of a theory-informed mHealth intervention to improve adherence and viral suppression among HIV-positive women initiating ART or changing regimens due to virologic failure in Mombasa, Kenya.

METHODS: Women were randomized to intervention and standard of care control conditions, and were followed for six months after ART initiation or regimen change. Text messages were informed by the Information-Motivation-Behavioral Skills theory and personalized based on the participant's name, language, religion, and parity. Tailored text messages were sent automatically via the TextIt platform. Women were called by a nurse if they had a concern. Self-reported adherence was measured monthly using a visual analogue scale (VAS) and dichotomized as 100% vs <100%. HIV RNA viral load was measured at months three and six, and dichotomized as <30 copies/mL ("suppressed") vs >30 copies/mL ("detectable"). At month six, women responded to an IMB questionnaire and provided qualitative feedback about the intervention.

RESULTS: A total of 119 women participated in the RCT. Six months following treatment initiation, 78% (35/45) of intervention and 69% (34/49) of control participants were virally suppressed (p=0.37). At month six, 100% adherence by VAS was higher among women in the intervention arm (41/47, 87%) compared to the control arm (40/50, 80%) (p=0.3); there was a significant difference in the first month following treatment initiation (53/57, 93% vs 37/52, 71%, p=0.003). Intervention participants had higher scores in subsets of the IMB constructs compared to control participants; information (mean 88 vs 85, p=0.38), motivation (mean 71 vs 67, p=0.38), and behavioral skills (mean 81 vs 77, p=0.26), although differences were not statistically significant. Qualitative exit interviews suggested high satisfaction and perceived impact of the intervention.

CONCLUSIONS: This pilot trial of an mHealth intervention to support ART adherence in high-risk women demonstrated high feasibility and acceptability, and preliminary efficacy results appear promising.

PED1085

WOMEN'S MOVING INTO SEX WORK AND VULNERABILITY TO HIV TRANSMISSION: A STUDY IN BANGLADESH

N. Huda[1], P. Rawstorne[1], N. Stephenson[1]
[1]The University of New South Wales, School of Public Health and Community Medicine, Sydney, Australia

BACKGROUND: Given that sex work is stigmatized and quasi-legal in Bangladesh, a question may arise why women join sex work. Several studies have mentioned trafficking as the primary reason for women's entry into sex work. While this is true, a complete understanding of Bangladeshi women's involvement in sex work is poorly understood. This study aims to contribute to an understanding of socio-cultural factors that shape women's moving into sex work.

METHODS: 400 female sex workers (FSWs) completed a cross-sectional survey and 10 FSWs and 13 other stakeholders attended semi-structured in-depth interviews during mid-2017. Through the survey and in-depth interviews, participants were asked questions about women's involvement in sex work in a brothel setting in Bangladesh. Survey data were analyzed using SPSS software. Descriptive statistics were used to summarize the results. Qualitative data were analyzed thematically.

RESULTS: While most women moved into sex work through trafficking (71% of survey participants and 90% of FSWs in interviews), some women did not regard themselves as having been trafficked (29% of survey participants and 10% of FSWs in interviews). Survey findings demonstrated the key people involved in trafficking, including pimps (66.7%), neighbors (10.0%), family members (11.5%), madams (4.6%), boyfriends (4.6%), and thugs (2.5%). Interview participants recounted that poverty, exploitation, inadequate employment opportunities, and limited education contributed to women's trafficking into sex work. Participants' narratives also suggested that non-trafficked women's experiences of poverty, rape, forced prostitution, divorce, and false marriage prompted them to choose sex work as a means of survival. Once entered sex work, women felt obligated to choose sex work as their sole form of employment to survive and meet the subsistence and educational needs of their family members including parents, siblings, or children.

CONCLUSIONS: Despite quasi-legal status, sex work can be recognized as a viable form of employment to earn money for supporting women and their family members. It is also important to create alternative employment opportunities for women who experienced socio-cultural factors. The complete decriminalization of sex work and proper implementation of laws are vital to safeguard women from trafficking and exploitation, enhance agency, and reduce their HIV vulnerability.

MEDICAL GENDER AFFIRMATION TREATMENT IS ASSOCIATED WITH INCREASED HIV/STI TESTING IN AN ONLINE SAMPLE TRANSGENDER WOMEN IN THE US

M. Zlotorzynska[1], S.D. Baral[2], A. Scheim[3], C.E. Lyons[2], J.L. Maksut[2], J.M. Wiginton[2], C. Logie[4], S.W. Beckham[2], T. Sanchez[1]
[1]Emory University, Atlanta, United States, [2]Johns Hopkins University, Baltimore, United States, [3]Drexel University, Philadelphia, United States, [4]University of Toronto, Toronto, Canada

BACKGROUND: Transgender women are disproportionately affected by HIV and STI infection. Medical gender affirming treatment (GAT) may facilitate uptake of testing and prevention services. We assessed HIV/STI testing and PrEP use in a cross-sectional online survey of US transgender women.

METHODS: Social media advertisements were used to recruit participants age 15+ who identified as transgender women or whose gender identity was female and reported male sex assigned at birth. Analyses were restricted to those who reported past year anal and/or vaginal sex. Modified Poisson models tested associations between GAT (hormone therapy with or without gender-affirming surgery) and HIV and STI (syphilis, gonorrhea, chlamydia) testing, controlling for age, race/ethnicity, county population density and any healthcare provider visit in the past year. Past year PrEP use was also assessed but could not be modeled due to limited use.

RESULTS: Of 267 participants in the analysis, 58.4% reported current hormone therapy only and 10.9% reported both hormone therapy and at least one gender-affirming surgery. Compared to those who did not receive GAT, participants who did were more likely to report being tested for an STI in the past year (49.2% vs. 18.3%; adjusted prevalence ratio [aPR]=2.34; 95% Confidence Interval [CI]: 1.40-3.89). Among HIV-negative/unknown status participants, those who had received GAT were more likely to have been tested for HIV, both ever (70.7% vs. 30.9%, aPR=1.80; 95% CI:1.26-2.56) and in the past year (53.0% vs. 21.0%, aPR=2.09; 95% CI:1.32-3.31). Associations for STI or HIV testing did not vary by type of GAT received. The prevalence of past year PrEP use varied by receipt of GAT: 13.8% of participants who received hormones and surgery, 9.0% of those who received only hormones, and 1.2% of those who did not receive any GAT.

CONCLUSIONS: These findings suggest that gender affirmative services for transgender women in the US provides derivative benefits in increased HIV/STI testing and PrEP use, independent of general healthcare engagement. Transgender women remain at among the highest risk of HIV in the US and around the world, and these data support scaling up integrated models of gender affirmative healthcare and HIV services to optimize both HIV and health outcomes.

PED1087

HARNESSING RESILIENCE IN VIOLENCE AND HIV PREVENTION INTERVENTION RESEARCH WITH, FOR, AND BY TRANSGENDER WOMEN OF COLOR IN DETROIT, MICHIGAN, USA

K. Gamarel[1], L. Jadwin-Cakmak[1], A. Lacombe-Duncan[2], R. Trammell[1], L. Reyes[3], C. Burks[3], B. Campbell[3], G. Harper[1], E. Arnold[4]
[1]University of Michigan, Health Behavior & Health Education, Ann Arbor, United States, [2]University of Michigan, School of Social Work, Ann Arbor, United States, [3]Trans Sistas of Color Project, Detroit, United States, [4]University of California, San Francisco, United States

BACKGROUND: Transgender women of color experience intersectional forms of stigma and violence, which have been linked to HIV transmission risk and inequities in HIV prevention and care continuum outcomes. To date, little research has focused on what fosters resilience (i.e., healthy adaptation in the face of adversity) among transgender women of color, which may guide effective HIV prevention and treatment programming for this priority population.

METHODS: Between January and March 2019, we conducted five focus groups (n=33 participants) with transgender women of color as part of the Love Her Collective, a community-academic partnership. The overall goal of the study was to identify the HIV-related health needs of transgender women of color in Detroit, Michigan. Focus groups were audio-recorded and transcribed. We employed a phenomenological analytic approach to explore and refine themes related to resilience, stigma, and violence.

RESULTS: Participants ranged in age from 18 to 66 (M=31); 79% identified as Black, and 18% identified as Multiracial; 63% were living with HIV and 29% did not know their status. Participants described their own past and current stigmatizing and traumatic experiences (e.g., down-low or secret relationships, exploitation, fears of being "clocked" and murdered) and discussed how these experiences motivated them to engage in actions to address violence and safety for all transgender women of color. We identified four overarching themes that fostered resilience in this context: 1) Activism led by transgender women of color; 2) Solidarity and safety in numbers; 3) Self-respect and healing; and 4) Instrumental support in the form of emergency funds and peer navigation. Although many participants were under-/unemployed, which posed one barrier to accessing services, they frequently shared resources and helped other transgender women of color navigate fragmented and discriminatory healthcare and social services.

CONCLUSIONS: Transgender women of color engage in a multitude of activities to combat and heal from stigma and violence. Findings highlight the need to address violence and stigma in HIV prevention and treatment efforts, and for these efforts to include community-action activism projects to foster empowerment and supportive groups to promote safety and solidarity. HIV prevention and treatment efforts should also incorporate individual-level healing and economic empowerment.

PED1088

HIV PRE-EXPOSURE PROPHYLAXIS (PREP) IN GENDER-DIVERSE PREP USERS IN GERMANY: FINDINGS FROM THE PRAPP STUDY 2019

M. Appenroth[1,2], U. Marcus[1], S. Albrecht[3], K. Jansen[1], B. Gunsenheimer-Bartmeyer[1], V. Bremer[1], U. Koppe[1]
[1]Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany, [2]Institute of Public Health, Charité Universitätsmedizin, Berlin, Germany, [3]Robert Koch Institute, Department of Epidemiology and Health Monitoring, Berlin, Germany

BACKGROUND: Gender-diverse people face adverse socioeconomic conditions including financial instability and unemployment, which might impact access to HIV pre-exposure prophylaxis (PrEP). We want to investigate how gender-diverse people use PrEP in Germany.
METHODS: From April to June 2019, we recruited PrEP users in Germany on MSM geolocation dating apps, community-based HIV testing sites and a community website for an anonymous online survey. Factors associated with gender-diverse PrEP users were assessed with univariable logistic regression.
RESULTS: We recruited 3,071 PrEP users, 96.3% provided information on gender identity and sex assigned at birth. Of these, 2,911 said that their current gender identity matches their sex assigned at birth, whereas 47 were gender-diverse, i.e. their gender identity and sex assigned at birth differed. The group of gender-diverse PrEP users included 26 identifying as non-binary, 10 as trans male, 6 as male, 3 as trans female, and 2 as intersex.
Gender-diverse PrEP users were younger than other PrEP users (median 29 years, IQR 24-33 vs. 37 years, IQR 30-45, p<0.001) and more likely to be born outside Germany (OR = 4.2, 95% 2.0 – 8.8). They were more likely to live on an annual gross income <30,000 EUR or have no income at all (71.4% vs. 29.0%, OR = 6.1, 95% CI 2.9 – 12.8).
Regarding their PrEP use, gender-diverse participants were more likely to obtain PrEP by traveling to another country (OR = 5.8, 95% CI 2.4 – 14.3). They also stated more often that they were not able to afford generic PrEP in Germany for a price of 40-70€ per month (OR = 5.3, 95% CI 2.5 – 11.4) or had difficulties affording it (OR = 4.0, 95% CI 1.9 – 8.4).
CONCLUSIONS: Gender-diverse PrEP users faced economic difficulties and more often sought access to PrEP outside the German healthcare system. Coverage of PrEP by statutory health insurances, as implemented in Germany since September 2019, might help people in this vulnerable population to overcome financial barriers to accessing PrEP. However, other barriers to accessing health care faced by gender diverse people still need to be addressed.

PED1089

SEXUAL AND MENTAL HEALTH MORBIDITY INDICATORS OF ASSIGNED-FEMALE-AT-BIRTH (AFB) MEN-WHO-HAVE-SEX-WITH-MEN (MSM) IN EUROPE: FINDINGS FROM EMIS 2017

U. Koppe[1], M. Appenroth[1,2], F. Hickson[3], A.J. Schmidt[3], P. Weatherburn[3]
[1]Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany, [2]Institute of Public Health, Charité Universitätsmedizin, Berlin, Germany, [3]London School of Hygiene & Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom

BACKGROUND: The group men-who-have-sex-with-men (MSM) include people who were assigned-female-at-birth (AFB) and who now identify as men. We analyzed indicators of sexual and mental health morbidities from the 2017 European MSM Internet Survey (EMIS), comparing AFB MSM with those assigned-male-at birth (AMB).
METHODS: Opportunistic multi-language online sexual health survey for MSM, primarily recruited through MSM dating apps (fieldwork Oct 2017– Jan 2018). Differences between AFB and AMB MSM were analyzed using multivariable logistic regression adjusting for age, country and employment status.
RESULTS: Of 125,720 participants in Europe, 0.5% (n=674) indicated they were AFB. Compared to AMB MSM, AFB participants were more likely to indicate: severe anxiety & depression (21.1% vs 7.6%, adjusted odds ratio [aOR]=2.27, 95% confidence interval (CI) 1.87–2.75): recent thoughts of self-harm (45.6% vs 20.7%, aOR=2.49, 95% CI 2.13–2.91); being unhappy with their sex life (33.1% vs 22.4%, aOR=1.53, 95% CI 1.30–1.81); and alcohol dependency (25.3% vs 18.3%, aOR=1.39, 95% CI 1.17–1.66). In contrast, they were less likely to report living with diagnosed HIV (1.6% vs 10.5%, aOR=0.19, 95% CI 0.11–0.35) or being diagnosed in the last 12 months with syphilis (1.0% vs 4.4%, aOR=0.25, 95% CI 0.12–0.52) or gonorrhea (2.6% vs 5.3%, aOR=0.43, 95% CI 0.27–0.70).
CONCLUSIONS: Poor mental health, alcohol dependence and sexual unhappiness were more prevalent in AFB MSM compared to AMB MSM. Conversely, diagnoses of STIs were less common. To facilitate planning and to increase inclusion, sex-assigned-at-birth should be routinely collected in MSM surveys.

PED1090

DETERMINANTS OF UTILIZATION OF HIV AND OTHER HEALTH SERVICE AMONG TRANS PEOPLE IN FOUR COUNTRIES - NEPAL, INDONESIA, VIETNAM AND THAILAND: FINDINGS FROM A QUALITATIVE STUDY

S. Badgujar[1], J. Wong[1], C. Young[1], M. Dhakal[2], U. Shrestha[2], W.A. Reswana[3], C.t. Ha[4], T. Nakor[5]
[1]Asia Pacific Transgender Network, Bangkok, Thailand, [2]Blue Diamond Society, Kathmandu, Nepal, [3]Gaya Warna Lentera Indonesia (GWL-INA), Jakarta, Indonesia, [4]Centre for Supporting Community Development Initiatives (SCDI) and Vietnam Network of Transgender People (VNTG), Hanoi, Vietnam, [5]Sisters Foundation, Bangkok, Thailand

BACKGROUND: Asia-pacific region has 60% of the world's transgender population and the HIV prevalence among them is quite high. However, there is lack of understanding of challenges faced by the transgender community. A Key Population Research Advocacy-KPRA study was undertaken from August 2018 to May 2019 in four countries—Indonesia, Nepal, Thailand, and Vietnam to understand the existing situation and generate evidence for advocacy.
METHODS: The study was undertaken with 996 transgender people in four countries. The respondents were 75% trans-women, 23% trans-men, and 2% gender non-conforming persons. The age of participants was 18 years and above. The data was entered into REDCap, a web based application designed to capture clinical and field research and analysed by using SPSS.
RESULTS: 90% of trans-women respondents were aware of STIs, and over two-thirds have tested for STI and 75% shared that they had tested for HIV. Indonesia had the highest numbers of people living with HIV (n=47, 23%). 21% HIV+ respondents in Indonesia, 29% in Nepal, 40% in Thailand, and 50% in Vietnam mentioned delay in initiating treatment due to fear of discrimination and non-confidentiality or disclosure of their positive status.
Despite of high level of education respondents mentioned that they have limited work opportunity and most of them are working in the entertainment industry, beautician or unemployed. Transgender community also faces several mental stress and many of them thought of committing suicide at some point. The mean age at first

attempt of suicide is 15.5 years and only 15% have seek professional help for the same.

Respondents from Vietnam (99%) and Thailand (97%) has health insurance, while in Nepal (90%) and Indonesia (60%) respondents do not have health insurance. The hormonal treatment were sourced through friends, pharmacies, online stores, and other non-medical sources. Also, less than 5% sought advised from health professional before using hormones.

CONCLUSIONS: The findings from the study highlighted the need of addressing stigma and discrimination along with ensuring provision of social services including employment opportunities and health insurance. There is need for inclusion of trans affirming services, mental health and counselling to improve the well-being of transgender community.

PED1091

FACTORS ASSOCIATED WITH ATTITUDES TO HIV-1 CURE RESEARCH AMONG TRANSGENDER WOMEN AND TRAVESTIS IN SÃO PAULO, BRAZIL

R.J. Wozniak[1], N.B. Cerqueira[2], M.C.S. Dantas[2], B. Mahafe[2], D.A.C. Barros[2], E.A.d. Medeiros[2], A.C.S.d. Oliveira[2], T. Sabino[2], V.I. Avelino-Silva[2], C. Johnston[1], J.L. Marston[1], S.C. Bidegain[1], M. Magnus[3], E.G. Kallas[2], D.F. Nixon[1,2], C.S. Donini[2]

[1]Weill Cornell Medicine, Division of Infectious Diseases, Department of Medicine, New York, United States, [2]School of Medicine, University of São Paulo, Department of Infectious and Parasitic Diseases, São Paulo, Brazil, [3]The George Washington University, Department of Epidemiology, Washington DC, United States

BACKGROUND: Understanding the perceptions of the groups most affected by the HIV-1 epidemic is fundamental in guiding strategies for HIV-1 cure research. In Brazil, transgender women and travestis are 55 times more likely to be infected with HIV-1 than the general population. They are also less likely to have access to health information or to be included as participants in clinical studies overall.

METHODS: To better understand the perceptions of HIV-1 cure research and factors associated with participating in HIV-1 studies, a self-administered questionnaire was distributed among 118 transgender women and travestis in São Paulo, Brazil, between July-August, 2019.

RESULTS: Most participants (73%) had previously heard about HIV-1 cure research; 42% believed there is currently a cure for HIV-1. Most reported that they were willing to participate in online surveys, person to person interviews, focus group discussions, and studies involving blood draws; however, participants were less willing to consider participating in more complex studies, such as those involving gene editing or T-cell therapy. The biggest motivating factors that contributed to participation in HIV-1 cure research included gaining additional knowledge about HIV-1 infection (77%), as well as the potential for a longer and healthier life for all (73%). Side effects likely to discourage participation in research were dermatologic (43%), musculoskeletal (41%), HIV-1-related (40%), toxicities (40%) and psychological factors (39%). This study also showed ambivalence in answers to several of the questions due to missing data and uncertain responses, suggesting a limited understanding of HIV-1 cure research in the trans-identifying community.

CONCLUSIONS: This study provides novel insight on attitudes to HIV-1 cure research in the transgender and travesti population of São Paulo as well as the improvements that are needed to strengthen the dialogue between scientists and the vulnerable populations that are most affected by HIV-1. It is essential to continue developing collaborations between scientific investigators, community educators, transgender women, and travestis in order to ensure that future HIV-1 cure research is inclusive and supportive of the perspectives of the trans-identifying community.

TRANSGENDER AND CISGENDER INDIVIDUALS IN ARGENTINA DISENGAGED FROM HIV CARE: EXAMINING POTENTIAL CONTRIBUTORS

P.D. Radusky[1,2], I. Aristegui[1,3], L. Mandell[4], V. Zalazar[1], N. Cardozo[1,5], M. Alcaide[4], S. Weiss[4], O. Sued[1], D. Jones[4]

[1]Fundación Huésped, Research Department, Buenos Aires, Argentina, [2]Universidad de Buenos Aires, School of Psychology, Buenos Aires, Argentina, [3]Universidad de Palermo, Buenos Aires, Argentina, [4]University of Miami Miller School of Medicine, Department of Psychiatry and Behavioral Sciences, Miami, United States, [5]Association of Transvestites, Transsexuals, and Transgenders of Argentina (A.T.T.T.A.), Buenos Aires, Argentina

BACKGROUND: Transgender women (TGW) endure social exclusion and stigma, placing them in a context of high psychosocial vulnerability (sex work, unstable housing, exposure to violence, etc.). This is strongly associated with high HIV prevalence in this population (34%, in Argentina) and lower adherence to antiretroviral treatment (ART). This study compared two samples of people living with HIV (TGW vs. cisgender participants [CP]) who were disengaged from HIV care.

METHODS: The COPA2 study (NCT02846350) enrolled viremic HIV-positive individuals, re-engaging in care at baseline, to explore the impact of motivational interviewing on viral suppression. Disengagement from care was defined as at least 3 missed pharmacy pick-ups in the last 6 months, or no physician visits in the last year. TGW were included to identify factors associated with gender identity. Participants completed questionnaires assessing sociodemographic information, depression (BDI-IA), drug (DAST-10) and alcohol use (AUDIT), patient-provider relationship quality, adherence (VAS) and treatment-related factors. Analyses included chi-square tests exploring the association between variables and ANCOVAs comparing groups controlling for age.

RESULTS: The samples consisted of 41 TGW and 360 CP (177 male, 183 female). TGW were significantly younger (mean age 33.43 ±8.84 years, vs. 39.14 ±10.96 for CP). Around 80% of each group had completed high school education or less; 34.1% of TGW and 28.1% of CP met criteria for moderate to severe depression (BDI≥17). Transgender identity was associated with not having health insurance ($p<.001$), use of drugs ($p<.001$), particularly cocaine ($p=.005$), in the last 6 months, and hazardous drinking ($p=.001$). TGW showed more negative consequences related to drug use ($F(1,398)=26.999$, $p<.001$), more hazardous alcohol use ($F(1,398)=14.198$, $p<.001$), lower patient-provider relationship quality ($F(1,398)=7.805$, $p=.005$) and lower adherence ($F(1,398)=5.725$, $p=.017$) than CP. No other significant differences were identified.

CONCLUSIONS: TGW in this sample had characteristics (e.g., depression, drug and alcohol use) and experiences (e.g., poor patient-provider relationship quality) that may negatively impact adherence and retention in care, highlighting the need for comprehensive programs for this population. Harm reduction should be a key component in HIV care to address substance use. Healthcare teams should receive formal training in patient-provider communication skills and trans-specific competencies to enhance TGW's adherence and retention.

PED1093

SEXUAL RISK AND PRECAUTION BEHAVIOURS AMONG ASSIGNED-FEMALE-AT-BIRTH (AFB) MEN-WHO-HAVE-SEX-WITH-MEN (MSM) IN EUROPE: FINDINGS FROM EMIS 2017

M. Appenroth[1,2], U. Koppe[1], F. Hickson[3], A.J. Schmidt[3], P. Weatherburn[3]
[1]Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany, [2]Institute of Public Health, Charité Universitätsmedizin, Berlin, Germany, [3]London School of Hygiene & Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom

BACKGROUND: The group of men, who have sex with men (MSM) includes people who are assigned-female-at-birth (AFB) and who now identify as men. Differences in sexual risk behaviours between AFB and MSM assigned male-at-birth (AMB) are known with little confidence. We compared quantitative behavioural indicators from the 2017 European Men-who-have-sex-with-men Internet Survey (EMIS) for AFB and AMB MSM.

METHODS: Opportunistic multi-language online sexual health survey for MSM, primarily recruited through MSM dating apps (fieldwork Oct 2017– Jan 2018). Differences between AFB and AMB MSM were analyzed using multivariable logistic regression adjusting for age, country and employment status.

RESULTS: Of 125,720 participants in Europe, 0.5% (n=674) indicated they were AFB. AFB men were less likely than AMB men to have had (in last 12 months) 5 or more non-steady male partners (16.5% vs 45.1%, adjusted odds ratio [aOR]=0.27, 95% confidence interval (CI) 0.22–0.33), condomless intercourse with a non-steady male partner of unknown HIV status (12.1% vs 23.9%, aOR=0.45, 95%CI 0.36–0.57), condomless intercourse with two or more steady male partners (4.7% vs 8.6%, aOR=0.57, 95%CI 0.40–0.82), or to have combined sex and stimulant drugs in the past 4 weeks (2.5% vs 5.3%, aOR=0.51, 95%CI 0.32–0.83). They were also less likely to be currently taking PrEP (1.2% vs 3.1%, aOR=0.44, 95%CI 0.22–0.89).

CONCLUSIONS: Both risk and precaution behaviours were less prevalent in AFB MSM than among AMB MSM. To facilitate planning and to increase inclusion, sex assigned at birth and current gender identity should be routinely collected in MSM surveys.

PED1094

LACK OF HIV TESTING AMONG ADULT TRANSGENDER WOMEN SEEKING HORMONE THERAPY IN ARGENTINA

I. Aristegui[1,2], O. Sued[1], N. Cabrera[3,1], Y. Duran[3], C.E. Calvar[3]
[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Universidad de Palermo, Research in Psychology Department, Buenos Aires, Argentina, [3]Hospital Dr. Juan A. Fernandez, Endocrine Unit, Buenos Aires, Argentina

BACKGROUND: Transgender women's (TGW) HIV prevalence is 34% in Argentina. Despite efforts to improve the continuum of care, TGW still are lately diagnosed. Since the enactment of the Gender Identity Law, health services providing hormone therapy (HT) have become the gateway to healthcare and a unique opportunity to access other health services. Our objective was to determine HIV prevalence and to identify predictors of lack of testing among TGW seeking HT at a public hospital in Buenos Aires.

METHODS: Data from medical records of TGW consulting for HT between July 2012 and December 2019 was used. As the standard of care, individuals at risk of acquiring HIV, unaware of their HIV status, or with outdated results, were invited to test for HIV. Chi-square and Mann–Whitney U test analyses were conducted to compare groups (known/unknown HIV-status). Multivariable logistic regression was performed to examine for predictors.

RESULTS: A total of 411 TGW visited the clinic. At first visit, 38.4% (n=158) have never tested for HIV, 27.7% (n=114) were HIV-positive and 33.8% (n=139) were HIV-negative. At follow up, 75/158 participants with unknown status tested for HIV (3 were HIV-positive). 56.4% of HIV-positive TGW reported a history of sex work. TGW still with unknown-HIV status (n=83) were significantly younger (30.8 vs 23.5 years, p=.001), reported less history of sex work (18.1% vs 38.4%, OR 2.8; IC 95%: 1.5-5.2: p=.001), and were less likely to have used HT (44.6% vs 65.9%, OR 2.4; IC 95%: 1.5-3.9: p=.001).

CONCLUSIONS: Young TGW who are not involved in sex work or have never used hormones seem not to perceive themselves at risk or are not adequately reached by HIV testing campaigns. To fill in this gap, health programs should design strategies that target this particular subgroup focusing on prevention, testing, and avoidance of risk behaviors. Also, given the high prevalence of HIV among TGW, comprehensive approaches and stronger liaisons with different services are needed. HT can be an opportunity to improve HIV testing and linkage to care, improving overall transgender health.

PED1095

SEXUAL BEHAVIOURS AND EXPOSURE TO HIV AND OTHER STIS IN TRANSGENDER MEN IN ARGENTINA

V. Zalazar[1], I. Puhlmann[2], M. Romero[2], P. Radusky[1,3], C. Frola[1,4], N. Cardozo[1,2], S. Fabian[1,5], M. Duarte[1,2], P. Cahn[1], I. Aristegui[1,6], O. Sued[1]
[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Asociacion de Travestis, Transexuales y Transgeneros de Argentina (A.T.T.T.A.), Buenos Aires, Argentina, [3]Universidad de Buenos Aires, School of Psychology, Buenos Aires, Argentina, [4]Juan A. Fernandez Hospital, Division of Infectious Diseases, Buenos Aires, Argentina, [5]Asociacion Civil Hotel Gondolin, Buenos Aires, Argentina, [6]Universidad de Palermo, Buenos Aires, Argentina

BACKGROUND: Historically, transgender studies have focused on transgender women. In contrast, transgender masculinities (TGM) have remained understudied, although limited research suggests they also are at risk of acquiring HIV. Thus, there is a need to identify sexual risk and preventive behaviours for HIV and other STIs in TGM.

METHODS: Data was collected from an online national survey, designed based on the results of a TGM focus group. The final draft was reviewed and approved by TGM activists. The survey was conducted between May and September 2019 through social media. It included questions regarding socio-demographics, gender identity and sexuality (e.g., attraction, behaviours, etc.).

RESULTS: From a total of 415 TGM, 50.1% self-identified as trans men, 20.7% as men, 15.4% as non-binary/genderfluid/agender/other and 13.7% as transmasculine. The median age was 23 (IQR: 19–27), 7.5% were foreign-born and 74.2% completed secondary education. Regarding sexual orientation, 33.3% identified as heterosexual, 25.5% pansexual, 24% bisexual and 6.3% homosexual. In terms of sexual attraction, 47.7% was attracted to cisgender men, 82.4% to cisgender women, 52.5% to transgender men, 50.4% to transgender women and 47.7% to non-binary. In the last month, 47% had had sex with cisgender women, 20% with cisgender men, 9.4% with transgender men, 6.8% with non-binary and 4.6% with transgender women. Additionally, 38.3% of TGM had used alcohol or drugs with their partners before or during sex. Only 52.4% reported using condoms, 4.7% dental dam and 42.4% nothing, as regular preventive methods. Also, 17% had a history of transactional sex and only 58.3% used protection

during these sexual relations. In their last sexual relation, 63.8% had not used protection, being the main reason, having been tested for HIV with their partner (42.3%).

CONCLUSIONS: TGM reported a broad variability in sexual behaviours, including relationships with a high HIV-prevalence population. A high proportion of TGM engage in unprotected sex suggesting increased levels of exposure to HIV and other STIs, usually neglected by prevention programs and public policies. This initial evidence contributes to raising awareness and visibility on the exposure of TGM to HIV and STIs and on the need to design specific strategies targeting this population.

HOUSING AND ENGAGEMENT IN CARE INFLUENCING HIV SCREENING AMONG TRANSGENDER INDIVIDUALS IN SOUTH FLORIDA

E. Cyrus, PhD, MPH[1], H. Perez-Gilbe, MLIS, MPH[2], G. Wuyke, MSc[3], S. Johnson, MPH[3], F. Fajardo, MLIS, MPA, MA[4], A.N. Garba, MD, PhD, MPH[4], J. Deviéux, PhD[3], C. Holder, MD[4]

[1]Florida International University Robert Stempel College of Public Health and Social Work, Epidemiology, Miami, United States, [2]University of California, Libraries, Irvine, United States, [3]Florida International University Robert Stempel College of Public Health and Social Work, Health Promotion and Disease Prevention, Miami, United States, [4]Florida International University Herbert Werthem College of Medicine, Miami, United States

BACKGROUND: Transgender individuals are considered most at risk for acquiring HIV, representing the highest number of newly confirmed cases. The Southeast region of the United States has emerged as an area of immediate concern, especially South Florida with the areas of highest prevalence in the country. HIV screening is a critical step in the HIV continuum to lower incidence and facilitate viral load suppression among populations most at risk. There are few studies assessing factors associated with HIV screening among transgender individuals living in the Southeast region of the United States. The objective of this study was to assess factors influencing engagement in routine care and HIV screening among transgender individuals in South Florida.

METHODS: An observational, cross-sectional study was conducted with participants recruited between Miami-Dade and Broward Counties. Sixty-eight participants were recruited during Fall 2016. They completed a questionnaire as part of a pilot pre-exposure prophylaxis (PrEP) study. Correlations were examined between socio-demographic factors, HIV risk, access to care, and engagement in routine care. Significant correlations were entered into two logistic regression models to estimate predictors of HIV screening and knowledge of HIV status.

RESULTS: Almost half (48.5%) of respondents were Latinx, 38.2% Black, 10.3% non-Latinx White (NLW), and 3% other. Seventy-eight percent reported access and routine engagement in care within the past year, 25% had not screened for HIV in the past year and of those who screened,13.4% reported living with HIV. Regression analysis revealed that participants with routine engagement in care were twice as likely to screen for HIV (p=0.02). Unstable housing (38.8%) was associated with no HIV test in the past year (p=.05) and living with HIV (p=0.02).

CONCLUSIONS: Stable housing, which has been demonstrated to influence willingness to take PrEP, and engagement in routine care can increase the likelihood of a transgender individual engaging in annual HIV screening. Further research is needed to explore additional factors that contribute to unstable house and inconsistent engagement in care, so that effective interventions can be developed to improve engagement in care among transgender individuals who do not have adequate housing or access to care.

PED1097

INFORMING RESEARCH ON INTERVENTIONS TO REDUCE HIV RISK BEHAVIOR AMONG TRANSGENDER WOMEN AND THEIR PRIMARY SEX PARTNERS: FORMATIVE RESEARCH FOR THE IT TAKES TWO (T2) COUPLES STUDY

E.S. Stein[1], B. McCree[2], A. Jackson[2], C. Clynes[2], D. Olem[2], D. Chakravarty[2], D. Operario[3], K. Gamarel[4], J.M. Sevelius[2]

[1]University of California San Francisco (UCSF), HIV/AIDS, Infectious Diseases, and Global Medicine, San Francisco, United States, [2]University of California San Francisco (UCSF), Division of Prevention Sciences, San Francisco, United States, [3]Brown University, Public Health Behavior and Social Sciences, Providence, United States, [4]University of Michigan, Health Behavior and Health Education, Ann Arbor, United States

BACKGROUND: Transgender ('trans') women are a priority population for HIV prevention efforts. A significant number of new HIV infections among trans women occur in the context of primary partnerships; however, there are few couples-focused HIV prevention interventions designed with and for trans women of color. For the past 10 years, we have engaged in community-centered research to identify intervention targets to prevent HIV transmission among trans women and their partners using qualitative, survey, and intervention adaptation methodologies. Our collective work has led to the implementation of "It Takes Two (T2)" which is a randomized controlled trial (RCT) of a multi-session couples-based HIV prevention intervention.

METHODS: In February and March 2019, we conducted two focus groups (n=11) with trans women and individual in-depth interviews with cisgender male partners of trans women (n=4). Focus groups and in-depth interviews sought to identify potential adaptations to the intervention protocol that had demonstrated feasibility, acceptability, and preliminary efficacy in a pilot RCT. Focus groups and in-depth interviews were audio-recorded and transcribed. We employed thematic and content analysis to inform T2 study implementation.

RESULTS: Overall, trans women and cis-gender male partners were enthusiastic about the couples-based HIV prevention intervention. We identified four main themes that were relevant to study implementation:

(1) avoid hetero-normative and binary eligibility criteria for partners (i.e., HIV risk does not only occur with cis-gender men); (

2) the need for creative strategies to engage partners who may be on the "down-low" and secretive about their relationship due to shame and stigma;

(3) potential concerns about sessions being delivered by a peer counselor who is a trans woman (e.g., jealousy, fears of unfaithfulness, relationship conflict); and

(4) flexibility in scheduling and adequate incentives to compensate participants for time and transportation.

CONCLUSIONS: These findings were incorporated into the T2 intervention protocol and study design, and T2 recently opened and five couples have been enrolled as of January 2020. Formative data highlight the importance of continuously engaging in cultural humility, collaborating with community, and accounting for evolving definitions of HIV transmission risk and the relationship needs of trans women in the development and implementation of intervention research.

PED1098

FACTORS ASSOCIATED RECENT HIV TESTING AMONG TRANSGENDER WOMEN IN CAMBODIA: FINDINGS FROM A NATIONAL SURVEY USING RESPONDENT DRIVEN SAMPLING METHOD

P. Chhoun[1], S. Chhim[2], N. Chann[3], S. Eng[1], S. Tuot[1], P. Mun[3], S.C. Choub[1], S. Yi[1,4,5]

[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]FHI 360, Phnom Penh, Cambodia, [3]National Center for HIV/AIDS, Dermatiology and STD, Surveillance Unit, Phnom Penh, Cambodia, [4]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [5]Touro University California, Center for Global Health Research, Vallejo, United States

BACKGROUND: Globally, the prevalence of HIV in transgender women is among the highest in all key populations, and a large proportion of transgender women are unaware of their HIV status. This study aimed to identify factors associated with recent HIV testing among transgender women in Cambodia.

METHODS: This national survey was conducted in 2016 among a nationally representative sample of transgender women recruited from the capital city and 12 provinces with a high HIV burden using Respondent Driven Sampling method. Face-to-face interviews were conducted using a structured questionnaire. A multivariable logistic regression analysis was performed to explore factors associated with recent HIV testing. This study was approved by the Cambodian National Ethics Committee for Health Research.

RESULTS: This study included 1,375 transgender women with a mean age of 25.8 years (SD= 7.1). Of the total, 49.2% had been tested for HIV in the past six months. After adjustment, participants who had been testing for HIV in the past six months remained significantly less likely to be a student (AOR= 0.36, 95% CI= 0.20-0.65), to perceive that they were unlikely to be HIV infected (AOR= 0.50, 95% CI= 0.32-0.78), and to report always using condoms with male non-commercial partners in the past three months (AOR= 0.65, 95% CI= 0.49-0.85) compared to those who had not been tested. Regarding access to community-based HIV services, participants who had been testing for HIV in the past six months remained significantly more likely to report having been reached by community-based HIV services in the past six months (AOR= 5.01, 95% CI= 3.29-7.65) and receiving some forms of HIV education and materials in the past six months (AOR= 1.65, 95% CI= 1.06-2.58) compared to those who had not been tested.

CONCLUSIONS: More than half of transgender women in this study had not been tested for HIV in the past six months despite the availability of extensive community-based HIV testing services across the country. HIV testing promotion programs with both HIV education and HIV testing services should be tailored to reach sub-groups of this high-risk population who have not been reached by the existing strategies.

PED1099

ENGAGING COMMUNITY LEADERSHIP TO OVERCOME HIV TESTING BARRIERS AMONG TRANSGENDER PEOPLE IN INDIA

K. Krishnan[1], M.R. Parthasarathy[1], T. Maheshwari[1], J. Bhaishya[2], B. George[1]

[1]FHI 360, LINKAGES, New Delhi, India, [2]USAID India, Health, New Delhi, India

BACKGROUND: Transgender (trans) people experience an elevated risk of HIV infection and barriers to accessing HIV services. Community-centric HIV service-delivery approaches may be optimally positioned to meet the differentiated preferences and needs of trans people who would otherwise be left behind and accelerate HIV epidemic control. The PEPFAR/USAID funded LINKAGES project led by FHI 360 piloted three HIV community engagement strategies in trans Interventions across six high burden districts in India.

DESCRIPTION: We reviewed and analyzed routine program data to assess the differential outcomes of three community engagement strategies to close HIV service access gaps among trans people. First, implementation of the enhanced peer outreach approach (EPOA) facilitated peer-led referrals to HIV testing and other services from trans people in the community. Second, the project supported community-led interventions (CLIs) involving service mobilization conducted by community-based organizations (CBOs). Third, community- based HIV testing and counseling (CBHTC) was prioritized to bring HIV testing service outside of clinical facilities to at-risk individuals in remote locations who might not otherwise access testing. Implementation and performance of the three approaches were monitored separately. Prevention services including HIV testing were provided. Individuals with positive HIV test results were offered assisted peer navigation for initiating ART.

LESSONS LEARNED: From October 2016 to September 2019, the project tested 1,376 trans people for HIV with an overall case detection rate of 6.39 % (n=88). Antiretroviral therapy (ART) initiation was 68.18% (n=60). Across the three community engagement models, EPOA was the most efficient reaching 674 trans people, had a case detection rate of 9.34% (n=63), and 70% ART initiation. The CLI approach that reached 622 trans people, had a case detection rate of 2.57% (n=16), and of whom 69% initiated ART. The CBHTC approach reached 78 trans people with a case detection rate of 11.53% (n=9), and of whom 56% were initiated on ART.

CONCLUSIONS/NEXT STEPS: The results showed that all three approaches expanded reach and case findings among trans people who otherwise would not have accessed HIV services. Integrating community-centric prevention approaches tailored to the local context and scaled up within the national HIV program will help countries achieve saturation coverage and epidemic control.

THE ROLE OF POLICE HARASSMENT, MENTAL HEALTH AND SUBSTANCE USE IN RETENTION IN HIV CARE AMONG TRANSGENDER WOMEN IN A TRANS-SENSITIVE CLINIC IN BUENOS AIRES, ARGENTINA

I. Aristegui[1,2], P. Radusky[1,3], V. Zalazar[1], C. Frola[1,4], N.F. Cardozo[1,5,6], M. Duarte[1,5,7], S. Fabian[8], A. Gun[1], M. Romero[5,6,7], P. Cahn[1], O. Sued[1]

[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Universidad de Palermo, Research in Psychology Department, Buenos Aires, Argentina, [3]Universidad de Buenos Aires, School of Psychology, Buenos Aires, Argentina, [4]Hospital Dr. Juan A. Fernandez, Infectious Diseases Unit, Buenos Aires, Argentina, [5]Asociación de Travestis, Transexuales y Transgéneros de Argentina (A.T.T.T.A.), Buenos Aires, Argentina, [6]REDLACTRANS, Buenos Aires, Argentina, [7]Casa Trans, Buenos Aires, Argentina, [8]Asociación Civil Gondolin, Buenos Aires, Argentina

BACKGROUND: In Argentina, HIV prevalence among transgender women (TGW) is 34% and morbi-mortality is still high. Engagement and retention of TGW in HIV care are precluded by the number of syndemic factors negatively affecting this population. Thus, our purpose was to identify psychosocial factors associated with retention in care among TGW initiating ART.

METHODS: TRANSVIIV is a single-arm prospective clinical trial designed to assess retention, viral suppression and adherence to DTG-TDF/FTC among HIV-naive TGWs in the context of a trans-competent

multidisciplinary clinic (physicians, psychologists, peer navigators, endocrinologists). Participants were interviewed longitudinally on socio-demographic characteristics, sexual behavior, gender identity-related stigma in different settings (healthcare, education, housing, work, police), alcohol (AUDIT) and drug (DAST) use, depression (CES-D), anxiety (STAI), personality traits (PID-5-BF), quality of life (PWI-A), and HIV-related stigma (Berger). Retention was defined as completing the assessment at week-48 (+/- 4 weeks).

RESULTS: 61 TGW were enrolled, 19.7% lately diagnosed (≤200 CD4), median age 28 (IQR 25-32). High levels of psycho-social vulnerability were observed at baseline: 60.7% ≤ high-school, 53.3% unstable housing, 29.5% foreign-born, 77% sex work, 65.6% regular drug use, 52.5% hazardous drinking, 50.8% depressive symptoms, 44.3% physical and 32.8% sexual violence last year. Moreover, 31% reported being arrested (sex work/drug dealing) and 18% experienced police harassment last year. At week 48, 77% (n=47) were retained in care and 72% (n=44) were virologically suppressed. Those with failed retention at week 48 reported at baseline more experiences of police harassment (OR=0.16, 95%CI 0.04–0.65), negative affectivity (OR=.27, 95% CI 0.07–1.01) drug/alcohol consumption with clients during sexual encounters (t(55)=-2.76, p=.008), and lower quality of life (t(59)=-2.09, p=.041), than TGW that were retained. The remaining factors were not significantly different.

CONCLUSIONS: The combination and high burden of syndemic psychosocial problems predict failure in retention in a prospective trial of TGW initiating ART. Although trans-competent HIV care may help to counteract the negative effect of syndemic factors on health outcomes, programs that aim at improving engagement and retention should incorporate mental health care, drug harm reduction and skills to cope with violence. More research is needed to identify specific interventions for reducing its impact.

HIV AND STI POSITIVITY RATES AMONG TRANSGENDER PEOPLE ATTENDING TWO LARGE STI CLINICS IN THE NETHERLANDS

S. Drückler[1], C. Daans[1,2], E. Hoornenborg[1], H. de Vries[3,1], M. den Heijer[2], M. Prins[1,4], S. Kuizenga-Wessel[5], M. van Rooijen[1]
[1]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [2]Amsterdam UMC, Department of Internal Medicine, Center of Expertise on Gender Dysphoria, Amsterdam, Netherlands, [3]Amsterdam University Medical Centers, University of Amsterdam, Department of Dermatology, Amsterdam Institute for Infection & Immunity (AI&II), Amsterdam, Netherlands, [4]Amsterdam University Medical Center, University of Amsterdam, Division of Infectious Diseases, Amsterdam, Netherlands, [5]Public Health Service Haaglanden, Department of Sexual Health, The Hague, Netherlands

BACKGROUND: We assessed HIV and STI positivity rates, sociodemographic characteristics and sexual (risk)behavior among transgender people (TGP) with different gender-identities visiting the STI clinics in Amsterdam and The Hague.

METHODS: We retrieved data from all TGP who were tested at the STI clinic of Amsterdam and The Hague. Data of the first consultation in the study period (2017-2018) was included. To identify one's gender-identity a "2-step" methodology was used: 1) the assigned gender at birth was asked (assigned male at birth (AMAB) or assigned female at birth (AFAB); 2) the current gender-identity (Figure 1). HIV and STI (chlamydia, gonorrhea and/or syphilis) positivity rates and sexual (risk)behavior were studied using descriptive statistics.

RESULTS: The gender-identities of 329 TGP visiting the STI clinic of Amsterdam and The Hague showed a large diversity (Figure).

[Figure]

STI positivity rate ranged from 10% to 22% among AMABs (Table). Positive rate was lower in AFABs. Two of 45 non-binary AMABs (4.4%) were newly diagnosed with HIV. HIV prevalence varied from 0% (AFAB) to 15% (AMAB). Sex work was most frequently reported among transwomen (63.5%).

[Table]

CONCLUSIONS: To our best knowledge, this is the first study among TGP visiting Dutch STI clinics reporting different gender-identities and related HIV and STI positivity rates. We found that more AMABs than AFABs attended the STI clinics, but numbers were relatively small. HIV and STI positivity rates were substantial among AMABs, and higher than among AFABs. Offering gender-affirming sexual health care might increase HIV and STI testing uptake among these underserved key populations.

PED1102

INTEGRATING TRANSGENDER HEALTH INTO HIV AND SEXUAL AND REPRODUCTIVE HEALTH AND RIGHTS (SRHR) PROGRAMMING IN INDONESIA, NEPAL, THAILAND AND VIETNAM

J. Wong[1], R. Cortes[1], C. Young[1], S. Zaidi[1]
[1]Asia Pacific Transgender Network (APTN), Bangkok, Thailand

BACKGROUND: Although the transgender community has become more visible, their health needs are unrecognized and they lack access to competent, quality care in HIV and sexual and reproductive health and rights (SRHR) programming. The Key Population and Research Advocacy (KPRA) project of the Asia Pacific Transgender Network (APTN) documented the barriers to access to health services for transgender people in Indonesia, Nepal, Thailand, and Vietnam. The transgender-led study builds capacity of trans people in conducting qualitative research and uses evidence-based advocacy for better health care and HIV programmes for transgender people.

METHODS: APTN and country partners collected information from 996 transgender people in urban centers of Indonesia, Nepal, Thailand, and Vietnam. 75% were trans women, 23% were trans men, and 2% gender non-conforming. The KPRA project used different interview methods; focus group discussions, key informant interviews, and community-based surveys, to capture the lived experience of transgender people. The data was entered into REDCap, a web-based application designed to capture clinical and field research, and analysed using SPSS.

RESULTS: The majority of respondents had been tested for HIV, from 81% in Indonesia to 74% in Vietnam. Indonesia reported the highest number of HIV positive cases (n=47) while Vietnam reported only 2. However, those participants who had tested positive for HIV delayed

seeking treatment. The most common reason for delaying treatment was 'fear of discrimination' followed by the lack of knowledge on transgender health needs by the healthcare providers. Transgender sex workers were more likely to delay treatment because of dual discrimination. At least 10% of respondents did not utilize HIV prevention services. Respondents preferred utilizing CBO-led health services for SRHR issues. Respondents reported that barriers, whether practical or gender-related, to accessing health services were correlated with worse physical and mental health.

CONCLUSIONS: Although the majority of participants had been tested for HIV, the numbers were below the 90% target set by UNAIDS for 2020. It is urgent that health care providers be trained in addressing the health needs of transgender people, and implement strategies that reduce discrimination. Governments should invest in community-led health services, including treatment for HIV.

PED1103

AVAILABILITY, ACCESSIBILITY AND BARRIERS TO HIV, GENDER-AFFIRMING AND OTHER HEALTHCARE SERVICES FOR TRANSGENDER PEOPLE IN LAO PDR, MONGOLIA, PAPUA NEW GUINEA, PHILIPPINES, SRI LANKA AND TIMOR LESTE

R. Cortes[1], J. Wong[1], C. Young[1]
[1]*Asia Pacific Transgender Network (APTN), Bangkok, Thailand*

BACKGROUND: Sustainability of HIV Services for Key Populations in Asia (SKPA) Program (multi-country Global Fund grant), aims to promote sustainable services for key populations to stop HIV transmission and AIDS-related deaths by 2030. The Asia Pacific Transgender Network (APTN) is a regional sub-recipient, providing transgender health technical assistance to six countries: Lao PDR, Mongolia, Papua New Guinea, Philippines, Sri Lanka and Timor Leste.

DESCRIPTION: The program initially rolled-out in Sri Lanka and completed three focus group discussions (FGDs) with 24 trans participants in November 2019, using the FGD tool/methodology from APTN's "Key Populations Research and Advocacy" project. The FGDs focused on availability, accessibility, quality, gaps and barriers to HIV, gender-affirming, and other healthcare services among trans people. Furthermore, APTN convened 14 trans and gender diverse participants (i.e. health workers/advocates) from six countries for a regional capacity building on transgender health and HIV service and advocacy. During the workshop, the FGD tool was rolled-out to gather insights from the group on the same topic.

LESSONS LEARNED: In Sri Lanka, FGD trans participants were generally aware of HIV and gender-affirming services offered but often chose not to access free healthcare services due to stigma and discrimination from medical staff, and biased provision of services. Trans women particularly expressed concerns of negative attitudes of doctors and nurses, fear of negative treatment, and concerns related to confidentiality or being 'outed' inside the HIV testing clinic. Philippines participants shared that HIV screening, counseling, confirmatory testing, diagnosis and treatment are available, similar to Sri Lanka and other countries where mobile and HIV-specific clinics and support groups are also available. However, across many of the other countries, HIV-related services are not provided outside of city centers, making access in rural areas difficult.

CONCLUSIONS/NEXT STEPS: Across the FGDs in Sri Lanka and during the workshop, participants agreed that a major barrier in accessing HIV, gender-affirming, and general healthcare services is the lack of trans-competent and sensitized healthcare providers. APTN's sees this as important to provide technical assistance to these countries to start up and/or upscale provision of trans-competent and responsive HIV and gender-affirming care based on evidence from further FGDs conducted in countries.

PED1104

BUILDING THE CAPACITY OF TRANSGENDER COMMUNITIES ON MONITORING AND OVERSIGHT OF GLOBAL FUND ON HIV PROCESSES IN INDIA, PHILIPPINES AND THAILAND

R. Cortes[1], J. Wong[1], C. Young[1]
[1]*Asia Pacific Transgender Network (APTN), Bangkok, Thailand*

BACKGROUND: Under the Community, Rights and Gender - Strategic Initiative (SI) of Global Fund (GF), in partnership with Global Action for Trans Equality (GATE), the Asia Pacific Transgender Network (APTN) conducted capacity building workshops based on the developed monitoring and oversight training module. This aims to develop the skills and capacities of transgender communities to monitor and meaningfully engage in GF processes on HIV.

DESCRIPTION: In February 2019, APTN collaborated with trans-led and inclusive organizations: LakanBini Advocates Pilipinas, India HIV/AIDS Alliance and Sisters Foundation in Thailand, to organize three workshops for trans and gender diverse people which included lectures, discussions, brainstorming, role-playing games, and presentations. The monitoring and oversight workshops comprised of four modules: Global Fund 101, Meaningful Involvement, Monitoring and Evaluation, and GF Thematic Guidance.

LESSONS LEARNED: In all three workshops conducted, the trans participants learned on how to use the monitoring and oversight tool to ensure they play a pivotal role in the in all GF processes throughout the grant cycle. Participants were able to identify platforms to be engaged especially in current GF in-country projects, and opportunities to request for funding support and technical assistance. The importance of monitoring and evaluation was also emphasized, along with strategies to strengthen concept notes and project proposals were shared. Some of the key learnings shared throughout the workshops include: ensure advocacy and funding requests are supported by trans-specific data; practice evidence-based decision-making to improve project performance; develop a robust monitoring and evaluation system that enhances program implementation; and ensure complementarity of project proposals with existing GF projects.

CONCLUSIONS/NEXT STEPS: Prior to the workshops, only a few trans participants were aware of the GF processes or how they could participate and be represented throughout the processes. Communities play an important role and should be involved throughout all GF processes and other international grants. The CRG Technical Assistance should be maximized which provides short-term support to strengthen trans engagement and inclusion. By equipping the community with the necessary knowledge and skills, transgender people are able to keep national, regional, and global mechanisms accountable to ensure that the populations that need it most are benefitting from this financial mechanism.

PED1105

FEASIBILITY AND ACCEPTABILITY OF HIV PREVENTION RESEARCH AMONG YOUNG TRANSGENDER WOMEN WHO SELL OR TRADE SEX IN BANGKOK AND PATTAYA, THAILAND

T. Chemnasiri[1,2], A. Varangrat[1,2], K. Okanurak[3], S. Janyam[4], D. Linjongrat[5], A. Hickey[1,2], S.H.H. Mon[6], M. Decker[6], A. Wirtz[6], E.F. Dunne[1,2], C. Beyrer[6]
[1]U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]Thailand Ministry of Public Health - U.S. Centers for Disease Control and Prevention Collaboration, Nonthaburi, Thailand, [3]Mahidol University, Faculty of Tropical Medicine, Bangkok, Thailand, [4]Service Workers in Group Foundation, Bangkok, Thailand, [5]Rainbow Sky Association of Thailand, Bangkok, Thailand, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

BACKGROUND: Transgender women, particularly young transgender women (YTGW) who sell or trade sex, are one of the populations most affected by the HIV epidemic in Thailand. We assessed acceptability, feasibility and optimal design of a combination HIV preventive intervention for YTGW in Bangkok and Pattaya using qualitative methods.

METHODS: We conducted key informant interviews with YTGW aged 18-26 years residing in Bangkok or Pattaya, Thailand who sold or traded sex in the last 12 months from July 2016-July 2018. We analyzed 21 key-informant interviews with a focus on sexual decision-making, health seeking behavior, HIV prevention knowledge and practice, PrEP knowledge, and feasibility and acceptability of participation in a PrEP study using Atlas.ti software.

RESULTS: Most YTGW interviewed reported high interest in HIV prevention and PrEP research, particularly in access to routine health checks and HIV prevention services. YTGW believed HIV prevention research participation supported consistent condom use and improved condom negotiation skills, while reducing potential HIV exposures due to condom breakage. However, participants requested other PrEP regimens for varied sex patterns. They reported that daily PrEP exceeded their level of risk due to infrequent transactional sex. Some participants criticized previous PrEP studies as complicated and time-consuming. Concerns related to PrEP use included: pain associated with blood-based HIV tests, size of PrEP pill, potential side effects from PrEP, and knowledge of HIV status. Perceived concerns included PrEP interaction with hormones, long-term side effects, and PrEP associated-stigma. Participants were also concerned that PrEP was not 100% effective, and may promote more condomless sex. Many acknowledged PrEP as a tool to increase the negotiated price for transactional sex. YTGW suggested additional options, such as combination formulations for HIV and STI prevention and/or beauty supplements (eg., hormones, glutathione, and collagen) should be considered.

CONCLUSIONS: PrEP research and implementation have both positive and negative impact for YTGW who sell or trade sex. Optimal research implementation among this high-risk population should be responsive to perceived concerns and challenges, and supportive of ways to improve prevention. Improving knowledge about PrEP, and reducing HIV/PrEP stigma among YTGW, could increase interest in research and PrEP uptake.

PED1106

HIV TESTING, STI DIAGNOSIS, KNOWLEDGE OF U=U AND WILLINGNESS TO USE PREP AMONG TRANSGENDER MEN IN ARGENTINA

I. Aristegui[1,2], V. Zalazar[1], I. Puhlmann[3,4], M. Romero[3,5,4], P. Radusky[1,6], C. Frola[1,7], N. Cardozo[1,3,5], M. Duarte[1,4], S. Fabian[1,8], P. Cahn[1], O. Sued[1]
[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Universidad de Palermo, Research in Psychology Department, Buenos Aires, Argentina, [3]Asociación de Travestis, Transexuales y Transgéneros de Argentina (A.T.T.T.A.), Buenos Aires, Argentina, [4]Casa Trans, Buenos Aires, Argentina, [5]REDLACTRANS, Buenos Aires, Argentina, [6]Universidad de Buenos Aires, School of Psychology, Buenos Aires, Argentina, [7]Hospital Dr. Juan A. Fernandez, Infectious Diseases Unit, Buenos Aires, Argentina, [8]Asociación Civil Gondolin, Buenos Aires, Argentina

BACKGROUND: Transgender women have among the highest rates of HIV infection but little is known about HIV risk, prevalence, and knowledge about prevention among among transgender masculinities (TGM). Thus, our objective was to explore HIV testing, self-reported HIV/STI prevalence and knowledge on prevention methods among Argentinean TGM.

METHODS: Data was gathered between May and September 2019 through an online national survey directed to TGM. The questionnaire was informed by the results of focus groups and designed and reviewed by TGM activists and disseminated by a trans NGO through social media. Descriptive statistics were used to summarize data and HIV and STIs self-reported diagnoses

RESULTS: The survey was completed by 415 TGM, median age 23 years (IQR: 19–27), 74.2% completed secondary education, 61.6% had health insurance, 7.5% were foreign-born. Regarding health 20% discussed about HIV or STI with a provider, and 36.9 had a gynecologist appointment last year (30.6 previously). Regarding gender-affirming therapies, , 54.7% were using hormones, 31.4% had mastectomy and 1.8%, genital surgery (e.g., hysterectomy, phalloplasty). Nearly half (44.2%) was tested for HIV in the last year, but 30.5% never tested, being the main reasons 'not considering at risk' (n=32), 'not having the opportunity/never offered' (n=23), 'don't dare to ask for' (n=14), 'having a stable partner' (n=12), 'not knowing the test or where to test' (n=8), 'not having symptoms' (n=4). Self-reported diagnoses were: 4.6% HPV, 3.4% genital herpes, 2.7% chlamydia, 0.7% HIV, 0.7% syphilis, 0.7% gonorrhea, 0.5% hepatitis B, 0.2% hepatitis C. Only 38.1% correctly identified the U=U concept, whereas 30% had misconceptions and another 30% did not know. Regarding PreP, 55.7% would be willing to use it, 15,9% would not and 28.4%, was unsure.

CONCLUSIONS: Albeit the majority of TGM have access to education and health, e.g., gender-affirming procedures, a significant proportion do not have access to HIV testing, are not informed about the benefits of treatment as prevention and are hesitant about the use of PrEP. Trans-competent healthcare professional could contribute to diminish these gaps. More studies are needed to characterize risk behaviour and its reasons among this population in order to tailor specific HIV preventive interventions.

PED1107

IMPROVEMENTS IN MENTAL HEALTH AND QUALITY OF LIFE AMONG TRANSGENDER WOMEN AFTER 48 WEEKS ON ANTIRETROVIRAL TREATMENT IN A TRANS-SENSITIVE HIV CARE SERVICE IN BUENOS AIRES, ARGENTINA

P.D. Radusky[1,2], C. Frola[3,1], V. Zalazar[1], N. Cardozo[1,4,5], S. Fabian[1,6], M. Duarte[1,4,7], M. Romero[4,5,7], P. Cahn[1], O. Sued[1], I. Aristegui[1,8]
[1]Fundación Huésped, Research Department, Buenos Aires, Argentina, [2]Universidad de Buenos Aires, School of Psychology, Buenos Aires, Argentina, [3]Hospital Juan A. Fernández, Infectious Diseases Unit, Buenos Aires, Argentina, [4]Association of Transvestites, Transsexuals, and Transgenders of Argentina (A.T.T.T.A.), Buenos Aires, Argentina, [5]REDLACTRANS, Buenos Aires, Argentina, [6]Asociación Civil Gondolin, Buenos Aires, Argentina, [7]Casa Trans, Buenos Aires, Argentina, [8]Universidad de Palermo, Buenos Aires, Argentina

BACKGROUND: Exposure to gender identity stigma (GIS) and violence increases transgender women's (TGW) context of vulnerability and exclusion, negatively affecting their mental health and their access and retention in HIV care. This study analyzed changes in GIS and mental health in naïve TGW initiating ART in a multidisciplinary trans-sensitive HIV service, after 48 weeks in HIV care.

METHODS: Psychosocial interviews were conducted at baseline and after 48 weeks in an HIV clinic that included peer-navigators, trans-competent professionals, sensitized staff and hormone therapy. Information on socio-demographic characteristics, alcohol (AUDIT) and drug use (DAST-10), depression (CES-D), suicidal ideation, anxiety (STAI), maladaptive personality traits (PID-5), HIV-related stigma (Berger), social support (Duke) and GIS was gathered. Internalized GIS involves negative emotions (e.g., shame, guilt), anticipation of rejection and self-isolation. Enacted GIS comprises actual experiences of discrimination. T-tests were run to explore changes between baseline and 48 weeks, and multivariate linear regression, to test relations between GIS and mental health outcomes.

RESULTS: Participants were 61 TGW, median age 28 (IQR 25-32), 29.5% foreign-born, 60.7% high school or less, 77% sex work and 52.5% unstable housing. A significant number experienced GIS during last year in healthcare services (45.9%), sex work venues (44.3%), housing (29.5%) and by police (18%). At baseline, 50.8% showed significant depression, 65.6% drug use and 52.5% hazardous drinking in the last year. After 48 weeks, TGW significantly reduced their levels of depression ($t(45)=2.133$, $p=.038$), anxiety ($t(45)=2.644$, $p=.011$), negative affect ($t(45)=2.630$, $p=.012$), HIV-related stigma ($t(45)=1.968$, $p=.055$), and GIS, both enacted ($t(46)=5.390$, $p=.000$) and internalized ($t(46)=4.637$, $p=.000$); and significantly improved their quality of life ($t(46)=-3.667$, $p=.001$). The remaining indicators were not significantly modified. High levels of total GIS combined with low social support predicted the presence of depressive symptoms ($R^2=.51$, $F(2,43)=22.75$, $p\leq.000$).

CONCLUSIONS: Although a trans-sensitive healthcare service seems to have a gender affirmative impact on TGW that contributes to reduce GIS and to improve mental health, this strategy is not enough. Effective HIV care for TGW not only should include multidisciplinary trans-sensitive services but also should implement specific strategies such as interventions for depression, harm reduction, and health empowerment to enhance retention in HIV care.

PED1108

EXPANDING THE SCOPE OF COMMUNITY-BASED ORGANISATIONS IMPLEMENTING HIV/STI INTERVENTIONS TO INCLUDE GENDER-AFFIRMING HEALTHCARE SERVICES FOR TRANSGENDER WOMEN: EXPERIENCE FROM SOUTHERN INDIA

L. Ramakrishnan[1], A. Gunaseelan[2], S.S.A. Fathima[2], K. Mobina[2], M. Thilothama[2], T. Rajakumari[2], A. Hazra[1], M. Prabakar[3], S. Menon[2], S.S. Raghavan[1]
[1]SAATHII, Chennai, India, [2]Sahodaran, Chennai, India, [3]Consultant, Chennai, India

BACKGROUND: In India, health interventions for transgender women are largely confined to HIV/STI prevention and treatment services. However, community needs extend to gender-affirming general and transition-related healthcare, spanning mental health, hormone therapy, laser therapy and surgery. NGO SAATHII and community-based sexual health organisation Sahodaran demonstrated the feasibility of expanding the scope of transgender healthcare beyond HIV by adding on gender-affirming health services in southern India, with support from WHO and MAC AIDS Fund.

DESCRIPTION: The project was implemented in Chennai and Thiruvallur districts of Tamil Nadu, from Sept 2017 to October 2018, by a four-member team of trans women having prior experience in HIV/STI programs. The team was first trained on core issues relating to transgender health, and on engaging with healthcare providers outside the HIV/STI domain. The team then mobilized trans women from various community spaces, provided peer counseling, assessed their health needs,and referred them to relevant healthcare providers, accompanying them where necessary. Simultaneously the team mapped healthcare providers in the public and private sector based on community-articulated needs, sensitized them on trans women's healthcare needs, and motivated them to provide stigma-free and affordable care.

LESSONS LEARNED: Over an eight-month period, 915 transgender women were reached and served, and each received at least one peer-counseling session and one referral based on needs identified. Of these, 30% received a second peer counseling session, and 36% a second referral. In parallel, the project team identified and referred clients to 63 healthcare providers across 12 specialties, and of these, 21% were accompanied referrals. Trans women seeking gender-affirming surgery, endocrinology, psychiatric and dermatological care constituted 41% of the clients, while 27% sought general healthcare from providers who would respect their gender identity. Fifty clients (5%) were below 18 years, and sought consultations with pediatricians who would help their natal families accept their gender identity. Clients seeking HIV/RTI services made up 14% of the group.

CONCLUSIONS/NEXT STEPS: Community-based organizations implementing HIV interventions have in-house skills in peer-counseling, referrals and stigma-reduction, which can be leveraged, with additional capacity strengthening, to expand access to a wide range of gender-affirming general and transition-related healthcare.

PED1109

ONE SHOP STOP APPROACH FROM PREVENTION AND RETAINING IN CARE CASCADE FOR TRANSGENDER PERSON IN INDIA

F. Khan[1], A. Aher[1]
[1]*India HIV/AIDS Alliance, Care and Support Division, Delhi, India*

BACKGROUND: In India, people with a wide range of transgender-related identities, cultures and experiences exist. As per National AIDS control Organization (NACO) HIV estimation 2015, HIV prevalence estimated at 0.26% whereas among transgender it is 7.5%. Hence considers them transgender and Hijra TGH) as a key population and designed TG-specific HIV prevention programme. Linkage gaps: Among TG who tested positive at ICTC, only 80.8% are linked to ART centers. As of May 2017, 6792 TGs were registered in ART programme but, of them, only 3506 were in active care which is 51.6% of total registration, and among registered TG only 2380 has started ART (35%)

DESCRIPTION: With the support of GFATM and NACO 10 care and support centers (CSC) for TG community under Vihaan progamme was established as pilot initiative. The programme has adopted differentiated care strategy to reach out community for HIV related services as one stop shop starting from prevention (460 Support group meetings were organized on treatment retention and adherence, 1331 people received peer counselling, 1202 people received prevention services) as well as transgender specific services such as 803 people provided information on feminization process, 596 provided information on SRS, 154 people refer to STI treatment. 47 advocacy meetings were organized for demand generation for social protection schemes

LESSONS LEARNED:

- TG CSC has provided a platform where both HIV related and Transgender related services available. This has resulted in increased linkage with ART centers, 35% increased ART initiation and retention.
- Early identification of 35 positive clients and linkages with ARV treatment were highly possible due to this combination approach.
- One shop stop approach which is starting from prevention and retaining in care cascade
- Community led advocacy demand particular he social protection schemes is making positive impact

CONCLUSIONS/NEXT STEPS:

- TG specific intervention among the TG PLHIV is supplementing the National AIDS response to reduce the missing gaps.
- It can be replicated with other key populations based on this evidence.
- Collaboration with other health and non-health programme to increase the service packages

PED1110

EXPLORATION OF HIV RISKS AND SERVICE MODALITY FOR TRANSGENDER PEOPLE THROUGH COLLABORATION WITH COMMUNITY ORGANIZATIONS

L. Cai[1], H. Zhang[1], Y. Hu[2], R. Xiong[2]
[1]*China AIDS Information Network, Beijing, China,* [2]*NCAIDS, China CDC, Beijing, China*

BACKGROUND: The unique vulnerabilities of transgender people have not been adequately studied, nor their service needs adequately addressed in China, in ways that set them apart from MSMs. Online social networks have enabled CBOs better reach this population, and better understand their behaviors. Supported by NCAIDS of China CDC, China AIDS Information Network (CHAIN) worked with community organizations to conduct this study.

METHODS: From July to September 2019, CHAIN worked with 6 CBOs in Tianjin, Beijing, Yunnan and Sichuan to conduct an online survey among 205 transgender people born male and over age 24, and personal interviews of 20, on their sexual behaviors, healthcare use, social discrimination and psychosocial needs. Data collection and analysis used a combination of quantitative and qualitative methods.

RESULTS: The survey found 32.9% of respondents ever buying or selling sex, and another 16.8% have sex work as their sole income source. Consistent condom use rate when buying or selling sex was 75.9%. Over half (50.7%) of respondents wanted more tailored HIV prevention education, and 13.7% want more convenience and confidentiality in HIV testing. They also want more practical support on prevention, physical and psychological wellness, legal assistance, and free quality condoms and lubricants.

Among the 68.8% respondents who reported discrimination and violence, 82.3% experienced verbal abuse, 78.7% experienced unfair treatment, 18.4% experienced physical violence, and 14.2% experienced sexual violence, which came from classmates (31.2%), police (28.4%), neighbors (28.4%), family members (27%), friends (27%), colleagues (21.3%) and strangers (17%). Sexual violence came from sex partner or clients.

Over 88% of respondents sought psychological support, mainly from peers (65.7%), counselors (52.5%) or friends (47.5%). About 25% turn to surgeons for emotional support. Only 20.4% talked to parents.

CONCLUSIONS: Transgender people need tailored HIV prevention education. Well-implemented protective laws are needed to combat discrimination and violence. Health services should go beyond HIV-STI prevention to address their psychosocial needs, including professional mental health counseling. Service providers, especially health workers, should learn how to address the unique needs of this group with respect to their dignity and confidentiality. Transgender people need more convenient HIV testing, and affordable condoms and lubricants.

PED1111

ART AS A POWERFUL TOOL FOR BUILDING A TRUSTFUL SUPPORT NETWORK FOR THE TGW COMMUNITY – THE TRANSCRIÇÕES PROJECT

L. Monteiro[1], A. Chaves[1], C. Jalil[1], J. Freitas[1], L. Kamel[1], D. Bezerra[1], B. Grinsztejn João[1]
[1]Instituto Nacional de Infectologia - Fiocruz, Rio de Janeiro, Brazil

BACKGROUND: Of the populations affected by HIV, evidence shows that TGW carry the heaviest HIV burden globally. Transphobia is associated with higher rates of social isolation, increased risk of HIV acquisition and impaired access to treatment and prevention services. In 2015, an art focused program, known as Transcrições was conceived to build bridges and foster relationships with the TGW community through art related activities. This program was designed as a preparedness step for establishing a TGW referral center for health care and research at Fiocruz, a major public health research institution in Brazil.

DESCRIPTION: The development of the Transcrições art workshops was inspired by Paulo Freire's Pedagogy of the Oppressed, the artist Lygia Clark's therapeutical propositions, and the Relational Aesthetics theory. Conducted monthly, these workshops aimed to improve body consciousness, emphasize active listening and group awareness, and increase trust and empathy among the participants through an exchange of personal experiences and aspirations. Museum and drama play tours were organized to encourage attendance of the TGW population at cultural facilities. Overall, 310 TGW attended 52 meetings, lectures and tours, with average frequency of 35 participants.

LESSONS LEARNED: In a qualitative assessment performed in December 2019 among 33 TGW, all participants described the Transcricoes project art workshops as highly empowering; 72% (n=24) described the project as pivotal in increasing their self-confidence and sense of belonging; for 33% (n=11) it aided their recovery from social isolation and profound depression. The use of art was shown to be a powerful tool for fostering self-esteem, encouraging social interactions, forming new friendships and inspiring resiliency. Over the past four years, through this increased community engagement, Fiocruz was able to successfully recruit and retain this population in its HIV prevention clinical trials. The TGW presence at the research institute was extremely positive for Fiocruz, offering the opportunity to embrace a greater and more diverse audience and also develop cutting edge scientific studies benefitting the TGW community.

CONCLUSIONS/NEXT STEPS: We will expand and promote workshops in disenfranchised neighborhoods in Rio de Janeiro and create partnerships with other cultural agents, health services and institutions.

PED1112

EQUITY IN ACTION: A NATIONAL TRANSGENDER PROFESSIONAL DEVELOPMENT INSTITUTE

M. Everett, MHS[1], J. Fuega, MPH[1], T. Moatan, MBA-HRM[2]
[1]ETR, Oakland, United States, [2]San Francisco Community Health, Chicago, United States

BACKGROUND: Among the 3 million HIV tests reported to CDC in 2015, the percentage of transgender people who received a new HIV diagnosis was more than triple the national average. Transgender professionals are often recruited into the HIV/AIDS workforce (H/AWF) but are not always equipped with the skills needed for their complex dual roles as employees and members of the focus population. The purpose of the "Be the Change: National Transgender Professional Development Institute" (TPDI) was to provide in-depth training to members of the Transgender HIV/AIDS workforce (TH/AWF) to transition them from client to staff role, develop protective boundaries, learn management skills, develop leadership skills and understand their role within their organization.

DESCRIPTION: In June 2018 ETR, in collaboration with seven Transgender identified consultants, hosted TPDI in Oakland, California, a two-day training for TH/AWF staff. Twenty-three Transgender persons from across the United States attended sessions focused on: High Impact Prevention (HIP), Project Leadership, Project Management, and Dual role navigation. TPDI's goal was to provide proactive professional development and ongoing capacity building support to agencies employing transgender persons to successfully implement HIP services with an emphasis on CDC grantees.

LESSONS LEARNED: Participants self-reported a mean increase in skills (3.04/3.63 on a 5-point scale) and knowledge (2.73/3.73 on a 5-point scale). Participants felt empowered to apply knowledge and skills gained to their organizational work. This extensive professional development training was especially beneficial for early career members of the TH/AWF. The "For Us by Us" trans-led sessions created opportunities for Trans leaders to build the capacity of others. Regional mini-TPDI trainings has the potential to address more specific and unique challenges in TH/AWF development.

CONCLUSIONS/NEXT STEPS: TPDI was critical in providing opportunities for transgender-led capacity building in efforts to end the HIV epidemic. The Institute provided the greater TH/AWF with a model for assessing Transgender communities and institutions that employ and support them. This model also supports a "with us and with them" collaborative facilitation model that allowed for continued learning. Next steps include distributing lessons from the TPDI model toward empowering the TH/AWF to apply skills beyond responses to the HIV epidemic.

PED1113

HOW FAR ARE WE FROM ENDING AIDS AMONG TRANSGENDER PEOPLE?

E. Lamontagne[1,2], S. Howell[3,4,5], A. Yakusik[2]
[1]Aix-Marseille University, CNRS, EHESS, Centrale Marseille, AMSE, Les Milles, Marseille, France, [2]UNAIDS, Strategic Information Department, Geneva, Switzerland, [3]LGBT Foundation, San Francisco, United States, [4]Hornet, San Francisco, United States, [5]Johns Hopkins University, Centre for Public Health and Human Rights, Baltimore, United States

BACKGROUND: Social, economic and structural factors can contribute to the higher transmission of HIV in the transgender community and dissuade them from seeking healthcare.

We conducted the global Lesbian, Gay, Bisexual, Transgender, Intersex and plus (LGBTI+) Happiness survey to examine how various demographic, economic, socioecological, psychosocial, attitudinal and behavioural variables potentiate HIV risk behaviour.

METHODS: We used a socioecological approach to identify the relevant variables, select established instruments and validated questions and scores. Members of the LGBTI+ community were involved in each steps of the survey.

This anonymous online survey was accessible in 30 languages from May to December 2019 through a secure encrypted internet link.

It was broadcasted worldwide through LGBTI+ social networks and social media. The survey was also promoted at country-level thanks to the support of national LGBTI+ organisations, activists, and development partners.

RESULTS: We collected responses from a convenience sample of 5.698 transgender participants (39% transgender men, 61% transgender women) from 175 countries and territories. Our initial findings indicate that most (58%) of the transgender respondents faced transphobic reactions within the last year. Felt and enacted stigma in health facilities keep 57% away from accessing health care facilities for their sexual health or for HIV-related services. A large proportion (38%) of transgender people are exposed to economic vulnerability. 26% are doing sex work, increasing their vulnerability to HIV infection.

With respect to the HIV response, we found that 35% of participants never had an HIV test. Self-reported HIV prevalence is 8.5% and 28% don't know their status. 28% of those who reported that they were living with HIV are not accessing treatment. Finally, among those accessing treatment, 36% are not virally suppressed.

CONCLUSIONS: The HIV response is still far from meeting the 90-90-90 targets among the transgender people. Stigma and discrimination faced by transgender people hamper the HIV response and increase their vulnerability to HIV infection. Socioecological factors must be addressed in order to end the epidemic among transgender people.

PED1114

IMPROVING THE ACCESS TO AND RETENTION IN HIV PRIMARY CARE FOR AFRICAN AMERICAN TRANSGENDER WOMEN IN OAKLAND, CA, USA

T. Nemoto[1], M. Iwamoto[1], S. Suico[1], V. Stanislaus[1]
[1]*Public Health Institute, Oakland, United States*

BACKGROUND: In Oakland, high HIV sero-prevalence and a lack of access to HIV primary care among African American transgender women have been reported. Through the HRSA SPNS initiative, the Princess Project was implemented to enhance engagement and retention in HIV care for African American transgender women living with HIV in Oakland.

DESCRIPTION: The Princess Project implemented the trans-sensitive intervention consisted of a series of individual peer counseling sessions by trans Health Educators. The motivational interviewing techniques were used to assist participants to attain personalized goals to increase their access and retention in HIV care. A total of 60 participants enrolled in the Project. At the end of intervention, a convenience sample of 12 participants who had completed the intervention (n=7) or dropped out (n=5) was selected for qualitative interviews.

LESSONS LEARNED: About half of the participants completed the intervention session. Those who completed the intervention highly valued personal connection and interaction with a Health Educator: "Cause I just felt really safe with her talking...And it's just nice to know I can connect with a person on that level..."; "Get to know myself better and deeper... at the time I had nobody to talk to about the issue." Being homeless, disrespected at clinics, and strong stigma in the community were reported as barriers to accessing HIV care; however, those who completed the intervention tended to report positive engagement with clinical staff and stay in the care: "He (my doctor) respects me, calls me 'Ma'am', you know what I mean? He doesn't call me a 'dude'. He respects that I go by [my name] and not my legal name."

CONCLUSIONS/NEXT STEPS: Qualitative data from the peer-based Princess Project showed that personal engagement with Health Educators was a key to the participants' successful retention to the project. Client-centered motivational enhancement intervention with transgender Heath Educators, effectively increased the participant's skills to exercise self-reflection and empowered them to focus on their health and well-being. Future programs to increase their engagement in HIV primary care need to address stigma in African American communities through educational media campaigns.

PED1115

LEVERAGING LEGAL SERVICES IN A CLINICAL SETTING TO REDUCE THE IMPACT OF HIV ON TRANSGENDER COMMUNITIES

D. Faessler[1], N. Wilson[1], L. Galbreth[1]
[1]*East Bay Community Law Center, a Clinic of UC Berkeley School of Law, Health & Welfare, Berkeley, United States*

BACKGROUND: The HIV/AIDS Law Project of the East Bay Community Law Center (EBCLC), a teaching clinic of UC Berkeley School of Law, reduces the impact of HIV on transgender communities by addressing barriers to holistic legal services. This helps transgender communities become more secure, healthy, and hopeful.

Legal services ranks as the #1 service need for transgender women and #2 for transgender men (2019 Horizons Foundation study). According to the US Centers for Disease Control and Prevention, in 2017, transgender individuals tested for HIV were three times more likely to be diagnosed. Additionally, transgender women of color have heightened risk of HIV.

EBCLC deepens access to health, housing, public benefits, immigration status, and employment for low-income transgender adults and youth affected by HIV/AIDS and other conditions by providing holistic legal services and connection to community partners.

DESCRIPTION: Since 1989, EBCLC has collaborated with Alameda County HIV/AIDS medical providers to offer holistic legal services that address underlying social conditions of poverty for PLWHA. These conditions include threats to housing, stable income, and immigration status.

Through our work, we have recognized barriers transgender clients face in accessing legal services. In response, EBCLC created trainings for the next generation of service providers in areas such as Trans 101, implicit bias, and equitable hiring practices. Additionally, we have changed the physical space, student curriculum, and client interview questions.

Further, we have broadened our legal services to include insurance coverage for transition-related care, as well as name and gender marker changes.

LESSONS LEARNED:

- Training future clinicians to offer safe and affirming services is essential to reducing the disproportionate impact of HIV on transgender communities.
- Name and gender marker changes allow clients to be more safe and healthy, and create an entry point for additional legal services.
- Access to transition-related care improves personal safety and agency.
- Medical-Legal Partnerships provide holistic and interdisciplinary collaboration to meet PLWHA where they are.

CONCLUSIONS/NEXT STEPS: To limit the disproportionate impact of HIV among transgender communities, clinical programs should create internal trainings and policies that make services more accessible while exploring the import of providing additional services to meet the specific needs in local transgender communities.

PED1116

SOCIO SEROLOGICAL STUDY OF TRANSGENDER WOMEN IN DOMINICAN REPUBLIC: HIV AND STIGMA

H. Budhwani[1], K.R. Hearld[2], S. Butame[3], L. Tapia[4], S. Naar[3], R.M. Rodriguez-Lauzurique[4], R. Paulino-Ramirez[4]
[1]University of Alabama at Birmingham School of Public Health, Health Care Organization and Policy, Birmingham, United States, [2]University of Alabama at Birmingham, Health Services Administration, Birmingham, United States, [3]Florida State University College of Medicine, Center for Translational Behavioral Science, Tallahassee, United States, [4]Universidad Iberoamericana (UNIBE), Santo Domingo, Dominican Republic

BACKGROUND: In 2016, our study team conducted the first and only national self-report survey with serological sampling of transgender women in Dominican Republic and across the Caribbean. To our knowledge, our results offer the only comprehensive national narrative of the transgender experience in the region. Thus, there are two key purposes of this abstract. This first is to characterize transgender women and their experiences in Dominican Republic. The second is to examine associations between stigma, violence, and HIV to identify areas of intervention.

METHODS: Data for this study (both self-reported and serological) were collected in 2016 from rural and urban communities across Dominican Republic (N=212). We conduct logistic and negative binomial fixed-effects regression modeling to estimate relationship between violence, stigma, substance use, and HIV/STI serostatus.

RESULTS: Participant average age was 27 years; only 30% were near or above the local federal poverty line. About 75% participated in sex work; 13% reported cocaine use and 42% abused alcohol. Nearly 40% were living with HIV and almost half were serologically reactive for syphilis. A quarter reported experiencing violence; 63% reported experiencing at least one stigma event. Using logistic regression we estimated that respondents who have ever had participated in sex work were associated with 4.7 times higher odds of experiencing violence (OR:4.71, p<0.05). Likewise, respondents who abused alcohol were associated with 2.9 times higher odds of experiencing violence compared to respondents with lower risk (OR:2.92, p<0.01). Through our negative binomial regression model we found that respondents near or above the poverty line reported experiencing less stigma (IRR:0.66, p<0.05). Respondents who have ever had participated in sex work were more likely to have report stigma (IRR:1.60, p<0.05). Respondents living with HIV were more likely to have reporting perceiving and experiencing stigma compared to their uninfected peers (IRR:1.41, p<0.05).

CONCLUSIONS: Findings can inform health policy to benefit sexual and gender minorities, specifically transgender women, and to inform structural and behavior public health interventions designed to reduce HIV risk, fortify the individual against the deleterious effects of stigma, and improve health outcomes of transgender women in Dominican Republic and across the Spanish-speaking Caribbean.

PED1118

RECONCEPTUALIZING GENDER AND GENDER EXPRESSIONS IN JAMAICA: CHALLENGES AND OPPORTUNITIES FOR HIV PREVENTION AND TREATMENT AMONG JAMAICAN PEOPLE OF TRANS EXPERIENCE

O. Harris[1]
[1]University of California, Community Health Systems, San Francisco, United States

BACKGROUND: In 2018, sexual and gender minority (SGM) people comprise between 27,000 to 33,000 Jamaicans who are at greater risk for health disparities including very high rates of HIV and mental health conditions. Sexual and gender minorities (SGM), specifically transgender people, experience disparate rates of stigma, violence, and poor mental health in Jamaica. Intersectional stigma, often related to intersecting identities (i.e., HIV status or gender identity) increases the risk of violence, and can often be deadly for many Jamaican transgender individuals. This study focuses on gender and gender expressions in Jamaica and examines the challenges and opportunities for HIV prevention and care for persons of trans experience.

METHODS: In this interpretative qualitative phenomenological study, we used semi-structured in-depth interviews with individuals as the primary sources for data collection. We recruited 40 people of trans experience in 2019 from three high-disease burden areas (Kingston, Montego Bay, and St. Ann's Bay) in Jamaica. Data were recorded, transcribed verbatim, and analyzed using thematic content analysis.

RESULTS: Participants were aged 18-30 years of age and self-identified as trans men, trans women, or genderqueer. Participants reported initially identifying as either gay or lesbian during their early childhood years, with acceptance of a trans identity must later in their mid to late adolescent years. Participants described the dangers they encounter on a routine bases once they have begun gender affirming care. More than a third of the sample disclosed a significant history of violence that were rooted in their collective identities as gender nonconforming or a person of trans experience. These violent experiences led to most participants stopping gender affirming care as well as disengaging from HIV prevention and care services.

CONCLUSIONS: Our findings serve as a catalyst for understanding gender and gender expressions within the Caribbean cultural context. These findings also help us to understand how the cultural rejection of gender variant or gender nonconforming individuals serves as a significant barrier to HIV prevention and treatment efforts for people of trans experience in Jamaica.

YOUNG KEY POPULATIONS

PED1119

INTERSECTIONS OF FINANCIAL AGENCY, GENDER DYNAMICS, AND HIV RISK: A QUALITATIVE STUDY WITH ADOLESCENT GIRLS AND YOUNG WOMEN IN ZAMBIA

L. Gauer Bermudez[1], S. Mathur[2], D. Mulenga[3], M. Musheke[3]
[1]Columbia University, School of Social Work, New York, United States, [2]Population Council, Washington, D.C., United States, [3]Population Council, Lusaka, Zambia

BACKGROUND: Recent research has demonstrated that economic interventions may have positive effects on reducing HIV risk among adolescent girls and young women (AGYW) in sub-Saharan Africa. Some evidence points to the value of individual financial agency for AGYW and the potential association between decision-making power in the financial realm and bargaining power in sexual relationships. However, this evidence is mixed, nuanced, and limited. This paper explores how AGYW in Zambia understand financial agency and its effect on their intimate relationships.

METHODS: In-depth qualitative interviews were conducted with 30 females between the ages of 15 and 24 years residing in Kalingalinga, a low income, high density residential area approximately 8km east of Lusaka's central business district. Data were analyzed using thematic content analysis.

RESULTS: Participants spoke of the ability to earn and spend one's own money, as a reality for some and an aspiration for many females in urban Zambia but one that came with cultural and religious caveats that influenced perceptions of such agency for women. The transfer of financial independence to sexual agency within relationships was viewed as a mechanism for sexual HIV risk reduction; however, male sexual privilege was an obstacle irrespective of financial decision-making power. Women's sexual agency was viewed as greater in non-martial relationships as opposed to within marriage, where religious mores on headship created a power imbalance.

CONCLUSIONS: Programs aiming to enhance financial agency for AGYW have the potential to reduce HIV sexual risk for this age cohort in Zambia, particularly engagement in transactional sex. Yet, to be most effective and to address norms of male dominance, which may continue to keep AGYW in positions of vulnerability regardless of increased financial power, such programs should be integrated with broader, gender transformative programming that address drivers of inequity in sexual relationships, including within marriage.

PED1120

TRANSFORMING HIV RISK ENVIRONMENTS AMONG ADOLESCENT AND YOUNG KEY POPULATIONS IN THE ASIA-PACIFIC REGION AMIDST EXPANDING EPIDEMICS: A FOUR-COUNTRY CASE STUDY

P.A. Newman[1], S.M. Prabhu[2], S. Tepjan[3], S. Boborakhimov[3], UNICEF East Asia and Pacific Regional Office & Inter-agency Task Team (IATT) Study Group
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]UNICEF East Asia and Pacific Regional Office, Knowledge and Advocacy, Bangkok, Thailand, [3]VOICES-Thailand Foundation, Chiang Mai, Thailand

BACKGROUND: Young people (15-24-years-old) accounted for 26% of new HIV infections in the Asia-Pacific in 2018. HIV prevalence more than doubled among young MSM in Indonesia, the Philippines, and Thailand from 2010-2018. We explored risk environments of adolescent and young key populations (AYKP) and how AYKP navigate HIV and sexual and reproductive health (SRH) across school, home, online/offline communications, and health/mental health-care in Indonesia, the Philippines, Thailand, and Vietnam to promote refocused, locally-relevant HIV responses.

METHODS: We conducted an explanatory multiple-case study using a risk environment framework, shifting focus from individuals to social-structural conditions. Youth-led focus group discussions (FGDs) were conducted with diverse AYKP. A researcher-youth co-developed topic-guide explored experiences in education, families, communications, and health/mental health regarding HIV and SRH. Semi-structured key informant (KI) interviews with HIV/SRH and youth experts in each country explored risk environments, resources, policies, and strategic initiatives. FGDs and interviews were transcribed, translated into English, reviewed within-country using thematic analysis, and synthesized and contrasted across countries. Themes and draft reports were shared and stakeholder input integrated.

RESULTS: From November 2018-October 2019, we conducted 16 FGDs (4/country) with 139 young people (16/18-24 years; 55 girls/women, 73 boys/men, 11 transgender persons) and 37 KI interviews (15 women, 18 men, 4 transgender persons) with multisectoral government, UN-agency, NGO, and youth/AYKP experts (N=176). Risk environments manifested in widespread absence of comprehensive sexuality education (CSE): schools expected home-based CSE, parents expected school-based CSE; AYKP reported information from neither, instead utilizing social media/Internet. Young MSM and transgender persons recounted school bullying, harassment/violence, and lack of teacher/healthcare provider/parental support, exacerbating stigma and fears of disclosure that inhibited support/health-seeking behaviors. Peer educators/navigators, AYKP/youth-networks, and social media were primary venues for HIV/SRH education and social support amidst restrictive government policies and healthcare practices that created pervasive barriers across the HIV prevention/treatment cascade.

CONCLUSIONS: Promoting intersectoral, multilevel youth-engaged strategies that build on existing strengths and transforming HIV risk environments—capacitating peer-support networks, accelerating CSE/HIV prevention/testing via social media, expanding access to youth-friendly HIV/SRH and broader health/social services, and amending restrictive government policies/laws (e.g. creating legal access to condoms/HIV-testing for minors)—are fundamental to ending the epidemic among young people.

PED1121

USING RIDESHARE INCENTIVES IN ADOLESCENT AND YOUNG ADULT HIV PREVENTION RESEARCH

W. Vickroy[1], M. Castillo[1], A. Schlupp[1], A. Lopez[1], R. Sanders[2]
[1]The Children's Hospital of Philadelphia, Adolescent Medicine, Philadelphia, United States, [2]The Johns Hopkins University, Baltimore, United States

BACKGROUND: Public health experts have begun to examine rideshare services (e.g. Lyft and Uber) for addressing transportation barriers to medical care. Clinical trials with youth cite transportation barriers as an impediment to enrollment, but few studies explore rideshare as a solution. Providing Unique Support for Health (PUSH) utilizes rideshare to enhance recruitment and retention. PUSH is a multi-arm RCT to support young Black and Latinx MSM and transgender women ages 15-24 with PrEP and ART adherence. Here we examine rideshare's impact on reaching youth with greater HIV risk factors.

METHODS: Youth interested in screening for PUSH study participation can opt-in to rideshare to and from the study site, an adolescent health clinic in urban Philadelphia. Study staff request rides online and participants receive links to ride details. On arrival, participants enroll in the study and complete the baseline visit involving a confidential web-based survey and rapid HIV testing. Survey data was analyzed for demographic differences and HIV risk factors including unprotected anal sex, housing instability, and HIV testing history. Study retention was also examined.

RESULTS: 123 participants completed baseline surveys. 37 opted-in to receive rideshare, 36 opted-out and 50 enrolled before implementation. Rideshare users were slightly younger (median age 20 vs 21), were more likely to experience homelessness (27% vs 19.7%), and reported fewer sex partners (4 vs 10 on average) than non-rideshare participants. More rideshare users reported never using a condom in the last three months (35.7% vs. 17.5%) and more also reported never having an HIV test before (27% vs 13.9%). Participants with rideshare were more likely to return for follow-up (69.5% vs 55.8%).

CONCLUSIONS: Transportation barriers should be considered and addressed in research and programming alike. Rideshare is one method of doing so. It enhances sampling and retention in youth-tailored interventions by meeting a variety of adolescents and young adults exactly where they are. In an integrated clinical setting especially, participants can also benefit from linkage to resources and medical care. Effectively reaching a diverse sample of youth with varying risk factors, and from communities who lack representation in research, can translate to better informed HIV prevention efforts and practices.

PED1122

'GETTING RID OF A DAILY PILL WOULD BE GREAT!' VERSUS 'IT'S SO HARD TO KNOW IN ADVANCE I'M HAVING SEX...': ADOLESCENTS' WILLINGNESS TO USE EVENT-DRIVEN PREP IN BRAZIL

E. Zucchi[1], S. Brasil[2], D. Ferraz[3], L. Pedrana[4], R.L.e.S. Oliveira[4], I. Sorrentino[5], I. Dourado[4], L.F.A. Deus[6], L. Magno[2], A. Grangeiro[5], M.T. Couto[5]
[1]Universidade Católica de Santos, Programa de Pós-Graduação em Saúde Coletiva, Santos, Brazil, [2]Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil, [3]Fundação Oswaldo Cruz, Escola de Governo em Saúde, Brasilia, Brazil, [4]Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, [5]Universidade de São Paulo, Faculdade de Medicina, São Paulo, Brazil, [6]Universidade Federal do Rio Grande do Sul, Programa de Pós-graduação em Psicologia Social e Institucional, Porto Alegre, Brazil

BACKGROUND: Event-driven PrEP (ED-PrEP) involves taking 2 pills of antiretrovirals 2-24 hs before sex +2 pills 24hs and 48hs, respectively, after the first dose. It has proved to be effective among adult men who have sex with men (MSM), and it is indicated if sex is predictable or infrequent. Evidence of this regimen among adolescent MSM and transgender women (TGW) is lacking. We analyzed knowledge and willingness to use ED-PrEP among adolescents MSM and TGW in Brazil.

METHODS: Data was collected as part of a daily PrEP demonstration study (PrEP1519) run in three Brazilian cities. Participants were MSM and TGW aged 15-19 years, who could opt to use PrEP (PrEP arm) or other HIV prevention methods (non-PrEP arm). Twenty-two semi-structured interviews with selected participants (16 PrEP users) were conducted in the cities of São Paulo and Salvador in 2019. Interviewers explained ED-PrEP beforehand to participants. Interviews were transcribed, and coded for analysis.

RESULTS: Despite very little knowledge of ED-PrEP, half of participants in both study arms indicated high willingness to use it. Reported advantages included: 'being free' from a daily medication and being able to manage prevention according to their 'actual' need. Disadvantages referred to difficulty in planning sexual encounters, especially among those not using hookup apps. ED-PrEP was perceived as 'complicated' and 'weird', because taking pills in the event of an unplanned sexual encounter was considered unlikely. Comparing to daily regimen, ED-PrEP was perceived either as not 'efficient' because of less quantity of drug in the body, or more 'toxic', causing more adverse events, interaction with feminizing hormone therapy and organ injuries.

CONCLUSIONS: Information on ED-PrEP has not reached adolescents MSM and TGW in Brazil. Once informed, their willingness to choose this regimen is likely to be high. Predictability of sexual activity and 'pill fatigue' - either experienced or imagined - play an important role in determining such willingness. Evidence from demonstration studies of ED-PrEP among these groups is needed to better understand how this regimen can best suit the prevention needs of particular groups of young MSM and TGW, thus contributing to better inform PrEP guidelines in Brazil and globally.

PED1123

HEALTH BEHAVIORS OF YOUNG MEN WHO HAVE SEX WITH MEN LIVING WITH HIV AND THEIR PERSPECTIVE ON HIV SERVICES IN A TERTIARY CARE HOSPITAL IN CHIANG MAI, THAILAND

L. Aurpibul[1], Q. Kaewpoowat[2], C. Pradsarakee[1], S. Chairat[1], R. Chaiwarith[2], A. Tangmunkongvorakul[1]
[1]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [2]Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

BACKGROUND: With increased number of young men who have sex with men (YMSM) who were newly infected with HIV, and linked to care for antiretroviral treatment(ART), many studies described low virologic suppression rate, and poor retention in care. This study aims to determine health behaviors of YMSM and their perspective on HIV services which might affect treatment outcome.

METHODS: The mixed-method cross-sectional study was conducted at Chiang Mai University(CMU) hospital. Inclusion criteria were:
1) Biological male aged 18-<25 years,
2) being an MSM by self-report,
3) having HIV infection, and
4) attending HIV services at CMU hospital.
Data was collected by self-administered questionnaires from all, and by in-depth interview in subset of participants.

RESULTS: 100YMSM were enrolled. Their median age was 23 years (IQR 21-24). About half (48%) were students. Their gender role included gay men (84%), bisexual men (9%), and transwomen (5%). Forty-five percent started ART within 2 months after HIV diagnosis. Forty-one percent, 25%, and 19% disclosed HIV status to family members/relative, partner, and friends, respectively; 25% disclosed to no one. The health behaviors are shown in Table 1; 53% reported 100% condom used. Nurse and doctors' service behaviors, and visit duration were the most important factors affecting their willingness to attend clinic. In-depth interview reviewed that many were struggle with self-stigma and social disclosure. Support from family members, partner, and friends were significant for most YMSM. Most were satisfied with services; some mentioned lengthy waiting duration and

crowded clinic area, but they were acceptable. Favorable service behaviors included polite words, sufficient time with doctors, and clear explanation about their conditions. Confidentiality and privacy were unexpected emerging themes rose by many YMSM.

Characteristics	Total	Those who were studying	Those who were working
Number of participants	100	48	52
Smoking			
never	78	37 (77%)	41 (79%)
past	7	3 (6%)	4 (8%)
current	15	8 (17%)	7 (13%)
Alcohol use			
never	22	15 (31%)	7 (13%)
occasionally	48	20 (42%)	28 (54%)
hazardous use	26	13 (27%)	13 (25%)
suspected alkocil addict	4	0	4 (8%)
Other substances use			
never	89	43 (90%)	46 (88%)
past	6	3 (6%)	3 (6%)

80-100%	30	16 (33%)	14 (27%)
50-80%	9	4 (8%)	5 (10%)
< 30%	6	3 (6%)	3 (6%)
Never use	2	2 (4%)	0
Adherence to ART			
>95%	64	31 (65%)	33 (63%)
80-95%	32	16 (33%)	16 (31%)
50-<80%	4	1 (2%)	3 (6%)
Social disclosure of HIV status			
To everyone	1	0	1 (2%)
To family/ relatives	41	17 (35%)	24 (46%)
To partner	25	12 (25%)	13 (25%)
To some friends	19	13 (27%)	6 (12%)
To no one	25	12 (25%)	13 (25%)

[Table 1. Health behaviours of young men who have sex with men who participated in this study]

CONCLUSIONS: Most health behaviors of YMSM in this study were favorable, except for low rate of condom use which remains a concern. Service behaviors, visit duration, confidentiality, and privacy in clinic were important to them.

PED1124

VIRAL SUPPRESSION AND BARRIERS TO MEDICAL CARE ENGAGEMENT IN A NATIONAL PROBABILITY SAMPLE OF HIV-POSITIVE YOUNG BLACK MEN WHO HAVE SEX WITH MEN

L. Beer[1], Y. Tie[1], S. Dasgupta[1], R.L. Shouse[1], Medical Monitoring Project
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

BACKGROUND: U.S. young black men who have sex with men (YBMSM) are disproportionately affected by HIV; understanding reasons for suboptimal levels of viral suppression and HIV care engagement among this population is essential, but population-based data are lacking. We report factors associated with sustained viral suppression (SVS) and barriers to care engagement among HIV-positive YBMSM.

METHODS: The Medical Monitoring Project collects interview and medical record data from a probability sample of U.S. adults with diagnosed HIV. Using weighted data collected 6/2015-5/2018 from 344 YBMSM aged 18-29 years, we examined the prevalence of SVS (all viral loads in past 12 months <200 copies/mL or undetectable). We assessed associations between selected characteristics and SVS using prevalence ratios with predicted marginal means and evaluated significant differences (P<0.05). Among YBMSM who reported seeing a provider less often than they needed, we assessed barriers to HIV medical care engagement. Care engagement was defined as having >2 elements of medical care at least 90 days apart in the past 12 months (e.g., viral load testing, encounter with a provider). We created a three-level variable categorized as: not taking antiretroviral therapy (ART), adherence score <85, and adherence score >85 (adherence score range: 0-100). Estimates marked with an asterisk may be unstable due to small sample sizes.

RESULTS: Overall, 47% of YBMSM had SVS. SVS was significantly lower among YBMSM who experienced homelessness than those who did not (29% vs. 50%), did not receive care in a Ryan White HIV/AIDS Program-funded medical facility than those who did (39% vs. 53%), were not engaged in care compared with those who were (12%* vs. 64%), and were not taking ART compared with those with adherence scores <85 or >85 (7%* vs. 54% or 56%). The most commonly reported barriers to care engagement were problems with money or insurance (64%*), having other things going on in one's life that made getting care difficult (47%*), and not feeling sick (33%*).

CONCLUSIONS: U.S. YBMSM have low levels of viral suppression and many face financial barriers to care engagement. Tailored programs to increase ART use and alleviate barriers to care may improve clinical outcomes among HIV-positive YBMSM.

PED1125

REACHING OUR YOUNGEST POPULATION: A TAILORED DIFFERENTIATED SERVICE DELIVERY MODEL FOR INFANTS AND THEIR CAREGIVERS LIVING WITH HIV IN MBABANE, ESWATINI

A. Small[1,2], S. Perry[1,2], N. Mthethwa[3], B. Lukhele[1,2,2], S. Masilela[1], N. Lukhele[1], M. Simelane[1], S. Dlamini[1], J. Petrus[1,2]
[1]Baylor Children's Foundation, Mbabane, Eswatini, [2]Baylor College of Medicine, Houston, United States, [3]Eswatini National AIDS Program, Mbabane, Eswatini

BACKGROUND: Globally, infants and young children living with HIV lag far behind WHO viral load (VL) suppression targets. Achieving viral suppression at the peak of a child's cognitive development should be a priority. Baylor Center of Excellence in Mbabane, Eswatini developed Baby Club (BC) as a differentiated service delivery (DSD) model to provide group psychosocial support during clinical visits in order to prioritize the care of these vulnerable patients.

DESCRIPTION: Children <3 years old living with HIV and their primary caregivers were invited to attend monthly Baby Club sessions in which the dyads were seen by a clinical provider and attended a group session. Mothers received comprehensive health services and participated in hour-long group discussions on varied topics including adherence, HIV, job skills, domestic violence advocacy and normal child development. Children also received routine health care including vaccines. While awaiting services, children played with books and toys in the meeting room while mothers shared advice. VL suppression rates were reviewed prior to BC initiation and quarterly. Caregivers were given transport support and lunch via UNICEF funding.

LESSONS LEARNED: Prior to BC inception, the viral suppression rate for children < 3 years and their mothers was 35 and 33% respectively. After two years of BC sessions, 38 babies were enrolled with 31 suppressed (82%). 28 of the 31 mothers were suppressed (90%). 7 dyads graduated when the child turned 3 years of age and all the mothers and children were suppressed. Comparatively, 56% of 3-4 year olds that had not been involved in BC were suppressed. Psychosocial stressors contributing to infection of the child must be addressed

immediately as challenges are worsened with the requirements of taking care of an HIV positive infant. The majority of children that remain unsuppressed also have mothers that are unsuppressed.

CONCLUSIONS/NEXT STEPS: A monthly psychosocial support and playgroup coordinated with health services proves a successful DSD model for our infants and caregivers. Women naturally helped each other to improve adherence and often commented that the BC session was the only time they were able to discuss their child's status openly in a non-stigmatizing environment.

PED1126

EVALUATION OF NUTRITIONAL CONDITIONS, HAEMOGLOBIN LEVELS, RETENTION IN CARE AND VIRAL SUPPRESSION IN A COHORT OF HIV INFECTED MALAWIAN ADOLESCENTS RECEIVING A ONE-YEAR TAILORED INTERVENTION WITHIN DREAM PROGRAM

F. Ciccacci[1], K. Wouters[2], S. Orlando[3], J.B. Sagno[4], M. Kamponda[4], J. Gondwe[4], R. Lunghi[5], M.C. Marazzi[6], L. Palombi[3]
[1]UniCamillus, International University of Health and Medical Science, Rome, Italy, [2]Institute of Tropical Medicine, Department of Clinical Sciences, Antwerp, Belgium, [3]University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [4]Community of Sant'Egidio, DREAM Program, Blantyre, Malawi, [5]Community of Sant'Egidio, DREAM Program, Rome, Italy, [6]LUMSA, Rome, Italy

BACKGROUND: UNICEF estimated 1.770.000 adolescents living with HIV in 2017, more than 80% living in Sub-Saharan Africa. In Malawi, 25.000 boys and 46.000 girls are estimated to live with HIV. Objective of the presented program is to improve conditions of HIV+ adolescents through a specific adolescent-friendly service implemented in a DREAM health centre in Malawi.

DESCRIPTION: We conducted a retrospective analysis of routine electronic medical records of adolescent patients in care in the DREAM centre in Blantyre (Malawi).

All HIV+ patients aged 10-19 in care in DREAM centre in Blantyre on 17/12/2016 were included and followed up to 01/01/2018. The service was organized in one adult-free day, with some side activities managed by a coordinator and youth leaders. The new adolescent-cantered service in Blantyre DREAM facility started on 17 December 2016. Once a month (last Saturday of every month), the centre is open uniquely for the adolescents. On the "adolescent day", many clinical and non-clinical activities are carried out: medical examination, medical counselling, blood sample review, drugs refill, teen clubs, role plays, organization of out-reach sensitization activities. The service is managed by a coordinator, who works in partnership with some youth leader. Youth leaders are a cornerstone of the service, as they are peer-to-peer educators carrying out many activities (sensitization of fellow adolescents at the centre, in schools and communities, counselling to peers with drug adherence problems). All the patients aged 10 to 19 years are invited to join the service.

LESSONS LEARNED: Assessments at the end of period (EOP) were performed.

On 17/12/2016, 425 patients were enrolled. Follow-up status at EOP was: 403(94,8%) in care, 7(1,6%) LTFU, 2(0,5%) died and 13(3,1%) transferred. Rates of death and LTFU were respectively 0,72/100 and 2,9/100 person-years. 50,6% (198/391) of patients had an improvement in BAZ. 70,2%(33/47) of patients malnourished at baseline improved (higher improvement in older patients). HGB levels increased from 12,5mg/dl±1,5 to 13,1mg/dl±1,9 (sign=0,000). At the EOP, 79,0%(309/391) of patients had viral suppression.

CONCLUSIONS/NEXT STEPS: Care of adolescent HIV+ patients remains a challenge, but the implementation of specific projects involving adolescents and youth leaders can increase adherence and VL suppression.

PED1127

SERVICE-USE AND RESILIENCE AMONG ADOLESCENTS LIVING WITH HIV (ALHIV) IN BLANTYRE, MALAWI

B.N. Kaunda-Khangamwa[1,2], I. Maposa[1], S. Phiri[3], R. Dambe[4], M.E. Phiri[4], K. Malisita[4], E. Mtagalume[4], E. Chipeta[5], A. Munthali[6], L. Manderson[1,7,8]
[1]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [2]University of Malawi, College of Medicine, School of Public Health and Family Medicine, MAC-Communicable Diseases Action Center, Blantyre, Malawi, [3]Lighthouse Trust, Lilongwe, Malawi, [4]Umodzi Family Centre, Lighthouse Trust, Blantyre, Malawi, [5]University of Malawi, College of Medicine, School of Public Health and Family Medicine. Centre for Reproductive Health, Blantyre, Malawi, [6]University of Malawi, Chancellor College, Center for Social Research, Zomba, Malawi, [7]Monash University, School of Social Sciences, Melbourne, Australia, [8]Brown University, Institute at Brown for Environment and Society, Providence, United States

BACKGROUND: Adolescents experience high levels of risks including living with chronic conditions, non-availability of services, abuse, family dysfunction and community danger. These issues all warrant service usage and support, including to build resilience, but access to resources among ALHIV in Malawi is limited. Few studies have looked at the interaction of social, community and health services provision and utilization in relation to resilience. This study focused on ALHIV, health workers and parents/caregivers to examine formal and alternative service use and resilience in Blantyre, Malawi.

METHODS: A self-administered questionnaire with 406 ALHIV, 26 in-depth interviews with ALHIV, 12 group discussions with 144 caregivers and 35 health workers attending a 2-day workshop explored the frequency of service use. For ALHIV, data collection focused on the frequency and satisfaction with services with which they had most contact. Structural equation modelling (SEM) and regression analysis determined associations between service-use and resilience-related variables.

RESULTS: ALHIV, health workers and parents/caregivers commonly mentioned: ART and teen-club clinics, the community teen-club, youth-friendly services, and educational support. About 70% ALHIV were concurrent clients of three or more services, with the majority most satisfied with the teen-club clinic. The multi-method analysis showed variations in internal and external forms of risks, range of services and frequency of use, satisfaction and supports. Reliability coefficients, alpha on all services, risks and scores confirmed internal consistency of above 0.70 except for caregivers/parents. SEM paths showed moderate correlations on risk and service use. High resilience scores were influenced by service use. Young men who were out-of-school were most likely to use services. The qualitative data reflect more complex interactions on access to services, with caregivers and adolescents seeking alternative care from spiritual and traditional healers.

CONCLUSIONS: ALHIV used multiple services. Peer, personal and community risks and interaction with service use were critical in the lives of ALHIV. Positive experiences within the teen-club clinic, community and education-based services show that ALHIV have access to many service providers. Indigenous services such as spiritual and traditional healing are increasingly sought out by ALHIV and their caregivers, and this may affect patterns of service use overtime.

PED1128

ASPIRATIONS AND MEDIA USAGE OF SOUTH AFRICAN AGYW: SIMILARITIES AND DIFFERENCES ACROSS URBAN-RURAL LOCALES

M. Dugas[1], K. Crowley[1,2], G.G. Gao[1], L. McHarry[3], L. Kenmuir[3], J. Piper[4], J. Cummins[4], F. Veronese[4], R. Agarwal[1]
[1]University of Maryland, Center for Health Information and Decision Systems, College Park, United States, [2]University of Maryland, School of Information Studies, College Park, United States, [3]Kantar, Cape Town, South Africa, [4]National Institute of Allergy and Infectious Diseases, Division of AIDS, Prevention Science Program, Bethesda, United States

BACKGROUND: Communication used for enhancing awareness and promotion of HIV prevention products should be consistent with the aspirations of the target audience and delivered through their preferred media channels, but there is often a mismatch. Better understanding of the aspirations and media use of urban and rural adolescent girls and young women (AGYW) in South Africa, given the constraints and opportunities offered by their environments, may improve such efforts.

METHODS: 1,500 South African AGYW aged 14-25 completed a face-to-face, tablet-aided survey that assessed a wide range of consumer and lifestyle behaviors. We compared aspirations (role models, most important personal decision, and products desired) and media usage (internet usage, frequency of online and offline activities) of AGYW who lived in metro regions (n = 900) to those in small urban/rural regions (n = 600).

RESULTS: Overall, there was considerable similarity in aspirations among AGYW though several notable differences were found. For example, respondents most frequently selected 'my mother' as their role model; however, the proportion was significantly smaller among AGYW living in metro regions (58.6%) than the small urban/rural group (64.3%). Complementing this, a greater proportion of the metro group reported their father (9.9% vs. 5.7%) or an actor (8.2% vs. 4.7%) as role models than the small urban/rural group. Comparisons of media usage found that most reported using the Internet several times a day (52.9% of metro, 51.8% of small urban/rural AGYW) but a greater proportion of small urban/rural AGYW reported never using the Internet (22.8% vs. 18.2%). Among respondents who had access to the Internet, metro AGYW (vs. small urban/rural) also reported greater engagement with a variety of specific online activities including instant messaging/chatting (the most frequent activity among both groups), email, and visiting blogs/forums. Other online activities, like browsing social networks, streaming videos, and buying products, showed no differences.

CONCLUSIONS: South African AGYW living in metro and small urban/rural locales largely shared similar aspirations and media usage habits, which may be contrary to assumptions about both groups. Nonetheless, subtle differences reflect emerging trends in gender dynamics and technology, with potential implications for framing of HIV prevention efforts.

PED1129

ADVERSE CHILDHOOD EXPERIENCES AND CHILD BEHAVIOR PROBLEMS IN AN HIV PREVALENT POPULATION IN KWAZULU NATAL, SOUTH AFRICA

M. Nazareth[1], J. Kvalsvig[2], C. Mellins[3], C. Desmond[2], S. Kauchali[4,5], L. Davidson[1,5]
[1]Columbia University Mailman School of Public Health, Epidemiology, New York, United States, [2]University of Kwa-Zulu Natal, School of Nursing and Public Health, Durban, South Africa, [3]Columbia University and New York State Psychiatric Institute, HIV Center for Clinical and Behavioral Studies, New York, United States, [4]Nelson Mandela University, Port Elizabeth, South Africa, [5]Columbia University College of Physicians and Surgeons, Department of Pediatrics, New York, United States

BACKGROUND: Adverse childhood experiences (ACEs) are associated with negative adult health, with most studies completed in high income countries. Little is known about earlier effects of ACEs on child behavior, particularly in low-to-middle-income countries (LMIC) and in context of the HIV epidemic. This study reports the relationship between ACEs and child behavior among children in Kwa-Zulu Natal, South Africa, the epicenter of the HIV epidemic.

METHODS: Data come from a population-based cohort study, Asenze, completed in a peri-rural Zulu areaof South Africa. Our ACE measure included factors from traditional ACE measures (Parental death/abandonment), and factors specific to the context of this population (Caregiver HIV infection). Data included family information, child HIV-status, and ACEs when children were on average 5 years old and child behavior problems (Strengths and Difficulties Questionnaire (SDQ)) approximately two years later (average age 7 years). Logistic regression examined relationships adjusted for family disorganization (CHAOS score), between ACE score and the SDQ Total Difficulties score (dichotomized as top 10% vs. the rest) as well as selected SDQ subscales.

RESULTS: A significant relationship between overall ACE exposure and SDQ total Difficulties was observed (OR=1.30 (1.08-1.57)). In our sample, 5% of children and 26% of caregivers were living with HIV. Caregiver HIV-status was univariately associated with increase in child SDQ total Difficulties and it contributed to the sum of ACEs as well. A similar relationship between total ACE and child behavior was also seen for emotional symptoms (OR=1.30 (1.08-1.55)) and conduct problem (OR=1.23 (1.05-1.49)) sub-scales, but not for hyperactivity (OR=0.96 (0.82-1.12)).

CONCLUSIONS: Exposure to ACEs and later child behavior within this LMIC population demonstrated an early negative impact of ACEs. Previous research has focused on effects of ACEs on adult health, this study showed an early relationship between ACE and child behavior that may be a part of the mechanism through which later health effects arise. In this context, HIV+ caregiver status was related to the outcome of child behavior difficulties, and future examinations of ACE in LMIC or other areas with high prevalence of HIV should consider using HIV status as a component of the ACE measure.

PED1130

PRELIMINARY RESULTS FROM A COMBINATION HIV TESTING INTERVENTION FOR YOUNG MEN INCLUDING MEN WHO HAVE SEX WITH MEN (MSM) IN IBADAN, NIGERIA

R. Garofalo[1,2], A. Adetunji[3], L. Kuhns[1,2], A.K. Johnson[1,2], K. Kuti[3], O. Omigbodun[3], O. Awolude[3], O. Okonkwor[2,1], B. Oladeji[3], A. Muldoon[2], B. Kapogiannis[4], B. Berzins[1], B. Taiwo[5]

[1]Northwestern University Feinberg School of Medicine, Chicago, United States, [2]Lurie Children's Hospital, Adolescent Medicine, Chicago, United States, [3]University of Ibadan, Ibadan, Nigeria, [4]National Institute of Child Health & Development, Bethesda, United States, [5]Northwestern University Feinberg School of Medicine, Infectious Diseases, Chicago, United States

BACKGROUND: Nigerian youth, particularly young men who have sex with men (YMSM), have been disproportionately impacted HIV infection. iCARE Nigeria is a multi-phase trial designed to adapt, investigate and implement combination evidence-based interventions to promote HIV testing and care outcomes among youth (ages 15-24 years) in Nigeria. We report interim findings from phase one of an intervention using mHealth (focused on social media outreach) and peer navigation to promote HIV testing among high-risk young men, including YMSM, in Ibadan, Nigeria.

METHODS: Community and stakeholder perspectives guided adaptation of evidence-based mHealth and peer-navigation interventions for HIV testing to a Nigerian setting. Peer navigators conducted social media outreach promoting sexual health and then navigated interested individuals to HIV counseling and testing. Peer navigators conducted HIV rapid tests, offering young men options for clinic, community, or home-based testing. Descriptive and bivariate analyses describe outcomes to-date.

RESULTS: During 24 weeks of implementation (June-November 2019), 215 young men were tested for HIV (mean age = 21.6 years; range = 16-24 years); 175 were referred through social media (81.4%), 1 by a boyfriend/sex partner (0.5%), and 39 by a friend (18.1%). Of those referred through social media, WhatsApp was the most popular (48.0%), followed by Facebook (34.3%) and Grindr (17.7%). With regard to HIV testing location, 57.2% chose to test in a community-based setting; 41.4% opted for home-based testing. Only 1.4% (N=3) tested in a clinic. Twenty-four percent (N=52) reported no previous HIV testing. Twenty young men (9.3%) were confirmed HIV seropositive. Among those testing positive for HIV, 50% (N=10) reported testing HIV negative within the past year. Four HIV-positive individuals reported never previously testing for HIV (20.0%).

CONCLUSIONS: These findings demonstrate early success of a combination approach in reaching young men at-risk, including YMSM, with social media and peer-navigation to promote HIV testing, despite high levels of secrecy and stigma that accompany same-sex behavior in Nigeria. These data suggest that this approach can be used successfully to identify new HIV cases in a key population critical to Nigeria's ongoing efforts to control the HIV epidemic, and may hold promise in other places where MSM behavior is stigmatized.

IN UTERO ATAZANAVIR EXPOSURE AND RISK OF MULTIPLE NEURODEVELOPMENTAL PROBLEMS AMONG 5-YEAR-OLD CHILDREN WHO ARE HIV-EXPOSED AND UNINFECTED (CHEU)

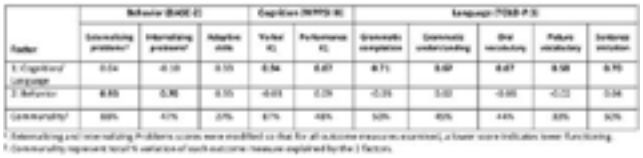
T.-J. Yao[1], J. Zhang[1], P. Williams[1], M. Rice[2], R. Smith[3], C. Mellins[4], S. Redmond[5], C. Crowell[6], P. Torre[7], H. Hoffman[8], T. Frederick[9], K. Malee[10]

[1]Harvard TH Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [2]University of Kansas, Lawrence, United States, [3]University of Illinois, Chicago, United States, [4]Columbia University, New York, United States, [5]University of Utah, Salt Lake City, United States, [6]University of Washington, Seattle, United States, [7]San Diego State University, San Diego, United States, [8]National Institute on Deafness and Other Communication Disorders, Bethesda, United States, [9]University of Southern California, Los Angeles, United States, [10]Northwestern University Feinberg School of Medicine, Chicago, United States

BACKGROUND: Atazanavir (ATV) is a preferred protease inhibitor and most frequently given with tenofovir/emtricitabine (TDF/FTC), and occasionally with zidovudine/lamivudine (ZDV/3TC), to prevent HIV transmission. Studies have reported associations of prenatal exposure to ATV with early neurodevelopmental problems in multiple domains among CHEU.

METHODS: Monolingual English-speaking CHEU from the Surveillance Monitoring for ART Toxicities (SMARTT) Study of the PHACS network were evaluated using age-appropriate measures of cognition, language and behavior at five years old. Exploratory factor analysis (EFA) using ten composite scores (Table 1a) was performed to estimate underlying factors responsible for covariation of these domains. Mean differences of standardized factor scores between CHEU exposed to TDF/FTC with or without ATV versus ZDV/3TC without ATV were estimated using general linear models. Separate analyses were conducted for children exposed to antiretroviral medications (ARVs) at conception, and whose mothers initiated ARVs during trimesters 1 or 2/3. Generalized estimating equations were fit, accounting for the clustering effect of research clinics and adjusting for confounders.

RESULTS: Among 860 eligible CHEU, 585 were exposed to TDF/FTC with or without ATV, or ZDV/3TC without ATV, and had valid composite scores. Two factors were identified, explaining 27-89% variability of the ten composite scores (Table 1a).



[Table 1a. Factor loadings from EFA to each outcome measure from Behavioral Assessment System for Children (BASC-2), Wechsler Preschool and Primary Scale of Intelligence (WPPSI-III) and Test of Language Development-Primary (TOLD-P:3)]

Factor 1 contributed to cognitive and language domains; Factor 2 contributed to the behavioral domain. Lower (worse) standardized factor scores were observed in CHEU with post-conception exposure initiation (Table 1b, row 1).

Differences in factor scores for TDF/FTC and/or ATV relative to ZDV/3TC were not evident for cognition/language, but were negative for behavioral functioning among CHEU in the post-conception strata, especially for CHEU exposed to TDF/FTC/ATV when ARVs were initiated in trimester 1, with an estimated 1.39 (95%CI: -2.06, -0.72) lower score (Table 1b).

[Table 1b. Overall unadjusted mean (SD) of standardized factor[1] score (Row 1), and adjusted mean difference (95% CI) versus ZDT/3TC without ATV (refernce group) for CHEU exposed to TDF/FTC/ATV (Row 2) or TDF/FTC without ATV (Row 3), by timing of ARVs exposure initiation]

CONCLUSIONS: In utero exposure to TDF/FTC/ATV was associated with parent-reported behavioral concerns regarding young CHEU whose mothers initiated ARVs during pregnancy.

PED1132

2019 WORLD AIDS DAY ADOLESCENT & YOUNG PEOPLE ORAL PRESENTATION: USING SOCIAL MEDIA AS A TOOL TO ENGAGE YOUNG PEOPLE IN HIV/AIDS PROGRAMMING AND RESPONSE

A. Alabi[1], T. Oladele[2], O. Ajiboye[2], H. Yahaya[2]
[1]National Agency for Control of AIDS, NACA, Special Duties, Abuja, Nigeria, [2]National Agency for Control of AIDS, NACA, Community Prevention & Care Services, Abuja, Nigeria

BACKGROUND: Adolescent and young people (AYP) in Nigeria constitute a third of the population. Often times, engaging AYPs in policy discourse such as HIV/AIDS is challenging as their areas of interests revolve mainly around sports and entertainment. Currently, there is limited access to HIV testing services (HTS) for the majority of adolescents and young people in Nigeria. One reason is that adolescents below the age of 18 cannot carry out HIV testing without the permission of their parents or guardians.

DESCRIPTION: As part of the 2019 WAD commemoration, the National Agency for the Control of AIDS (NACA) with her partners decided to engage AYP using social media as a tool in the policy discourse on revising the age of consent among AYPs for HIV testing. A competition was organized for adolescents between the ages of 14 and 18. The competition was in three stages between 8th and 25th of November 2019.

The first stage was essay writing on the topic "At what age do you think a young person should be allowed to test for HIV without needing the permission of the parents or guardian?"

The best twenty essays were selected for the second stage is a video presentation of their essay. These videos were uploaded for voting on the NACA Social Media platforms after obtaining parent/guardian permission and the final stage was the presentation by the top five contestants at the Presidential Villa in Abuja, Nigeria.

LESSONS LEARNED: Over 240,000 people were reached, AYPs accounting for 76.8%. 30,000 people engaged in sharing the posts, adding comments and likes, 1000 new people followed our Facebook, Instagram and Twitter pages. Majority of whom were AYPs. Prior to this, AYPs constituted less than 30% of those who liked or engaged in discussion on our social media platforms. A WhatsApp group was also constituted for the Top20 contestants who are being mentored on HIV issues and can serve as peer influencers and social ambassador.

CONCLUSIONS/NEXT STEPS: Social media is a highly veritable tool for reaching adolescents and young people in Nigeria. It is very efficient in catching their attention and getting their inputs on critical issues such as HIV.

PED1133

RISK PERCEPTION, PREP ADHERENCE AND SEXUAL RISK AMONG SEXUAL AND GENDER MINORITY YOUTH

L. Hightow-Weidman[1], K. Knudtson[1], A. McGee[1], A. Rao[2], K. Claude[1], K. Muessig[3]
[1]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [2]Emory University, Atlanta, United States, [3]University of North Carolina at Chapel Hill, Gillings School of Public Health, Chapel Hill, United States

BACKGROUND: P3 (Prepared, Protected, emPowered) is a theory-based, comprehensive social networking PrEP adherence app for young men who have sex with men (YMSM) and transwomen who have sex with men (YTW), which encourages engagement through game-based elements.

METHODS: A randomized-controlled trial comparing P3 to standard of care began enrollment in May 2019. Descriptive analyses of baseline variables are presented. Five questions assessing cognitive appraisal of HIV risk were adapted from the perceived risk of HIV infection scale. A composite measure was created (range 5-26) where scores >16 suggest high perceived risk.

RESULTS: 98 participants (40.8% of planned sample) taking or prescribed PrEP at 7 US cities have been enrolled. Median age is 22 years, 26.5% Black and 30.6% Hispanic. Top reasons reported for starting or restarting PrEP were wanting to: be in control of sexual health (95.9%), be safe and healthy (91.8%), reduce anxiety around having sex (79.6%), and have a better future (60.2%).

Of those currently taking or with history of PrEP use (n=93), 37 (39.8%) reported ever stopping for 7 days or more, 20 of those reported stopping in the past 3 months. The main reported reasons for stopping PrEP included: kept forgetting to take pill (54.1%), not having sex (43.2%), and couldn't make follow-up visits (16.2%). A majority (86.7%) reported anal sex in the past 3 months with cisgender men/transgender women; 78.8% condomless. 19 participants (19.4%) reported PrEP adherence of <60% in the past month, 6 of whom said that based on this level of adherence, they felt mostly or fully protected from HIV.

Among those reporting receptive anal sex in the past month, 16.3% reported that their decision about condom use was influenced by whether or not they took PrEP every day; compared to 10.2% of those who reported insertive anal sex. The mean composite risk perception score was 13.89, suggesting low overall perceived risk.

CONCLUSIONS: The relationship between risk perception, PrEP adherence and engagement in sexual risk behaviors among youth is complex. Given issues with PrEP uptake and persistence among sexual and gender minority youth, baseline data from P3 can help inform individual, dyadic and structural interventions.

PED1134

UNDERSTANDING 'SILENCED HEALTH EXPERIENCES' OF YOUNG PEOPLE ACCESSING HIV SERVICES THROUGH BODY-MAP STORYTELLING

D.L. Bose[1], S.U. Hadi[1], J. Mukherjee[1], P. Saha[1], K. Goyal[2]
[1]IAVI, New Delhi, India, [2]DCT Mindlinks, New Delhi, India

BACKGROUND: 'Silences Framework' (Serrant, 2011) helps understand sensitive issues and marginalized perspectives on health, particularly HIV. Body Maps have helped unravel multilayered and often 'silenced' health experiences and their impact on health-seeking behaviors (Gastaldo, 2018). Recognizing the need to explore such 'si-

lences' in the lived experiences of young people accessing HIV services, a two-day community workshop was organized in New Delhi to deconstruct complex HIV experiences through body map storytelling.

DESCRIPTION: 32 young participants representing key population groups including transwomen, MSM and PLHIV were divided in four groups to draw a life-size outline of the human body and scan it to visually map:

a) personal/community health priorities;

b) stakeholders impacting health or health decisions; and

c) nature of impact.

The body maps triggered open community conversations bringing out silenced experiences, which were analyzed deductively using a theoretical thematic approach.

LESSONS LEARNED: One of the commonly shared themes reiterated by participants across different contexts was "breach of trust" by close confidantes – especially with respect to disclosure of HIV status – and how it affected their own construct of self, capacity to cope with external stigma, and trust in healthcare services and motivation to seek care. "Breach" was experienced across various settings such as HR in the workplace, professor in school, and relatives and friends in family/social networks.

Another recurring experience was "fear of relationship loss." Young people often found themselves caught in situations where their agency in and access to HIV services was determined by perceived and/or actual impact on their relationship with partner(s). Examples ranged from fears regarding:

a) the impact of medication on desirability, ability to conceive and libido;

b) ability to devote time and energy to the relationship and meet 'obligations'; and,

c) shifts in power dynamics impacting the long-term sustainability of the relationship.

CONCLUSIONS/NEXT STEPS: Silenced health experiences – though often invisible and missed out by traditional methods of inquiry – have an indelible impact in shaping people's health choices. They represent critical pockets of inquiry that need further research and consideration in order to inform the design of the next generation of more responsive HIV services.

PED1135

DREAMS: A MULTIDIMENSIONAL APPROACH TO PROMOTE HIV PREVENTION AND ADDRESS RISK REDUCTION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN WESTERN TANZANIA

V. Anyoti[1], N. Bahati[1], O. Msumi[1], D. Laki[1], H. Mziray[1], S. Kingazi[1], D. Nyogea[1], M. Mahiti[1], F. Morales[1], J. Kessy[2], L. Modest[2], L. Lwamulaza[2], C. Mwafimbo[2], N. Makyao[2], O. Rwabigayo[3], K. Kazaura[3], D. Magese[3], J. Kitalile[3], J. Franks[4], C. Wells[4], B. Senyana[4], M. Ali Mahdi[4], E. Pimentel[5]

[1]ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, United Republic of, [3]U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]ICAP at Columbia University, New York, United States, [5]ICAP at Columbia University, Maputo, Mozambique

BACKGROUND: In Eastern and Southern Africa adolescent girls and young women (AGYW) represent 25% of incident HIV infections. AGYW vulnerability to HIV results from intersecting factors: poverty, gender inequality, sexual violence, low HIV awareness and poor prevention-related behavioral skills like condom use. PEPFAR's DREAMS initiative aims to reduce HIV infection among AGYW with combined ("layered") interventions addressing behavioral, normative, and structural factors underlying HIV vulnerability.

DESCRIPTION: From January through September 2019 ICAP implemented DREAMS for out-of-school, sexually active AGYW in rural communities in western Tanzania, including Lake Victoria islands. Layered DREAMS interventions included social-behavioral change communication (BCC) (10 sessions); family planning counseling and commodities (FP); HIV testing services (HTS); and economic strengthening (ES) consisting of financial literacy (10 sessions) and formation of mutual savings and loan groups to support members' enterprises. HIV Pre-exposure prophylaxis (PrEP) services began in July 2019. DREAMS clients are screened for HTS eligibility following completion of four BCC sessions; those at risk for HIV receive HTS. Trained peer AGYW Community Outreach Volunteers (COVs) form ES groups, deliver sessions, make referrals, and track participation. Groups of 20 to 25 members name their group, elect group leaders, and complete sessions together.

LESSONS LEARNED: 68 COVs were trained to provide and track layered interventions; 12 of them (17.6%) dropped out before September 2019. Table 1 shows routinely reported aggregate data from DREAMS from January to September 2019:

Enrolled in DREAMS	17,229 enrolled, 134 (0.78%) drop outs
Completed primary package of interventions	6,631 (38.4%)
Number of condoms provided (male and female)	35.536
HTS	10,561 screened for HTS, 9,398 Eligible for and received HTS
Newly-diagnosed HIV positive	71 (0.76% positivity rate)
Clients linked to care and treatment	71 (100% ART initiation)
Total Savings	15,574 USD
Income-generating activities established	2,101 (new individual small businesses established)
PrEP	40 PrEP_NEW, 27 (68%) one month PrEP refill
Referrals provided	374 FP, 201 STI, 17 GBV, 22 TB

[Table 1: October 2018 - September 2019 DREAMS Achievements No. of AGYW (15-24 years)]

CONCLUSIONS/NEXT STEPS: Reasons for missed sessions include sickness and family activities. High retention of AGYW could be due to interest in ES activities and BCC activities meeting the needs of AGYW. ES retention was high; however, uptake for referrals to STI and PrEP was low. ES groups will be used as a platform to strengthen uptake to PrEP, HTS, and referrals.

PED1136

TRACKING MOBILITY TO IMPROVE RETENTION OF YOUNG FEMALE SEX WORKERS IN KAMPALA, UGANDA IN ZETRA; A RANDOMIZED CONTROLLED TRIAL

R. King[1], E. Muhanguzi[2], F. Kasujja[3], M. Nakitto[3], M. Mirembe[3], D. Bagiire[3], J. Seeley[3]

[1]University of California, Global Health Sciences, San Francisco, Uganda, [2]University of California, San Francisco, United States, [3]MRC/UVRI and London School of Hygiene and Tropical Medicine, Kampala, Uganda

BACKGROUND: Young women at high risk (YWHR) 15 to 24 years old are at very high risk of sexually transmitted infections (STIs) and HIV. YWHR HIV prevalence in Kampala is estimated at 26% and preventive services are very limited. Little is known about the high mobility

that exposes YWHR to risk of HIV/STIs. Patterns of mobility are highly relevant to better understand barriers to retention in research and health services. We investigated mobility among YWHR participants in ZETRA, a randomized controlled trial designed to assess the effectiveness of an HIV prevention intervention on reducing unprotected sex among YWHR in Kampala using Google maps and qualitative interviews.

METHODS: Women's eligibility criteria: 15-24 years-old, HIV-negative, engaged in sex work. Participants were randomized to intervention (four group and three individual sessions covering health literacy and social media skills development) or control (standard-of-care at a specialized clinic for high-risk women). Follow-up visits were scheduled at 6, 12, 18 months post-enrolment. Participants used Google maps to identify work venues at 12 and 18 months. We analyzed mapping data using Python software, conducted 30 interviews with YWHR, bar owners/managers, male partners and 'queen-mothers' on topics including distance, frequency and reasons for mobility.

RESULTS: Of 644 participants, 56% have primary or no education. Currently, 216 participants have attended 12-and 18-month study visits. Participants mapped over 740 work venues. All (100%) participants have identified different venues over follow-up, including Sudan, Dubai, Kenya, rural and urban Uganda. 31% of women moved across >4 different work venues by month 18. Qualitative explanations for mobility included: violence, lack of agency, social networks and extreme poverty. For example, bar owners commented on the need to have `fresh faces' frequently, to satisfy their clients; forcing women to move.

CONCLUSIONS: YWHR are highly mobile. To reach epidemic control, research and care retention strategies for YWHR should be tailored to suit mobility patterns. Peers, bar and lodge managers who have influence on YWHR lives and mobility could be engaged in intervention strategies. A mobile clinic in active work venues is being piloted for feasibility among these highly mobile participants.

PED1137

GAY APP USE AMONG MSM ATTENDING UNIVERSITY IN CHINA: IMPLICATIONS FOR HIV INTERVENTION

S. Fan[1,2], P. Li[1], T. Yuan[3], H. Zou[3,4]
[1]Sun Yat-sen University, School of Public Health, Guangzhou, China, [2]Southwest Medical University, School of Public Health, Luzhou, China, [3]Sun Yat-sen University, School of Public Health (Shenzhen), Shenzhen, China, [4]University of New South Wales, Kirby Institute, Sydney, Australia

BACKGROUND: Men who have sex with men (MSM) attending university are a high-risk population for HIV infection in China. Recent years saw the widespread use of gay application (app) in MSM. Along with the increasing popularity of gay apps, concerns are raised over its linkage to HIV infection and related risky behaviors. To characterize the gay app use and provide evidence for implementing interventions via gay app, we conducted this study to evaluate gay app use and related behaviors among MSM attending university in China.

METHODS: MSM attending university were recruited in China from January to March 2019. A self-administrated online questionnaire was conducted to collect information on social demographics, sexual behaviors, and gay app use among MSM attending university in 4 provinces in China. Descriptive analysis was carried out for all variables and outcomes. Factors associated with behaviors via gay app use were assessed by univariate and multivariate logistic regression.

RESULTS: A total of 447 MSM attending university were recruited. The mean age was 20.4±1.5 years old. Almost all (98.2%) reported ever using gay apps. The most popular gay apps were Blued (97.5%) and Aloha (51.5%). 80.6% had been using gay apps for over 12 months; 31.2% used gay apps on a daily basis; 17.6% used gay apps for over one hour every day. MSM attending university who used gay apps to seek sex partners were more likely to have multiple sex partners in the past 3 months (AOR: 11.19, 95%CI: 5.54-25.85), engage in group sex in the past 3 months (AOR: 6.46, 95%CI: 3.54-12.68), engage in commercial sex (AOR: 2.56, 95%CI:1.10-6.71), and use recreational drugs during sex (AOR: 2.05, 95% CI:1.34-3.16) (P for all<0.05).

CONCLUSIONS: Our study found high prevalence of gay app use and sexual risk behaviors among MSM attending university in China. These findings suggest that gay app may be an effective tool to implement HIV interventions. Further research is needed to develop targeted app-based HIV interventions among MSM attending university.

SEXUAL HEALTH, VIOLENCE AND DISCRIMINATION AMONG LGBTQ YOUTH IN SAO PAULO, BRAZIL: RESULTS FROM PROJECT SILK

D. Barros[1], S. Funari[1], I. Prado[1], B. Puccinelli[1], V. Barchin[1], M.A. Sousa Mascena Veras[1], M. R. Friedman[2], NUDHES - LGBT+ Human Rights and Health Study Group
[1]Santa Casa School of Medical Sciences, Collective Health, Sao Paulo, Brazil, [2]Graduate School of Public Health - University of Pittsburgh, Department of Infectious Diseases and Microbiology, Pittsburgh, United States

BACKGROUND: A disproportionate burden of new HIV infections among young gay men, other men who have sex with men, and transgender individuals suggests that the HIV epidemic may be growing fastest in this sub-population in Brazil. Due to social marginalization, this population experiences severe stigma, poverty and victimization, which limits access to HIV care and other rights – a situation that grew worse after the installation of a new, right-wing federal government. This study aimed to explore these challenges and identify new tools for improving prevention in HIV among LGBTQ youth in Sao Paulo, Brazil.

METHODS: Between June and August 2019, a total of 139 participants were recruited through referral from key informants and snowball sampling to complete a questionnaire that captured information about sexual behavior, mental health, resilience, and discrimination. Self-administered surveys were conducted using a community-based research space located in a building that hosts groups working on human rights, harm reduction, and HIV prevention.

RESULTS: Among 139 participants, 74% identified as gay, 11% trans, and 15% queer/gender fluid. 56% were black, and 79% were younger than 25 years. Most participants (86%) had their first sexual experience before age 18 and 7% reported that this first sexual experience was forced. 79% have been tested for HIV at least once - 9% reported living with HIV and 7% tested positive before age 25. 44% tested positive for another sexually transmitted infection. Because of their sexual orientation or transgender status, 40% reported verbal assaults in the previous 12 months, 27% reported threats of physical abuse, and 10% reported beatings. During the 2018 presidential elections, 29% suffered verbal abuse, 7% were beaten, and 13% had their social media accounts vandalized. 69% stated that anti-gay/trans discrimination affects their ability to have a normal life.

CONCLUSIONS: Hate crimes against LGBTQ individuals in Sao Paulo peaked in the months leading up to the October 2018 presidential election. The rise in anti-LGBTQ violence under a new far-right government has profoundly affected efforts to address public attitudes toward HIV and encourage preventive practices. In the face of growing LGBTQ intolerance and government censorship, HIV prevention programs and community mobilization should be strengthened.

PED1139

KNOWLEDGE OF HIV, ACCESS TO HIV TESTING AND AWARENESS OF PEP, PREP AND U=U AMONG ADOLESCENT BOYS AND YOUNG MEN WHO HAVE SEX WITH MEN IN ARGENTINA

M. Muñoz[1], V. Zalazar[2], M. Vázquez[1], J.A. Sotelo[3], S. Palini[1], M. Orlando[3], N. Linares[3], M. Devoto Córdoba[3], J.C. Escobar[1], A. Adaszko[3]
[1]Ministry of Health, Adolescents and Youth Direction, Buenos Aires, Argentina, [2]External Consultant, Buenos Aires, Argentina, [3]Ministry of Health, HIV and STI Direction, Buenos Aires, Argentina

BACKGROUND: In Argentina, adolescent boys and young men accounted for ~73% of new HIV diagnoses among men who had sex with other men, between 2014-2016. Thus, there is a necessity to explore knowledge gaps in HIV that hinder their access to prevention and healthcare. This study focus on analyzing knowledge of HIV, access to HIV testing and awareness of combination prevention strategies (PeP, PreP and U=U) among adolescent boys and young men who have sex with men to develop policies targeting this vulnerable group.

METHODS: During 2018-2019, a qualitative exploratory study was conducted among 100 cisgender men who have sex with men between 15 and 24 years old in Buenos Aires Metropolitan Area, Mendoza city and Santa Fe city, in Argentina. An online survey was lunched through LGBT and people living with HIV NGOs social media of the three sites to invite participants to focus groups. Eleven focus groups and 26 individual interviews were conducted and analyzed using ATLAS.TI © by categories and site.

RESULTS: Participants stated they have some basic information about HIV but was restricted because of the heteronormative perspective prevalent on schools. They usually look for information on the internet sites and social media, aware that this information could be misleading. In relation to HIV testing participants expressed that they do not avoid testing because of HIV misconceptions (e.g.: HIV as a terminal illness) as previous generations, however what they fear the social stigma linked to HIV in the gay community and society as whole. There is limited awareness regarding PeP, PrEP and U = U. Most information about these strategies are found in social media, NGOs of people living with HIV, TV shows online or stream and dating app such as Grindr.

CONCLUSIONS: The lack of comprehensive sexuality education and insufficient information disseminated online, combined with the stigma still related to HIV, are key barriers to HIV prevention, testing and access to healthcare among these adolescent boys and young men. National polices should address combination prevention tools awareness and implementation with online communication strategies specific for this group, as well as, endorsing the implementation of the Comprehensive Sexuality Education Law.

PED1140

BARRIERS AND FACILITATORS OF HIV PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG YOUNG MEN WHO HAVE SEX WITH MEN (YMSM) AND YOUNG TRANSGENDER WOMEN (YTGW) IN NORTHEAST BRAZIL

L. Magno[1], M. Castellanos[2], L. da Silva[2], R. Loreno[1], É. Rufino[1], I. Dourado[2]
[1]Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil, [2]Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil

BACKGROUND: Fastest growing rates of HIV infection globally and in Brazil occur among YMSM and YTGW. However, data about effectiveness of PrEP in adolescents is still limited in most countries. Brazil is in the process of making PrEP available for these groups through a demonstration Project but to date there is extremely limited data regarding their knowledge and willingness to use PrEP. Our goal is to figure out barriers and facilitators of PrEP use among YMSM and YTGW in Salvador, one of the largest cities in Northeast Brazil.

METHODS: This is the first multi-city PrEP demonstration and scale-up study (PrEP15-19 Brazil Study) among YMSM and YTGW at high risk of HIV in Brazil and Latin America. We conducted a survey as part of formative research among 123 YMSM and YTGW ages 15-22 years old at schools, youth LGBT gathering/venues and youth LGBT parties in Salvador between AugustDecember 2018. Data on PrEP knowledge and willingness to use, sociodemographics, gender and sexual identity, and HIV risk perception were collected. Descriptive statistics and odds ratios with 95% confidence intervals were obtained using bivariate analysis.

RESULTS: 94.2% YMSM and 5.8% YTGW were recruited from three venues: 48.8% in youth LGBT parties, 37.4% in youth LGBT gathering/venues and 13.8% in schools. 74.3% identified as gays and 25.7% as bisexuals. Most (52.0%) were young (15-19 yo); blacks (60.2%); 26.2% had less than 8 years of education, a third were in high school (34.4%) and 39.3% at university; 61.0% did not know about PrEP before the study; 80.5% were willing to use PrEP upon awareness. Factors associated with PrEP knowledge were: older age (OR=1.57); recruitment at youth LGBT parties (OR=10.3), at LGBT gathering/venues (14.9) vs at schools; higher education (OR=8.18); perception of AIDS not as a serious disease (OR=3.71); These factors were also associated with willingness to use PrEP except recruitment, those recruited at schools (OR=1.96) were more willing to use PrEP.

CONCLUSIONS: Figuring out barriers and facilitators of PrEP use is necessary in order to guarantee that YMSM and YTGW will access PrEP at a pioneer demonstration Project. Schools are important venues for PrEP awareness among young key populations.

ADOLESCENTS, SEXUALITY AND RELATIONSHIPS

ADOLESCENT MSM'S EXPERIENCES AND PERSPECTIVES OF SEXUAL HEALTH AND HIV PREVENTION ACCESS: FINDINGS FROM ONLINE AND IN-PERSON FOCUS GROUPS WITH YOUTH FROM ACROSS THE UNITED STATES

T. Wang[1], S. Cahill[1], H. Fontenot[1], S. Geffen[1], K. Mayer[2], M. Johns[3], R. Dunville[3]
[1]The Fenway Institute, Health Policy, Boston, United States, [2]The Fenway Institute, Boston, United States, [3]Centers for Disease Control and Prevention, Division of Adolescent and School Health, Atlanta, United States

BACKGROUND: In the US, men who have sex with men (MSM) are at high risk for HIV infection. HIV incidence among young black MSM is almost three times that of young white or Latino MSM age 13-24. HIV infections among Latino MSM 13-24 increased by 17% for 2010-2016. Adolescent MSM (AMSM) experience specific barriers to healthcare due to discrimination and stigma, in addition to barriers commonly experienced by all youth, such as affordability and privacy concerns. In order to build effective, evidenced-based interventions to reduce HIV infections among AMSM, a greater understanding of the facilitators and barriers of AMSM's access to HIV prevention is necessary.

METHODS: Two online and two in-person focus groups were conducted with AMSM, ages 13-18, from across the United States. Participants were recruited via advertisements posted on social media and distributed through a network of youth-serving organizations. Qualitative data were analyzed by the study team using content analysis in NVivo.

RESULTS: Twenty-one racially diverse AMSM participated in four focus groups (average age = 16.4). Across all groups, four unique themes emerged:

(1) barriers to HIV prevention, including stigma, fear of being outed, affordability, and privacy;

(2) attitudes about sex, dating, and safer sex strategies;

(3) sexual identity formation and sources of support; and,

(4) challenges to obtaining comprehensive sexual health information.

Participants described providers' promoting stigma and scare tactics, a lack of provider knowledge of certain prevention strategies like PrEP, and difficulty accessing reliable and affirming sexual health information. Participants reported learning more about sex from porn and dating apps than from schools or providers. Participants, especially AMSM of color, emphasized the need for mentors with shared identities.

CONCLUSIONS: AMSM experience the same structural barriers to accessing HIV prevention as most adolescents, such as embarrassment and concerns parents will find out. Our study highlights additional barriers experienced by AMSM associated with stigma and fear of being outed. Findings illustrate current gaps in sexual health knowledge, as well as barriers and facilitators to obtaining sexual health information, sexual healthcare, and affirming education and support specifically for AMSM. Findings will inform the development of effective, targeted HIV prevention strategies for AMSM.

PED1142

COMMUNITY SPACES, COMMUNITY GROUPS, AND HIV ACQUISITION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN IN RURAL SOUTH AFRICA: A LONGITUDINAL ANALYSIS OF HIV PREVENTION TRIALS NETWORK 068 DATA

N.L. Bhushan[1], M.C. Stoner[2], R. Twine[3], K. Kahn[3], S.A. Lippman[4,3], A.E. Pettifor[5,3]
[1]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [2]RTI International, Women's Global Health Imperative, San Francisco, United States, [3]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, Johannesburg, United States, [4]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [5]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States

BACKGROUND: As adolescent girls and young women (AGYW) transition to adulthood, there are numerous changes occurring in their lives that make context a critical consideration for HIV prevention interventions. Beyond parental homes and school, few studies have examined what types of naturally existing social groups and community spaces might be protective for AGYW HIV acquisition and related risky sexual behaviors.

METHODS: Data are from HIV Prevention Trials Network 068, a longitudinal conditional cash transfer study of AGYW (age 13-23) in rural South Africa. Generalized estimating equations with a log link, binomial distribution, and an independent correlation structure were used to assess the association between community group membership, time spent in community spaces outside of home and school, HIV incidence, and sexual behaviors (unprotected sex, transactional sex, and having an older partner).

RESULTS: A total of 2,245 AGYW were followed for up to four years. Membership in church groups (aIRR: 0.75, 95% CI: 0.53, 0.91), dance groups (aIRR: 0.89, 95% CI; 0.80, 0.98), and spending any time at church (aIRR: 0.88, 95% CI: 0.79, 0.98) was protective for HIV infection. Conversely, spending any time at shebeens (drinking establishments) was associated with an increased incidence of HIV infection (aIRR: 1.27, 95% CI: 1.15, 1.41). Membership in church groups and spending any time at family member's home and at church was protective for unprotected sex, transactional sex and older partnerships while spending any time at boyfriends' homes and shebeens increased risk.

CONCLUSIONS: Our results suggest that community spaces and groups that include an element of adult supervision are protective against HIV infection and risky sexual behaviors, while spaces and groups that provide an opportunity for AGYW to interact with boyfriends or meet new partners, are risky. Research that untangles whether protective community spaces and groups simply limit opportunities for risky sexual behavior, or also imbue norms related to protective sexual behaviors, is important for the development of future HIV prevention interventions.

PED1143

ADOLESCENT MOTHERHOOD PREDICTS HIV INCIDENCE AMONG YOUNG WOMEN IN SOUTH AFRICA ENROLLED IN HPTN 068

A.K. Groves[1], N.L. Bhushan[2], M.C. Stoner[3], K. Kahn[4,5], R. Twine[4], A.E. Pettifor[2,6]
[1]Drexel Dornsife School of Public Health, Community Health and Prevention, Philadelphia, United States, [2]University of North Carolina, Chapel Hill, United States, [3]RTI International, Women's Global Health Imperative, Berkeley, United States, [4]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Agincourt, South Africa, [5]INDEPTH Network, Accra, Ghana, [6]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa

BACKGROUND: Adolescent motherhood is common in South Africa and occurs against a backdrop of high HIV risk. However, there has been limited study of whether adolescent motherhood increases risk of HIV acquisition and engagement in high-risk sexual partnerships, even though early childbearing may result in social and economic strains for young mothers.

METHODS: Data are from HIV Prevention Trials Network (HPTN) 068, a longitudinal conditional cash transfer study of AGYW (age 13-23) in rural South Africa. We used generalized estimating equations with a log link and binomial distribution to determine if adolescent motherhood (live birth before age 19) was associated with transactional sex (TS) and intimate partner violence (IPV). We used HIV cases for the time point after motherhood to assess whether motherhood predicted incident HIV infection. AGYW who were lost to follow up did not differ on motherhood, TS or IPV.

RESULTS: Of 2,533 AGYW whom were HIV-negative at baseline, 6% were adolescent mothers at baseline and 12% total were adolescent mothers by the end of the study period. At baseline, adolescent mothers were less likely to report both parents living (59% vs 69%), more likely to be in the poorest SES quintile (35% vs 25%) and more likely to report recent depression (28% vs 17%). After controlling for covariates, adolescent motherhood was associated with increased incident HIV acquisition (RR: 1.31 (95% CI: 1.10, 1.42). Adolescent mothers were also more likely to report TS (PR: 2.62, 95% CI: 1.92, 3.57) and IPV (PR: 1.29, 95% CI: 1.07, 1.57) at the same time period than adolescent non-mothers, after controlling for covariates.

CONCLUSIONS: Adolescent mothers had a higher risk of HIV acquisition and were more likely to be in high risk sexual partnerships over the study period than other AGYW. Adolescent mothers as a unique sub-population of AGYW have received limited attention to date. Further research is needed to understand how the social and economic strains of motherhood influence their sexual relationships. Furthermore, tailored combination interventions that account for the unique context of adolescent motherhood while increasing access to pre-exposure prophylaxis are critical for the long-term health of adolescent mothers and their children.

PED1144

PREVENTION AND RESPONSE TO GIRLS AND WOMEN LIVING WITH HIV/AIDS IN POST-WAR AREAS (NAKIVALE REFUGEE SETTLEMENT) IN UGANDA

N. Nabulumba[1]
[1]American Refugee Committee, WASH, Mbarara, Uganda

BACKGROUND: American Refugee Committee is a non-profitable organization whose main objective is to offer community based protection using different approaches in prevention and response against gender based violence in post war areas. During the transition process, refugees—particularly girls and women—face many challenges. However, in abide to overcome these encounters, such vulnerable groups are exposed to risks of rape and involvement in commercial sex. Retrospectively, because gender-based violence is one of the key causes of high spread of HIV, ARC adopted the Start Awareness Support Action (SASA) approach against gender based violence and HIV spread to help achieve the following objectives; prevention of HIV, respond to the needs of victims of HIV/Aids and create awareness in communities about the prevention measures for HIV.

DESCRIPTION: The SASA project was designed and implemented in (2016-18) in Nakivale Refugee camp with a population over 119,500 refugees. During the project, capable community members were trained on reporting and handling cases, leaders were empowered on handling emergency cases, new guidelines on sexual exploitation and abuse were initiated within the refugee settlement. Toll-free and a feedback challenge locally named "Kuja-Kuja" was installed, where insight staff communicated directly with the community. Awareness and free counseling services were conducted at individual, community levels and timely home visits to families with victims of HIV. Annual review meetings were conducted with stakeholders to monitor the progress of the SASA approach.

LESSONS LEARNED: Through community engagement, the percentage of people who tested weekly raised from 27%— 52%. Mass media campaigns created a positive impact on information-flow. Empowering HIV social groups in combined livelihood activities improved their living standards and enactment of the "sexual exploitation and abuse police" reduced on chances of manipulation of refugees in camps.

CONCLUSIONS/NEXT STEPS: Notwithstanding the few challenges, the SASA approach reduced the spread of HIV quit significantly by 56%, improved financial sustainability at household level, reduced gender based violence cases at station polices and information-flow created more awareness within refugee settlements. Livelihood training in agriculture and hair dressing among women and young girls within camps. However, more funding should be allocated to women groups that seem more vulnerable.

PED1145

CHARACTERISTICS OF PREVIOUSLY UNDIAGNOSED ADOLESCENT GIRLS AND YOUNG WOMEN WITH HIV AND HIV RISK BEHAVIORS ASSOCIATED WITH CHILDHOOD VIOLENCE: EVIDENCE FROM THE LESOTHO VIOLENCE AGAINST CHILDREN AND YOUTH SURVEY, 2018

A. Howard[1], M. Conkling[2], R. Maraisane[3], A. Low[4], L. Chiang[5], P. Patel[6], G. Massetti[5], J. Hegle[6], J. Saul[7], L. Musi[8]
[1]Strategic Innovative Solutions, LLC, Washington D.C., United States, [2]U.S. Centers for Disease Control and Prevention, Maseru, Lesotho, [3]Columbia University, ICAP, Maseru, Lesotho, [4]Columbia University, ICAP, New York, United States, [5]U.S. Centers for Disease Control and Prevention, Division of Violence Prevention, Atlanta, United States, [6]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [7]U.S. Department of State, Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington D.C., United States, [8]UNICEF, Maseru, Lesotho

BACKGROUND: Adolescent girls and young women (AGYW) in Lesotho experience a disproportionally high rate of HIV infection compared with male adolescents. Reasons for the disparities are complex, and involve structural, biological, and behavioral factors, includ-

ing violence. These most current population data provide insight into understanding the unique risks of AGYW, imperative to achieving HIV epidemic control.

METHODS: The Violence Against Children and Youth Survey (VACS) questionnaire and HIV testing were completed by a nationally representative sample of adolescent girls and young women (AGYW), 13-24 years, in Lesotho. To assess characteristics of AGYW with undiagnosed HIV and examine associations between HIV risk behaviors and childhood violence, we conducted logistic regressions using SAS 9.4.

RESULTS: Among 6,563 AGYW surveyed, 7.3% were HIV positive. HIV positive status differed significantly by age: 3.5% (95%CI: 2.6-4.3%) ages 13-17 and 10.1% (95% CI: 8.6-11.6%) ages 18-24. Although 98.2% of AGYW with HIV had previously been tested, only 82.4% knew their status.

Previously undiagnosed positives (n=73) had higher odds of unknown partners' status (adjusted odds ratio (AOR): 3.5, 95%CI: 1.8-6.8), early sexual debut (AOR: 2.4, 95%CI: 1.1-4.8), multiple lifetime partners (AOR: 2.1, 95%CI: 1.0-4.0), and pregnancy (AOR: 1.8, 95%CI: 1.1-2.8); and lower odds of being under 18 (AOR: 0.2, 95%CI: 0.1-0.6) and in school (AOR: 0.3, 95%CI: 0.1-0.6) compared to negative AGYW.

Among all AGYW, those with childhood sexual violence (n=738) had increased odds of HIV risk behaviors including early sexual debut (AOR: 3.5, 95%CI: 2.7-4.5), multiple lifetime partners (AOR: 2.5, 95%CI: 1.9-3.2), and transactional sex in the past 12 months (AOR: 2.3, 95%CI: 1.3-4.0) compared with AGYW with no childhood sexual violence. Those with childhood emotional violence had higher odds of early sexual debut (AOR: 1.5, 95%CI: 1.1-2.1), multiple lifetime partners (AOR: 1.7, 95%CI: 1.2-2.2), and transactional sex in the past 12 months (AOR: 2.3, 95%CI: 1.2-4.6) compared to AGYW with no childhood emotional violence.

CONCLUSIONS: Programs should consider these characteristics of undiagnosed AGYW with HIV in targeting prevention and testing toward those at highest HIV risk. Because AGYW who experience violence engage in more risk behaviors, early prevention of childhood violence remains critical for HIV epidemic control in Lesotho.

PED1146

CAREGIVER AND NON-CAREGIVER COMMUNICATION ABOUT SEXUALITY WITH INDIGENOUS ADOLESCENTS OF THE COMARCA NGÄBE-BUGLÉ IN PANAMA

A. Gabster[1,2], B. Cislaghi[3], J.M. Pascale[2], E. Socha[4], P. Mayaud[1]
[1]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom, [2]Instituto Conmemorativo Gorgas de Estudios de la Salud, Genomica y Proteomica, Panama City, Panama, [3]London School of Hygiene and Tropical Medicine, Public Health and Policy, London, United Kingdom, [4]Community Development Network of the Americas, Panama City, Panama

BACKGROUND: Indigenous adolescents of the Comarca Ngäbe-Buglé (CNB) in Panama are vulnerable to HIV/sexually transmitted infection (STI) acquisition in part due to limited access to health and education services, whilst specific cultural factors have been scarcely explored. Previous research in non-indigenous contexts has shown that communication about sexuality with either caregivers or non-caregivers affect adolescent sexual decision-making. Understanding who indigenous adolescents in Panama learn from about sexuality and the impact of this communication on subsequent sexual behavior and STI outcomes would lay the path for the development of culturally sensitive interventions to prevent HIV/STI in this highly vulnerable group.

METHODS: From January to November 2018, we conducted a mixed-method study in the CNB, the largest indigenous region in Panama. The quantitative component consisted of a cross-sectional study of 700 randomly selected school-going 14-19-year-old students. Self-administered questionnaires collected data on socio-demographics, sexual behaviors, and participants´ communication with caregivers and non-caregivers on sexuality topics. Participants were also tested for HIV/STI. In the qualitative component, we used in-depth interviews with 16 caregivers, in addition to ethnographic research.

RESULTS: In the quantitative study, we found that adolescents communicated with both caregivers and non-caregivers on topics such as delaying sexual initiation, pregnancy/pregnancy prevention, and STI prevention. Communication with caregivers and non-caregivers was associated with decreased reports of sexual debut and influenced STI outcomes positively. In the qualitative study, we found that caregivers generally felt embarrassed/inadequate to talk about sexuality. Traditional coming-of-age rituals, i.e. möngöndre (for girls) and grön (for boys), included teachings on sexual behavior, but are not as thoroughly practiced today as they were in the past.

CONCLUSIONS: Communication about sexuality with both caregivers and non-caregivers play an essential positive role in indigenous adolescents´ sexuality and sexual health. A revitalization (and modernization) of some components of traditional ritualscould be beneficial to increase intergenerational communication on sexuality with adolescents of the CNB.

PED1147

WHO IS MAKING SCHOOL GIRLS IN WESTERN KENYA PREGNANT AND HOW ARE THEY COPING WITH PREGNANCY AND MOTHERHOOD? IMPLICATIONS FOR HIV PREVENTION

H. Mangla[1], C. Oketch[1], C. Magak[1], G. Okumu[1], K. Agot[2]
[1]Nyanza Initiative for Girls' Education & Empowerment, Kisumu, Kenya, [2]Impact Research and Development Organization, Kisumu, Kenya

BACKGROUND: Teenage pregnancy not only exposes adolescents to the risk for HIV, it also takes them out of school. School attendance, especially single-gender boarding secondary school, is protective against HIV. By age 18, 39.9% of girls in Kenya have begun childbearing. Although girls who get pregnant in school are allowed by law to resume schooling post-delivery, majority do not. We carried out a survey of girls who dropped out of school due to pregnancy, to understand the reasons for and consequences of teen pregnancy and motherhood and implications for HIV programming.

METHODS: We randomly selected one Sub-County in four Counties along Lake Victoria region where HIV is highest nationally (13-21% against 5%), randomly selected 30% of the Wards and 50% of the schools. Principals shared a list of girls who dropped out in the previous 5 years. Research assistants visited the homes to obtain consent, assess eligibility (aged 13-21 years and got pregnant while in school), and conduct the interview.

RESULTS: We enrolled 289 adolescent girls and young women age 13-21 years; 93.5% single, mean age 18.1 years, 60.2% had sex by age 15, age at first pregnancy was 16.1, 72.7% reported being enticed with money/gifts to have sex, and 56% reported multiple lifetime sexual partners, with <2% reporting consistent condom use. Majority got pregnant in Grade 7 or 10 (57% and 68%, respectively), 92% of whom were from mixed-gender day schools. Over half (52.1%) reported being made pregnant by school-mates and 21.7% by motorbike riders providing public transport; teachers accounted for only 3.6% while

5.7% did not know the man's occupation. 47% and 33% felt sex education and good parenting practices, respectively, would reduce teenage pregnancy. 47.3% reported different levels of support from the baby's father, 15% in exchange for sex – exposing them to HIV and another pregnancy.

CONCLUSIONS: Teenage pregnancy remains a reproductive health concern in day schools, and schoolmates are responsible for the majority. Concerted sex, HIV and pregnancy education (and contraceptive education, with parental support) and good parenting practices are needed to address teenage pregnancy; laws should be enacted to hold those responsible accountable.

GENDER ISSUES AND GENDERED RELATIONSHIPS

PED1148

GENDER ROLE CONFLICT, HEALTH, AND STIGMA AMONG MEN WITH HIV IN WESTERN KENYA

A. McDonough[1], L. Sheira[2], R. Burger[3], E. Weke[4], P. Wekesa[4], E.A. Frongillo[5], S.L. Dworkin[6], E.A. Bukusi[4,7], C.R. Cohen[3], S.D. Weiser[2]
[1]University of California, San Francisco, United States, [2]University of California, Department of Medicine, San Francisco, United States, [3]University of California, Department of Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [4]Kenya Medical Research Institute, Nairobi, Kenya, [5]University of South Carolina, Arnold School of Public Health, Department of Health Promotion, Education, and Behavior, Columbia, United States, [6]University of Washington Bothell School of Nursing and Health Studies, Bothell, United States, [7]University of Washington, Department of Obstetrics and Gynecology, Seattle, United States

BACKGROUND: Increased gender role conflict (tensions between ideal male gender norms and men's ability to fulfill these) is associated with poor health and poor mental health outcomes in the general population. Few studies have examined the relationship between gender role conflict and HIV in sub-Saharan Africa. To our knowledge there is no previous data on health impacts of gender role conflict among men with HIV, even though they are at higher risk for poor physical and mental health outcomes.

METHODS: To examine relationships between gender role conflict, mental health, and HIV health, we analyzed cross-sectional baseline data among a cohort of men (n=321) enrolled in the Shamba Maisha multisectoral livelihood intervention RCT (NCT02815579) in western Kenya. An adapted 22-item Gender Role Conflict Scale (GRCS) was administered along with adapted versions of the Hopkins Depression Checklist, Medical Outcomes Study HIV-Health Survey (MOS-HIV), AIDS-related Stigma Scale, and AUDIT-C alcohol use questionnaire. Viral load was tested during a clinic visit at baseline. We used multivariable linear regression to investigate associations, adjusting for age, education, marital status, travel time to clinic, and years on ARVs.

RESULTS: In adjusted models, higher GRCS scores, representing a lower degree of gender role conflict, were associated with lower odds of having a detectable viral load (cut-off 1000 copies, aOR 0.25, 95% confidence interval 0.08, 0.81, p<0.05), lower odds of screening positive for depression (aOR 0.16, 95% confidence interval 0.07, 0.38), lower anticipated stigma scores (b -0.43, standard error (SE) 0.11), lower internalized stigma scores (b -0.71, SE 0.13), lower enacted stigma scores (b -0.27, SE 0.06, and higher mental health-related quality of life scores (b 13.53, SE 3.14) (all p<0.001). There were no statistically significant associations between GRCS score, physical health-related quality of life and hazardous drinking.

CONCLUSIONS: Men living with HIV in western Kenya who experience gender role conflict are more likely to experience worse mental health and HIV-related outcomes. Studies are needed to elucidate the directionality and mechanisms of these relationships. If confirmed in future studies, gender role conflict may be an important and understudied target for interventions to improve the health of HIV-infected men.

BIDIRECTIONAL VIOLENCE IS ASSOCIATED WITH POOR ENGAGEMENT IN HIV CARE AND TREATMENT IN MALAWIAN COUPLES

A. Conroy[1], A. Leddy[1], L. Darbes[2], T. Neilands[1], J. Mkandawire[3], R. Stephenson[2]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]University of Michigan, Department of Health Behavior and Biological Sciences, Ann Arbor, United States, [3]Invest in Knowledge, Zomba, Malawi

BACKGROUND: Growing evidence suggests that intimate partner violence (IPV) is a barrier to engagement in HIV care. Bidirectional IPV—being both a perpetrator and victim—may be the most common pattern of IPV, yet no research has examined its effect on engagement in care, which could identify couples in most need of interventions.

METHODS: Married couples (N = 211) with at least one partner on antiretroviral therapy were recruited from HIV clinic waiting rooms in Zomba, Malawi. Partners completed separate surveys on physical, sexual, and emotional IPV, medication adherence, and appointment attendance. We created categorical variables indicating no violence, perpetrator-only, victim-only, and bidirectional violence. Generalized estimating equation regression models tested for associations between IPV and engagement in care.

RESULTS: The bidirectional pattern represented 25.4%, 35.5%, and 34.0% of all physical, sexual, and emotional IPV. Physical IPV victimization-only (adjusted odds ratio (AOR): 0.28, 95% confidence interval (CI): 0.08, 0.92) was associated with lower adherence, but the association was stronger for bidirectional physical IPV (AOR: 0.10, 95% CI: 0.02, 0.51). Bidirectional sexual IPV was also associated with lower adherence (AOR: 0.14, 95% CI: 0.02, 0.80). Bidirectional physical IPV (AOR: 4.04, 94% CI: 1.35, 12.14) and emotional IPV (AOR: 3.78, 95% CI: 1.78, 8.05) were associated with missing 1+ appointment.

CONCLUSIONS: Interventions to address the health effects of bidirectional IPV, which may be greater than victim-only or perpetrator-only IPV, should intervene with both partners to break cycles of violence. Couple-based interventions may be a viable option by intervening on both partners' trauma and aggression simultaneously.

PED1150

CERVICAL CANCER KNOWLEDGE AND ATTITUDES AMONG HIV-POSITIVE MEN IN MALAWI: A QUALITATIVE STUDY

M. Mphande[1], S. Lewis[2], B.A. Banda[1], H. Sigauke[1], P. Kawale[3], A. Aubrey Kang'oma[1], K. Dovel[2], A. Amberbir[1], A. Moses[1], S. Gupta[1], R.M. Hoffman[2], C. Moucheraud[2]
[1]Partners in Hope, Lilongwe, Malawi, [2]University of California, David Geffen School of Medicine, Los Angeles, United States, [3]African Institute for Development Policy, Lilongwe, Malawi

BACKGROUND: Malawi has the highest burden of cervical cancer. Studies show that engaging men in women's reproductive health services improves women's use of services and health outcomes. However, little is known about men's knowledge and opinions of cervical cancer disease, screening and treatment services. We explored HIV-positive men views of cervical cancer to inform strategies to increase women's uptake of screening and treatment.
METHODS: In-depth interviews were conducted with HIV-positive men who reported having a female partner at a large, free antiretroviral therapy (ART) clinic in Lilongwe, Malawi to assess their knowledge and opinions about cervical cancer, screening, and treatment. Data were collected between June – July 2019. Qualitative data were analyzed via thematic coding, and compared by respondent age and whether his partner has ever been screened for cervical cancer or not.
RESULTS: We interviewed 109 men, median age 44 years (IQR 40,50). Men had a general knowledge about cervical cancer and transmission, with most correctly identifying sexual risk factors, particularly younger men. However, the majority of respondents – those with screened partners and those without -- were unable to describe screening procedures. Most men nonetheless believed it was important for their partners to screen for cervical cancer, and that they should support their partners through encouragement and accompanying their partners for screening. Men were generally not concerned about safety or discomfort associated with screening, but some older men expressed concerns about service provision by male providers and worried about sexually inappropriate behavior from male providers during a screening. Among strategies for male engagement, some respondents suggested working with community leaders and through community outreach meetings to improve men's knowledge to better assist their partners.
CONCLUSIONS: Men have limited knowledge about cervical cancer screening, but high stated willingness to support screening and treatment. Programs should aim to educate men about cervical cancer, and promote partner involvement in screening and treatment. Strategies should also consider men's concerns around provider gender.

PED1151

PREVALENCE AND NATURE OF GENDER-BASED VIOLENCE AMONG FEMALE ENTERTAINMENT WORKERS IN CAMBODIA: A MIXED METHODS STUDY

S. Tuot[1], S. Yem[1], K. Kathryn[2], P. Chhoun[1], S. Yi[1,3,2]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]Touro University California, San Francisco, United States, [3]National University of Singapore, Singapore, Singapore

BACKGROUND: Gender-based violence (GBV) is strongly associated with an increased risk of HIV, especially, for key populations including female entertainment workers (FEWs). Despite the need for the information, data on GBV among FEWs in Cambodia are scarcely available. This study aims to investigate the prevalence and nature of GBV among FEWs in Cambodia.
METHODS: A mixed-method study was conducted in early 2018 in a municipality and six provinces among 652 FEWs. Time location sampling (TLS) was used to recruit survey respondent and convenience sampling was used for qualitative. A semi-structured questionnaire collected information on the intersection of gender and violence, the intersection between entertainment work and violence, and investigated access and availability to health care. A structured questionnaire was used to collect data on prevalence of various forms of violence. Content analysis was conducted for qualitative data, and descriptive analyses were conducted using STATA 13.0.
RESULTS: In total, 35 in-depth interviews and 652 interviews with FEWs were conducted. Over 10% of participants reported experiencing physical violence and 7% reported experiencing sexual violence. Women reported that their husband, rather than the clients, was more often the perpetrator of physical violence, whereas the clients rather than their husband, was more often the perpetrator of sexual violence. FEW overwhelmingly spoke about feeling degraded through harassment, verbal abused as well as other forms of violence that they sometimes termed 'more severe' such as physical abuse and rape. Of the women who had experienced violence, 25% did not tell anyone, and a much lower percentage sought medical (8%), legal (9%) or social (3%) support. Perceived barriers to seeking care included believing that the experience was not severe enough to seeking care, fear of retribution, not trusting the system and loyalty/attachment to the abusing partner/husband. Lastly, women did not know where to seek services or if they existed and overwhelmingly wanted counseling services.
CONCLUSIONS: GBV is a major issue faced by women who work in the entertainment industry across all country and across of type of establishments. To truly make strides to reduce GBV, there are needs of a multi-sectoral response with commitments from multi stakeholders.

PED1152

PREVALENCE OF PREP USE AND PARTNER SUPPORT AMONG MALE COUPLES IN THE SAN FRANCISCO BAY AREA OF USA

C. Hoff[1], D. Chakravarty[2], T. Neilands[2], L. Darbes[3]
[1]San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States, [2]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [3]University of Michigan, Nursing, Ann Arbor, United States

BACKGROUND: Early studies investigating intentions to use PrEP among male couples report mixed findings — in some cases PrEP is viewed positively because it offers added protection from HIV infection that would be beneficial to couples, while other studies demonstrate reluctance to initiating PrEP because couples consider themselves to not be at risk for HIV, often citing a monogamous agreement. However, few couples were actually taking PrEP at the time of these reports. Therefore, little is known about actual PrEP use among male couples.
METHODS: We recruited 280 male couples (560 individuals) — 80% concordant HIV-negative and 20% serodiscordant— from July 2017 to November 2019 for an HIV prevention intervention trial in the San Francisco Bay Area using active and passive strategies. We generated select frequencies related to PrEP use among HIV-negative

participants in each couple-serostatus group separately, but found no substantive differences between groups, for the variables of interest. Therefore, we present results below from all HIV-negative participants (N=502).

RESULTS: The median age was 34 years (SD: 11.5). The median relationship length was 4 years (SD: 7.5) and 22% reported monogamous agreements. Over 60% of HIV-negative men reported ever using PrEP. The most endorsed reasons for starting PrEP included: wanting to protect self from HIV, wanting to protect self from HIV in an open relationship, the ability to have sex without a condom and the suggestion to use PrEP from one's doctor. 51% reported taking PrEP in the previous three months. Among this subgroup, 86% reported talking openly with others about their PrEP use and 98% had told their primary partner about their PrEP use. Of those who told their primary partner, over 97% reported their partner was supportive of their PrEP use. Finally, 81% took PrEP daily and 93% felt confident in their ability to take PrEP as prescribed.

CONCLUSIONS: PrEP use is expanding and partner support for PrEP is high among male couples. Open dialogue among partners about PrEP use suggests couples are making sexual health decisions together; this may aid in consistent use. Encouraging couples to have on-going discussions about PrEP use and sexual agreements will support long term sexual health.

PED1153

EDUCATION AND AWARENESS ON THE VIOLENCE AGAINST PERSONS PROHIBITION ACT (VAPP ACT) AS A TOOL FOR REDUCING GENDER INEQUALITIES AND HIV INFECTION: LESSONS LEARNED FROM BAWRI COMMUNITY IN FCT NIGERIA

O.E. Maduabum[1,2], E. Durojaye[3], C. Okeke[4], G. Iloh[4]
[1]University of Abuja, Social Science /Medical Sociology, Abuja, Nigeria, [2]Concern Women International Development Initiative (CWIDI), Programme, Abuja, Nigeria, [3]University of Western Cape, Dullah Omar Institute, Cape Town, South Africa, [4]Concern Women International Development Initiative, Abuja, Nigeria

BACKGROUND: The Violence against Persons Prohibition Act (VAPP Act) was enacted in 2015 to address the high incidence of GBV in Nigeria. However, women and girls have continued to experience all forms of violence including intimate partner violence sexual violence, rape, domestic violence etc, which hinder women's ability to negotiate use of condom and expose them to HIV infection.

Those in rural communities, lack understating of the provisions and importance of the Act. (CWIDI) with support from Women Deliver International, embarked on sensitization and awareness programmes for 4000 young girls on the VAPP ACT in Bwari community FCT, Nigeria.

DESCRIPTION: CWIDI hosted a radio phone in show in Abuja to educate the populace on the provisions of the Act including the link between gender-based violence and HIV, protections available and the reporting procedures to the police for the purpose of obtaining a restraining order, hot lines and shelter homes . Community engagements were organised on the VAPP Act to reach about 4000 women and girls in Bwari, a semi-rural community in Abuja, Federal Capital city of Nigeria. In addition, District heads in Bwari community were trained as VAPP Act champions and presently adding their voice to the campaign against GBV as well as acting as watch-dogs in the community to stymie violence in all ramifications against women and girls.

LESSONS LEARNED: The project led to increased in knowledge about the VAPP Act, and its relevance for protecting women against violence and HIV. Also, engaging with Districts heads, played an important role in the reduction of number of sexual abuse cases recorded . This has a positive implication for HIV infection in the community. The project equally encourages women and girls to speak out thus breaking the silence on this issue.

CONCLUSIONS/NEXT STEPS: Implementation on a wider scale and translating the abridge version of the Act in local languages should be considered, especially among girls aged 10-15 in and out of school. Also, there is need for constant engagement with women leaders including traditional and religious leaders as advocates of the Act. And adoption of a peer to peer approach to encourage and break the culture of silence.

PED1154

TALES OF OPPRESSION AND DOMINANCE: A GENDERED ANALYSIS OF HIV VULNERABILITIES AMONG FEMALES WHO INJECT DRUGS (FWID) IN DHAKA, BANGLADESH

S. Irfan[1], M.N.M. Khan[1,2], T. Hassan[1], S.I. Khan[1]
[1]International Centre for Diarrhoeal Diseases Research, Programme for HIV and AIDS, Dhaka, Bangladesh, [2]The Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan

BACKGROUND: Compared to their male counterparts, females who inject drugs (FWID) are more vulnerable to HIV infection. FWID are also labeled as "bridging populations" due to their HIV transmission potential via both the injection and sexual routes to their male partners. FWID are coined as vessels for HIV infections, without considering the underlying contexts that mold their sexual and injection behaviors. To inform more tailored and gender-sensitive harm reduction interventions, an ethnographic study explored gender-based vulnerabilities experienced by FWID. In light of the recent increase of HIV prevalence among FWID in Dhaka, Bangladesh, this paper for the first time has examined underlying risks and contexts constructed within a gendered framework.

METHODS: Under a classical ethnographic research design, between April 2018 and May 2019, prolonged participatory observations, fifteen in-depth interviews and two focus group discussions with FWID receiving harm reduction services, alongside two key informant interviews with harm reduction service providers were conducted with FWID. Data were thematically analysed under the "doing gender" framework.

RESULTS: Findings alluded to the dependence of FWID on their male partners due to the males' ability to provide asylum and protection within the patriarchal male dominated Bangladeshi society. This dynamic inaugurated the drug-injecting careers of several FWID. Due to anticipatory fears of domestic violence and being evicted from their relationship and hence, their shelter, FWID felt compelled to conform to their gender role of obeying their partner's commands. Consequently, decisions regarding drug collection and financing, use of sterile injection equipment and condom use were predominantly were predominantly dictated by the male partner, and followed accordingly. Moreover, several FWID partook in poly drug use in order to enhance their ability to uptake more transactional sex clients, thus exacerbating their vulnerabilities. It was also revealed that harm reduction interventions lacked gender-sensitive services; hence gender-based vulnerabilities remained unaddressed.

CONCLUSIONS: Findings alluded to the subservience of FWID towards their male partners, as per their socio-culturally constructed gender roles. However, the complexities created by the gender dichotomy were overlooked in conventional harm reduction interventions. Thus, tailored, holistic interventions need to be redesigned immediately for FWID in Bangladesh and elsewhere.

PED1155

"VIOLENCE IS EVERYWHERE": BUILDING RESILIENCE TO ADDRESS LINKAGES BETWEEN VIOLENCE AGAINST WOMEN AND HIV IN THE MIDDLE EAST AND NORTH AFRICA

L. Orza[1], R. Wahab[2], S. Salem[3], E. Bell[4], F. Hale[4], G. Eid[5]
[1]Frontline AIDS, Brighton, United Kingdom, [2]MENA Rosa, Beirut, Lebanon, [3]UNAIDS, Cairo, Egypt, [4]Salamander Trust, London, United Kingdom, [5]Independent, Beirut, Lebanon

BACKGROUND: Approximately 40% of adults living with HIV in the Middle East and North Africa (MENA) region are women, with acquisition primarily through sexual transmission. Evidence shows that GBV contributes to HIV acquisition. Leadership and Research Now (LEARN) MENA aimed to aimed to strengthen the HIV response and contribute towards the elimination of GBV in the MENA region by better understanding and responding to HIV-GBV linkages, and by strengthening the capacity of women living with and most affected by HIV to prevent and address GBV.
DESCRIPTION: The project utilised the Actions Linking Initiatives on Violence Against Women and HIV Everywhere (ALIV[H]E) Framework: a women-centred tool that enables women in their diversity to strengthen programmes and services that respond to GBV in the context of HIV. By applying ALIV[H]E methodology and values, the project sought to galvanize a sustainable response to GBV-HIV linkages in MENA, through: capacity-strengthening of the regional network of WLHIV (MENARosa); leadership of WLHIV and women in their diversity to advocate on GBV; participatory action research to understand GBV-HIV linkages in the region; and national stakeholder dialogues.
LESSONS LEARNED: Gender norms combined with HIV stigma and discrimination leave marginalised women in the MENA region vulnerable to violence in different settings. The project found that GBV was both a cause and consequence of HIV among marginalized women in the region. Most women who participated in the project reported experiencing violence in 3 or more settings, and nearly all feared violence. This underscores the fact that GBV constrains life choices, including women's ability to protect themselves from, or live well with, HIV. Women in their diversity also revealed extraordinary resilience and mutual support, and are emerging as powerful leaders.
CONCLUSIONS/NEXT STEPS: LEARN MENA has galvanised stakeholders to raise awareness of the need to prevent and address GBV-HIV linkages in MENA through: individual agency and community action; timely and responsive service provision, and a more protective and accountable legal environment. The project has built the resilience of women with HIV in the region to lead this work. Momentum to implement an emerging women-led agenda needs to be maintained through partnerships, technical support, resources and political will.

PED1156

KNOWLEDGE OF PREVENTION OF MOTHER-TO-CHILD TRANSMISSION OF HIV SERVICES AMONG MALE PARTNERS IN RURAL NIGERIA

K. Ukwaja[1,2], U.U. Ebenezer[1,3], E. Moffatt[4]
[1]Annabelles Bogi Development Initiative, Abakaliki, Nigeria, [2]Alex Ekwueme Federal University Teaching Hospital, Abakaliki, Nigeria, [3]University of Nigeria, Health Administration and Management, Enugu, Nigeria, [4]ViiV Healthcare Limited, Positive Action for Children Fund, Brentford, United Kingdom

BACKGROUND: Poor male partner involvement in the prevention of mother-to-child transmission (PMTCT) undermines the potential benefits of HIV preventive efforts. However, the factors associated with poor knowledge of male partners in PMTCT are not well known in Nigeria and need to be investigated. The objective of this study was to determine knowledge of PMTCT and the associated factors among adult males in rural districts of Ebonyi State, Nigeria.
METHODS: This was a community-based cross-sectional survey conducted from September to October 2019 among men with wives of child-bearing age in two rural districts of Ebonyi State, Nigeria. Systematic random sampling was used to get the total of 450 participants. Multivariable logistic regression analysis was used to identify the determinants of knowledge of MTCT and PMTCT.
RESULTS: A total of 450 men completed the survey – mean age 40.6 ± 8.7 years. Also, 164 (36.4%) had primary education and 163 (36.2%) had secondary education. A total of 449 (99.8%) were married; 445 (98.9%) were currently living with their partners and 142 (31.6%) had a pregnant female partner at the time of the survey. The mean knowledge score was 15.0 ± 2.7 (maximum 19). Overall, 330 (73.3%) of the respondents had good knowledge score (≥70 correct knowledge). In the multivariable logistic regression analysis, having a secondary (aOR 2.0; 95% CI 1.1 – 3.8) or tertiary education (aOR 4.0; 95% CI 1.2 – 13.9), and the belief that men should accompany their female partners to antenatal care/health facility visits (aOR 2.4; 95% CI 1.2 – 4.9) were independent determinants of good knowledge of MTCT and PMTCT.
CONCLUSIONS: Male partners of rural women have a high knowledge of MTCT and PMTCT in rural Nigeria. This level of knowledge can be leveraged upon to initiate and sustain rural-based PMTCT intervention programs.

GENDER-TRANSFORMATIVE APPROACHES

PED1157

HOW TO CHANGE GENDER NORMS TO IMPROVE HIV SERVICE UPTAKE: QUALITATIVE FINDINGS FROM A COMMUNITY MOBILIZATION INTERVENTION IN SOUTH AFRICA

A. Leddy[1], A. Gottert[2], N. Haberland[2], J. Hove[3], R. West[1], A. Pettifor[4,3], S. Lippman[1,3], R. Mathebula[5], X. Gómez-Olivé[3], R. Twine[3], D. Peacock[6,7], K. Kahn[3], J. Pulerwitz[2]
[1]University of California, San Francisco, United States, [2]Population Council, Washington, United States, [3]University of the Witwatersrand, Johannesburg, South Africa, [4]University of North Carolina at Chapel Hill, Chapel Hill, United States, [5]Sonke Gender Justice, Cape Town, South Africa, [6]Promundo, Washington, United States, [7]University of Cape Town, Cape Town, South Africa

BACKGROUND: Increasingly, interventions to improve men's and women's engagement in HIV testing and antiretroviral therapy (ART) are explicitly addressing restrictive and inequitable gender norms. However, how and why gender norms/attitudes change, and how this translates into HIV service uptake, remain poorly understood. We implemented a qualitative sub-study during a community mobilization trial in rural South Africa that sought to reduce inequitable gender norms and other social barriers to HIV service engagement.
METHODS: We conducted 55 in-depth interviews in 2018, during the final months of the three-year intervention in Mpumalanga province. Participants included 25 intervention community members (48% women; 60% HIV-positive) and 30 intervention staff/community opinion leaders (70% women). Interviews explored shifts in gender norms/attitudes and HIV service use during the intervention; analysis involved an inductive-deductive approach.
RESULTS: We identified three potential avenues for gender norms change, which, when coupled with specific strategies, may lead to HIV service uptake: (1) Challenging norms that men should be tough and avoid help-seeking, combined with information on the health and preventive benefits of early ART, appeared to ease some men's fears of a positive diagnosis and facilitated uptake of HIV testing and other services. (2) Challenging norms about male control over women in relationships, combined with skill-building around equitable communication and conflict resolution, encouraged couples to consult and support each other around HIV testing and treatment. For example, less conflict and violence eased women's disclosure-related fears - facilitating ART initiation/adherence. (3) Challenging the norm that women are solely responsible for the family's health, combined with information about the benefits of ART, encouraged men to test for HIV proactively rather than reactively testing based on their partner's results. However, some men still perceived clinics as unaccommodating of men (e.g., long wait-times, few male staff), and suggested community-based testing.
CONCLUSIONS: Promoting critical reflection among men and women around restrictive/inequitable gender norms that act as barriers to care appears promising for increasing HIV service engagement. To ensure behavior change, this should be coupled with information (e.g., about ART benefits), skill-building activities (e.g., about equitable couple communication), and HIV services that are accessible to men.

SEXUAL BELIEFS AND HIV RISK DURING PREGNANCY AND BREASTFEEDING IN FOUR AFRICAN COUNTRIES: QUALITATIVE FINDINGS FROM THE MTN-041/MAMMA STUDY

J. Ryan[1], I. Hawley[1], P. Musara[2], N. Macagna[3], K. Reddy[4], V. Guma[5], L. Seyama[6], J. Piper[7], V. Flax[8], A. van der Straten[9]
[1]Women's Global Health Imperative (WGHI), RTI International, San Francisco, United States, [2]University of Zimbabwe, College of Health Sciences - Clinical Trials Research Centre, Harare, Zimbabwe, [3]FHI 360, Durham, United States, [4]University of the Witwatersrand, Wits Reproductive Health and HIV Institute (Wits RHI), Johannesburg, South Africa, [5]Makerere University, Johns Hopkins University Research Collaboration, Kampala, Uganda, [6]University of Malawi, Johns Hopkins Project - College of Medicine, Blantyre, Malawi, [7]NIH/NIAID, DAIDS, Bethesda, United States, [8]RTI International, Research Triangle Park, United States, [9]University of California, Center for AIDS Prevention Studies (CAPS), San Francisco, United States

BACKGROUND: Pregnant and breastfeeding (P/BF) women in sub-Saharan Africa are at heightened risk of HIV acquisition and perinatal transmission due to biological and behavioral factors. In preparation for phase 3b trials with P/BF women, we explored perceptions of HIV risk and attitudes about a vaginal ring and oral PrEP for HIV prevention in Malawi, South Africa, Uganda and Zimbabwe.
METHODS: We conducted focus group discussions (FGDs) with three community-recruited groups: HIV-uninfected women aged 18-40 (8 FGDs) who were currently or recently P/BF, men aged 18+ (8 FGDs) whose partners' were currently/recently P/BF, and mothers/mothers-in-law of P/BF women (grandmothers; 7 FGDs). Participants also completed a survey, viewed an educational video, and handled placebo products. English translations of FGD transcripts were coded (Dedoose software, v7.0.23) using a socio-ecological framework and analyzed thematically.
RESULTS: All participant groups described pregnancy and breastfeeding as times of high HIV risk primarily because men have multiple concurrent sexual partners; indeed, 37% of P/BF women indicated that their partner may be having sex with someone else. Participants explained that men seek other sexual partners because of beliefs that P/BF women have lower libido, are sexually unattractive, or sex may harm the unborn baby, and to adhere to late pregnancy and postpartum periods of abstinence. P/BF women and grandmothers noted the conflict women face in deciding whether to follow cultural norms and heal from delivery or to resume sex quickly postpartum to prevent men from seeking sex elsewhere. Female participants explained they often prioritize their partner's sexual needs because of pressure they feel to please the men. Despite concern about side effects for mother and baby, new prevention options were welcomed during pregnancy and breastfeeding, particularly given men's reluctance to use condoms and to test for HIV.
CONCLUSIONS: Understanding norms and conditions around sexual behavior during pregnancy and breastfeeding can help address the heightened HIV risk during these periods and highlights the need for new prevention options for women. Involving key influencers including male partners and grandmothers could strengthen future prevention efforts. The complex and interactive nature of social rules and expectations around sexual behavior warrant further study in these settings.

SEXUALITIES AND SEXUAL CULTURES: MEANINGS, IDENTITIES, NORMS AND COMMUNITIES

PED1159

DEVELOPMENT AND VALIDATION OF THE COUPLE SEXUAL SATISFACTION SCALE FOR HIV AND SEXUAL HEALTH RESEARCH

A. Conroy[1], A. Ruark[2], T. Neilands[1], L. Darbes[3], M. Johnson[1], J. Mkandawire[4]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]Stellenbosch University, Ukwanda Centre for Rural Health, Stellenbosch, South Africa, [3]University of Michigan, Department of Health Behavior and Biological Sciences, Ann Arbor, United States, [4]Invest in Knowledge, Zomba, Malawi

BACKGROUND: Sexual satisfaction is an important, but overlooked, dimension of couple relationship quality with significant implications for HIV prevention, care, and treatment. Most sexual satisfaction scales have been developed in the US using small convenience samples and have limited generalizability to other cultural contexts. We developed and validated the Couple Sexual Satisfaction Scale (CSSS) to measure sexual satisfaction in heterosexual couples in sub-Saharan Africa (SSA).

METHODS: To generate scale items, we conducted qualitative interviews with partnered women and men in Swaziland (N=27) and Malawi (N=34) to explore the meaning of sexual satisfaction. Resulting items were added to a survey administered to 211 couples living with HIV in Malawi. We performed an exploratory factor analysis (EFA) to identify the factor structure and performed a confirmatory factor analysis (CFA) to verify the factor structure. To assess validity, we tested for associations between the CSSS and relationship quality, and HIV-related health behaviors. Regression coefficients were computed using generalized estimating equations clustering on the couple identifier and controlling for relationship length and couple HIV status.

RESULTS: The EFA yielded two factors, general sexual satisfaction (13-item CSSS-Gen subscale; e.g., "I am satisfied with the sweetness of sex in our relationship") and HIV-specific sexual satisfaction (4-item CSSS-HIV subscale; e.g., "Antiretrovirals have made sex less satisfying") that accounted for 78% of the shared variance. The CFA supported the two-factor solution: $\chi 2$ (118)=203.60, p<0.001; SRMR=0.05; RMSEA=0.05. Couples reporting higher CSSS-Gen were more likely to report higher coital frequency and relationship quality (intimacy, trust, unity, equality, relationship satisfaction, commitment, partner social support; p<0.001) and had lower odds of consistent condom use and physical and emotional violence. Couples reporting higher CSSS-HIV were more likely to report higher coital frequency and relationship quality (trust, partner support; p<0.05), and had a lower odds of consistent condom use and sexual violence.

CONCLUSIONS: The CSSS demonstrated good psychometric properties. CSSS-Gen showed stronger associations with relationship quality than CSSS-HIV, suggesting the need for more research on HIV-specific sexual satisfaction. The CSSS is a valuable scale for measuring relationship dynamics, providing new opportunities to study sexual satisfaction and relationship, HIV, and sexual health outcomes among couples in SSA.

PED1160

KUWENTONG POSITIBO: UNFOLDING IDENTITIES AND HUMAN POTENTIALS OF SELECTED PEOPLE LIVING WITH HIV (PLHIV) THROUGH THEIR COUNTER NARRATIVES

E. Bagasol[1]
[1]LoveYourself Inc., Program, Manadaluyong, Philippines

BACKGROUND: Labels and names ascribed to any particular social group do more than merely describe and characterize the people who comprise it, as much as they allow for or inhibit the realization of full potential of these groups and individuals. People Living with HIV (PLHIV) have been subjected to abuses despite various efforts to recognize HIV/AIDS as a preventable and curable condition. This is especially because the language ascribed to them continues to misrepresent their identities, reinforcing the deeply entrenched belief that they are abnormal, sinful, and contagious individuals who should be avoided and condemned than cured.

This study argues that these misrepresentations are (re)produced by dominant narratives on HIV/AIDS that dilute PLHIV's own narratives and their identities, and fit them into restricting and dehumanizing stereotypes. Nevertheless, many PLHIV are able to resist misrepresentation by "queering" and countering dominant discourses through the narratives they tell about themselves.

METHODS: This research explored how queer identities and human potentials are constructed from the counter narratives of six PLHIV who were purposively selected to participate in the narrative interviewing with the researchers.

Guided by some principles of narrative inquiry and Queer theory, this study:

1) narrated their individual stories of living with HIV;

2) analyzed the dominant and counter narratives from their stories; and,

3) unfolded queer identities from their counter narratives.

RESULTS: Findings revealed that PLHIV are not passive "oppressed" individuals but have the agency to fight for their rights and represent themselves through their own narratives. As a matter of fact, some PLHIV have become successful in their own fields and many of them have been involved in the advocacy as leaders and volunteers to their own PLHIV community. A closer look at their stories also showed that the interplay of dominant and counter narratives is dynamic and fluid.

CONCLUSIONS: This study provides insights that could strengthen HIV/AIDS initiatives in the field of DevCom, and offers a discussion on its implications on DevCom practice that draw parallelisms between the recognition of (queer) identities and the "[giving of] voice to the voiceless" (Quebral, 2012, p.11).

SEXUAL DESIRE AND PLEASURE IN THE CONTEXT OF THE HIV PRE-EXPOSURE PROPHYLAXIS (PREP)

R.R. Da Silva Brandao[1], A. Ianni[1]
[1]University of Sao Paulo, Policies, Management and Health, Sao Paulo, Brazil

BACKGROUND: This study explores both the sexual desires and pleasure in the context of HIV pre-exposure prophylaxis (PrEP) use among gays, bisexuals and other men who have sex with men (gbMSM). The aim of this article is to discuss the experiences of PrEP

users, especially GBMSM, regarding sexual desire and pleasure, considering biomedical interventions as a means of producing erotic experiences mediated by technical-scientific incorporation.

METHODS: This study analyzed data collected from interactions of PrEP users and their interlocutors in a Facebook® discussion group on PrEP and HIV/AIDS, which has more than 20000 members, predominantly GBMSM from the United States. Including a pilot-phase, we analysed data from a active 3-month-period in 2018. Based on the method of content analysis with thematic categories, we focused our attention on the discussions content, checking in which ways individuals presented their personal issues, particularly their routines, conflicts, and successes on PrEP use. A structured analysis script was developed to capturing specific and detailed experiences, which helped us filter all the selected posts.

RESULTS: Our main findings suggest the practical concept of bareback sex was dismantled into notions of 'natural' and 'unnatural sex', while these categories were linked to condomless sex, acquisitions of Sexually Transmission Infections (STI) and their perceptions of intimacy. Specifically, individuals on PrEP had hotter sex while having condomless sex, which was linked to an ideal of ‚natural sex' they value. Besides on PrEP, individuals reported concurrent use of antibiotic prophylaxis and recreational drugs use. When negotiating their sexual practices, PrEP users see STI and sexual mucosal contact as two major factors that influence their pleasure and in which mediate their choices towards STI/HIV prevention. In addition, their perceptions of sexual intimacy were strongly linked to physical contact with sexual partners. Individuals also believed they could enhance pleasure and desire by acknowledging their inner subjectivity and societal positions about PrEP.

CONCLUSIONS: We argue that the individuals on PrEP play a positive and conflicting ethic towards sex amidst the use of biomedical interventions. This has direct implications for both health care providers and PrEP-users towards a better understading of GBMSM sexuality and intimacy while on PrEP.

"GOTTA BE THE MAN, RIGHT? HOW I BE THE MAN AND WORK AT THE DOLLAR STORE?": MASCULINITY, RELATIONSHIPS AND HIV RISK AMONG DISADVANTAGED BLACK HETEROSEXUAL MEN

A. Rosenberg[1], A.K. Groves[2], P. Schlesinger[1], A. Dawson[3], K.M. Blankenship[4]
[1]Yale School of Public Health, Epidemiology of Microbial Diseases, New Haven, United States, [2]Drexel University's Dornsife School of Public Health, Community Health and Prevention, Philadelphia, United States, [3]Howard University, Department of Sociology and Criminology, Washington, DC, United States, [4]American University, Department of Sociology, Washington, DC, United States

BACKGROUND: Researchers have suggested that many Black heterosexual men from disadvantaged backgrounds are often locked out of mainstream pathways to establish masculine identity, and thus perform gender in hypermasculine ways (e.g. multiple sexual partners, virility). Such norms and associated sexual behavior have been studied for HIV risk implications. However, demonstrations of masculinity in the broader context of pursuit of (or refrain from) intimate partnerships have not been explored fully. We consider masculinity norms in intimate relationships to deepen our understanding of Black heterosexual men's HIV-related protection strategies.

METHODS: Data are from 76 longitudinal in-depth interviews with 21 low income Black heterosexual men (ages 25-64) in a small Northeast city conducted 2017-2019. Twenty of the men have a history of incarceration. Interviews addressed participants' economic situation, criminal justice involvement, housing, sexual health and HIV risk, substance use, relationships and social networks.

RESULTS: Most participants wanted a monogamous, committed relationship and saw sex in committed relationships as more satisfying than casual sex. Men's perceived ability to contribute to a relationship economically and emotionally was equated with "being a man" and seen as a prerequisite for pursuing a relationship. However, because of their current conditions--underemployed and unstably housed--they felt inadequate and thus avoided pursuing committed relationships. Paradoxically, they felt committed relationships were the safest form of sexual relationships for HIV protection. They recognized HIV risk in casual and non-monogamous relationships and employed different protection strategies, including abstaining, using condoms, oral sex, frequent HIV tests, and tentative trust of partners' self-reported status.

CONCLUSIONS: While studies of masculinity and HIV risk among disadvantaged heterosexual Black men often highlight HIV risk factors associated with hypermasculinity, our findings indicate that Black men perform gender in traditional ways and long for committed relationships. When considering how masculinity impacts HIV risk, we must be alert to structural barriers to the attainment of "manhood" and the ways in which men are locked out of committed relationships when considering HIV risk. Both avoidance of committed relationships and manifestations of hypermasculinity eare reactions to larger structural problems that need to be addressed to lower HIV risk among disadvantaged heterosexual Black men and their partners.

ACCESS TO AND MODELS OF INTEGRATED HIV AND OTHER SERVICES, SUCH AS HARM REDUCTION, SRHR, TB, NCDS AND MENTAL HEALTH

PED1163

IMPROVING FAMILY-CENTERED HIV CARE DURING PREGNANCY: MEN'S PERSPECTIVES ON MEETING THEIR SEXUAL AND REPRODUCTIVE HEALTH NEEDS IN ZAMBIA

T.F.L. Matenga[1], J.M. Zulu[1], S. Nkwema[2], P. Shankalala[3], K. Hampanda[4]
[1]University of Zambia, Health Promotion and Education, Lusaka, Zambia, [2]University of Zambia, Department of Health Promotion and Education, Lusaka, Zambia, [3]University of Zambia Teaching Hospital, Pedaitric Center of Excellence, Lusaka, Zambia, [4]University of Colorado, Department of Community and Behavioral Health, Colorado, United States

BACKGROUND: Across sub-Saharan Africa (SAA), male partner involvement during antenatal care (ANC) is associated with improved maternal and child health outcomes, including the prevention of mother to child transmission (PMTCT). There is limited understanding of men's sexual and reproductive health needs in couples affected by HIV and whether male involvement in ANC can extend to improvements in men's health. The aim of this study was to understand how HIV services around the time of pregnancy could better meet the sexual and reproductive health needs of men with HIV and at high risk of HIV in Zambia.

METHODS: The study implored a qualitative research design using in-depth interviews with 18 male partners of pregnant women living with HIV in Lusaka, Zambia. Atlas.ti was used to code, catego-

rize, classify, store and manage the data. Thematic analysis highlighted men's perspectives on their sexual and reproductive health needs.

RESULTS: Most men understood and endorsed the importance of escorting their pregnant female partners for ANC and the need to be aware of PMTCT. Yet, they believed that they lacked information about promoting their own sexual and reproductive health needs and regarded ANC as a woman's space where their health needs were generally neglected. There was a strong desire for more education that was specific to men's sexual and reproductive health, especially because all the couples were affected by HIV. Men requested education on safe sex, the use of condoms in sero-concordant and sero-discordant relationships and general health information. Although men stated they were the main decision-makers regarding sexual and reproductive issues such as pregnancy, most men were not confident in their ability to promote sexual and reproductive health in the family because of their limited knowledge in this area.

CONCLUSIONS: With the emphasis on PMTCT in many SSA settings, men's sexual and reproductive health needs have been neglected. Male involvement in ANC offers one strategy to promote both PMTCT efforts and male engagement in health care. There is need for programs that address the specific health needs of men that focus on improving service delivery to accommodate men's sexual and reproductive health, especially in couples affected by HIV.

PED1164

A RANDOMIZED, CONTROLLED TRIAL OF SCALABLE, NON-SPECIALIST MENTAL HEALTH CARE FOR HIV-POSITIVE WOMEN IN KENYA AFFECTED BY GENDER-BASED VIOLENCE

S.M. Meffert[1], T.C. Neylan[1], C.E. McCulloch[2], K. Blum[1], C.R. Cohen[3], E.A. Bukusi[4], H. Verdeli[5], J.C. Markowitz[5], J.G. Kahn[6], D. Bukusi[7], H. Thirumurthy[8], G. Rota[9], R. Rota[9], G. Oketch[9], L. Opiyo[9], M. Gandhi[10], L. Ongeri[4]

[1]University of California, Psychiatry, San Francisco, United States, [2]University of California, Epidemiology & Biostatistics, San Francisco, United States, [3]University of California, Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [4]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [5]Columbia University, Psychiatry, New York City, United States, [6]University of California, Institute for Health Policy Studies, San Francisco, United States, [7]Kenyatta National Hospital, Nairobi, Kenya, [8]University of Pennsylvania, Medical Ethics & Health Policy, Philadelphia, United States, [9]Family AIDS Care and Education Services (FACES) and Global Programs for Research and Training (GPRT), Kisumu, Kenya, [10]University of California, Division of HIV, Infectious Diseases, and Global Medicine, San Francisco, United States

BACKGROUND: HIV-positive women suffer a high burden of mental disorders due in part to Gender Based Violence (GBV). Co-morbid depression and posttraumatic stress disorder (PTSD) are typical psychiatric consequences of GBV. Despite the attention received by the HIV-GBV syndemic, few clinics have integrated formal mental health care. This problem is acute in Sub-Saharan Africa, where the world's majority of HIV-positive women live and where prevalence of GBV against HIV-positive women is high.

METHODS: We conducted a randomized, controlled trial using an effectiveness-implementation-hybrid design. HIV-positive women affected by GBV with both Major Depressive Disorder (MDD) and PTSD were randomized to 12 sessions of Interpersonal Psychotherapy (IPT) plus Treatment As Usual (TAU) or TAU. After 12 weeks, those assigned to TAU were given IPT. Non-specialists (no prior mental health education required) were trained to deliver IPT inside the HIV clinic. Participants were re-assessed at 6 and 9 months, by which time all had received IPT. The primary outcomes were MDD and PTSD (Mini International Neuropsychiatric Interview [MINI]).

RESULTS: 261 participants were enrolled between May 2015 and July 2016. Using multilevel mixed-effects logistic regression, participants randomized to IPT+TAU had 75% lower odds of MDD (odds ratio [OR] after intervention 0.25, 95% CI [0.11 to 0.59], p=0.002) and 62% lower odds of PTSD (OR after intervention 0.38, [0.16 to 0.91], p= 0.03), than Wait List-TAU. IPT+TAU recipients had nearly a 19% reduction in disability and 35% decrease in work absenteeism, both significantly greater than controls. Gains were maintained at 6 and 9 month follow-up.

CONCLUSIONS: We showed that non-specialist IPT for depression and PTSD can be integrated with HIV care with excellent mental health results. Because depression and PTSD are associated with suboptimal HIV outcomes, as we pursue elimination of HIV, it is essential to employ scalable, evidence-based solutions for high risk psychiatric co-morbidity.

GENDERED SYNDEMIC OF VIOLENCE, TRAUMA AND ADDICTION AS A BARRIER TO ANTIRETROVIRAL THERAPY ADHERENCE AMONG WOMEN LIVING WITH HIV IN METRO VANCOUVER, CANADA: CALL FOR CULTURALLY SAFE, TRAUMA-INFORMED CARE

M. Erickson[1], K. Shannon[1,2], F. Ranville[1], P. Magagula[3], M. Braschel[1], A. Ratzlaff[4], N. Pick[2,5], M. Kestler[5], K. Deering[1,2]

[1]Centre for Gender and Sexual Health Equity, Vancouver, Canada, [2]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [3]Afro-Canadian Positive Network of BC, Surrey, Canada, [4]Queen's University, Kingston, Canada, [5]BC Women's Hospital, Oak Tree Clinic, Vancouver, Canada

BACKGROUND: Adherence to antiretroviral therapy (ART) is a critical component of the HIV care continuum, yet despite recent advancements in ART, cisgender (cis) and transgender (trans) women living with HIV (WLWH) continue to experience sub-optimal adherence and viral load suppression. Gaps remain in our understanding regarding the design of programs with women that can facilitate adherence. The objectives of this study were, among WLWH, to: 1) describe different types of support needed to take ART); and 2) investigate the social and structural correlates associated with needing support for ART adherence.

METHODS: Data are drawn from SHAWNA (Sexual health and HIV/AIDS: Women's Longitudinal Needs Assessment), a community-based open research cohort with cis and trans WLWH, aged 14+ who live or access HIV services in Metro Vancouver, Canada (2014-present). Baseline and semi-annual questionnaires are administered by trained community and peer research associate interviewers alongside a clinical visit with a sexual health research nurse to support education and linkages to care. Bivariate and multivariable logistic regression using generalized estimating equations (GEE) and an exchangeable working correlation matrix was used to prospectively model factors associated with needing supports for ART adherence.

RESULTS: Among 276 WLWH, 51% (n=142) reported needing supports for ART adherence during the study period. Participants reported many interpersonal, structural and community and clinical supports that would facilitate and support ART adherence, including improved access to food (23%), addictions support (20%), improved housing (20%), peer support (18%) and transportation support (18%)

among others. In multivariable logistic regression, women who: were Indigenous (adjusted odds ratio (AOR):1.70, 95% confidence intervals[CI]:1.07-2.72), Afro-Canadian/Black or otherwise racialized (AOR:2.36, 95%CI:1.09-5.12); reported illicit drug use (AOR:2.15, 95%CI:1.43-3.22); reported physical violence (AOR:1.54, 95%CI:1.03-2.31); and reported lifetime post-traumatic stress disorder (AOR: 1.97, 95%CI:1.22-3.18) had increased odds of needing support for ART adherence.

CONCLUSIONS: This research suggests a critical need for trauma-informed and culturally safe practice and services for WLWH along the HIV care continuum to support ART adherence. All services should be developed by, with and for WLWH and tailored according to gender identity, taking into account history, culture, and trauma, including the broad negative impacts of settler colonialism for Indigenous people.

PED1166

FROM HIV TESTING TO LINKAGE: AN INNOVATIVE APPROACH OFFERED IN STI CARE FOCUSED ON MEN IN RECIFE, BRAZIL

F.J. Figueroa[1], L.H. Fernandes da Silva[1], R. da Costa Galvão[1], F.S. Figueiroa Gama[1], B. de Jesus[1], R. Chuster[1], M. Pedrola[2], A. S. Benzaken[3], F. Rick[3]

[1]AIDS Healthcare Foundation - Brazil, Recife, Brazil, [2]AIDS Healthcare Foundation - Argentina, Buenos Aires, Argentina, [3]AIDS Healthcare Foundation, Manaus, Brazil

BACKGROUND: In May 2018, AIDS Healthcare Foundation (AHF) launched a wellness center – an innovative Sexually Transmitted Infections(STI) clinic for men, free of charge, in response to the increase HIV incidence among gay and other men who have sex with men(MSM) in Recife, Brazil. The aim of this abstract is to show how a differentiated approach to STI can contribute to expanding HIV diagnosis.

DESCRIPTION: The Clinic has expanded working hours, central location, communication and marketing tailored to men, multidisciplinary team, stigma-free services and an individual-centered approach. Is the only STIs specialized clinic in the region, and offers rapid tests for syphilis, HIV, Hepatitis B and C, diagnosis and treatment for STIs and linkage to HIV care.

Diagnosis	Total (N)	Positivity Ratio (%)*
HIV	621	6.17
Syphilis	2249	22.34
Hepatitis B	57	0.57
Hepatitis C	49	0.49
HPV infection	1040	10.33
Candidiasis	730	7.25
Urethral discharge	794	7.89
Herpes	443	4.40
Lymphogranuloma Venereum	34	0.34
Proctitis	145	1.44
Chancroid	309	3.07
Molluscum contagiosum	43	0.43
Orchitis	16	0.16
Others	444	4.41
Total	6974	Not applicable

[Table 1. Total diagnosis and positivity ratio among all clients assisted from May 2018 to November 2019, AHF Wellness Center, Recife, Brazil
**Positive ratio calculated based on 10,066 total clients]*

LESSONS LEARNED: From May 2018 to November 2019 10,066 clients were assisted, with an average age 33.69(12.31±SD) and 6.17% of HIV positivity ratio(621/10.066). Among 621 HIV positive clients, 91.6%(569/621) were MSM, 7.8%(48/621) were heterosexual; 6974 had at least one STI diagnosis. 88.7%(551/621) of HIV positive clients were linked to care. Hence, STI services can works as a gateway for HIV diagnosis and linkage.

CONCLUSIONS/NEXT STEPS: An innovative model focused on a target population showed to be sustainable and productive. Governments and non-governmental organizations can work together to expand access to STI care and HIV testing. Based on this model, AHF is opening a new wellness center focused on key population in the center of São Paulo, which is considered the "epicenter" of the HIV epidemic. Also, there is a planned expansion of outreach activities in poor areas by mobile clinics to expand access to STI care in Recife.

PED1167

BARRIERS AND ENHANCERS TO RETENTION IN INTEGRATED HIV AND MATERNAL AND CHILD HEALTH CARE: THE IEDEA-KENYA PMTCT COHORT

J. Humphrey[1], B. Kipchumba[2], M. Alera[3], E.J. Pfeiffer[4], J. Songok[5], W. Mwangi[2], W. Kosgei[2], B. Musick[6], C. Yiannoutsos[6], J. Wachira[5], K. Wools-Kaloustian[1]

[1]Indiana University School of Medicine, Indianapolis, United States, [2]Moi Teaching and Referral Hospital, Eldoret, Kenya, [3]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [4]Rhode Island College, Providence, United States, [5]Moi University College of Health Sciences, Eldoret, Kenya, [6]Indiana University Richard M. Fairbanks School of Public Health, Indianapolis, United States

BACKGROUND: Retention in care is a major challenge for pregnant and postpartum women living with HIV (WLHIV) in resource-limited settings. However, the factors influencing retention from the perspectives of women who are lost to follow-up (LTFU) are poorly understood. We explored these factors within an enhanced sub-cohort of the East Africa International Epidemiology Databases to Evaluate AIDS Consortium.

METHODS: From 3/2018 to 2/2019, a purposeful sample of pregnant and ≤6 months postpartum WLHIV ≥18 years of age were recruited from 5 integrated HIV and maternal and child health (HIV-MCH) clinics in Kenya. Women retained in care were recruited at the facility; women LTFU (last visit >90 days) were recruited through community tracking. A trained interviewer conducted semi-structured interviews in Kiswahili or English. Transcripts were analyzed thematically by two investigators based on codes developed from the literature using a social-ecological framework.

RESULTS: 41 WLHIV were interviewed: median (IQR) age 27 (23-32) years, 71% pregnant and 29% postpartum, 46% newly diagnosed with HIV during pregnancy, 27% had not disclosed their HIV status to their partner, and 39% had been LTFU. In the individual domain, prior PMTCT experience and desires to safeguard the infant's health enhanced retention but were offset by perceived lack of value in MCH services following the main infant immunization period (i.e. through 6-9 months postdelivery). In the peer/family domain, male partner financial and motivational support (or lack thereof) featured prominently. In the community/society domain, some women experienced social pressure to attend MCH while others experienced pressure to utilize traditional birth attendants. In the healthcare environment, long queues, frequent appointments and negative provider attitudes were key barriers. HIV-related stigma and fear of disclosure crossed multiple domains, particularly for LTFU women, and were driven by

perceptions of HIV as a fatal disease and fear of partner abandonment and violence. Both retained and LTFU women perceived that integrated HIV-MCH services increased the risk of disclosure.

CONCLUSIONS: Retention was influenced by multiple, complex social-ecological factors for pregnant and postpartum WLHIV. Stigma and fear of disclosure were prominent barriers for LTFU women. Refining the structure and efficiency of HIV-MCH clinics are potentially mutable ways to enhance retention.

PED1168

BUILDING RESILIENCE IN PARTNERSHIP WITH TRANSITIONAL AGE YOUTH LIVING WITH HIV

E. Kersey[1], L. Khoddam-Khorasani[2], A. Vaewsorn[2], S. Eskridge[1], P. Barresi[1], C. Dawson Rose[2]
[1]Larkin Street Youth Services, San Francisco, United States, [2]University of California, School of Nursing, Department of Community Health Systems, San Francisco, United States

BACKGROUND: The purpose of our program was to build resilience and provide psychoeducation about co-occurring trauma and substance use to transitional age youth (TAY) living with HIV (YLWH) and experiencing homelessness or marginal housing in San Francisco. This population reports high levels of substance use, Adverse Childhood Events, and symptoms of depression, as well as engagement in transactional sex, chemsex, and sex with multiple concurrent partners.

DESCRIPTION: Through a collaboration between a university and a community-based organization for TAY, the Seeking Safety (SS) program was adapted for sexual and gender minority YLWH. SS groups were delivered in weekly one-hour sessions over eight weeks in an open-group format, facilitated by behavioral health care nurses. Ten (8-week) groups were conducted at the CBO's HIV service site. Sessions included a check-in; a skills-based activity based on a PTSD/substance use topic selected by group members (e.g., Compassion, Healing from Anger and Healthy Relationships); and a check out. The implementation team conducted an evaluation of the SS program.

LESSONS LEARNED: Our evaluation is the first to demonstrate the acceptability of SS among homeless/marginally housed YLWH, and the feasibility of providing this intervention in a residential setting for young people. Group participants reported feeling comfortable and safe in the group, learning new skills for identifying how substance use and other behaviors may be linked to their trauma histories, developing a sense of community support among other YLWH, and satisfaction with the group being located where they also received services and housing. Implementation of the SS model supported organizational sustainability by building capacity and creating a flexible, adaptable structure for facilitation that could be implemented by staff (and potentially youth peers) with training and a brief weekly clinical supervision session.

CONCLUSIONS/NEXT STEPS: Seeking Safety is a low-threshold group intervention that addresses trauma and substance use YLWH. It was acceptable to YLWH and feasible to run in a youth-focused, residential community-based organization. Specific research on trauma-informed treatment for substance-using YLWH is imperative to standardize inclusive treatment. The Seeking Safety model provides a customizable treatment that remains flexible to the multiple trauma related challenges for substance using YLWH.

PED1169

AN EVALUATION OF COMMUNITY BASED INTERVENTION FOR HIV PREVENTION: BROTHA2BROTHA MODEL IN HARARE PROVINCE FROM 2017 TO 2018

W. Chikanya[1], A. Muzondiona[2], M. Masiya[3]
[1]University of Zimbabwe, College of Health Sciences, Department of Community Medicine, Harare, Zimbabwe, [2]National AIDS Council, Management, Harare, Zimbabwe, [3]University of Zimbabwe, College of Health Sciences, Community Medicine, Harare, Zimbabwe

BACKGROUND: In Zimbabwe, 36% young men have basic knowledge HIV prevention, 50% of the young men don't know their status and are less likely to start HIV treatment than women. 60% of youths in Zimbabwe use illicit drugs. The Brotha2brotha program was designed to promote HIV prevention, uptake of Adolescent SRHR services, reduction of illicit drug use and teaching of life skills among vulnerable young boys and adolescents. Young men aged 10 - 24 years were recruited into the B2B in the districts of Harare. An evaluation done to assess the impact of the program among the youth of Harare.

METHODS: The evaluation employed an analytical cross sectional study of the B2B program. Interviewer-administered questionnaires were compiled in Harare at baseline, mid-term (12 months) and end line (24 months) of the study. Key informants such as the Brotha-2brotha mentors and Behavioral change officers were also interviewed. Inclusion criteria were to interview youths aged 10 - 24 years at baseline and those who had benefited from the program during its implementation. Data processed and analysed using EPI INFO.

RESULTS: Among the 300 questionnaires answered (90% response rate) were analyzed and mean age was 19 years. 85% of the participants reported to have utilized the HIV prevention and the Adolescent SRHR knowledge which they acquired to empower themselves. There was significant increase on uptake of VMMC and HTS service uptake among the youths ($p<0.001$). 62% of the boys in the sampled in Chitungwiza district were circumcised after exposure to the program. Level of drug and substance abuse among the youths in the communities of Hatfield and Mbare declined by 36% (2018 VFU reports). Income generating projects like building, welding, car washing among others were embraced by most youths, with those given loans to start projects by SMEs department doing well. The default rate on loan repayments from B2B members was below 5%.

CONCLUSIONS: Evaluation analysis illustrated that this model is effective in promoting HIV prevention and uptake of services among youths. B2B can be used as a tool to generate demand, disseminate comprehensive HIV, gender transformation, behavioral change and ASRHR information for vulnerable youths and adolescents.

PED1170

LONGITUDINAL TRAJECTORY PATTERNS OF ALCOHOL USE IN PATIENTS WITH HIV IN NORTHERN VIETNAM

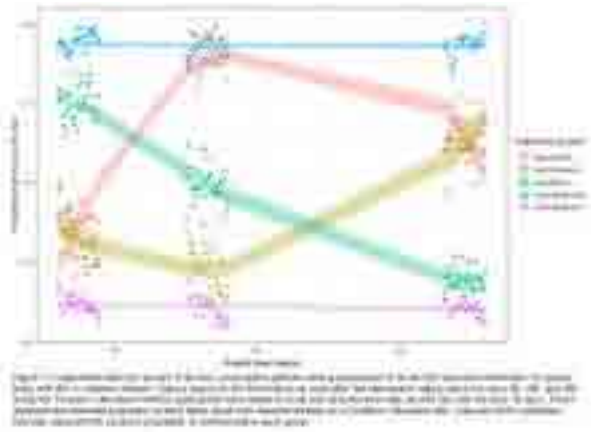
M.K. Smith[1], C.A. Latkin[2], T. Sripaipan[3], T.V. Ha[3], B.X. Quynh[4], V.F. Go[3]
[1]University of Minnesota Twin Cities, Div of Epidemiology & Community Health, Minneapolis, United States, [2]Johns Hopkins University, Baltimore, United States, [3]University of North Carolina, Chapel Hill, United States, [4]University of North Carolina Project Vietnam, Hanoi, Vietnam

BACKGROUND: Prevalence of alcohol use disorder (AUD) is higher in people living with HIV than in the general population in Vietnam where sociocultural norms drive alcohol consumption. Results of the

REDART trial found that a targeted intervention to reduce alcohol consumption in treated patients living with HIV was highly effective. Closer analysis of participants' longitudinal consumption patterns is needed to better understand intervention mechanisms and their real-world applicability.

METHODS: Consumption patterns were documented by asking REDART trial participants to recall daily use over in the past 30 days at each of three follow-up visits (3, 6, 12 months). We used group-based trajectory modeling to describe common longitudinal trajectories. Multinomial logistic regression models were then used to assess the relationship between trajectory group membership and trial arm. Models were adjusted for demographic variables, pre-trial consumption habits, and a scale indicating readiness to reduce consumption.

RESULTS: We identified five trajectory groups. A predicted 44% of participants exhibited „consistently low" alcohol consumption; 19.7% „consistently high," 14.9% „declining," 12.2% „late increasing," and 9.3% „rise and fall." Those randomized to the intervention group were more likely to be in the "consistently low" group than in any other group, though findings lacked statistical significance for the "declining" and "consistently high" groups. Older age, being an ethnic minority (non-Kinh), and heavy drinking at baseline were predictive of membership in a suboptimal trajectory groups, while higher baseline readiness scores were protective against it.



CONCLUSIONS: The most common trajectory among REDART trial participants was a consistently low consumption pattern, to which intervention arm participants were more likely to belong. A wide variety of other consumption trajectories were also observed, including several suboptimal patterns. Insights from such analyses can inform screening strategies to identify and engage with individuals who face higher risk of suboptimal trajectory patterns, and for tailoring interventions to address their needs.

PED1171

DEPRESSION AND CONDOMLESS SEX IN HIV POSITIVE PATIENTS

S. Akbarpour[1], A. Najafi[1], K. Sadeghniiat[1], E. Rezaei[2], S. Ghodrati[1], M. Mahboobi[3], P. Afsar Kazerooni[3]
[1]Tehran University of Medical Sciences, Occupational Sleep Research Center, Tehran, Iran, Islamic Republic of, [2]Kerman University of Medical Sciences, HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman, Iran, Islamic Republic of, [3]Center for Disease Control (CDC), Ministry of Health and Medical Education, Tehran, Iran, Islamic Republic of

BACKGROUND: Background: Depression is a common psychological disorder among people who are living with HIV/AIDS. Few studies in the Iran have assessed the relationship of condom use and depression in this group of people. We examined whether depression is related to lack of condom use in Iranian HIV positive people.

METHODS: Methods: We recruited patients from 6 Voluntary Counselling and Testing (VCT) centers with heterogenic pattern of HIV positive persons in Tehran. Eighty-seven HIV positive people, age>= 30 years, completed a Depression Anxiety Stress Scales (DASS) questionnaires and demographic, treatment and condom use questions. DASS depression score ≥10 was defined as depression. Chi-squared test and logistic regression model was used to assess association.

RESULTS: Results: A total of 87 patients aged 21-62 years old (82.8% men) were enrolled in the study. About 62.1 % (n= 54) of patients had depression. Condomless sex was reported as 40.7 (n=22) and 15.2 % (n= 5) in depressed and normal patients, respectively. Age and sex adjusted Odds ratio in multiple logistic analysis indicated that depression is significantly associated with lack of condom use (OR= 2.87, P-value = 0.038).

CONCLUSIONS: Conclusions: The present study highlighted high prevalence of depression and low prevalence of condom use among HIV positive persons and the strong association between these two items. Depression is important health implication which requires special attention in this group of people. Development of depression management programs is warranted to increase condom use in the patients with HIV.

PED1172

PROJECT LAST MILE IN SOUTH AFRICA SUPPORTS A NATIONAL DIFFERENTIATED SERVICE DELIVERY (DSD) MODEL FOR INTEGRATED DISEASE MANAGEMENT AND IMPROVED ACCESS TO ANTIRETROVIRALS (ARVS)

S. Christie[1,2], L. Liu[1], P. Roberts[3], M. Pillay[3], E. Linnander[1,2], M. Desai[1]
[1]Yale School of Public Health, Global Health Leadership Initiative, New Haven, United States, [2]Yale School of Public Health, Department of Health Policy and Management, New Haven, United States, [3]Project Last Mile, Johannesburg, South Africa

BACKGROUND: South Africa is home to 7.7 million people living with HIV and supports the largest antiretroviral therapy (ART) program globally. Non-communicable diseases threaten public health accounting for 51% of mortality. Despite global investment in HIV and the parallel threat of NCDs, there are few examples of integrated programs that leverage resources to tackle both. In 2014, the National Department of Health (NDoH) launched the Centralised Chronic Medicines Dispensing and Distribution (CCMDD) program to provide patients on antiretrovirals (ARVs) with differentiated access to medications via community-based pick-up points. The program ex-

panded to include other chronic diseases, including diabetes and hypertension, and co-morbidities. The study aims to describe the national expansion of CCMDD, and to examine the profile of CCMDD patients over time.

METHODS: Yale monitors CCMDD enrollment as part of its mixed methods evaluation for Project Last Mile (PLM), the National Strategic Partner for CCMDD since 2016. Yale has conducted four annual waves of qualitative data collection to understand stakeholder experiences with PLM. Cumulative data on CCMDD uptake [i.e., patients enrolled, facilities registered, pick-up points established] as well as where patients collect their medications [from external pick-up points (PuPs); adherence/outreach clubs; or facility-based fast lanes], and what they collect [ART only; Chronic only; and ART-Chronic] were extracted for analysis.

RESULTS: As of October 2019, 3,436 health facilities were registered across 46 health districts with 2,037 external PuPs established. A total of 2,008,172 patients were active on CCMDD, including 76% collecting ART [64% ART only, 12% ART plus Chron]; 479,120 [24%] were collecting for chronic diseases only, which significantly expanded since November 2018 (p <.05). Further, 734,005 (37%) of patients were collecting from external PuPs, a 73% uptick from 2018. The greater availability of external PuPs correlated with growth of patient selection of external PuPs over time (p<.01). Stakeholders confirmed that expanding the program to patients with NCDs destigmatized uptake, and credited PLM with external PuP expansion.

CONCLUSIONS: A growing number of patients are accessing medications via CCMDD, and a significant proportion have NCDs. As external pick-up points increase, demand improves. This signals potential for expanding this integrated differentiated service delivery model in similar settings.

PED1173

HAVING A PARTNER OF UNKNOWN HIV STATUS IS ASSOCIATED WITH MAJOR DEPRESSIVE SYMPTOMS AMONG PREGNANT HIV-UNINFECTED WOMEN IN KENYA

A. Larsen[1,2], J. Pintye[2], M.M. Marwa[3], S. Watoyi[3], J. Kinuthia[3], F. Abuna[3], L. Gomez[2], J. Dettinger[2], J. Baeten[1,2,4], G. John-Stewart[1,2,4,5]
[1]University of Washington, Department of Epidemiology, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]University of Nairobi/Kenyatta National Hospital, Kisumu, Kenya, [4]University of Washington, Department of Medicine, Seattle, United States, [5]University of Washington, Department of Pediatrics, Seattle, United States

BACKGROUND: Risk of HIV acquisition is elevated during pregnancy. Not knowing a sexual partner's HIV status is a risk factor for HIV acquisition. Partner HIV testing, PrEP use, and partner antiretroviral treatment can protect women and infants from HIV. Depression influences the ability of women to protect themselves from HIV during pregnancy. We evaluated depression and HIV risk factors among pregnant women.

METHODS: In an ongoing cluster RCT (NCT03070600), study nurses administered surveys to HIV uninfected pregnant women age 15-45 years at 20 public sector clinics in Western Kenya from January 2018-January 2019. At enrollment, women were assessed for depressive symptoms using the Patient Health Questionnaire-2 (PHQ-2); major depression was defined as scores ≥3. Women self-reported their partner's HIV status and self-perceived HIV risk (Extremely/very unlikely, somewhat/very likely). We calculated prevalence ratios using Poisson regression models, clustering by facility.

RESULTS: Among 4,145 pregnant HIV-uninfected women analyzed, median age was 23 years (IQR:20-28), median gestational age was 24 weeks (IQR:20-30), 84% were married, and 14% were employed. One in ten women screened PHQ-2 positive, consistent with major depressive symptoms (393/4145, 10%). Nearly half (1887/2200, 46%) self-perceived their risk for HIV as "somewhat or very likely", and frequency of major depressive symptoms was 60% higher among women with self-perceived high HIV risk [12% vs. 7%, Prevalence Ratio [PR]: 1.62, 95%CI:1.05-2.52, p=0.031]. Median lifetime number of sexual partners was higher among depressed versus non-depressed women (3 partners [IQR]:3[2-4] vs. 2[2-3], p<0.001), and frequency of depression was higher with each additional sexual partner [PR: 1.03, 95% CI: 1.01-1.05, p=0.002].

Twenty-six percent of women did not know their partner's HIV status (1089/4145); depression was more frequent among those with unknown partner HIV status versus those who knew their partner's status (13% vs 8%, PR:1.49 95% CI:1.03-2.13, p=0.032].

CONCLUSIONS: In this large study of pregnant women, symptoms of major depression were associated with not knowing partner HIV status, number of lifetime sexual partners, and self-perceived HIV risk. Addressing psychosocial issues may improve HIV prevention strategies among pregnant women in HIV high-burden settings.

PED1174

MISSION POSSIBLE: INTEGRATING GENERAL HEALTH SERVICES WITH CARE CASCADE OF HIV EXPOSED INFANTS USING ACTIVE CASE FOLLOW UP RESULTS IN REDUCING POSITIVITY: AN EXPERIENCE FROM AHANA PROJECT IN INDIA

K. Biswas[1], R. KB[1], S. Kanoujia[1], M. Singh[1], R. Mitra[2]
[1]Plan India, Monitoring & Evaluation, New Delhi, India, [2]Plan India, Programme, New Delhi, India

BACKGROUND: While Govt. of India has a goal of achieving EMTCT by 2020 the performance remained dismal as only 38% pregnant women screened for HIV against HMIS registration in 2016-17, ART linkage was poor and lack of cascade management resulted in huge linkage loss, and vertical transmission was high. Complementing Govt.'s effort Project Ahana was launched supported by The Global Fund in 14 states of India. Expansion of service access and active case follow up has resulted in bridging the service gap and also improved cascade management.

DESCRIPTION: Intensive outreach mechanism were put in place to follow up every HIV positive pregnant women with PMTCT services. Around 11,218 pregnant women were followed up and record was maintained in a prospective cohort. The cohort recorded follow up services and complete infant cascade. The cohort data for the period of Jan, 2016 to September 19 was analysed.

LESSONS LEARNED: Analysis from national data suggests, HIV positivity was 6.35% during 2016-17 amongst the HIV exposed infants when tested at 18 months since birth. Seventy six children confirmed as HIV positive out of 2,332 children (3.26%) completed 18 months and received HIV testing. Linkages to EID testing within 2 months of birth improved from 36% during 2016-17 to more than 90% in the period of April to Sept, 19.

CONCLUSIONS/NEXT STEPS: Single window care provision by integrating services across sector based on gap analysis using PLHIV cohort and regular outreach follow up with HIV exposed infants has resulted in reducing the vertical transmission from mother to child. Learning suggests, ensuring linkage, maintaining adherence of the

pregnant women and following up of HIV exposed infants with EID testing and other necessary care and support services aligned with general public health services is critical. Ahana demonstrate a successful model of PMTCT through integration of general health services with HIV.

OVERCOMING ACCESS BARRIERS TO ADDRESSING THE IMPACT OF HIV-ASSOCIATED NEUROCOGNITIVE DISORDER ON THE MENTAL HEALTH OF PEOPLE LIVING WITH HIV: SERVICE PROVIDER PERSPECTIVES AND STRATEGIES

R. Liboro[1,2], S.B. Rourke[3,4], F. Ibañez-Carrasco[3,5], A. Eaton[6], D. Pugh[5,7], C. Medina[8,9], A. Rae[10], P.A. Shuper[2,11], L.E. Ross[2,11]
[1]University of Nevada, Psychology, Las Vegas, United States, [2]Centre for Addiction and Mental Health, Institute for Mental Health Policy Research, Toronto, Canada, [3]St. Michael's Hospital, Centre for Urban Health Solutions, Li Ka Shing Knowledge Institute, Toronto, Canada, [4]University of Toronto, Psychiatry, Toronto, Canada, [5]Universities Without Walls, Toronto, Canada, [6]University of Toronto, Social Work, Toronto, Canada, [7]Sherbourne Health, LGBTQ Health Team, Toronto, Canada, [8]Prisoners' HIV/AIDS Support Action Network, Toronto, Canada, [9]Latinos Positivos, Toronto, Canada, [10]Crossing Genres, Toronto, Canada, [11]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada

BACKGROUND: Since the advent of combination antiretroviral therapy, the incidence of dementia related to HIV-Associated Neurocognitive Disorder (HAND) has become rare. However, research has documented that milder forms of HAND have increased in prevalence in recent decades. In this context, people living with HIV/HAND (PLWH[2)] have been experiencing challenges performing complex activities of daily living, especially when mental health (MH) issues coexist, which service providers have to address in their work.

METHODS: From June 2016 to May 2017, we conducted semistructured, one-on-one interviews with providers (*n=33;* Table 1) from the Ontario HIV sector to obtain their perspectives on the impact of HAND on their clients' MH, and how to address this impact. We employed Thematic Analysis (Braun & Clarke, 2006) on our interview data to generate our results.

Identifies As	Female = 18	Male = 15	Straight = 25	Gay = 8	Genderqueer = 1	Cis = 32	Trans = 0
Age Range	<25 y/o = 1		25-34 y/o = 11	35-44 y/o = 10	45-54y/o = 7	55-64y/o = 4	
Race/ Ethnicity	White = 19	Black = 4	Latino = 2	S/SE/E Asian = 6	W Asian/M Eastern = 1		Aboriginal = 1
Region	Downtown Toronto = 21			Greater Toronto Area = 6		Southwest Ontario = 6	

[Table 1]

RESULTS: We generated two superordinate themes: (1) barriers to addressing the impact of HAND and (2) strategies providers used to overcome barriers. Three types of barriers were identified. *Personal barriers* included providers' lack of awareness and knowledge of HAND. *Service access barriers* included limited availability of local primary care and MH services; limited access to MH services with adequate expertise/experience working with PLWH[2]; and HIV stigma. *Systemic barriers* were related to lack of capacity in the Ontario HIV sector. Three types of strategies to overcome barriers were identified. *Intrapersonal strategies* involved staying informed about HAND. *Interpersonal strategies* included providing practical assistance, counselling, and referrals. *Organizational strategies* included creating dedicated support groups for PLWH[2]; partnering with organizations with services not available within their organization; and advocating for greater access to MH services with expertise/experience working with PLWH[2].

CONCLUSIONS: Our findings have substantial implications for informing/influencing national and global intervention programs supporting the MH of PLWH[2].

PED1176

WE ARE ALL WOMEN: BARRIERS AND FACILITATORS TO INCLUSION OF TRANSGENDER WOMEN IN HIV TREATMENT AND SUPPORT SERVICES DESIGNED FOR CISGENDER WOMEN

J. Sevelius[1], L. Moran[1], S. Weber[1], C. Watson[2], J. Keatley[1], J. Auerbach[1]
[1]University of California, Medicine, San Francisco, United States, [2]University of California, San Francisco General Hospital, San Francisco, United States

BACKGROUND: In HIV research, services, and programming, it is increasingly urgent to disaggregate transgender women from the behavioral risk category of "men who have sex with men (MSM)." Transgender women, as women, share more in common with cisgender (non-transgender) women with respect to sociocultural context and factors influencing HIV risk and outcomes, particularly trauma, than they do with MSM. However, it is not yet clear whether both transgender and cisgender women would find integrated, all-women HIV programs and services desirable and beneficial.

METHODS: We Are All Women was a qualitative study conducted between April 2016 and January 2017 utilizing a conceptual framework based on gender affirmation and trauma-informed care to explore barriers and facilitators to inclusion of transgender women in HIV treatment and support services traditionally focused on cisgender women. Purposive sampling was used to recruit participants for 6 semi-structured, facilitated focus groups with cisgender and transgender women (2 with cis women 2 with trans women, and 2 with cis and trans women together) and 5 semi-structured, in-depth interviews with HIV care providers in the San Francisco Bay Area. Focus groups were in person, lasted one hour, and consisted of 2 facilitators and 2-11 participants (totaling 10 trans and 22 cis women). Interviews with providers were conducted by phone and lasted 60-90 minutes. All sessions were recorded and transcribed.

RESULTS: Both trans women and cis women identified the desire for gender affirmation, a feeling of safety (specifically space without men), and potential community-building within a care and healing context as powerful facilitators of an inclusive all-women care environment. Primary barriers to integrated cis and trans women care were acceptability and feasibility. Although cis women generally expressed acceptability, their language and behavior sometimes reflected discomfort that distanced and stigmatized trans women. The combination of high needs—particularly associated with trauma—and constrained resources raised questions about the feasibility of integrated services.

CONCLUSIONS: Although both transgender and cisgender women generally supported the idea of trans-inclusive all-women HIV services, they identified interpersonal and structural challenges in implementing them. Notwithstanding, they identified strategies related to physical environment, community engagement, and trans visibility that would make such services attractive.

PED1177

BARRIERS AND FACILITATORS TO ENGAGEMENT WITH THE CASCADE OF HIV CARE IN THE PHILIPPINES AMONG MEN WHO HAVE SEX WITH MEN (MSM): FINDINGS FROM A COMPREHENSIVE QUALITATIVE ENQUIRY

B.M. Hollingshead[1,2,3], A. Bourne[1], G. Dowsett[1]
[1]Australian Research Centre in Sex, Health and Society (ARCSHS), La Trobe University, Melbourne, Australia, [2]New Zealand People Living with HIV Stigma Index, Positive Women, Auckland, New Zealand, [3]New Zealand AIDS Foundation, Auckland, New Zealand

BACKGROUND: The HIV epidemic in the Philippines has been expanding rapidly, with MSM accounting for most new diagnoses. Epidemiological surveillance in the Philippines shows high levels of people presenting with advanced infection (1,312 in January to July 2019) and high levels of mortality (460 in January to July 2019). Such numbers reflect delays, failures and missed opportunities in the HIV care cascade. This research sought to understand the social contexts that make MSM more vulnerable to HIV and to identify barriers and facilitators to their seeking testing and treatment.

METHODS: Qualitative research was conducted in Manila, the Philippines, from July to November 2018. The methodology comprised twenty key informant interviews with healthcare workers, researchers and policymakers, and three focus group discussions with seventeen healthcare workers from community-based HIV/AIDS organisations. They explored the social contexts of HIV transmission and how organisations understood these and responded. Interviews were transcribed and coded in NVivo to generate themes.

RESULTS: Participants reported a widespread lack of awareness of HIV among MSM, with illness often undetected if physical symptoms were not present. Fear of discrimination after a positive result also influenced the desire to test. However, new models of community-based testing are emerging that seek to reach more MSM, addressing some barriers yet creating new complexities for healthcare workers. Significant barriers exist in linking people to care with high levels of 'lost to follow-up', and the responsibility and failure to engage often misdirected at the individual. Many participants noted the continued need to travel long distances to access treatment hubs, and for these trips to occur regularly due to medication 'stock outs' and procurement issues, affecting adherence. New models for treatment are also emerging to address these barriers, with the rise of one-stop-shops for testing and treatment and digital health interventions to encourage adherence.

CONCLUSIONS: In order to understand the drivers of barriers and facilitators to the Cascade of Care, the social context in which individuals engage with it needs to be understood and addressed. MSM face multiple challenges in their attempts to seek testing and treatment, with new approaches needed to ensure they achieve an undetectable viral load.

PED1178

FACILITATORS AND BARRIERS OF HEALTHCARE ACCESS AMONG HIV-POSITIVE STIMULANT USERS

S. Causey[1], S. Towe[1], Y. Xu[1], J. Hartsock[1], C. Meade[1]
[1]Duke University School of Medicine, Psychiatry and Behavioral Sciences, Durham, United States

BACKGROUND: Drug users account for a large portion of HIV/AIDS cases in the United States and many are not receiving medical care, despite the publically supported national HIV care system. As a result, HIV-positive drug users continue to have poorer HIV clinical outcomes and faster progression to AIDS than nonusers. Prior research suggests that stimulant users are affected by unique stressors that impact healthcare utilization and access. Our study aimed to examine factors affecting HIV-positive stimulant users and their perception of healthcare access. Specifically, we sought to test a predictive model examining the relationship between latent constructs (i.e., socioeconomic status, mental health, stimulant use), health literacy, distrust and healthcare access.

METHODS: Participants completed a 2-3 hour study visit which included questionnaires and audio computer-assisted self-interview (ACASI) technology that assessed correlates of healthcare access: health literacy, healthcare distrust and environmental stressors. Structural equation modeling was performed in SAS 9.4. Multiple linear regression was performed in SPSS 26.0.

RESULTS: 104 participants with mean age 48.2 ± 9.8 yrs completed the survey; the majority were male (65.4) and African American (83.7%). Mental health, stimulant use, and socioeconomic status were identified as latent constructs significantly associated with health literacy. Direct effects were significant for the association between health literacy and healthcare access (B=.47, p=.01) and distrust and healthcare access (B=-.24, p=.00). Individuals who reported higher health literacy and lower distrust were more likely to report higher perceived healthcare access. No indirect effects were found.

CONCLUSIONS: Our findings suggest that health literacy and distrust of healthcare systems may be underestimated in their role in perceived healthcare access among HIV-positive stimulant users. Addressing these issues during patient-provider interactions may help improve perceptions of healthcare access among HIV-positive drug users, particularly those negotiating continuum of HIV care along with mental health issues and chronic poverty.

PED1179

'I CANNOT FAIL TO COME AFTER PEOPLE ARE WORRIED ABOUT ME': FACTORS AND MECHANISMS ENABLING RETURN TO HIV CARE AMONG PREVIOUSLY DISENGAGED PATIENTS IN ZAMBIA

L.K. Beres[1], C. Mwamba[2], C. Bolton Moore[2], S. Simbeza[2], S.M. Topp[3], K. Sikombe[2], N. Mukamba[2], E. Geng[4], C.B. Holmes[5], C. Kennedy[1], I. Sikazwe[2], J.A. Denison[1]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [3]James Cook University, Townsville, Australia, [4]Washington University in St. Louis, School of Medicine, St. Louis, United States, [5]Georgetown University, Washington, United States

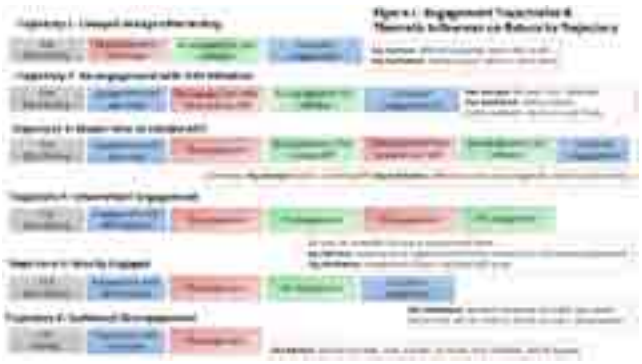
BACKGROUND: While dynamic movement of patients in and out of HIV care is common, the ability of HIV programs to facilitate return to care is impeded by limited data on what influences re-engagement. Understanding the positive behavior of return to care among patients living with HIV is critical for long-term continuity of care. Our study identified both factors that influenced and the mechanisms that enabled return.

METHODS: We conducted narrative interviews with twenty purposefully sampled people living with HIV in Lusaka, Zambia who had disengaged from HIV care and subsequently re-engaged. We applied thematic narrative analysis informed by a social ecological approach.

RESULTS: Participants included 13 women and 7 men aged 21–50 years from 10 health facilities. We identified six return trajectories based on patterns of engagement since HIV testing. (Figure 1) Important, interactive re-engagement facilitators included encourage-

ment, having a personal connection to the facility through a family member or friendly health care worker, experiences of symptomatic illness, the desire to avoid future illness, facility outreach after missed visits, and securing ART outside of the routine clinic visit system. While activated under specific constellations of conditions, across the varied narratives there were five underlying mechanisms of return:

1) patients feeling valued,
2) establishing supportive accountability through caring relationships with health care workers or family,
3) guidance on practical steps required to re-start care,
4) improved treatment accessibility, and
5) identifying and supporting management of specific barriers, such as depression.



[Figure 1.]

CONCLUSIONS: Re-engagement, which is often cyclical, depends on factors and contexts coming together to enable patient return. Understanding a patient's engagement trajectory may help to identify key re-engagement facilitators. A supportive environment for return would include health care worker friendliness and easier ART access to better accommodate individual patient needs. Efforts to increase return should target the specific mechanisms underlying diverse re-engagement facilitators.

REASONS FOR PRESENTATION WITH ADVANCED HIV DISEASE AMONG INDIVIDUALS IN BOTSWANA: A MIXED-METHOD STUDY

K. Tsholo[1], N. Lungu[2], D. Lawrence[3,1], J. Jarvis[3,1], N. Tlhako[1], P. Pule[4], M. Mosepele[1,5]
[1]Botswana Harvard Partnership, Ambition-cm, Gaborone, Botswana, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]London School of Hygiene and Tropical Medicine, Ambition-cm, London, United Kingdom, [4]Ministry of Health and Wellnes, Medicine, Gaborone, Botswana, [5]University of Botswana, Medicine, Gaborone, Botswana

BACKGROUND: Botswana has an established antiretroviral therapy (ART) programme with good population-level coverage, but the burden of advanced HIV-disease remains high. We aimed to understand barriers to HIV testing and effective treatment leading to advanced HIV.

METHODS: A mixed-methods study at Princess Marina Hospital, Gaborone. We collected demographic and clinical data from a convenience sample of admissions during the period July 2017–May 2019. In-depth interviews were conducted with a purposively selected subset of 18 patients and analysed using the Health Belief Model framework.

RESULTS: 294 admissions with advanced HIV were included (Table 1). Of 291 with available data, 18%(51/291) did not know their HIV-status; 18%(52/291) knew their HIV-positive status but were not in care; 3%(9/291) were in HIV-care but not on ART; and 13%(37/291) had defaulted ART. 48%(141/291) reported being on ART, 35% of whom(50/141) had a suppressed viral load.Eighteen interviews were conducted. Participants knew their sexual behaviours could lead to HIV exposure but did not consider themselves susceptible, so delayed testing. When testing, services were well regarded. HIV infection was frequently stigmatised and was particularly severe if manifesting in weight loss or inability to perform usual social roles and addressing these issues were the benefits of treatment. Acute illness presented a cue to action. Barriers to care among ART-experienced participants were limited benefits following early initiation, side-effects, waiting times and healthcare worker attitudes.

Participant Demographics
n 294, age median (range) 38 years (18-78 years), female %(n) 43(126)

Diagnoses		% (n)
Cryptococcal meningitis		29 (84)
Other CNS infections		9 (26)
Respiratory infections (exc PTB)		19 (57)
Pulmonary TB		13 (37)
Extra-pulmonary TB (exp TBM)		7 (19)
Malignancy		8 (24)
Gastrointestinal infection		5 (14)
Other		11 (33)
Point in the Care Cascade n=291		% (n)
New HIV diagnosis		18 (52)
Known HIV diagnosis		82 (239)
	Not in care	18 (52)
	In care, never on ART	3 (9)
	In care, defaulted ART	13 (37)
	On ART	48 (141)
Of those on ART:	Suppressed	35 (50)
	Detectable	24 (34)
	No recent viral load	40 (57)

ART: Antiretroviral therapy, CNS: Central nervous system, PTB: Pulmonary tuberculosis. Other CNS infections: Tuberculous meningitis (11), bacterial meningitis (7), viral meningitis (7), space occupying lesion (1), seizures (1). Respiratory infections: Pneumocystis pneumonia (44), bacterial pneumonia (12), empyema (1). Malignancy: Kaposi Sarcoma (15), cervical cancer (7), vulval cancer (1), lymphoma (1). Other: Anaemia (10), pancytopenia (4), cytomegalovirus (1), myelitis (1), sepsis (1).

[Figure 1. Demographics, diagnoses and point in the care cascade]

CONCLUSIONS: Most patients(82%) developing advanced HIV disease already knew their HIV status, but were not effectively engaging in care or taking ART. There is shame surrounding HIV infection and disbelief concerning risk. Limited understanding of the benefits of early ART and healthcare related factors including waiting times and staff attitudes were barriers to effective care. Differentiated models of care are needed to engage and retain all patient groups in care.

ANTIRETROVIRAL THERAPY (INCLUDING TREATMENT AS PREVENTION)

PED1181

A RANDOMIZED CONTROLLED TRIAL OF COGNITIVE BEHAVIORAL THERAPY OUTCOME FOR ADHERENCE AND DEPRESSION (CBT-AD) AMONG HIV PATIENTS ON ANTI RETRO VIRAL THERAPY (ART) IN JIMMA UNIVERSITY MEDICAL CENTER (JUMC)

A. Gizaw[1], H. Haileselassie[2]
[1]Jimma University, Health, Behavior and Society, Jimma, Ethiopia, [2]Jimma University, Department of Psychiatry, Jimma, Ethiopia

BACKGROUND: Persons living with HIV/AIDS (PLHIV) are able to live full lifespans after infection, however, rates of anxiety disorders among this population are elevated compared to national samples. Depression symptoms and disorders have a negative effect on medication adherence, quality of life and other psychological disorders, such as depression. The aim of this study was to evaluate Cognitive Behavioral Therapy Outcome for Adherence and Depression (CBT-AD) reduction.

METHODS: A two arm, randomized, controlled, trial comparing CBT-AD was employed. The study intervention activities lasted for 6 months from February 1st 2018 to July 30th 2018. Eligible 274 HIV infected patients were selected by using simple random sampling technique. ANCOVA and repeated measures analyses were done to know between and within subject variability. Variables with p-value less than ≤0.05 used as cutoff point for statistical significance.

RESULTS: CBT-AD (N=134 participants) had significant large effect size improvements in depression (f= 853.21, p < .001, partial eta squared=0.78), perceived stigma (f=125.54, p < 0.001, partial eta squared= 0.317), sleep quality (f=20.10, p<0.001, partial eta squared= 0.317) compared to control group (n=140 participants) at post treatment (4 months). Over three follow-ups, CBT-AD groups (n==122 participants) maintained lower depressive symptoms (f=507.97, p<0.001, partial eta squared= 0.808), lower perceived stigma (f=1012.14, P<0.001, Partial Eta Squared=0.893) regardless of sociodemographic characteristic differences.

CONCLUSIONS: CBT was helpful to reduce depression, perceived stigma and improve ART medication adherence and sleep quality. Structured CBT should be integrated in the management of patients with depression, adherence, poor sleep quality and stigma.

PED1183

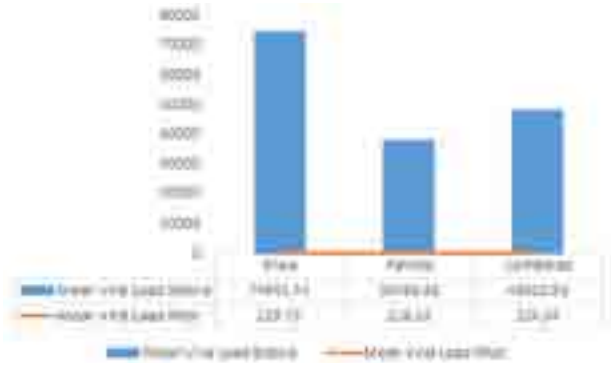
HERBAL MEDICINE CEASATION AND EFFICACY OF ANTIRETROVIRAL DRUGS IN THE TREATMENT OF HIV: STUDY OF NASARAWA STATE NIGERIA

E.O. Chukwu[1], A.N. Azihaiwe[2], C.E. Awunor[1], N.S. Otene[1]
[1]Aids Healthcare Foundation, Nursing (Prevention, Care and Treatment), Lafia, Nigeria, [2]Aids Healthcare Foundation, Care and Treatment, Lafia, Nigeria

BACKGROUND: Use of herbal medicine among HIV-infected individuals in Nigeria and Nasarawa State in particular is on the increase in the past decade and has led to number of mortality cases. Most common reasons for the usage include been promised cure by the traditional healers, traditional beliefs that herbal medicine is better than orthodox medicine, been tired of daily pills. This cross-sectional study was to assess herbal medicine utilization among PLHIV and its impacts on viral suppression during and after ceasation.

METHODS: Purposive sampling method was used disproportionately to select 89 participants from 7 ART facilities in Nasarawa State. Socio-demographic data were collected using structured, pretested questionnaire via interview while viral load result test, and ART regimen were collected from the clients' records for a period of 10 months. Analysis was done using MINITAB 14.

RESULTS: Result showed 100% [male-32 (28.3%), female-81 (71.7%)] aged between 18-60 years with average mean age of 35 years reported usage of herbal medicine from traditional healers. The average mean duration in care with concomitant use of herbs and ARVs was 10 months. All the clients were on first line ARV regimen (Tenofovir Disproxil Fumarate + Lamivudine + Dolutegravir OR Tenofovir Disproxil Fumarate + Lamivudine + Efavirenz). Concomitant use of ARVs and herbal medicine had average mean viral load result of 48810.86cp/ml. The mean viral load result after ceasation of concomitant use following 3-months enhanced adherence counseling was 224.54cp/ml showing the negative impacts of concomitant use of herbal medicine and ARVs on viral suppression.



[Figure]

CONCLUSIONS: Herbal medicine used by PLHIV in Nasarawa State negatively affects the efficacy of ARVs. Enhanced adherence counseling was found to be a very effective tool at ensuring cessation of herbal medicine usage among PLHIV. There is need for further studies on the components of these herbal medicine and its specific interaction with ARVs.

PED1184

U=U - CATALYST OR BARRIER FOR MEN'S ENGAGEMENT IN ART? STAKEHOLDER VIEWS FROM BLANTYRE, MALAWI

A. Berner-Rodoreda[1], R. Dambe[2], E. Ngwira[3], F. Neuhann[1], T. Bärnighausen[1], S. Phiri[2]
[1]University of Heidelberg, Institute of Global Health, Heidelberg, Germany, [2]Lighthouse Trust, Blantyre, Malawi, [3]Lilongwe University, Developmental Studies, Lilongwe, Malawi

BACKGROUND: The slogan **U**ndetectable = **U**ntransmittable, based on three studies which showed virtually no transmission from a virally suppressed PLHIV to their HIV-negative partner, became popular from 2014. We explored familiarity with this slogan among stakeholders in Blantyre, the Malawian city with the highest HIV prevalence rate (17.7%) and the worst viral load (VL) suppression rate (59.5%) in the country. Our particular interest was in stakeholders' views of the potential appeal of this slogan to men, as men's VL suppression lags behind women's in Malawi.

METHODS: The U=U data emerged from a qualitative study among stakeholders (n=16) and men on ART: n=24 with detectable VL , n=17 with undetectable VL, and 17 men in the community. We conducted

in-depth interviews (in Chichewa and English) in Blantyre and surrounding communities in November/December 2019 and translated and transcribed, coded and analyzed them. Stakeholders included health personnel of ART treatment sites, academics, NGO and church-based program implementers.

RESULTS: Out of 16 stakeholders, 14 - including all health personnel - were unfamiliar with the slogan. When explained, some stakeholders held positive views such as: boosting men's adherence; appealing to 'kind-hearted' men in preventing onward transmission; enabling discordant couples to forego condom use; motivating men to enquire about the HIV-status of their partner and contributing to an HIV-free generation. Stakeholders saw sexually active men and those spending time away from their families as benefitting most from U=U. Opinions varied on its appeal for male youth.

Widespread concerns related to: equating 'undetectable' with 'healed', which may impact adherence negatively; an increase in promiscuity and clients' re-infection. Some felt that a small risk of transmission remained. Especially health workers emphasized the need for protection through condoms and a reduction of partners.

CONCLUSIONS: The results show that the slogan U=U is largely unknown among HIV-stakeholders in a high prevalence area. If U=U is to have a positive effect on men's engagement with ART, 'undetectable' needs to be carefully explained and more information on the benefits of treatment for the client's own protection and that of others needs to be made known – to stakeholders, clients and communities.

PED1185

IMMEDIATE INITIATION TIME FOR ANTIRETROVIRAL TREATMENT OF HIV POSITIVE DIAGNOSED PATIENTS AND ASSOCIATED FACTORS IN CAMEROON

C. Kengne Nde[1], J.d.D. Anoubissi[1], A. Messeh[1], M. Ngo Nemb[1], M. Ngo Nemb[1], F. Tsimene[1], R. Onana Onana[1], F. Owona[1], D. Mvilongo[1], S.-C. Billong[2,3,4], J.-B. Elat Nfetam[2,4]
[1]National AIDS Control Committee, Central Technical Group, Yaounde, Cameroon, [2]National AIDS Control Committee, Yaounde, Cameroon, [3]University of Yaounde 1, Faculty of Medicine and Biomedical Sciences (FMBS), Yaounde, Cameroon, [4]National HIV Drug Resistance Surveillance and Prevention Working Group, National AIDS Control Committee, Yaounde, Cameroon

BACKGROUND: The World Health Organization recommends rapid (≤ 7 days) initiation of antiretroviral treatment (ART) for HIV-positive patients. The objective of our work was to estimate the initiation time for antiretroviral treatment of HIV positive diagnosed patients and associated risk factors in Cameroon.

METHODS: Based on a prospectively designed analysis, we conducted a cross-sectional study in the 10 regions of Cameroon from October to December 2017, targeting 5013 HIV positive patient on treatment over 60 sites selected according to locolisation of the site, number of patients on treatment and gender by using previous Demographic Health Surveys. All patients beyond 15 years old who visited the selected facilities were enrolled after giving their inform consent. We collected information about their HIV diagnosis, ART initiation and care services. We estimated the median initiation time and we compared it across different factors using log-rank test. We explored associated risk factors using cox model.

RESULTS: A total of 4338 patients were enrolled (86.4% sample coverage). The median age was 36 years [IQR: 29-45]. After being diagnosed 24.1% repeat their HIV test and 12.4% of them took others treatments (traditional, auto medication, delivery prayers) before starting ARV Treatment. The median initiation time for ART was 2 days [IQR :0-14] and was not different between gender (Log-rank statistic 3.3 vs -3.3: p-value=0.83). Patients living in urban area or did not took alternative treatment before starting ART were more likely to initiate ART immediately comparing to rural area or alternative treatment (RR:1.08; 95% CI:1.0-1.17; RR:1.67; 95% CI:1.47-1.89 respectively). Moreover, the relative risk to initiate ART was higher among patients who had no educational level (RR:1.39 95% CI: 1.15-1.67). Patients who lived less than 1km from the facility were more likely to initiate rapidly ART than those living more than 10 km from the facility (RR:1.23 95% CI: 1.10-1.38).

CONCLUSIONS: Our results show that the median of immediate initiation time for ART is in accordance with WHO recommendation. Our findings support the fact that specific strategies like in-depth counseling should be emphasized in patients, living far from facility in rural area and with no educational background.

PED1186

ENHANCING ACCESS TO AND THE PROMOTION OF ADHERENCE TO THERAPY FOR CLIENTS DISPLACED BY SOCIAL INSTABILITY USING MOBILE APPLICATIONS: THE CASE OF CAMEROON

S. Mantan Nchang[1], E. Ndeh Mboumien Ngang[2]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Programs, Douala, Cameroon, [2]Action Group on Governance and Environmental Management, Research, Bamenda, Cameroon

BACKGROUND: Cameroon for the past three years has been facing a sociopolitical crisis in its English-speaking regions. This situation has led to the loss of over 2000 lives and the displacement of close to 530.000 mostly internally and to neighboring Nigeria. As a result of this humanitarian crisis, access to the regions remains difficult, coupled with inaccessibility to counselling and other medical services by people living with HIV/AIDS (PLHIV). Thus, there has been a growing challenge of keeping track PLHIV who have moved and have become IDPs, with challenges in continuing their Antiretroviral therapy (ART) and other services.

DESCRIPTION: In the mist of this conflict, mobile phones and its innovative capabilities could be used to increase access to services for PLHIV . Through the mobile phone numbers of clients and those of caregivers accessed on our databases, at least 5000 clients have been traced to their new destinations and given the much needed support to access psychosocial counselling and linkages to treatment in the new destinations. These people have been able to access the needed services and avoid the discontinuity in their care and treatment.

LESSONS LEARNED: This paper presents the success and challenges in use of mobile technology in response to socio-political tensions that results in displacement of huge segments of populations including affected PLHIV, those in need of care and support. The purpose of the paper is first, to persuade the government of Cameroon to support and incorporate actions that increase the innovative use of mobile phone technologies to complement existing traditional approaches to counselling, psychosocial support and access to treatment. Secondly, to make suggestions on how civil society organisations and other collaborators in the HIV/AIDS landscape can synergize their resources to establish innovation ecosystems that inform systematic approaches to technology transfer and knowledge sharing for enhanced counselling, psychosocial support and improved access to treatment for PLHIV.

CONCLUSIONS/NEXT STEPS: In conclusion, the use of mobile phones and mobile applications is a great tool to bring back to care, patients declared lost to follow up. This is true especially for IDPs. Further research is needed to evaluate the impact of such interventions at a national level.

AWARENESS, INFORMATION AND RISK PERCEPTION REGARDING HIV TRANSMISSION AND PREVENTION

PED1187

LOW AWARENESS AND UPTAKE OF PREP AMONG THAI TRANSGENDER WOMEN: A PRE-ASSESSMENT BEFORE THE LAUNCH OF A TRANSGENDER WOMEN-SPECIFIC PREP CAMPAIGN

P. Srimanus[1], R. Janamnuaysook[1], K. Samitpol[1], K. Termvanich[1], J. Uttayananon[1], N. Rongram[2], S. Mills[2], R. Vannakit[3], P. Phanuphak[1], R. Ramautarsing[1], N. Phanuphak[1]
[1]PREVENTION, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]FHI 360 and U.S. Agency for International Development LINKAGES Project, Bangkok, Thailand, [3]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

BACKGROUND: Despite the known efficacy of pre-exposure prophylaxis (PrEP) in preventing HIV acquisition, awareness and uptake of PrEP remain very limited among Thai transgender women (TGW). As a leading transgender health clinic in Thailand, the Tangerine Community Health Clinic understands the need for TGW-specific PrEP demand generation. We conducted an assessment of PrEP awareness and willingness-to-use, as well as campaign preferences, among Thai TGW in order to guide the development of a TGW-specific PrEP awareness and demand generation campaign.

METHODS: In October 2019, a pre-campaign assessment was conducted among 100 participants who were self-identified as TGW, 18 years of age or older and self-reported sexually active within the last 6 months. Participants were recruited in person in public spaces around hotspot areas throughout Bangkok, Thailand. A self-administered questionnaire was used to assess their awareness and use of PrEP, reasons for not using PrEP if aware, and preferred advertising channels for a hypothetical TGW-specific PrEP campaign.

RESULTS: Of 100 respondents, 40% reported having heard of PrEP and 17% were currently using PrEP. Among those who have heard of PrEP, 42% heard from community health workers, 32% from friends, 21% from online media and 5% from healthcare providers. Among those who were aware but not on PrEP, the most common reason was perceived low HIV risk (83%), either because they used condoms or had clean-looking sexual partners. Respondents also reported not knowing where to access PrEP (26%) and not wanting routine HIV testing (15%). Online platforms were the most preferred channels (74%) among TGW to access PrEP information.

CONCLUSIONS: Our findings showed low levels of PrEP awareness, and reluctance to access PrEP driven by low levels of risk perception, even among individuals who may have substantial HIV risk. Our campaign will steer away from "loss-framed" promotion linked to HIV risk and instead focus on popular TGW influencers emphasizing a gain-frame perspective on increased confidence and control in their daily lives when using PrEP. Based on preferences for online communications, this campaign will focus 70% on online media platforms with 30% offline advertising through buses and public transportation platforms.

PED1188

MAKE ART STOP AIDS: USING PARTICIPATORY ARTS METHODS TO EMPOWER MALAWIAN YOUTH TO TAKE CONTROL OF THEIR SEXUAL AND REPRODUCTIVE HEALTH AND HIV AIDS

S.Z. Kalima[1], B. Chinkonda[2], C. Howell[3], H. Todd[4], L. Pemba[5], W. Mlotha[6], C. Bandawe[7]
[1]Art and Global Health center Africa, Programmes, Zomba, Malawi, [2]Art and Global Health Center, Research, Zomba, Malawi, [3]Dignitas International, Monitoring and Evaluation, Zomba, Malawi, [4]Art and Global Health Center Africa, Programmes, Zomba, Malawi, [5]Art and Global Health Center Africa, Monitoring and Evaluation, Zomba, Malawi, [6]Zomba District Health Office, Ministry of Health, Zomba, Malawi, [7]College of Medicine, Department of Mental Health, Zomba, Malawi

BACKGROUND: Project aimed to empower Malawian Youth to take control of their sexual and reproductive health, contributing to reduced HIV incidence and higher quality of life. The purpose of the project is to improve sexual and reproductive health (SRH) knowledge, attitudes and practices among tertiary and secondary school students through near-pear, participatory, arts-based approaches.

DESCRIPTION: 40 tertiary school students were trained in participatory, arts-based approaches and comprehensive SRH and HIV/AIDS. 234 secondary school students were trained in participatory, arts-based approaches and comprehensive SRH and HIV/AIDS · 3400 students were reached during Secondary school festivals and tertiary school performances · 445 of people reached through the tertiary school performances and festivals received HIV testing services during the events representing 13% HTS reach against target of 10% · 60 secondary school teachers trained in SRH and participatory methods so that they can bolster the work of MASA Squads and provide support to youth living with HIV (YLHIVs).

LESSONS LEARNED: The evaluation used a mixed methods cohort study design to compare students' SRH KAP before and after project participation. A total of 348 pre- and post-tests were conducted for quantitative data collection while qualitative data was collected through 11 focus groups and 5 in-depth interviews. Quantitative analysis, using a paired-sample t-test, revealed students had an average of 7.3% increase in SRH KAP upon project completion. Thematic analysis of the qualitative data showed that students felt MASA remedied shortcomings of previous SRH education. Students felt equipped, confident, and passionate about sharing their new knowledge with peers, siblings, and parents.

CONCLUSIONS/NEXT STEPS: - The project resulted in improved knowledge, attitude and practices of the students on HIV/AIDS issues.

- Future project iterations should place emphasis on the areas that the students expressed interest to learn more about, and topics where there was less change seen in the KAP surveys through this project like menstrual health, female condom usage and demonstration and gender based violence among girls and women living with HIV AIDS.

- Students felt the project would be essential for people in rural areas with less access to formal education, they wanted the project in more schools, for longer periods of time, and in more regions!

PED1189

USING INTERACTIVE BOARD GAMES TO REACH COMMERCIAL MOTORCYCLE (BODABODA) RIDERS IN UGANDA WITH HIV/AIDS INFORMATION AND SERVICES. A CASE STUDY OF WAKISO DISTRICT

P. Segawa[1]
[1]*Public Health Ambassadors Uganda, Programmes, Kampala, Uganda*

BACKGROUND: The Uganda AIDS Commission categorises commercial motorcycle riders (also locally known as Bodaboda) among the most at risk population to acquire HIV. A recent study by the Makerere University School of Public Health and the US Center for Diseases Control puts the HIV/AIDS prevalence rate at 7.5% among Bodaboda riders in Kampala compared to 4.5% among other men. This is due to their risky lifestyle of having multiple and irregular sexual partners coupled with poor health seeking behavior. The mobile nature of their passenger transportation work offers them very limited attention span to health related messages.

DESCRIPTION: Boda Beeramu is a unique innovative project that was designed by PHAU as a way of reaching Bodaboda riders in Wakiso district in Central Uganda with accurate information on HIV/AIDS prevention, treatment and care using designed custom-designed Ludo boards. The board games were designed with HIV messages on condom use, advocacy, sexual network, counselling and testing. Each bodaboda stage had an HIV Awareness Champion, well-trained with basic knowledge on HIV prevention, treatment and care, who clarifies on contentious issues that emerge from his fellow bodaboda riders. Furthermore, stage activations/outreaches were conducted to provide integrated HIV/AIDS Services complimented with condom distribution and themed IEC materials to foster interactive discussions on HIV/AIDS.

LESSONS LEARNED: 35 Bodaboda HIV awareness champions (peer educators) trained on basic HIV/AIDS treatment, prevention and care knowledge.

3000 bodaboda riders directly reached with accurate information on HIV/AIDS prevention, treatment and care (excluding those tested).

12 free HIV counselling and testing sessions conducted.

2117 people tested for HIV, 35 of whom tested positive and were effectively referred for treatment at AIDS Health Care Foundation (AHF) and public health facilities.

146880 condoms distributed during outreaches and in the 30 dispensers installed at different bodaboda stages we work with.

CONCLUSIONS/NEXT STEPS: In order to reach key populations with a very limited attention span to health messaging, innovating HIV projects around the things they love to interact with like board games (as the case is with Ugandan Bodaboda riders) is key. They play the game as they learn a thing or two about HIV.

PED1191

INCLUSIVE EDUCATION TO PREVENT HIV AMONG MSM AND TG IN BANGLADESH

U. Kanta[1], S. Ahmed[2]
[1]*Bandhu Social Welfare Society, Policy & Advocacy, Dhaka, Bangladesh,*
[2]*Bandhu Social Welfare Society, Executive Director, Dhaka, Bangladesh*

BACKGROUND: Bangladesh faces a concentrated epidemic; the overall HIV prevalence remains <1% but gradually increasing which is 0.9% in 2019 among MSM and TG. Bangladesh Government has taken all steps to prevent HIV since 1985 including HIV content in national curriculum. But HIV is still taboo and even teachers are not willing to discuss in the class, therefore the students are not getting information appropriately. MSM and TG are being deprived of their education rights, discriminated and harassed due to their gender identity and effeminate gesture that compel them to quit the schools.

DESCRIPTION: As a part of GO & NGO partnership, Bandhu started working with National Curriculum and Textbook Board (NCTB) in 2017 to develop inclusive curriculum and developed Supplementary Reading Material (SRM) in 2018 for Class VI which was tested in six schools in urban and rural settings in 2019. For SRM contents, NCTB conducted a research in 17 schools where opinion of students, teachers and guardians were recorded. NCTB also invited famous children-story writers to write life-oriented stories and after approval of NCTB, the SRM was given to 600 students as a pilot project in 2019 which was approved as inclusive curriculum for 2020.

LESSONS LEARNED: Evidence-based advocacy with burning issues may sensitize the influential people, therefore Education Ministry acknowledged the vulnerabilities of TG and gave priority to prevalence HIV through GO/NGO partnership. Content and dissemination of information is equally important particularly while dealing sensitive issues with the children. Involvement of popular writers was another timely decision to draw the attention of the students which reflects the commitment of 600 students and their guardians. Proper motivation is the best tool to involve children in the awareness campaign who can work as future catalysts.

CONCLUSIONS/NEXT STEPS: National inclusive-education curriculum was revised but requires further monitoring to fulfill the objective. More research is required and to ensure gender empowerment and gender equality, public-private partnership, 360-degree program is important.

"THE GENERATION WE HAVE IS ADDICTED TO DRUGS AND ALCOHOL": EXPLORING BARRIERS TO YOUNG MEN'S TRANSITION TO ADULTHOOD AND HIV-ACQUISITION RISK IN RURAL SOUTH AFRICA

O. Adeagbo[1,2], D. Gumede[1], T. Zuma[1], S. Hlongwane[1], A. Gibbs[3], N. Chimbindi[1,2], L. Sherr[4], G. Harling[1,4], N. McGrath[5,6], J. Seeley[7,1], M. Shahmanesh[4,1]
[1]*Africa Health Research Institute, Social Science and Research Ethics, Mtubatuba, South Africa,* [2]*University College London, London, United Kingdom,* [3]*South African Medical Research Council, Gender and Health Research Unit, Durban, South Africa,* [4]*University College London, Institute for Global Health, London, United Kingdom,* [5]*University of Southampton, Medicine, Southampton, United Kingdom,* [6]*Africa Health Research Institute, Mtubatuba, South Africa,* [7]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

BACKGROUND: In South Africa young men's transition to adulthood is complicated by historical disparities, racial inequalities, youth unemployment, violent crime, HIV/AIDS burden and other social challenges. We describe barriers to young men's transition to adulthood and the impact on HIV-acquisition risk behaviours in rural KwaZulu-Natal (KZN), South Africa with a high burden of HIV.

METHODS: Data were from 54 young men aged 15-24 years (twenty in-depth interviews and six focus group discussions were conducted in 2017-18). Participants were purposively selected from a rapid ethnographic study mapping the HIV prevention landscape for young people in the area. Following ethical approval and informed consent, participants explored their experiences of living in the community and transitioning into adulthood. Data were transcribed, translated verbatim, coded using NVivo and analysed thematically.

RESULTS: There are three interconnected challenges to young men's transition to adulthood: unemployment, substance abuse and risky behaviours. Unemployment was seen to expose them to crime and gangsterism causing early deaths and complicated by criminal records that limit their employability in an environment with few job opportunities. Substance abuse (e.g. alcohol and drugs) interfered with the young men's ability to complete high school, causing some to drop out of school. This led to limited skill development and unemployment. Most young men described being exposed to risky sexual behaviours while influenced by alcohol and drugs such as unprotected sex that could lead to becoming 'immature fathers' and/or contracting sexually transmitted infections and HIV. Young men felt pressured by peers and expected to exhibit these behaviours to affirm their sense of belonging as 'men' within their social networks. Overall, young men face a cycle of barriers which multiply their risks and potentially derail their future pathways.

CONCLUSIONS: South Africa is among the countries in Africa experiencing a 'youth bulge' and multiple transition barriers, particularly among young men, can lead to longer term negative health outcomes. The social pressures might increase their risk of contracting HIV. Interventions should engage men and empower them to tackle young men's wider social, structural and health needs to adequately navigate transition process in resource-constrained settings.

PED1193

HIV RISK PERCEPTION, WILLINGNESS AND INTEREST IN PREP AMONG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN IN YANGON, MYANMAR

Y.K. Aung[1], S.T. Thein[1]
[1]*Population Services International, Strategic Information, Yangon, Myanmar*

BACKGROUND: Pre-exposure prophylaxis (PrEP) is the use of an antiretroviral medication to prevent the acquisition of HIV infection by uninfected persons. Among populations at high-risk of HIV infection such as men who have sex with men (MSM) and transgender women (TGW), HIV risk perception is one of the indicators for successful PrEP uptake and adherence.

METHODS: Prior to PrEP implementation, Population Services International (PSI) Myanmar did a formative assessment of MSM/TGW in Yangon, Myanmar, during April 2019. At PSI drop-in centers (DiC), MSM/TGW who came in for a HIV test and had a negative test result were subsequently invited to a short interview. This assessment explored their HIV risk perception, knowledge of and willingness to take PrEP.

RESULTS: A total of 104 MSM/TGW agreed to participate. Of them, 13.5% self-identified as women/TGW and 75% were under 30 years of age. On HIV risk perception, 58.1% said that they had low risk of getting HIV infection, 32.3% said medium risk, and the rest (9.7%) high risk. On PrEP, 59.6% had never heard about it and 69.2% said they would take it if free while 42.3% said they would take it at a cost. Willingness to take PrEP for free was higher among those with medium risk perception than those with low risk perception (81.1% vs 65.1%). This difference was found to be statistically significant on multiple logistic regression [Odds ratio (OR) 3.39, 95% Confidence Interval (CI) 1.01-11.6]. However, significant difference was not found for willingness to take PrEP at a cost [OR 2.07, 95% CI 0.79 – 5.47]. Upon their interest for further information, the respondents ranked the potential side-effects of PrEP as the question of the highest importance.

CONCLUSIONS: As expected, we found that those with higher HIV risk perception were more willing to take PrEP if it were available for free. Still, such willingness might not be present to take PrEP at a cost. In addition, the majority had low risk perception and the concern of potential side effects. Therefore, these factors will have to be carefully addressed for a successful PrEP implementation.

PED1194

CHARACTERISTICS OF THE POPULATION THAT RESORT TO COMMUNITY TESTING SITES: COMPARISON BETWEEN HETEROSEXUAL MEN AND MSM

A.L. Rosa[1], G. Lobo[1]
[1]*Associação Abraço, Lisbon, Portugal*

BACKGROUND: In Portugal, trends show that new diagnoses have declined, and the 90-90-90 goals were achieved in 2017. Despite this scenario, Portugal exhibits one of the highest rates of new HIV/AIDS diagnoses among European countries. Moreover, the highest proportion of undiagnosed infections was among heterosexual males with an mean time from infection to diagnosis of 3.4 years. Testing constitutes an important prevention strategy, therefore merits an analysis of testing in heterosexual men.

METHODS: Observational, descriptive study. Abraço is a NGO with five screening sites nationwide, for HIV, HCV, HBV, and syphilis. Participants must be men, 18 years or older, who attended Abraço's screening site, during 2019, and provide informed consent. Participants were invited to answer an anonymous self-administered questionnaire that assessed sociodemographic, screening history, sexual practices and risk perception to HIV. Data were analyzed using the statistical package for Social Science (SPSS).

RESULTS: In 2019, 2532 men were tested, of which 1364 (53.9%) were heterosexual men. This group showed a mean of 36.1 years and had a college educational level (46.7%). For 88.7% was the first time in our screening site and the foremost reasons to do the screening were curiosity (57.9%). We observed in this sample 10 cases of reactive for HIV (0.7%); 4 cases of reactive for HCV (0.3%); 6 cases of reactive for HBV (0.4%); 10 cases of syphilis (0.7%). A third of the cases of HIV reactive never had been tested. The main reason for not using condoms was trust in a partner (29.3%). We observed that 34.7% of the Heterosexual men never had been tested for HIV in comparison with 26% of MSM. Heterosexual men show lower rates of use of our screening sites (p=0), regularity of HIV testing (p=0) and showed lower risk perception of HIV infection (p=0).

CONCLUSIONS: The number of undiagnosed heterosexual men in Portugal remains a concern, highlighting the need for more effective and innovative prevention and early diagnosis strategies. Context-specific studies to evaluate the effectiveness of interventions to address barriers to HIV testing are needed. Efforts are discussed to address the need for public awareness about HIV risk and the benefits of testing.

PED1195

HIV AND AIDS PREVENTION: KNOWLEDGE OF OLDER PERSONS IN THE WESTERN CAPE AND KWAZULU-NATAL PROVINCES, SOUTH AFRICA AND IN LESOTHO

S. Kalula[1], T. Blouws[1], M. Ramathebane[2]
[1]University of Cape Town, Medicine, Cape Town, South Africa, [2]National University of Lesotho, Pharmacy, Maseru, Lesotho

BACKGROUND: Population ageing and growing access to antiretroviral therapies in South Africa are resulting in ageing of the regional HIV and AIDS epidemic. Research and educational programmes have focused on persons < 50 years. Knowledge is needed to inform the development and testing of evidence-based, targeted HIV prevention intervention, as well as policies and best practice programmes for older persons.

METHODS: A cross-sectional, quantitative survey, and a qualitative study, and an HIV/AIDS education intervention and post intervention follow-up conducted between January 2016 and November 2018 to assess HIV and AIDS knowledge, attitudes and practices (KAP). A total sample of 1320 participants aged ≥50 years at five sites: two in the Western Cape and one in KwaZulu-Natal provinces of South Africa, and in Lesotho. Descriptive and logistic regression analyses were performed. Numerical variables were expressed as median and range, and categorical variables as frequencies.

Logistic regression analysis assessed an association between demographic characteristics and the Health Literacy score, and between demographic characteristics and the KAP score. Odds ratios (OR) and 95% confidence intervals (CI) measured association for bivariate analysis and adjusted odds ratios (AOR) for multivariate analysis.

RESULTS: A total of 1163 subjects participated in the quantitative surveys. Seventy percent were female, 26% married and 38% widowed. The median age was 63 years (range 50-98 years). The majority had a primary school education (54%); 15% had no schooling. Health literacy was inadequate in 56%. The knowledge, attitudes and practices (KAP) score was inadequate in 64%, but improved by 10% post educational intervention. The focus group discussions revealed three themes: The HIV/AIDS epidemic had impacted the subjects' communities heavily and continuing education is vital; Programmes have had minimal success in changing the tide of the epidemic and fear of stigmatisation remains; and societal shift in attitudes towards HIV/AIDS is needed for those living with HIV to feel accepted.

CONCLUSIONS: The KAP level in older persons is poor, and is a barrier to their dealing with own risk and that of their family and community of contracting the virus. Policy and programmes are needed, tailored to the older population, the majority of which has poor health literacy.

PED1196

GEBRAK (JOINT MOVEMENT WITH CADRES) TO STRENGTHEN ZERO STIGMA OF HIV AIDS STRATEGY ON ADOLESCENTS

R.A. Setyani[1], M.A. Fathoni[2]
[1]Respati University of Yogyakarta, Midwifery Profession Education, Yogyakarta, Indonesia, [2]Regional Development Planning Agency of Yogyakarta, Yogyakarta, Indonesia

BACKGROUND: Adolescents are vulnerable groups with the second highest HIV AIDS case in Indonesia. The lack of understanding of reproductive health and narcotics accompanied by the high stigma of society against HIV AIDS is the main contributing factor. Therefore, through the funding from the Ministry of Research and Technology of the Republic of Indonesia in 2019, we conducted a strategic study and initiated a community Empowerment program called GEBRAK (Joint movement with cadres). This innovation is a strategy in achieving zero stigma and discrimination in Three Zeros to increase youth participation in VCT (Voluntary Counseling and Testing) as HIV prevention and early detection efforts.

DESCRIPTION: GEBRAK (Joint movement with cadres) involved the role of cadres as the spearhead of health promotion in the community. This Program collaborates with Primary Health Centre as a VCT mobile service provider. In the first phase, we formed and trained cadres from youth community in Village with the name SETIA (HIV AIDS Adolescent Cadres). Furthermore, trained cadres will provide intensive education to teenagers in the village, school, and boarding house. In the final stage, the adolescent is invited to perform early detection of HIV. In order for the youth to be interested in VCT, we cooperate with the village device to conduct activities once a month, such as talk show, Bazaar, gymnastics, fun running, or music concerts.

LESSONS LEARNED: In a research we have done in January to December 2019, that GEBRAK intervention proved seven times more effective in increasing adolescents participation in VCT. There are 76% of 15 until 24 year old teenagers willing to VCT, with the reduction of negative stigma on HIV AIDS by 80%.

CONCLUSIONS/NEXT STEPS: GEBRAK is effective to increase youth participation in VCT, and reduces negative stigma about HIV AIDS needed cooperation between the Government, NGOS, health workers, cadres, and communities to make this program optimally. We have created a policy brief addressed to the Ministry of Health as an advocacy effort. Furthermore, we will conduct an in-depth review of the evaluation of GEBRAK implementation before finally becoming a health policy in the prevention and elimination of the stigma of HIV AIDS in Indonesia.

PED1197

DEVELOPMENT OF AN HIV PREVENTION DECISION SUPPORT TOOL TO IMPROVE MECHANISMS OF OFFERING PREP TO WOMEN IN A U.S. FAMILY PLANNING SETTING

W. Wilson[1], S. Wulf[1], T. Williams[2], S. Graves[2], S. Davis[2], R. Logan[3], J. Mims[2], K. Wilson[2], S. Weber[1], P. Rolle[2], C. Dehlendorf[1,4,5], D. Seidman[4]
[1]University of California, Department of Family and Community Medicine, San Francisco, United States, [2]State of Florida, Department of Health, Duval County Health Department, Jacksonville, United States, [3]University of South Florida, Tampa, United States, [4]University of California, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [5]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: The majority of new HIV diagnoses in the United States (US) occur in the southern US, and Black women are disproportionately affected, accounting for 69% of new HIV diagnoses among cisgender women. Pre-exposure prophylaxis (PrEP) use among Black women in the southern US is strikingly low, and Black women have one of the highest unmet needs for HIV prevention in the US. Interventions are needed in clinical settings, where women access care, to support awareness of HIV vulnerability, improve knowledge of HIV prevention options, facilitate informed decision-making, and motivate women to seek out and use HIV prevention strategies, including PrEP, as appropriate. We developed an HIV prevention decision support tool (DST) for women to use prior to family planning appointments in a family planning clinic in Duval County, Florida.

METHODS: We relied on available evidence regarding best practices for the structure and content of the DST. We gathered feedback via focus groups (N=8; total participants=43) and interviews (N=20) from predominantly cisgender women in Jacksonville, Florida and San Francisco, California. We also obtained iterative feedback from a community advisory board in Jacksonville comprised of leaders of community organizations and patients.

RESULTS: Based on feedback, the DST begins with offering information about vulnerabilities to HIV. The vast majority of participants recommended this information be as specific to the location of the clinic as possible, highlighting both behavioral vulnerabilities and structural vulnerabilities such as HIV rates by zip code. Participants appreciated examples of women who might consider PrEP. Participants valued not promoting one HIV prevention method over another and presenting information about side effects and safety clearly and directly to promote trust. Finally, participants agreed that the DST should be offered to everyone attending the clinics, and patients could assess for themselves how much to engage with the information in the DST.

CONCLUSIONS: An HIV prevention DST offers an innovative approach for providing universal education, facilitating women's agency to learn about and identify their vulnerabilities to HIV and interest in PrEP. DSTs may be an important mechanism to expand knowledge and use of PrEP among women in the US for whom it may be appropriate.

PED1198

PERCEIVED HEALTH AND STIGMA AMONG A POPULATION OF INDIVIDUALS DIAGNOSED WITH ACUTE HIV: REPORT FROM THE SEARCH010 COHORT

H.L. Peay[1], T. Jupimai[2], N. Ormsby[3], S. Rennie[3], R.J. Cadigan[3], K. Kuczynski[3], S.C. Isaacson[3], N. Phanuphak[4], E. Kroon[4], J. Ananworanich[5], S. Vasan[6], P. Prueksakaew[4], J. Intasan[4], G. Henderson[3]
[1]RTI International, Early Education, Disability, and Health Program, Durham, United States, [2]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [3]University of North Carolina, Department of Social Medicine, Chapel Hill, United States, [4]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [5]University of Amsterdam, Amsterdam, Netherlands, [6]US Military HIV Research Program, Bethesda, United States

BACKGROUND: Diagnosis during acute HIV infection (AHI) reveals individuals with high infectivity, need for ART initiation, and adherence counseling. Grace and colleagues (2015) described experiences of gay AHI-diagnosed men, including undetectability as an "emergent identity". AHI may also be associated with lower perceived HIV burden and internalized stigma compared to chronic HIV. We describe acute identity in a large cohort in Thailand, SEARCH010.

METHODS: We conducted an online survey in 2019 of SEARCH010 cohort members. The questionnaire included general health status, HIV burden (Brief IPQ measure, score range 0-80), Internalized AIDS-Related Stigma (score range 0-6); as well purposively-designed items on meaning of acute status, perceptions of ART, and infectiousness:

RESULTS: Among 408 participants almost all rated their health as excellent (27%), very good (46%), or good (26%). 91% reported undetectable viral load.

The mean HIV burden score on the IPQ was 26.1 (SD=10.8) out of a possible score of 80, indicating low overall HIV burden. Respondents also indicated high satisfaction with ART and low current side effects (M=8.0; M=2.6 respectively; scale 0-10). The mean internalized stigma score was 3.6 (SD=1.6). 25% reported not disclosing to anyone; those respondents had a mean stigma score of 3.7, which was not significantly higher than those who had disclosed (M=3.5).

Almost all (94%) agreed or strongly agreed that acute status means a better chance for cure from new treatments; 80% agreed or strongly agreed that their immune system is stronger than people treated later. 29% rated their risk of transmission with unprotected sex as medium or high, while 63% rated the risk as low or nonexistent.

CONCLUSIONS: In this research cohort diagnosed and treated at the earliest stage of infection, perceptions of general health status and strength of immune system were positive and illness burden low. Most reported an undetectable viral load and equated acute status with greater likelihood of cure, supporting the concept of an "acute identity". Yet our findings demonstrate higher internalized stigma compared to several chronic HIV populations. After achieving viral suppression through immediate ART after AHI diagnosis, it is notable that one-third weren't aware of or didn't internalize that Undetectable=Untransmittable.

PED1199

THE TRENDS OF COMPOSITE SCORES OF KNOWLEDGE AND ATTITUDES ABOUT HIV/AIDS IN 47 SUB-SAHARAN AFRICA COUNTRIES FROM 1998 TO 2017

X. Dai[1], H. Wang[1]
[1]University of Washington, Department of Health Metrics Science, Seattle, United States

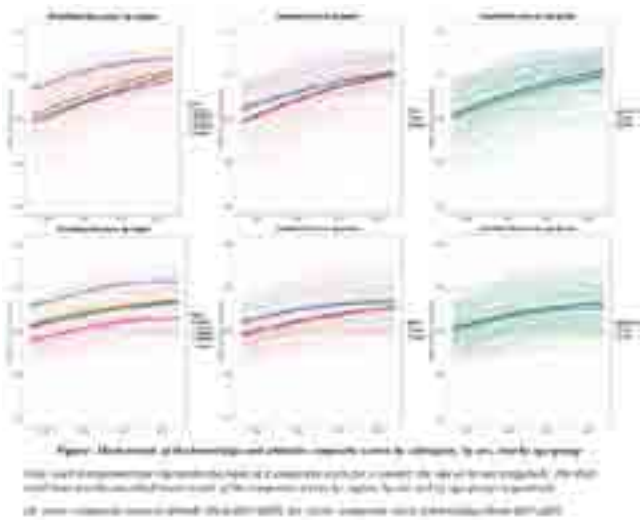
BACKGROUND: Knowing the level and trends of people's knowledge and attitudes about HIV/AIDS are crucial to the success of HIV/AIDS interventions and to understanding the evolution of HIV/AIDS epidemic. Although there are survey data on national levels of HIV/AIDS knowledge and attitudes, these data are sparse and sporadic over time and across counties and have rarely been complied to establish trends. To fill in the gap, this study estimated trends of composite scores of knowledge and attitudes about HIV/AIDS in 47 SSA countries from 1998 to 2017.

METHODS: We systematically searched for survey data on 16 key indicators of HIV/AIDS knowledge and attitudes for the 47 SSA countries from 1998 to 2017 in GHDx. We imputed the missing indicators using multiple imputation and synthesized the point estimates of each key indicator into trend using spatial-temporal Gaussian process regression (ST-GPR). Lastly, we calculated HIV/AIDS knowledge and attitude composite scores and their respective 95% confidence intervals using the simulated draws produced from ST-GPR.

RESULTS: We identified 220 surveys that had at least one of the 16 key indicators of HIV/AIDS knowledge and attitudes. The table and figure below showed the changes of knowledge and attitudes scores over time.

	knowledge score			attitude score		
	1998	2017	annualized rate (%)	1998	2017	annualized rate (%)
Overall	0.516	0.762	2.07	0.509	0.647	1.27
By region						
Central	0.496	0.758	2.26	0.525	0.663	1.23
Eastern/Northern	0.524	0.775	2.09	0.533	0.673	1.23
Southern	0.671	0.847	1.23	0.646	0.789	1.06
Western	0.472	0.725	2.28	0.445	0.579	1.39
By sex						
Male	0.554	0.768	1.73	0.546	0.664	1.04
Female	0.481	0.756	2.41	0.476	0.632	1.51
By age groups						
15-24	0.504	0.741	2.05	0.500	0.631	1.23
25-49	0.523	0.775	2.09	0.516	0.659	1.29

[Table. Changes of composite scores of knowledge and attitudes about HIV/AIDS]



CONCLUSIONS: Despite heterogeneity across countries, people's knowledge and attitudes about HIV/AIDS have generally improved from 1998 to 2017. However, the inequalities in knowledge and attitudes by sex and age are concerning given the demographic expansion of younger populations and the large fraction of new HIV cases among adolescents and young adults, particularly young women, in SSA.

PED1200

PROVIDING CONTRACEPTIVE SERVICES TO YOUNG PEOPLE IN SMALL MEDIUM ENTERPRISES AND VOCATIONAL TRAINING INSTITUTIONS: LESSONS FROM YOUTH ENTERPRISE MODEL PROJECT IN UGANDA

G. Walakira[1], L. Musinguzi[2], M.M. Kiheemu[3], S. Ajok[4], H. Sekajoolo[1]
[1]Straight Talk Foundation, Training and Development, Kampala, Uganda, [2]Makerere University, Department of Social Work and Social Administration, School of Social Sciences, Kampala, Uganda, [3]Independent Consultant, Kampala, Uganda, [4]Straight Talk Foundation, Kampala, Uganda

BACKGROUND: Although several interventions targeting young people's access to contraceptives exist at various levels, few rigorous evaluations that provide evidence of what works have been undertaken. Drawing from the experience of implementation of a 5 year UNFPA funded Youth Enterprise Model (YEM) project in two districts in Uganda, we argue that providing contraceptive services to young people can benefit from utilization of a multi-pronged approach that links the youth to existing points of access; the community; the institution (financial institutions and Vocational Training Institutions) and the Health facilities.

METHODS: A quasi-experimental design was used to compare contraceptive use in Kampala and Mubende districts where YEM was implemented and Wakiso and Mityana as comparison districts. Data for the study were drawn from interviews conducted between May and August 2018 with 1,261 young people aged 10-24 years selected from Vocational Training Institutes (VTIs) and Small and Medium Enterprises (SMEs). In addition, we conducted capacity assessment for 17 health facilities, 10 focus group discussions with young people and 15 in-depth interviews with project stakeholders. Data were analysed using multivariate logistic regressions. Comparison between intervention and control districts were done to establish the strength of the intervention.

RESULTS: Thirty two percent (32%) of young people have ever used a contraceptive method. Exposure to YEM had a significant influence on young people's knowledge of contraceptives with young people from intervention districts more likely to mention seven or more contraceptive methods compared to those from control districts (OR=1.567, P=0.000). The findings also suggest a strong association between exposure to an intervention and the likelihood that one will influence others to use contraceptives. Young people from intervention districts more likely to encourage their spouse and friends to use contraceptives to prevent unplanned pregnancy compared to those from control districts (OR=2.13, P=0.00) (OR=1.92, P=0.000).

CONCLUSIONS: Providing contraceptive services to young people requires a multi-pronged approach. Contraceptive use increases with availability of multiple points of access. We recommend that future interventions need to ensure integration of contraceptive services at such points as community, institution (financial and VTIs) and health facilities.

PED1201

BREAKING DOWN MISCONCEPTIONS ABOUT HIV AMONG YOUNG PEOPLE IN UGANDA - STRAIGHT TALK APPROACH TO COMPREHENSIVE SEXUALITY EDUCATION IN UGANDA

G. Walakira[1]
[1]*Straight Talk Foundation, Training and Development, Kampala, Uganda*

BACKGROUND: Young people continue to face considerable social and cultural barriers to accessing sexual and reproductive health information and services. There aren't many people talking to children and teenagers in remote and hard to reach areas in Uganda about sex, about their health and bodies. Because discussing sex and related matters is often taboo, young people are left to handle issues of sexual feelings, physical changes, disease prevention and avoidance of pregnancy alone. One of the biggest challenges in health communication is breaking down the „enormous wall" of misconceptions around sexual health and adolescence among young people.

DESCRIPTION: Straight Talk Foundation (STF), an indigenous not for profit organization operating in Uganda uses conversation to gradually break down misconceptions and getting kids to understand what it is to have a changing body.

STF approaches issues of adolescence and sexual health with a conversation approach rather than messaging. The Straight Talk newspapers feature real-life stories of ordinary Ugandan children and teenagers. The aim of the newspapers is to demystify growth and development and break down big issues, such as early marriage, rape, HIV/Aids and defilement.

400,000 copies for Young Talk and copies Straight Talk newsletters are distributed to numerous destinations on a quarterly basis.

Young Talk is distributed to 14,450 primary schools; Straight Talk is distributed to 3630 secondary schools. Besides schools, Young Talk and Straight Talk are also dispatched to 554 Tertiary institutions, 1883 Health centers, 528 Non Government Organization (NGOs), 1523 Community based organization (CBOs),80 Church of Uganda based institutions, 118 Catholic based institutions, 48 Islam based institutions, 78 Baptists, and 35 libraries.

LESSONS LEARNED: Boys who are exposed to Straight Talk media projects are 40% less likely to have started sex than boys who aren't. Many are more likely to be tested for HIV, are less likely to say their current girlfriend is casual.

CONCLUSIONS/NEXT STEPS: Straight Talk approach has proved very useful because it allows children access to information on HIV prevention and underlying sexuality/Adolescent Sexual Reproductive Health issues that they might be worried about, with their emotions or their bodies, that they might not be able to talk about at home.

COMBINATION HIV PREVENTION

PED1202

EFFECT OF A COMBINATION INCOME-GENERATING INTERVENTION ON HIV PREVENTIVE ATTITUDES AMONG ADOLESCENT GIRLS IN NIGERIA: RESULTS FROM A QUASI-EXPERIMENT

U. Nwaozuru[1,1], T. Gbajabiamila[2], C. Obiezu-Umeh[3], F. Uzoaru[3], W. Lawal[2], O. Ezechi[2], J. Iwelunmor[3]
[1]*Saint Louis University, Behavioral Science and Health Education, Saint Louis, United States,* [2]*Nigerian Institute of Medical Research, Lagos, Nigeria,* [3]*Saint Louis University College for Public Health and Social Justice, Saint Louis, United States*

BACKGROUND: Despite the growing interest in income-generating interventions to reduce HIV risk among young women, there has been limited research conducted in Nigeria to determine the extent to which such interventions may address the growing HIV risk and vulnerabilities among adolescent girls and young women (AGYW). The objective of this study was to examine the effect of a combination income-generating intervention on HIV prevention attitudes among in-school adolescent girls in Nigeria.

METHODS: We utilized a school-based quasi-experimental study design. One hundred and forty-seven girls from 4 secondary schools were assigned to receive the intervention conditions (4 sessions of HIV education + jewelry micro-enterprise training + youth development micro-credit for jewelry micro-enterprise) and 177 AGYW attending 3 secondary schools were assigned to the control condition (4 sessions of HIV education only). Changes in means scores from baseline to first follow-up between intervention and control groups were compared using t-test on each outcome. Multi-level linear regression models were conducted to examine the effect of the intervention on the primary outcomes (HIV prevention attitude, reduction in sexual risk-taking intentions and attitude towards toward income generation).

RESULTS: Of the 324 study participants, the mean (SD) age was 15.04 (0.89) years; 53% were Yorubas, 72% were Christians. Most of the participants (89.9%) lived with their parents and had never had sex (97.5%). Data obtained at baseline and immediately after completion of the intervention revealed a significant increase in attitude towards income-generation for participants in the intervention (M, +5.55) and control groups (M, +5.2), F=6.65, df=323, p=0.01. In the regression model, compared to the control group, participants in the intervention group demonstrated increased HIV prevention attitude (B=-0.08, t (0.036), 95% CI 4.89-4.72) and reduction in sexual risk-taking intentions (B=-16.68, t (3.18), 95% CI 6.30-27.06). Also, hope was significantly associated with a decrease in sexual risk-taking intentions (B=-0.144, t (2.52), 95% CI 0.25-0.31) and an increase in HIV prevention attitudes (B=0.21, t (2.23), 95% CI 0.006-0.11) in the regression models.

CONCLUSIONS: In addition to promoting HIV preventive attitudes, interventions promoting economic independence may contribute to reductions in HIV risk behaviors among adolescent girls and young women by promoting hope.

PED1203

EMPOWERING YOUNG EXPERTS: TRAINING ADOLESCENT GIRLS AND YOUNG WOMEN TO BE AGENTS OF CHANGE CAN INCREASE ORAL PREP UPTAKE

D. Nhamo[1], T. Mamvuto[1], N. Katsande[1], B. Chiururwi[1], M. Lanham[2], G. Morales[2], M. Garcia[2]
[1]Pangaea Zimbabwe AIDS Trust (PZAT), Community Medicine, Harare, Zimbabwe, [2]FHI 360, Durham, United States

BACKGROUND: Inadequate information, coupled with barriers to accessing HIV prevention services, makes it difficult for adolescent girls and young women (AGYW) to protect themselves against HIV. Building AGYW knowledge and skills to engage in advocacy and peer support around HIV prevention can change this dynamic and increase uptake of HIV prevention services, including oral pre-exposure prophylaxis (PrEP).

DESCRIPTION: We implemented the OPTIONS HIV Prevention Ambassador Training with 17 people already working as PrEP ambassadors in Mazowe District, Zimbabwe. Ambassadors were aged 16-59; 8 were under <24, and 7 were aged 25-35. Some were older than 35 (n=3) and/or male (n=3) who were already educating AGYW about PrEP and wanted additional training. Knowledge and attitudes about sexual and reproductive health and PrEP were assessed before and after the training through a pre/post survey. Ambassadors were followed up at six weeks and four months post-training to ask how they applied their training.

LESSONS LEARNED: Average scores measuring correct knowledge about PrEP increased by 39% post-training. Six weeks later, ambassadors reported referring 125 AGYW for PrEP initiation and re-initiation. Ambassadors reported increased motivation, knowledge, and confidence in their work and noted that the printed toolkit provided during the training made them feel more empowered to discuss HIV prevention with peers and community members.

At four months, ambassadors continued to find the toolkits helpful, with some reporting using the toolkits to prepare for literacy sessions and that peers borrowed toolkits to read. The most useful topics reported at four months were myths and misconceptions about PrEP and HIV and tips for using PrEP. Finally, ambassadors reported that the training and toolkit promoted their status in communities as professionals equipped with HIV prevention information, skills and tools. AGYW PrEP initiations were ~33 per month before the training and increased to a monthly average of 42 post-training, representing a 26% increase.

CONCLUSIONS/NEXT STEPS: The training empowered AGYW ambassadors to support HIV prevention among their peers, and PrEP initiations increased among AGYW in Mazowe District following the training. The OPTIONS HIV Prevention Ambassador Training fills an important need in delivering oral PrEP to AGYW and could be applied in other districts and countries.

COMMUNITY MOBILIZATION AND DEMAND CREATION

PED1204

IT TAKES A VILLAGE... OF TACTICS TO SUCCESSFULLY DRIVE DEMAND CREATION FOR HIV PREVENTION

E. Briedenhann[1], N. Sheobalak[1], P. Rosenberg[1], H. Subedar[2], S. Mullick[1]
[1]Wits Reproductive Health and HIV Institute, Implementation Science, Johannesburg, South Africa, [2]National Department of Health South Africa, Pretoria, South Africa

BACKGROUND: In 2016, South Africa (SA) introduced Pre-Exposure Prophylaxis (PrEP) as an additional HIV prevention method. Project PrEP, a Unitaid-funded initiative implemented by WitsRHI in collaboration with National Department of Health, is implementing PrEP for adolescent girls and young women (AGYW) as part of comprehensive sexual and reproductive health services in four priority clusters in SA. The project's demand creation arm aims to reach 90% (328 517) of AGYW within its catchment population.

METHODS: Utilizing a youth engagement process, the project developed a comprehensive demand creation strategy (Figure 1) combining innovative methods, including online and face-to-face.

[Figure 1. Project PrEP holistic and comprehensive demand creation and social mobilisation strategy]

Reach and engagement data are collected through attendance registers and, online engagement is measured through Facebook/Twitter metrics and Google analytics.

RESULTS: Table 1 shows reach by demographic group and channel for the period November 2018 to 2019 – total reach was 3.275 million (with some individuals reached through more than one channel).

[Table 1. Total demand creation reach for Project PrEP, November 2018-2019]

Online engagement on Facebook posts only, measured at 30828, excluding private messages received and responded to. Events and outreach were most effective at reaching AGYW directly with a strong call to action. A targeted social media approach worked best at creating awareness and driving demand for on-the-ground activities. Since inception in January 2018, Project PrEP has initiated 5736 individuals on PrEP, of which 3075 are AGYW.

CONCLUSIONS: The demand creation strategy demonstrated success in reaching a diverse audience with communication and successfully engaged young people and their communities while driving demand for PrEP. A combination of online/digital and face-to-face communication is required.

PED1205

USING HUMAN CENTERED DESIGN TO CREATE DEMAND AND INCREASE UTILIZATION OF HIV/AIDS SERVICES AMONG YOUNG PEOPLE IN UGANDA. A CASE STUDY OF HOIMA AND MASINDI DISTRICT

P. Segawa[1]
[1]*Public Health Ambassadors Uganda, Programmes, Kampala, Uganda*

BACKGROUND: Statistics show evidence of inadequate or lack of accurate HIV/AIDS and SRHR information and services among young people in Uganda. For instance, teenage pregnancy is higher among uneducated girls: 45% of girls without education have already had a baby, compared to 16% of girls with secondary education. (UBOS and Macro International Inc 2011). Young people are poorly informed about issues of HIV, STI and family planning hence making them more vulnerable to engage in risky sexual behaviors.

DESCRIPTION: Yo Space is a brand designed by the young people for the young people; to increase access and uptake of youth HIV/AIDS and SRH information and services. It was created as a result of an illuminating Human Centered Design (HCD) process where young people from various categories shared the barriers, they face around accessing and using high quality HIV/AIDS and SRHR information and services, how they react to them, and possible solutions to them. PHAU have been utilized to breathe life into Space in several districts; using edutainment and other behavior change strategies to increase the uptake of HIV/AIDS and SRHR information and services among young people through door-door sensitization using peer educators, community Market day outreaches, Institutional outreaches.

LESSONS LEARNED: - 35,382 young people were reached with age appropriate HIV/SRH information through door to door mobilization by our trained peer educators.

- 32,128 were referred to selected facilities to receive integrated HIV/SRHR services.
- 1,852 young people directly received HIV/SRHR information and services during the community/market day outreaches.
- 4,690 young people directly received HIV/SRHR information and services during the Institutional outreaches.
- 204,240 male condoms were distributed.

CONCLUSIONS/NEXT STEPS: Integrated HIV/AIDS interventions especially intended to reach the young women and girls should be brought where they are through peers they know, respect and often interact with. Musicians, actors, opinion leaders and public icons can be used as ambassadors in dissemination of HIV/AIDS information to influence behavior change, increase acceptability and utilization of services. This is due to the fact that all young people look up to these people as role models, mentors and sources of inspiration.

PED1206

SCALING UP HIV TESTING AND PREP UPTAKES AMONG MEN-WHO-HAVE-SEX-WITH MEN (MSM) THROUGH ONLINE OUTREACH ON DATING APPLICATIONS AND SOCIAL MEDIA

N. Rittiwong[1], S. Janyam[1], C. Phaengnongyang[1], A. Arunmanakul[2], R. Vannakit[3]
[1]*Service Workers in Group Foundation, Bangkok, Thailand,* [2]*Family Health International, LINKAGES Thailand Project, Bangkok, Thailand,* [3]*United States Agency for International Development, Regional Development Mission for Asia, Bangkok, Thailand*

BACKGROUND: Thai men who have sex with men (MSM) are increasingly using online platforms, especially social media and dating applications, to socialize and seek sexual partners. This is a challenge for organizations seeking to promote HIV and STI information and services. SWING as a part of the USAID- and PEPFAR-funded LINKAGES project has been implementing an online outreach program linked to an online reservation platform called TestMeNow.net.

DESCRIPTION: SWING identified popular online platforms - including LINE, Facebook, and the BlueD and Hornet dating apps - and used online influencers to deliver key HIV and sexual health messages via posts, chats and live streaming broadcasts. Influencers used monitored digital "tokens" to link clients to TestMeNow.net, where they made appointments for HIV, PrEP, and other services at LINKAGES-affiliated health facilities. Service uptake and outcomes were tracked by TestMeNow and verifiable by clinic registers.

LESSONS LEARNED: Between April and September 2019, 975 reservations were made, and 488 MSM received an HIV test. Online recruitment accounted for 27% of total HIV testing (n=1,840) during this period, and when compared with traditional outreach (n=161) or walk-in clients (n=1,191), individuals recruited online were more likely to be first-time testers (13% versus 6% and 1%, respectively), and more likely to test positive (7% versus 1% and 6%). Additionally, 25% of online HIV-negative clients (n=453) accessed PrEP, while none of the 159 HIV-negative outreach clients did so.

Performance was not uniform: general population social media (chiefly Facebook) reached and tested the most clients, but applications targeting MSM were more likely to reach clients who had not received an HIV test (21% versus 9%) and were slightly more likely to identify new cases of HIV infection (9% versus 7%). Clients on MSM apps who tested negative were also more likely to access PrEP (37% versus 21%).

CONCLUSIONS/NEXT STEPS: MSM-targeted online outreach with engagement of online influencers on social and online medias, especially MSM dating apps, can identify high-risk MSM and promote HIV testing and PrEP services to those in need. However, the absolute number of clients reached online remains low and to achieve epidemic impact this model needs to be brought to scale.

PED1207

THE BIG BROTHER-YOUNG BROTHER MENTORSHIP APPROACH TO HIV PREVENTION: A CASE OF ADOLESCENT BOYS AND YOUNG MEN IN MANICALAND PROVINCE OF ZIMBABWE

L. Munyonho[1], J. Wilford[1]
[1]*Students and Youth Working on Reproductive Health Action Team, Programmes, Harare, Zimbabwe*

BACKGROUND: The power and impact of same sex mentorship initiatives in HIV prevention among adolescent boys and young men remains unexplored and untapped in Zimbabwe yet young men and boys remain a vulnerable group to HIV infection. Adolescent boys and young men's access to comprehensive sexuality education and services remains compromised in the secondary schools of Manicaland province because most donor funded programmes focus on girls and young women.

DESCRIPTION: Through the Big Brother Young Brother Initiative, SAYWHAT facilitates for mentorship, capacity building and leadership skills development of male students in order to advance advocacy and influence meaningful decisions on the Sexual and Reproductive Health and Rights of adolescent boys and young men. The initiative is spearheaded by trained Big Brothers who are male students (19-24 years) in teacher training colleges who are on Teaching Practice at local Secondary Schools. They provide mentorship and to boys (15-19 years) in the Secondary Schools on key Sexual and Reproductive Health and Rights issues affecting them. The ‚Big Brother' support includes providing HIV prevention and management information, mentorship, counselling and HIV referral services to the Young Brothers. Twenty five Big Brothers were trained in September 2017, formed 25 Young Brother Clubs of 10 adolescent boys each and mentored 250 adolescent boys in 10 schools in Manicaland Province by September 2018.The initiative is still ongoing.

LESSONS LEARNED: Same sex mentorship is a powerful tool in scaling up access to HIV prevention services among adolescent boys. It empowers them to open up on issues of sexual abuse and HIV positivity and to make positive choices for a healthier future. Big Brothers referred 686 adolescent boys for HIV testing and counselling; 529 boys accessed HIV testing at local health facilities; 18 adolescent boys disclosed their HIV status; 2 Support Groups were formed in 2 schools with the support from the Big Brothers; and a Male Engagement Charter was signed with local schools development committees.

CONCLUSIONS/NEXT STEPS: Scale up use of the Big Brother-Young Brother Mentorship Approach to more schools in Manicaland Province and advocate the adoption of the Big Brother-Young Brother Mentorship Approach in the secondary schools HIV and AIDS curriculum.

PED1208

DEPLOYING TRADITIONAL HEALERS TO MOBILIZE HIGH RISK INDIVIDUALS FOR HIV TESTING SERVICES (HTS) IN KALIRO DISTRICT, UGANDA

E. Kayongo[1], P. Odeke[1], N. Tumwesigye[2], D. Lopez[1], D. Namatovu[1], R. Kansiime[1], M. Wananda[1], N. Kiige[1], B. Nayebare[1], P. Muhairwe[1], R. Mutonyi[3]
[1]*University Research Company, Community Systems, SBCC, Youth and Gender, Jinja, Uganda,* [2]*University Research Company, Chief of Party, Jinja, Uganda,* [3]*University Research Company, Health Systems Strengthening, Jinja, Uganda*

BACKGROUND: Achieving UNAIDS' 95-95-95 goals is reliant on timely identification and linkage of people living with HIV into uninterrupted care. Widespread use of traditional instead of modern health services is a major cause for delayed HIV diagnosis in Busoga region. Approximately 60% of people in Busoga region often seek traditional healers and spiritualist as their first and preferred line of care.

DESCRIPTION: From March to July 2018, the USAID Regional Health Integration to Enhance Services in East Central Uganda (RHITES-EC) alongside Busoga Kingdom engaged 54 traditional healers in high-burden sub-counties in Kaliro district to mobilize high-risk individuals for HIV testing services (HTS). The project used a modified village health team audience engagement and referral package to conduct a three-day training for 54 traditional healers. It included values clarification, addressing gaps in HIV knowledge, and strengthening communication/referral skills and use of tools.

LESSONS LEARNED: Results from 15 of the deployed traditional healers showed and increase in the number of clients referred for HTS from 0 in March 2018 to 120 by the end of July 2018. Of the 120, 114 were tested for HIV and 50 were found to be positive (44% yield). Additionally, four presumptive TB cases were referred for TB testing and one tested positive (25% yield). The healers attributed the willingness of their clients to go for HTS to the trust the clients had in them. "By the time I can convince a poor villager to bring me a whole goat in a day, what about convincing him to take an HIV test" said a spiritualist."

CONCLUSIONS/NEXT STEPS: Enlisting traditional healers as partners and referral agents, and training and equipping them with relevant tools and skills can be transformational, play a significant role in improving timely diagnosis of PLHIV, and should be considered for scale up. Caution needs to be taken to address the above shortfalls, such as low literacy levels and secretive operations of the traditional healers. These shortfalls could be addressed by further simplifying the support tools and addressing the fear of repremand and loss of revenue when they refer their clients.

PED1209

USING MULTIPLE ENTRY POINTS TO INCREASE SERVICE UPTAKE FOR HIV PREVENTION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN

F. Mashaba[1], D. Kisiyombe[2], N. Miller[1]
[1]*Pact, Programs, Mbabane, Eswatini,* [2]*Pact, Strategic Information, Mbabane, Eswatini*

BACKGROUND: Pact's USAID-funded Triple R project is supporting The Government of Eswatini to reach the 95-95-95 UNAIDS targets though high-impact HIV interventions targeting most vulnerable and at-risk populations. HIV risk behaviors impact adolescent girls and young women (AGYW): 50.6% of females 15 and older who reported sex before age 15 years were HIV positive, as well as 45.3% of

those with two or more sexual partners. Intimate partner violence peaks at 9.8% among women 20- 24 years[i] The project aims to increase uptake of high impact HIV prevention services among AGYW in Eswatini.

[i] Swaziland HIV Incidence Measurement Survey (SHIMS) 2: 2016-2017

DESCRIPTION: The Triple R project's mobilization and demand creation for HIV service uptake among AGYW is accomplished through small group sessions, interpersonal communication and social media. Home visits, group-based HIV prevention sessions, gender-based violence sessions, parenting sessions, and economic empowerment groups led by community workers are entry points for service provision. In 2019, the project mobilized 40,430 AGYW for HIV prevention messaging, 531 have tested for HIV and received their results and 206 have enrolled in PrEP. 847 AGYW accessed HIV information from the project through social media while 40,430 accessed HIV information through the community workers.

LESSONS LEARNED: Aligning HIV prevention sessions with outreach clinical services events increase uptake of services among AGYW. Locally recruited community workers have strong community connections due to their contextual knowledge that facilitates trusting relationships for service uptake and adherence to care among AGYW. Interpersonal communication is integral aspect in the mobilization of AGYW for service uptake. Furthermore, investing in the retention of community workers for improved institutional knowledge management and sustainability of quality service delivery is crucial.

CONCLUSIONS/NEXT STEPS: The Triple R project aims to increase uptake of high impact HIV prevention services among AGYW in Eswatini. Having multiple entry points provides them with the opportunity to connect to different community workers, build trusting relationships and access to customized health messages. Effective interpersonal communication skills enable community workers to build rapport and to confidently engage with AGYW. Further work is required to establish factors that influence AGYW's uptake of PrEP services.

PED1210

PROJECT LAST MILE AND GIRL CHAMP: THE IMPACT OF PRIVATE SECTOR STRATEGIC MARKETING EXPERTISE ON DEMAND FOR HEALTH SERVICES AMONGST ADOLESCENT GIRLS AND YOUNG WOMEN (AGYW) IN ESWATINI

S. Christie[1,2,3], M. Brault[4], A. Manchia[5], K. Mabuza[5], L. Curry[1,2], E. Linnander[1,2]
[1]Yale School of Public Health, Global Health Leadership Initiative, New Haven, United States, [2]Yale School of Public Health, Department of Health Policy and Management, New Haven, United States, [3]University of the Western Cape, School of Public Health, Bellville, South Africa, [4]Yale School of Public Health, Social and Behavioral Sciences, New Haven, United States, [5]Project Last Mile, Mbabane, Eswatini

BACKGROUND: In 2018, eSwatini had the highest HIV prevalence globally, with 27.3% of adults living with HIV. New HIV infections in young women quadruple those in young men (aged 15–24 years). Context-driven interventions that target adolescent girls and young women (AGYW) for HIV prevention and services are lacking. The private sector has potential to drive demand by leveraging strategic marketing processes that successfully engage youth with multinational brands. Project Last Mile (PLM) shares expertise from The Coca-Cola Company to strengthen public health systems in Africa. In eSwatini, PLM worked with the Ministry of Health to co-create Girl Champ (GC), an aspirational brand and community-mobilized response where AGYW can access information, support, and wellness activities in a girls-only environment during clinic-based events. The COACH curriculum was developed for clinic staff to provide youth-friendly care and reinforce messaging.

DESCRIPTION: Yale applied mixed methods to assess the impact of GC over time. Specifically, we assessed stakeholder experiences with implementing GC in Manzini region, through 16 qualitative interviews and 547 feedback surveys. We also tracked attendance at GC events, and quantified the proportion of those in attendance who were new to care and reached overall during activations. Data were abstracted from the Clinic Management Information System (CMIS) to explore pre-/post trends in AGYW health service utilization and HIV testing in two facilities where electronic data were available.

LESSONS LEARNED: In November 2018, GC was piloted in three clinics attracting 1,722 AGYW for participation, and reaching 19% of the AGYW population from participating tinkhundla (municipalities). Seventy-three percent (n=1,236) of attendees were newly registered for health services during GC events. Analysis of CMIS data showed no statistically significant improvements in number of facility visits or HIV Testing and Counseling (HTC) visits among AGYW at GC-experienced clinics over time. Feedback from AGYW participants was highly positive; interviews with key stakeholders described collective ownership, feasibility and endorsement for this approach.

CONCLUSIONS/NEXT STEPS: Public-private sector partnerships may be uniquely positioned to develop and implement novel demand creation interventions with significant reach to potentiate linkage to care. Interventions that emphasize health and wellness (gain-framing) vs. HIV prevention (risk-framing) may have more resonance with youth.

COMMUNITY-BASED APPROACHES (INCLUDING EMPOWERMENT, OUTREACH AND SERVICE DELIVERY)

PED1211

THE ROLE OF SPIRITUAL HEALERS IN LINKAGE TO CARE IN THE TREAT ALL ERA IN ZAMBIA: A QUALITATIVE STUDY

M. Nyasa[1], J. Chipungu[2], C. Mwamba[2], H. Smith[2], T. Savory[2], M. Lundamo[2], N. Katota[2], T. Banda[2], M. Herce[2]
[1]Centre for Infectious Disease Research in Zambia (CIDRZ), Implementation Science - Social Science Research Group, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia

BACKGROUND: Despite adoption of a universal "Test and Start" strategy in Zambia, recent programmatic data suggests that only 78% of people living with HIV were on treatment.The role played by non-clinical stakeholders in the decision to not start ART needs to be better understood. Within the Zambian context, this includes the role of spiritual healers.

METHODS: We implemented a qualitative study, nested within a larger retrospective cohort study, to add context and explanatory power to our analysis of routinely collected linkage data from Lusaka, Zambia. We conducted key informant interviews with 10 spiritual healers, in-depth interviews with 61 patients and 20 focus group discussions with health care workers (HCW) recruited through snowballing, purposive and convenience sampling respectively. Semi-structured interview and discussion guides sought to collect data about factors influencing linkage to care after a HIV positive diagnosis. A thematic

framework was developed for data analysis using both inductive reasoning based on emerging themes and deductive reasoning based on an empirically supported "linkage to care pathway".

RESULTS: HCWs reported that among influential people in patients' lives, spiritual healers had substantial power to stop their congregants from taking ART. Some ART patients confirmed that they did not return to care after being told by their spiritual healers that prayer and faith were the only cure for HIV. Others who had successfully linked to ART mentioned that spiritual healers had given them hope and helped them to accept their HIV positive status. All spiritual healers believed they successfully helped congregants to live positive lives through counseling. Only one spiritual healer, who had no basic HIV training, dissuaded congregants from taking ART, persuading them to instead rely on prayers. The rest, who mentioned receiving basic HIV training at their evangelical schools, encouraged patients to both take medication and to pray.

CONCLUSIONS: Spiritual healers can positively influence linkage to care when counseling people living with HIV. Basic HIV training for spiritual healers may be critical to facilitate linkage to ART. Evangelical schools and pastor and church leader education provide an opportunity to implement a curriculum on ART and HIV care.

PED1212

CREATING A PROFESSIONAL COMMUNITY OF FRONTLINE WORKERS AS AN INNOVATIVE METHOD TO IMPROVE THE CARE OF PEOPLE LIVING WITH HIV/AIDS

K. Hollbrook[1], D. Georgetti, RN/PHN[2], R. Maldondado[3], D. Evinger[1]
[1]PRC/SF HIV FOG, San Francisco, United States, [2]The Shanti Project/SF HIV FOG, San Francisco, United States, [3]Mission Neighborhood Health Center/SF HIV FOG, San Francisco, United States

BACKGROUND: People living with HIV/AIDS (PLWHA) in San Francisco are dependent on frontline workers at San Francisco Department of Public Health (SFDPH) clinics and non-profit organizations to navigate a convoluted landscape of services. Due to gaps in education, lack of local professional community support, low wages, and high turnover of frontline workers, PLWHA's access to care and services is diminished, leading to higher rates of mortality, morbidity, and suffering.

In 2015, the SF HIV Frontline Organizing Group (SF HIV FOG) was formed in response to a lack of inter-agency communication, disorganized access to information, and high turnover rates of frontline workers. SF HIV FOG created a forum for frontline workers to support each other in day-to-day tasks and enable access to education, empowering frontline workers to more effectively support PLWHA.

DESCRIPTION: SF HIV FOG is a grassroots collaboration between community-based HIV service organizations and representatives of SF DPH. It provides training and professional networking opportunities for frontline workers in San Francisco to improve inter-agency collaboration and community awareness, thus enhancing the delivery of services to PLWHA. Examples include training events on transgender care, HIV and aging, and public health insurance programs as well as supporting campaigns such as Undetectable equals Untransmittable (U=U).

LESSONS LEARNED: Through December 2019, SF HIV FOG delivered 21 trainings and events for more than 500 frontline workers. Participant evaluations show a 22% increase in content knowledge and a 95% recommendation rate. In 2019, 87% of respondents who attended trainings were able to implement information learned within 30 days of attending a specific training. 88% of respondents to the year-end survey report that the ListServ is a useful resource to efficiently problem-solve specific client issues.

CONCLUSIONS/NEXT STEPS: Results demonstrate that community-based organizations are an effective tool to supplement training for frontline workers and provide opportunities for professional development. The demand for training has led to the development of a coaching program as an alternative means for frontline workers to grow in their capacity to support PLWHA.

SF HIV FOG can serve as a model for agencies in other municipalities to support various providers who work with PLWHA.

PED1213

OPTIMIZING COMMUNITY CARE FOR ORPHANS AND VULNERABLE CHILDREN (OVC): A QUALITATIVE COMPARATIVE ANALYSIS OF THE ACTIONABLE DRIVERS OF CHANGES IN HIV STATUS KNOWLEDGE WITHIN AN OVC PROGRAM IN MOZAMBIQUE

Z. Allen[1,2], A. Davis[3], J. Chapman[1,2], N. Do Nascimento[1,2], D. Velthausz[4], R. Donco[4]
[1]MEASURE Evaluation, Chapel Hill, United States, [2]Palladium, Washington, DC, United States, [3]The U.S. Department of State, Washington, DC, United States, [4]Maraxis, Maputo, Mozambique

BACKGROUND: In Mozambique, 72% of people living with HIV (PLHIV) know their status, and 66% of HIV-exposed infants have been tested for HIV by eight weeks of age (UNAIDS, 2018). The U.S. government funds community organizations in Mozambique to support vulnerable families in accessing HIV testing and treatment services through case workers. Community-based case workers are widely accepted as critical to finding untested clients, but little is known about what makes these staff effective. MEASURE Evaluation—funded by the United States Agency for International Development*—sought to identify the combinations of case management attributes that lead to improvements in the first 90 in the UNAIDS 90-90-90 HIV prevention continuum: that is, the proportion of PLHIV who know their HIV status.

METHODS: Data were collected using qualitative and quantitative methods in August 2019. We selected six community-based organizations (CBOs) in three provinces in Mozambique. Of these CBOs, there was an even split between rural and urban and between high and low proportions of program beneficiaries with unknown HIV status. We applied fuzzy-set qualitative comparative analysis, based on 119 interviews with randomly selected case workers and their supervisors to answer the study's questions.

RESULTS: Results highlight the importance of case worker experience, CBO case worker management support strategies, right-sized caseloads that balance numbers of cases with complexity of cases, and covering job-related expenses (e.g., transportation and mobile phones) in achieving high rates of beneficiaries who know their HIV status.

CONCLUSIONS: Our findings suggest that CBOs can be highly effective in using case workers to address the first 90 by following these case management practices: a formal process to assign cases that considers workload; at least two types of support for case workers, such as weekly care team meetings, weekly supervisor meetings, and/or low supervision ratios; and covering case workers' job-related expenses. CBOs also benefit by hiring experienced case workers and training them continuously.

*This research was conducted with the support of the United States Agency for International Development (USAID) under the terms of MEASURE Evaluation cooperative agreement AID-OAA-L-14-00004. Views expressed are not necessarily those of USAID or the United States government.

PED1214

PERCEIVED CHALLENGES IN PROVIDING SERVICES FOR PEOPLE WHO USE DRUGS BY VIETNAMESE COMMUNITY HEALTH WORKERS

D.B. Nguyen[1,2], L. Li[2]
[1]Hanoi Medical University, Hanoi, Vietnam, [2]University of California, Los Angeles, United States

BACKGROUND: As a response to the dual epidemic of HIV and drug use, decentralization of services would play a crucial role in improving treatment continuum and outcomes among hard-to-reach populations including people who use drugs (PWUD). However, little is known about community health workers' (CHW) needs in providing services for PWUD. This study aims to investigate factors related to CHW's reported challenges in providing services for PWUD in Vietnam.

METHODS: A cross-sectional survey was conducted using audio computer-assisted self-interview method among 300 CHW among 60 communes in Vietnam, regarding their perception and attitude of providing services for PWUD. We used multi-item scales to measure CHW's negative attitudes toward PWUD, perceived challenges in service provision, perceived risk at work, institutional support, and job satisfaction. We used multiple linear regression to identify correlates of CHW's perception of challenges in providing services for PWUD.

RESULTS: Of all participants, 213 (71.0%) reported monthly contact with PWUD. After controlling for gender, occupation, time in the medical field and other job-related factors, participants with more education (β=-1.417, p=0.014) or monthly contacting with PWUD (β=-1.597, p=0.003) reported a lower level of perceived challenges. CHWs with a higher level of negative attitude toward PWUD (β=0.228, p<0.001) or perceived higher risk of working with PWUD (β=0.274, p<0.001) had a higher level of perceived challenges in providing services to the population. Perceived institutional support and job satisfaction were not associated with perceived challenges.

CONCLUSIONS: Most CHWs have initial contact with PWUD, which would facilitate service decentralization as a natural next step. Our findings suggest that stigma reduction interventions could be included in the medical training for HIV and addiction service decentralization.

PED1215

REDUCING HIV/AIDS RISK THROUGH ECONOMIC EMPOWERMENT AND HIV PREVENTION STRATEGIES FOR OUT-OF-SCHOOL ADOLESCENTS GIRLS AND YOUNG WOMEN (AGYW): A CASE IN MAYUGE DISTRICT, EASTERN UGANDA

P. Kigongo[1], M. Smedley[2]
[1]Act4Africa, Mayuge, Uganda, [2]Act4Africa, Manchester, United Kingdom

BACKGROUND: Uganda has the world's youngest population with 78% under the age of 30, and yet 21.4% of this fall below the poverty line. This is more pronounced in the rural areas, including Mayuge District in Eastern Uganda where only 22% have a secure income. In 2016, Act4Africa Uganda conducted a needs assessment and established that education was a problem for girls in Mayuge with consequences of increased poverty, unemployment, sex working, low levels of financial literacy and early marriages. Women's poverty and HIV vulnerability form a vicious cycle where poverty limits access to HIV prevention, care and treatment services.

DESCRIPTION: Working in partnership with the District Local Government and trained community mentors, out-of-school AGYW were identified and selected from four sub-counties across Mayuge district. 90 groups were created, with 30 members each of AGYW aged 15- 30 years. An integrated and holistic approach was employed to offer HIV/AIDS prevention knowledge and services to these groups through comprehensive HIV/AIDS information, mobile HIV/AIDS Counseling and Testing (HCT) clinics and distribution of condoms. These groups received economic empowerment through provision of financial literacy training and were supported to establish saving groups and income generating activities that were identified by the groups.

LESSONS LEARNED: From 2016 through December 2019, a total of 1,884 out-of-school AGYW attended basic financial training and 1, 203 enterprises set up with an equivalent of $ 40,035 saved in groups. A total of 8, 663 people, including both primary and secondary beneficiaries, were reached with HIV Counseling and Testing services, through these groups. Notably, 76% were AGYW aged 15- 30 years and of these 58% had not been tested previously. Out of these, four percent were tested positive and referred to the nearest health facility for enrollment into care and treatment. 9,022 packs of condoms were distributed and 8,749 IEC leaflets.

CONCLUSIONS/NEXT STEPS: HIV/AIDS prevention efforts in poor, rural communities can be effective if combined with poverty reduction programs. Availing community spaces in which peer groups of AGYW meet regularly to access HIV prevention and economic empowerment information and services is a great medium for reducing HIV/AIDS risk among out-of-school AGYW.

PED1216

OUTCOME OF INDEX TESTING AND LINKAGE AMONG KEY AND VULNERABLE POPULATIONS USING MOBILE HIV SERVICES IN MBEYA AND SONGWE REGIONS, TANZANIA

W. Olomi[1], W. William[1], E. Kapesa[1], A. Kway[1], N.E. Ntinginya[1], L. Maganga[1]
[1]National Institute for Medical Research, Mbeya Medical Research Center, Mbeya, Tanzania, United Republic of

BACKGROUND: To achieve the UNAIDS target of 95-95-95 by 2030 effective approaches to HIV testing are required. Index testing service has shown potential benefits in reaching and identifying new HIV positive clients, improving adherence to ART, and HIV prevention for the serodiscordant couples. Although there is growing evidence supports the feasibility and effectiveness of Index testing in identifying new HIV clients, but our literature search indicates paucity of data on its uptake through mobile HIV testing services. We aimed to assess outcome and lessons learned during the implementation of index testing among KVP.

DESCRIPTION: From January to September 2019 the mobile outreach team visited identified communities in the border regions of Mbeya and Songwe and offered country recommended HIV prevention services. HIV positive diagnosed clients were privately referred to nurse counselors for index-partner testing process and upon giving their consensus for "partner tracing", the counselors collected contact information for each index case notified. The client sexual part-

ners were contacted by the nurse counselor for HIV counseling and encouraged to undergo HIV testing, the result of partner HIV status and linkage to care were recorded in HTS register.

LESSONS LEARNED: A total of 241 HIV positive clients were approached for the index testing process; 200 index partners were successfully notified and tested by the mobile HIV services. A total of 106 (53%) were female partners, and of these 65% were married. Among the reached clients 56 (28%) tested HIV positive and of these 54 (96.4%) were successfully linked into HIV care and treatment. The positivity rate was higher among female index partners 33 (31%), divorced 18 (47%) and adolescents 9 (30%), The differences in positivity within the respective categories were statistically insignificant. HIV negative index partners were linked to the nearby clinics for pre-exposure prophylaxis.

CONCLUSIONS/NEXT STEPS: Index testing and linkage into care using mobile HIV services is feasible in these communities. The results shows that this approach is highly effective in early identification of clients with HIV and linking them into care, it also facilitates risk reduction among high-risk uninfected partners.

PED1217

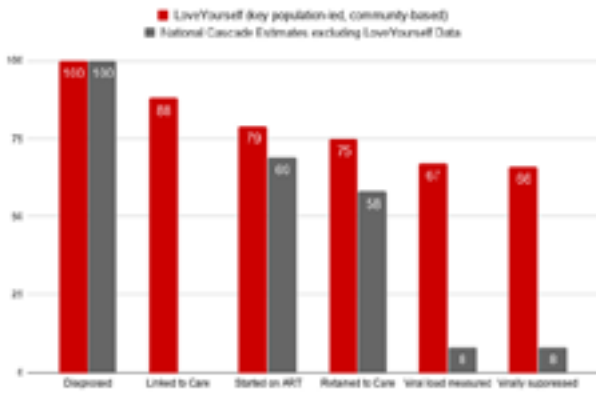
KEY POPULATION-LED, COMMUNITY-BASED TEST-AND-TREAT APPROACH TO ADDRESS THE GAPS IN THE HIV CARE CASCADE AMONG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER-WOMEN IN THE PHILIPPINES: A RETROSPECTIVE COHORT ANALYSIS

P. Eustaquio[1], K. Leyritana[2], S. Docken[3], L.P.L. Wulandari[3]
[1]Love Yourself, Inc., Treatment and Prevention, Mandaluyong, Philippines, [2]Sustained Health Initiatives of the Philippines, Inc., Mandaluyong, Philippines, [3]Kirby Institute, University of New South Wales, Sydney, Australia

BACKGROUND: The Philippines has the fastest growing epidemic in the world with HIV prevalences among men who have sex with men (MSM) and transgender-women (TGW) that are 49 and 25 times greater, respectively, than in the general population. These demand effective strategies for treatment in these key population (KP) groups. KP-specific service delivery and community-based interventions (CBI) are both determined to improve HIV response yet local CBI programs have not been evaluated within the Philippines. This study aims to evaluate care cascade outcomes in a KP-led, community-based HIV test-and-treat center and to determine factors that affect these outcomes.

METHODS: A retrospective cohort analysis was done among those who were diagnosed in a KP-led, community-based HIV test-and-treat center in the Philippines from January 2016 to March 2019. Enrollment among each component of the HIV care cascade and its predictors were determined.

RESULTS: Mere comparison with national estimates show apparent benefits. Largest attrition in the cascade of the KP-led, community-based center occurs in linkage to care while nationally, it is on viral load measurement. Using 90-90-90 UNAIDS outcomes measure, 75.3% were retained on ART and 87.5% were virally suppressed in the KP-led center, higher than national estimates 60% and 17%, respectively. Sexually-transmitted co-infection (*aOR*=.56, *p*=.047) was found to be a barrier to ART initiation while history of female sexual encounter (*aOR*=3.96, *p*=.000) and condom use (*aOR*=4.577, *p*=.000) were facilitators. Having more than one comorbid and/or co-infection at diagnosis, polypathology (*aOR*=.61, *p*=.038), makes viral suppression less likely but employment (*aOR*=1.60, *p*=.033) leads to otherwise.



[Figure 1. Comparison of HIV care cascade outcomes]

CONCLUSIONS: Care cascade outcomes among KP may be known to be poorer relative to the general population but outcome in this KP-led community-based intervention is promising. Results suggest that predictors go beyond clinical parameters and include behavioral and socio-economic factors. These factors are needed to be addressed to reach the UNAIDS 90-90-90 target.

PED1218

CROWDSOURCING OPEN CONTEST AS A TOOL FOR PRE-EXPOSURE PROPHYLAXIS (PREP) PROMOTION AND COMMUNITY ENGAGEMENT IN A U.S. HIV HIGH-BURDEN AREA

J. White[1], A. Matthews[2], M. Henry[3], M. Moran[1], K. Page[4], C. Latkin[1], J. Tucker[5], C. Yang[1]
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Community Expert Solutions, Durham, United States, [3]J.O.Y Baltimore and Know Your Place Movement, Baltimore, United States, [4]Johns Hopkins University School of Medicine, Baltimore, United States, [5]University of North Carolina, School of Medicine, Chapel Hill, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP) is an efficacious biomedical intervention that can reduce new HIV infections and is one of the four pillars of the U.S. Department of Health and Human Services (HHS) Ending the HIV Epidemic Initiative. Black communities in the southern U.S. bear a high burden of HIV, and yet PrEP awareness and uptake remain low. Novel approaches to promote PrEP are particularly needed. Open contests, a form of crowdsourcing, involve recruiting a large number of community members to develop solutions to public health problems in the form of a contest. My Voice My Choice (MVMC) was a crowdsourcing open contest for PrEP promotion messages among Black communities in Baltimore.

DESCRIPTION: Working with a community steering group, MVMC utilized social media and in-person events to engage communities for novel ideas that can promote PrEP awareness and update. Top finalists were chosen by a community panel of judges and community voting.

LESSONS LEARNED: MVMC received a total of 79 valid submissions in less than 3 months. Majority of the contestants (83%) were Black/African American, 40% were aged 18 to 24, 65% self-identified as homosexual, gay, queer, same gender loving, bisexual or pan sexual, and 73% had never taken PrEP. Top finalists were chosen after 155 online votes were submitted by community members in Baltimore. Qualitative in-depth interviews were conducted with 17 contest participants self-reported as non-Hispanic Black. The interview guide was developed using findings from HIV prevention research among Black sexual minority men in Baltimore and feedback from the com-

munity steering group. Thematic analysis was conducted on the qualitative interviews. Findings reveal crowdsourcing open contests to be a mechanism for fostering culturally meaningful PrEP promotion, building rapport with communities, and community engagement.

CONCLUSIONS/NEXT STEPS: MVMC demonstrated the feasibility and acceptability of a crowdsourcing open contest approach in the creation of community-engaged PrEP promotion messages. Crowdsourcing open contests can be a useful tool for PrEP promotion and other health promotion among U.S. Black communities. This approach could be used to identify and implement programs and policies that are more responsive to community needs and build up existing community assets.

PED1219

ONLINE TECHNOLOGIES AS SPACES OF 'RISK' AND OPPORTUNITY: COMMUNITY-BASED OUTREACH AND TESTING USING ONLINE SEXUAL NETWORKING APPLICATIONS IN THE PHILIPPINES

B.M. Hollingshead[1,2,3], A. Bourne[1], G. Dowsett[1]
[1]Australian Research Centre in Sex, Health and Society (ARCSHS), La Trobe University, Melbourne, Australia, [2]New Zealand AIDS Foundation, Auckland, New Zealand, [3]New Zealand People Living with HIV Stigma Index, Positive Women, Auckland, New Zealand

BACKGROUND: The HIV epidemic in the Philippines has been expanding rapidly, with most new diagnoses occurring among 'men who have sex with men' (MSM). However, the social contexts in which MSM negotiate HIV risk in the country remain underexamined, especially given the new and evolving phenomenon of seeking partners online via sexual networking technologies. 'Apps' have become a means of information dissemination and health promotion, yet the role of these interventions in the Philippines is unclear.

METHODS: The methodology comprised qualitative research conducted between July and November 2018 in Manila, the Philippines. Twenty key informant interviews and three focus group discussions were conducted with healthcare workers from community-based HIV/AIDS organisations and local government units, as well as policymakers, activists and researchers. This research sought to analyse emerging healthcare interventions that seek to reach MSM via sexual networking apps, with participants discussing the interventions delivered and how they perform.

RESULTS: The expanding epidemic was seen as being driven by new social contexts of sex as more MSM seek sex online. Sexual networking apps were seen as an opportunity for intervention, with participants reporting the capacity to reach new 'discreet' sexual subjectivities and the 'hard to reach'. Healthcare workers create profiles on sexual networking apps to raise awareness of HIV, message individuals deemed to be at high risk, and encourage HIV testing, with interventions seen to provide a window onto bodies of risk. While these address key areas of need, such as barriers to accessing information and service utilisation for underserved groups, their potential impact is limited due to the one-to-one style of engagement. Furthermore, healthcare workers report difficulty in their ability to link people to care.

CONCLUSIONS: Online technologies facilitate new ways to negotiate risk, and new opportunities for healthcare workers to intervene. While these interventions provide a community-based form of testing and may reach MSM otherwise inaccessible through physical outreach, they have created new complexities for healthcare workers by reconfiguring boundaries between them and target populations. Such interventions provide a new form of surveillance, with the impact on risk reduction unclear. Furthermore, sufficient resources are not provided to link patients testing positive to treatment.

PED1220

WORKING WITH YOUNG PEOPLE TO DESIGN AND IMPLEMENT AN INTERVENTION FOR PREP UPTAKE AND PERSISTENCE

S. Otticha[1], M. Hartmann[2], K. Agot[1], A. Minnis[2], S. Roberts[2]
[1]Impact Research and Development Organisation, Research, Kisumu, Kenya, [2]RTI International, Women's Global Health Imperative (WGHI), San Francisco, United States

BACKGROUND: Adolescent girls and young women (AGYW) in Kenya experience heightened risk for HIV, which is compounded by high rates of gender-based violence (GBV). We used a participatory process involving AGYW in developing an intervention to support their pre-exposure prophylaxis (PrEP) use in the context of GBV and gender inequality in Siaya County, Kenya.

DESCRIPTION: We conducted formative research with 24 AGYW to understand PrEP and GBV related challenges and intervention preferences.Through a series of 3 consultations with our youth advisory board (YAB), youth guided our formative research, interpreted results, and participated in a human-centred design workshop to identify appropriate interventions and contribute to their design. Additional workshops following intervention development helped pre-test the manualized components, including specific activities, language, and implementation factors.

LESSONS LEARNED: YAB engagement in the design of formative research, interpretation of results, intervention design and testing led to an intervention responsive to AGYW's stated needs for PrEP support in the context of their relationships. While the intervention conceptualized at the proposal stage of the research was clinic-based GBV screening and counselling, the formative research and YAB feedback identified a need to work at the community level, engage men in the intervention, and provide peer support. This led to the development of a manualized support club for AGYW interested in PrEP, community-based male sensitization sessions addressing male partner concerns with PrEP and couples-based community events. Intervention pre-testing with YAB and AGYW helped further refine the intervention, including specific stories for drama-based activities and the implementation of these performances at the couples' events. The intervention is being evaluated for acceptability and effectiveness through a six-month pilot community randomized control trial nested within the DREAMS program. Thus far nearly all (94%) participants reported they would recommend it to a friend.

CONCLUSIONS/NEXT STEPS: Youth engagement is critical to designing appropriate interventions addressing complex issues that affect them such as PrEP use in the context of GBV. Formative research with AGYW and early feedback from our YAB resulted in significant changes to the intervention design, as well as contextual changes to improve its implementation. While the pilot RCT is ongoing, preliminary findings suggest its acceptability.

PED1222

LESSONS FROM A COMBINATION PREVENTION APPROACH TO REDUCE TRANSMISSION OF HIV AMONG 15 – 29-YEAR-OLDS IN THE CONTEXT OF A GENERALIZED HIV/AIDS EPIDEMIC

C. Hulett[1], D. Kisyombe[1], N. Miller[1], E. Khulik[2]
[1]Pact Eswatini, Mbabane, Eswatini, [2]Pact DC, Washington, United States

BACKGROUND: Adolescent girls and young women (AGYW) in Eswatini are highly impacted by HIV. 29.8% of HIV+ females 15 – 24 years are unaware of their HIV status, while among those who are aware of their status, 83.7% are on treatment and 81.2% are virally suppressed[i]. Pact's PEPFAR/USAID-funded Triple R project responds to the HIV prevention needs of priority populations, especially AGYW, to halt to the spread of HIV and mitigate its impact on Eswatini.

[i] Swaziland HIV Incidence Measurement Survey (SHIMS) 2: 2016-2017

DESCRIPTION: After Triple R conducted vulnerability assessments in 2018, the project linked AGYW to trained Life Mentors (LMs) who used a 'safe spaces' model to deliver HIV prevention messaging on risk awareness, condom use, HTS, PrEP and PEP, livelihoods and linking AGYW to clinical services. A critical component of this approach was a combination of one-on-one and small groups mentorship in which LMs guide AGYW through discussions that directly impact their risk to HIV by using specially designed job aids.

LESSONS LEARNED: AGYW feedback through the mentorship activities provided valuable lessons on factors hindering their agency to protect themselves from infection. Prominent issues identified included economic dependence on sexual partners; low self-esteem; lack of condom negotiation skills; and, not knowing how to select a partner who cares about you. This feedback was then used to adapt the mentorship content to address these barriers.

	FY2018	FY2019	FY2020(Q1)
# AGYW Reached with HIV Prevention Messaging	15105	36584	12048
# AGYW Linked to Livelihood Activities	0	7774	3304
# AGYW Reached with HTS	2162	6542	1925
HIV Case Identification	31(1.4%)	152(2%)	25(1.3%)
# AGYW Reached with PrEP	0	176	297

[Table]

CONCLUSIONS/NEXT STEPS: Providing a tailored combination HIV prevention package driven by beneficiary feedback improves their understanding of risk and uptake of services. Strengthening SBCC components builds individual self-worth, provides practical skills on applying this knowledge (i.e. negotiating condom use) and provides support for linkages to services that will enable AGYW to gain economic independence. Altogether, this gives AGYW the agency to fully utilize the HIV prevention services that are then made available to them and reduces their risk of infection.

PED1223

A COMMUNITY-BASED INTERVENTION (MEN'S SPACES) TO ENGAGE MEN IN HIV AND SEXUAL HEALTH SERVICES IN MALAWI: A PILOT STUDY

I. Robson[1], M. Mphande[1], K. Phiri[1], K. Balakasi[1], M. Nyirenda[1], E. Chikuse[1], M. Sanena[1], A. Amberbir[1,2], S. Gupta[1,2], K. Dovel[1,2]
[1]Partners in Hope, Lilongwe, Malawi, [2]University of California, David Geffen School of Medicine, Division of Infectious Diseases, Department of Medicine, Los Angeles, United States

BACKGROUND: Men continue to have worse health outcomes than women, including greater HIV-related morbidity and mortality. Gender disparities are, in part, due to men's underutilization of health services. Further, men have inadequate knowledge or perceived importance of their own health. We developed and piloted a community-based intervention, "Men's Spaces", for men to discuss their health concerns, gain information about their own sexual health risks and needs, and develop strategies to overcome barriers to men's use of health services.

METHODS: We conducted formative data to inform intervention design: in-depth interviews with men (n=20) and focus group discussions with married women and Health Advisory Committees (n=46) across four communities in Southern Malawi. The Men's Spaces intervention was piloted in the same villages and included a one-time interactive session with men aged 25-40 regarding their sexual health, healthy relationships, strategies to overcome facility-level barriers to care, and blood-pressure screening and HIV testing/treatment. Exit surveys and medical chart reviews were conducted following Men's Spaces. Data were collected between October 2018 – June 2019.

RESULTS: Formative data show that men desired interventions focused on improving their own sexual health, strengthening intimate relationships, and promoting health seeking behaviour to facilitate income generation activities in the future. Men desired interventions with their peers in informal settings rather than formal, class-room style interventions. Men's Spaces was implemented with 183 men across four villages. The intervention lasted for an average of 3 hours with ~45 men per session. Attendees were mid-age (median 30yrs), 70% working, 61% had >2partners in past 12months, and 62% had not tested within 12months. All attendees reported they would attend Men's Spaces again and would encourage their peers to attend. 75% of attendees received HIV self-test (HIVST) kits and 44.3% used HIVST and immediately reported their test results to intervention staff. Six (7.4%) men were newly diagnosed as HIV-positive and five (83%) initiated ART that day.

CONCLUSIONS: Men were ready and willing to engage in health services and desired interventions focused on their own sexual health, strengthening romantic relationships, and income generation. A community, peer-based intervention was feasible and acceptable for men.

PED1224

NOVEL MECHANISMS FOR DIFFERENTIATED OUTREACH USING VIRTUAL PEER SUPPORT AND ACCESS TO HIV PREVENTION-TREATMENT SERVICES AMONG MSM AND TRANSGENDER YOUTH ACROSS INDIA

S. Rawat[1], A. Dange[1], D. Baruah[1], S. Sen[2], V.R. Anand[1], V.V. Patel[3]
[1]The Humsafar Trust, Research, Mumbai, India, [2]UM-DAE Centre for Excellence in Basic Sciences, University of Mumbai, Mumbai, India, [3]Albert Einstein College of Medicine, Montefiore Health System, Bronx, United States

BACKGROUND: Virtual spaces are being increasingly used by men who have sex with men (MSM) and transgender women (TGW) for establishing social and sexual connections. E-support groups may be crucial to providing LGBTQ communities access to peer-support, information, and linkage-to-care, particularly those closeted and in unfavorable socio-legal environments. This abstract present mixed-methods analyses of a LGBTQ youth e-support group serving as a novel model for differentiated outreach.

METHODS: We launched a secret Facebook™ Group (e-group) in 2011 for LGBTQ young people in India to provide an easy online forum for social connections, moderated by trained volunteer peers. Access to the private group is approved by moderators/members and group-members could then use the e-group to socialize online, seek information, or passively observe. We used Facebook™ Analytics and Grytics™ online-software to extract, de-identify, and analyze all e-group's posts/comments, likes/reactions from 2011–2018. To understand how the e-group may foster support for differentiated care, we used grounded theory to qualitatively analyze extracted posts/comments, and identified key themes and mechanisms.

RESULTS: Data (n=8372 members) comprised 107,934 posts, 802,554 comments, and 1,748,070 reactions. Most members were in age-groups 18–24 (25%) and 25–34 years (45%), respectively. Members were frequently from Mumbai (28%), Delhi (8%), Pune (7%), Kolkata (7%), and Bangalore (6%). Most posts (94.5%) received reactions and 57.8% posts received comments. Themes most often discussed were: Safer sex/HIV/STI information; crises support; social acceptance; general health; social events. The e-group facilitated access to crises support, addressed social acceptance issues (coming out, bullying, pressures to conform to heteronormativity), provided information on social events, and peer connections. Posts using quizzes, campaigns on HIV/STI information featured prominently to educate group members and appeared to increase members' motivation to test by improving HIV/STI awareness and risk-perception, addressing stigma, and countering myths/misconceptions.

CONCLUSIONS: E-support groups play an important role in connecting MSM and TGW youth to care and support services by fostering social support as well as HIV/STI awareness. In settings where marginalized youth fear HIV-related stigma, moderated online social support groups could contribute significantly to existing HIV interventions as a differentiated outreach and care model engaging hard-to-reach MSM and TGW youth.

PED1225

RESILIENCE IN AN AIDS SERVICE ORGANIZATION (ASO): INTEGRATING SYRINGE SERVICES, NARCAN TRAINING AND POST-OVERDOSE SUPPORT INTO HIV/STI PREVENTION AND TREATMENT FOR PEOPLE WHO INJECT DRUGS IN THE USA

M. Akstin[1], L. Cunningham[1], L. Brown[1], T.B. Masvawure[2], E. Foley[3]
[1]AIDS Project Worcester, Worcester, United States, [2]College of the Holy Cross, Health Studies Program, Center for Interdisciplinary Studies, Worcester, United States, [3]Clark University, International Development, Community and Environment, Worcester, United States

BACKGROUND: AIDS Project Worcester (APW) was established in 1987 and is located in Worcester, Massachusetts, the second largest city in New England. As the structural drivers of HIV and AIDS have shifted in the Northeast United States, APW has expanded its focus to include emerging health issues that affect its clientele. It was the first agency to offer Narcan (naloxone) trainings in central Massachusetts. We describe how our Narcan training and syringe services programs have strengthened our relationships with people who inject drugs (PWID) and enabled us to link them to HIV/STI and addiction care, support and treatment services.

DESCRIPTION: APW began offering Narcan training in central Massachusetts in 2007. Since 2011, we have trained 9,732 individuals, provided 5,606 refills, and saved 2,216 lives. Our Narcan program paved the way for a comprehensive syringe services program and a coordinated opioid overdose response in Worcester county. The syringe services program currently works with 2,005 unique clients and has had 4,910 client encounters through outreach and agency visits. In 2018, we collected 160,017 used syringes and distributed 97,817 clean syringes. We also provided blankets, food, condoms, conducted 2,100 HIV and STI screenings, and linked PWID to HIV and addiction care. We also piloted a post-overdose support team (POST) program that links overdose survivors to HIV/STI and addiction support services.

LESSONS LEARNED: APW's resilience as an ASO is attributable to three things: a) our adaptability, and responsiveness to emerging community needs; b) our "no-barriers to care" goal, through which we bring services directly to our clients via mobile outreach and; c) our cultural competency, as APW staff resemble clients in terms of race, ethnicity, class, sexual orientation, gender identity, addiction history, HIV status, and immigration status.

CONCLUSIONS/NEXT STEPS: As the opioid epidemic continues in the USA, ASOs need to provide comprehensive services to PWID. APW's incremental approach of community-engagement through Narcan training and scaling up to syringe services provides a model for other ASOs seeking to expand into this arena. Our Narcan trainings have helped de-stigmatize injection drug use and addiction support services in our target communities, and strengthened our relationships with PWIDs and their social networks.

PED1227

SUPPORTING THE '10-10-10': RESULTS FROM THE CEDAR PROJECT WELTEL MHEALTH PROGRAM FOR HIV-RELATED HEALTH AND WELLNESS AMONG YOUNG INDIGENOUS PEOPLE WHO HAVE USED DRUGS IN TWO CANADIAN CITIES

K. Jongbloed[1], S. Pooyak[2], V. Thomas[3], M.E. Pearce[1], A. Mazzuca[1], R. Sharma[1], L. Demerais[3], R.T. Lester[1], M.T. Schechter[1], P.M. Spittal[1], For the Cedar Project Partnership

[1]University of British Columbia, Vancouver, Canada, [2]Aboriginal HIV/AIDS Community-Based Research Collaborative Centre (AHA Centre), Victoria, Canada, [3]The Cedar Project, Prince George, Canada

BACKGROUND: Systemic oppression and lack of cultural safety impede Indigenous people living with/at risk of HIV from engagement with HIV prevention and cascade of care services. Indigenous leaders remain concerned that Indigenous peoples may become the '10-10-10' of UNAIDS 90-90-90 targets – those who are left behind. They have called for responses that acknowledge impacts of colonial traumas, while building on Indigenous resilience and wholistic perspectives of health and wellbeing. Simultaneously, use mHealth has emerged as a tool to support engagement in the HIV care cascade and ancillary services.

METHODS: This study presents results from a two-way supportive text messaging program to support HIV-related health and wellness among young Indigenous people who have used drugs living with/at risk of HIV. Cedar Project's WelTel mHealth Program consisted of a bundle of supports, including a mobile phone, long-distance plan, and weekly supportive text messaging with case managers. It was offered to 131 (52 HIV+) young Indigenous people who have used drugs in the Cedar Project cohort in two Canadian cities. Each Monday, a 'how's it going?' text was sent automatically. Case managers responded to all participants and followed up with those who replied with a specific need. A mixed-methods approach evaluated to what extent and in what ways the program supported HIV-related health and wellness.

RESULTS: Overall, 5217 'how's it going?' texts were sent September 2014-January 2016, of which 3982 (76.3%) received a response. The mHealth program facilitated family (re)connections and strengthened relationships with Case Managers to facilitate engagement with a variety of mainstream and Indigenous supports. Flexibility allowed it to be participant-led and self-determined. Among participants with HIV, receiving mHealth was associated with 2.09 (95%CI: 1.15-3.79; p=0.016) increase in odds of HIV viral suppression compared to the pre-program period. Among all participants, mHealth was associated with slightly higher mean resilience score (adjusted coefficient=3.02; 95%CI:0.34-5.69; p=0.027).

CONCLUSIONS: Cedar Project WelTel mHealth Program represents a feasible and valued tool to support culturally-safe, healing-informed, and strengths-based responses to HIV among young Indigenous people who have used drugs living with/at risk of HIV that nurtures connection to culture and family, and supports self-determination over health and wellness.

PED1228

CHAMPS IN ACTION: AN INNOVATIVE CAPACITY BUILDING MODEL OF HIV-STIGMA REDUCTION

J.P. Wong[1], S. Lome[2], J. Liu[1,1], A. Bisignano[2], M. Owino[2], A.T.-W. Li[2]

[1]Ryerson University, Toronto, Canada, [2]Committee for Accessible AIDS Treatment, Toronto, Canada

BACKGROUND: HIV stigma perpetuates marginalization and limits access to inclusive care by people living with HIV (PLHIV). Drawing on the positive empirical results of CHAMP, a stigma reduction intervention, an alliance of five ethno-specific AIDS service organizations (ASOs) in Toronto, Canada, secured resources to scale-up this intervention in Toronto's African, Caribbean, Asian and Latino communities. The planned total number of participants in the 5-year CHAMPs-In-Action project is 160/year x 4 years (n=640), with an anticipated minimum diffusion of reaching 800/year x 4 years (n=3200) through HIV championship and stigma reduction activities.

DESCRIPTION: Phase One of CHAMPs-In-Action uses an integrated model of 'train-the-trainer' and 'community-of-practice' to build capacity among PLHIV, project staff, volunteers and community leaders from the five alliance ASOs and communities to become CHAMP facilitators and advocates of stigma reduction. The program consists of:

(1) a four-day training on Acceptance and Commitment Therapy and Collective Empowerment;

(2) follow-up practice workshops, and

(3) onsite mentorship to deliver the CHAMP intervention.

Mixed methods of surveys and group discussions were used pre- and post- training to assess effectiveness of CHAMP and the implementation model.

LESSONS LEARNED: In Phase 1, two cohorts of PLHIV and non-PLHIV leaders, staff, and volunteers (n=20) completed the train-the-trainer program. Pre-and post-training measures showed that graduates had:

(1) increased psychological flexibility;

(2) improved mental wellbeing;

(3) increased self-efficacy in dealing with stigma related adversities, and,

(4) more confidence to challenge HIV stigma at the personal and community levels.

In addition, 17 graduates (85%) engaged in the community-of-practice program, in which they were mentored to co-facilitate seven community CHAMP stigma-reduction programs organized by the Alliance ASOs. These graduates trained 123 participants, including service providers, LGBTQ and newcomers in their respective ethnocultural communities.

CONCLUSIONS/NEXT STEPS: Community-based stigma reduction is critical to addressing HIV vulnerability in marginalized communities. The effectiveness of anti-stigma interventions can be enhanced through the integrated use of strength-based training, structured mentorship, and capacity building. Furthermore, community partnership and alliance building are needed to provide structured opportunities that enable graduates to apply their newly gained knowledge as CHAMP facilitators and HIV champions.

PED1229

INCREASING CLIENT ENROLLMENT IN COMMUNITY CLIENT LED ART DELIVERY (CCLAD) MODEL: A QUALITY IMPROVEMENT PROJECT AT FORT PORTAL REGIONAL REFERRAL HOSPITAL IN UGANDA

W. Akobye[1], K. Cyril[2], N. Jennifer[3], T. Carol[4], F. Tugumisirize[5], H. Mugarra Kabahwezi[6], P. Elyanu[6]
[1]Baylor College of Medicine Children's Foundation, Medical, Fort Portal, Uganda, [2]Fort Portal Regional Referral Hospital, Medical, Fort Portal, Uganda, [3]Fort Portal Regional Referral Hospital, Psychosocial, Fort Portal, Uganda, [4]Kabarole District Local Government, Medical, Fort Portal, Uganda, [5]Fort Portal Regional Referral Hospital, Administration, Fort Portal, Uganda, [6]Baylor College of Medicine Children's Foundation, Research, Kampala, Uganda

BACKGROUND: Differentiated ART Service Delivery (DSD) at Fort Portal Regional Referral Hospital (FPRRH) was launched in November-2017. Uganda's Ministry of Health recommends 15% of the stable clients in HIV care receive services in CCLAD. Clients in CCLAD model were 1.5% (93/6174) in September-2018 at FPRRH. We set out to increase the percentage enrollment in CCLAD to 15% by April-2019.

DESCRIPTION: A quality improvement project was conducted in FPRRH from September-2018 to April-2019. Health workers, expert clients, Community Based organizations, People Living with HIV/AIDS (PLHIV) representatives brainstormed to identify causes of low CCLAD enrollment using fishbone diagram. These were facility-related (inadequate clients' categorization according to clinical stability, knowledge gaps among health workers, inability to capture DSD in Electronic Medical Records, low data use, suboptimal advocacy for CCLAD) and client-related (limited awareness on DSD, stigma, and non-disclosure). Interventions from a driver diagram were prioritized in a focusing matrix, and included client sensitization by PLHIV, training of health workers, backlog DSD entry in revised EMR, weekly joint data review, and linkages to DSD by CBOs. Data on CCLAD was extracted from EMR, exported to excel, analyzed for proportion in CCLAD among the stable clients in Fast Track Drug Refill (FTDR).

LESSONS LEARNED: CCLAD enrolment increased from 1.5 % (93/6174), to 16 % (756/4768) between September-18 and February-2019; 507 (67%) were female. Six clients were under 25years.
During scale up of isoniazid preventive therapy and ART optimization in January-2019, clients in Fast Track Delivery Model who started a new drug were classified as unstable before MoH provided guidance in March-19 to maintain their clinical status as stable. This affected the denominator for the indicator.

[Figure 1. Proportion of stable clients enrolled in CCLAD at FPRRH Sep-18 to Apr-19.]

CONCLUSIONS/NEXT STEPS: Health worker training, peer-led patient engagement, and improved data systems favor implementation of new models/policies in HIV/AIDS management. Guideline modification should be adapted for DSD models, for uniform scale up of quality.

PED1324

ACCELERATING HIV STATUS DISCLOSURE BY CAREGIVERS OF ORPHANS AND VULNERABLE CHILDREN TO LAY SOCIAL WELFARE VOLUNTEERS IN TANZANIA

A. Exavery[1], A. Barankena[1], J. Charles[1], E. Kuhlik[2], T. Mbwambo[1], E. Jere[1]
[1]Pact, Dar es Salaam, Tanzania, United Republic of, [2]Pact, Inc., Washington, DC, United States

BACKGROUND: HIV status disclosure facilitates access to HIV-related prevention and treatment services and increases opportunities for social support, implementing HIV risk reduction with partners, and index testing for sexual partners or children. This study compares rates over time of adult HIV status disclosure to a community social welfare program in Tanzania.

METHODS: Community social welfare volunteers enrolled and provided services to caregivers of orphans and vulnerable children (OVC). The analysis included caregivers who were assessed at baseline (2017–2018), received services, and assessed again at midline (2019). Caregivers who reported having been tested were asked to voluntarily report the status in order for the volunteer to establish service needs and provide referrals. Those who reported their HIV status as negative or positive were grouped as "disclosed", and those who knew their status but did not report it were documented as "undisclosed." Stuart-Maxwell tests compared disclosure rates at baseline and midline.

RESULTS: 140,664 caregivers (72% female) from 70 councils of Tanzania were analyzed. The mean age of the caregivers at enrollment was 47.4 years. Overall HIV status disclosure to the project was 81.3% at baseline and significantly increased to 96.1% at midline ($p<0.001$). Disclosure at baseline varied significantly by sociodemographic characteristics ($p<0.05$), with higher disclosure in females, urban residence, and higher education, but the variations disappeared at the midline and remained around 96% across all sociodemographics ($p>0.05$). Male disclosure increased from 80.2% to 96.2%. Of the 26,329 caregivers who did not disclose their HIV status at baseline, 94.7% (n=24,933) had disclosed by midline, and 10.2% (n=2,675) were HIV positive and linked to HIV services.

CONCLUSIONS: Lay social welfare volunteers successfully encouraged HIV status disclosure among OVC caregivers in Tanzania, thereby broadening its services for HIV-positive caregivers. In contrast to volunteer health cadres, lay social welfare volunteers provide continuous and frequent household support for a wide range of needs, such as economic strengthening, parenting, and violence prevention and response. Integrating adult HIV disclosure is a strategy to improve linkages to index testing for children and linkage to ART services. Introduction of a validated adult HIV risk screening tool for use by community volunteers is recommended.

PED1230

NOT TOO YOUNG TO KNOW: ADVOCACY PROJECT BY ADOLESCENTS GIRLS AND BOYS AGES 10 TO 14 IN NIGERIA USING PHOTOVOICE

D. Faponle[1], B.E. Ajidagba[2], M.-M. Falana[3], F. Bamigboye[3]
[1]Kids & Teens Resource Centre, Monitoring & Evaluation, Akure, Nigeria, [2]Academy for Health Development, Programmes, Ile-Ife, Nigeria, [3]Kids & Teens Resource Centre, Programmes, Akure, Nigeria

BACKGROUND: Adolescents in Nigeria are at significant risk for poor sexual and reproductive health (SRH) outcomes. Adolescents, especially girls, have the right to be informed about Comprehensive Sexuality Education (CSE). Lack of knowledge often leads to risky behavior such as unsafe sex, which can lead to unwanted pregnancies, Sexually Transmitted Infection (STI), including HIV.

Not Too Young To KNOW": is a Women Deliver small grant-funded advocacy project aimed at building the capacity of young adolescent in using photography and digital storytelling to advocate for the adoption of the 2018 revised International Technical Guidance on Sexuality Education guidelines in Nigeria's secondary schools.

DESCRIPTION: From January to June 2019, 19 adolescents ages 10-14 from four different schools in Akure South Local Government Area in Ondo State, Nigeria were selected to participate in the project. They were trained on photography and photovoice and were able to use photography to show their knowledge gap on sexual and reproductive health especially HIV/AIDS. A photo exhibition took place, where the adolescents discussed and presented their pictures to stakeholders, parents, community and religious leaders and school principals. The concluding part of the project was various advocacy visits by the adolescents to the commissioners of Education, Health, Youth and Sports Development in the State. It gave the adolescents a platform to speak on issues about their sexual and reproductive Health and advocate for CSE in their schools.

LESSONS LEARNED: The project moved the needle for gender equality, it provided equal opportunities for girls and boys to acquire knowledge and skills in photography and advocacy. The inclusion of girls as beneficiaries and advocates for their reproductive health and rights brought awareness on the need for education and empowerment of the girl child. Majority of the duty bearers in the State are now important players in the quest for the adoption of the international technical guidelines on CSE in secondary schools.

CONCLUSIONS/NEXT STEPS: Involvement of the young adolescents as advocates on this project helped with the success recorded on the project. This approach should be continued in future advocacy projects where the direct benefactors and stakeholders are involved and engaged in implementation.

PED1231

GAPS IN HIV TRANSMISSION KNOWLEDGE AMONG MEN WHO HAVE SEX WITH MEN, TRANSGENDER WOMEN, AND GENDER QUEER INDIVIDUALS IN TWO CITIES IN ZIMBABWE

L. Parmley[1], I. Chingombe[2], M. Mapingure[2], O. Mugurungi[3], J.H. Rogers[4], A. Hakim[5], S. Miller[1], G. Musuka[2], T.G. Harris[1]
[1]ICAP at Columbia University, New York, United States, [2]ICAP at Columbia University, Harare, Zimbabwe, [3]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe, [4]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Harare, Zimbabwe, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Atlanta, United States

BACKGROUND: Key populations (KP), including men who have sex with men (MSM), transgender women (TGW), and gender queer (GQ) individuals are disproportionately affected by HIV. To inform HIV prevention programming among KP in Zimbabwe, we evaluated HIV knowledge in these groups

METHODS: From March-July 2019, 1194 MSM and 344 TGW/GQ ≥18 years were recruited for a cross-sectional survey using respondent-driven sampling (RDS) in Harare and Bulawayo, Zimbabwe. Consenting participants completed a questionnaire and received HIV testing. Comprehensive HIV knowledge—aligned to the UNAIDS definition—was defined by correctly answering five questions on HIV transmission risk. Additional questions specific to anal sex were also asked. We report sample proportions without RDS weights as the sample did not reach convergence for HIV. Pearson's Chi-squared and Fisher's exact tests were used to assess prevalence differences by demographic factors and HIV status.

RESULTS: Overall, comprehensive HIV knowledge varied significantly by city (Harare: 80.5%, Bulawayo: 65.6%, p<0.0001) but not by HIV status (p>0.05). For Bulawayo it varied significantly by gender identity; for Harare the difference was of borderline significance (Table). Approximately half of participants were aware that anal sex was the most efficient mode for sexual acquisition of HIV. Overall TGW/GQ participants were more aware than MSM (p<0.0001); this remained significant for Harare when stratified by city (Table). In both cities, less than one-third of participants reported condomless receptive anal intercourse (CRAI) put them most at risk for HIV, with most reporting that CRAI and condomless insertive anal sex carry the same risk (Table).

	Harare					Bulawayo				
	MSM (n=431)		TGW/GQ (n=287)			MSM (n=763)		TGW/GQ (n=57)		
	%	n	%	n	p-value	%	n	%	n	p-value
Comprehensive knowledge of HIV	83	357	77	221	0.05	67	513	44	25	<0.001
Anal sex is the most efficient method for sexual acquisition of HIV	55	236	65	187	0.006	48	364	56	32	0.22
If a condom is not used, what kind of anal sex puts you most at risk for HIV? (n=2 don't know/refuse)										
Insertive anal sex	3	14	2	5		28	211	18	10	
Receptive anal sex	19	82	23	65		20	152	32	18	
Both have the same risk	77	334	75	216		48	363	51	29	
Both have no risk	0	1	0	1	0.397	5	35	0	0	0.043

CONCLUSIONS: Findings highlight gaps in HIV transmission knowledge related to anal sex. TGW/GQ participants were more aware of the risks of HIV transmission through anal sex than MSM though awareness was low. Given misperceptions, messaging around HIV risk and CRAI for MSM and TGW/GQ should be strengthened in Harare and Bulawayo.

CONDOMS AND LUBRICANTS

PED1232

KHUSHPUDIS (PLEASURE PACKS): INNOVATIVE CONDOM-LUBRICANT PACKAGES FOR SOCIAL MARKETING AMONG YOUNG MSM-TG USING ONLINE AND OFFLINE PROMOTION TECHNIQUES IN MUMBAI, INDIA

A. Siroya[1], S. Rawat[2], T. Chopade[1], R. Jagtap[3], V. Anand[4]
[1]The Humsafar Trust, Advocacy, Mumbai, India, [2]The Humsafar Trust, Research, Mumbai, India, [3]The Humsafar Trust, Finance, Mumbai, India, [4]The Humsafar Trust, Mumbai, India

BACKGROUND: Young men who have sex with men (MSM) and transgender communities in India are disproportionately affected by HIV. Socio-cultural stigmas and hostile legal environments decrease access to HIV testing, condom–lubricant use, factual safe- sex information and increase vulnerability to violence. Water-based lubricant use is limited by inadequate provisions under national programs and unviable commercially-available options. Yaariyan, a youth LGBTQ initiative of The Humsafar Trust implemented a unique social-marketing strategy to facilitate MSM and TG youth's access to condoms, lubricants, and safe-sex information.

DESCRIPTION: Supported by The MTV Staying Alive Foundation, the social marketing campaign created Khushpudis (Pleasure Pack) comprising one regular condom, flavoured condom, a single-use water-based lubricant sachet, and a booklet on safe sex (condom- and lubricant use, pre- and post-exposure prophylaxis) and crises redressal information. The packaging allowed for Khushpudis to be carried discreetly and to convey safe-sex information in pocket-fit, non-clinical and colourful formats. The Khushpudis were launched and distributed free at an LGBTQ community-event in August 2017 and were socially marketed at INR 20/pack and offered a 50% discount to students and underprivileged communities from September 2017 following a selfie campaign. In the short duration around 5000 Khushpudis have been socially marketed to MSM and TG youth and 1000 distributed for free at community events.

LESSONS LEARNED: Strategies like Khushpudis encourage newer outlook toward existing strategies. Flavoured and regular condoms emphasize on consistent condom use for penetrative and oral sex. Single-use water-based lubricant sachets facilitate uptake and use of lubricants as opposed to commercially-available indiscreetly packaged lubricants. Vibrant, pocket-fitting educational material allows easy stowing in safe spaces such as wallets for later reading or around sex/facing crises. Further, community-led social media campaigns facilitate ownership and contribute to awareness and uptake.

CONCLUSIONS/NEXT STEPS: Khushpudis should be integrated into national HIV programs with an emphasis on social marketing for sustainability. Social media must be explored as a channel for promotion and demand generation. Groups working with key populations should consider adopting a model like Khushpudis into existing interventions to facilitate condom–lubricant use and uptake, particularly among young MSM and transgender populations.

COUPLES- OR FAMILY-CENTRED APPROACHES

PED1233

"THESE MEDICINES ARE THE ONES TO SAVE MY MARRIAGE": DYADIC-LEVEL INFLUENCE AND DECISION-MAKING AMONG SERODISCORDANT COUPLES IN TANZANIA RECEIVING ACCESS TO PREP

V. Fonner[1], J. Mbwambo[2], J. Ntogwisangu[2], C. Bailey[1], L. Goldsamt[3], I. Hamidu[2], T. Ruta[2], K. O'Reilly[1], M. Sweat[1]
[1]Medical University of South Carolina, Charleston, United States, [2]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of, [3]New York University, New York, United States

BACKGROUND: The Dyadic-based Diagnosis, Care, and Prevention (DDCP) study in Tanzania is investigating the feasibility and acceptability of an intervention among HIV-serodiscordant couples that provides access to pre-exposure prophylaxis (PrEP) for HIV-negative partners, regardless of the HIV-positive partner's ART status. This qualitative sub-study aimed to understand and describe how relationship factors affect couples' decisions to:
(1) participate in the DDCP study and
(2) utilize PrEP.

METHODS: Semi-structured in-depth interviews were conducted among a subset of DDCP participants (n=22) as well as individuals involved in serodiscordant relationships who declined study participation (n=9). Interviews focused on couples' decision-making regarding study participation and couple-level influence on medication use. Interviews were transcribed verbatim and translated from Kiswahili into English. Data were analyzed using thematic analysis.

RESULTS: Within the 31 interviews conducted, the mean age was 47.9 years (range: 32-71), and the sample included 13 HIV-negative (4 women; 9 men) and 18 HIV-positive individuals (12 women; 6 men). Discordance was often viewed as "a two-person secret" shared between partners. Couples perceived partner support as critical to maintaining the discordant relationship and showed support through gestures such as providing medication reminders and encouraging HIV testing for HIV-negative partners. Decisions to participate in the study were made jointly. No participants reported feeling coerced to join, although individuals frequently described being encouraged to join by their partners. Among non-participants, reasons for declining participation included lack of time/convenience or misunderstandings about the study. Among participants, PrEP availability for HIV-negative partners diminished HIV-positive partners' feelings of guilt and worry, and HIV-negative partners viewed PrEP as a means to support their partners while maintaining their health. Partners mostly supported the other's medication use. Overall HIV-positive partners' ART use did not significantly impact HIV-negative partners' PrEP use and vice versa. Couples frequently reported maintaining condom use while taking PrEP and/or ART, although for couples not using condoms, PrEP was seen as essential for relationship survival.

CONCLUSIONS: On the dyadic level, introducing PrEP was generally well-received by couples and provided important benefits to both partners. For research studies involving serodiscordant couples, partner-level influence on participation should be considered throughout recruitment, informed consent, and study implementation.

PED1234

COPING STRATEGIES AND NEEDS AMONG HIV-NEGATIVE WOMEN MARRIED TO HIV-POSITIVE MEN WHO HAVE SEX WITH MEN IN CHINA

W. Cao[1], H.M. Wong[2], C. Chang[3], E.P. Agudile[4], A.M. Ekström[5]
[1]Brown University, Center for Evidence Synthesis in Health, School of Public Health, Providence, United States, [2]The University of Hong Kong, Hong Kong, Hong Kong, SAR of China, [3]Peking University, Peking, China, [4]Harvard University, Boston, United States, [5]Karolinska Institutet, Stockholm, Sweden

BACKGROUND: Stigma towards men who have sex with men (MSM) is prevalent, and many MSM are married to women. This study aims to provide a comprehensive understanding of coping strategies and the need for support among HIV-negative women in serodiscordant relationships with HIV-positive MSM.

METHODS: We conducted 19 qualitative in-depth interviews with women in serodiscordant relationships, who were recruited by collaborating with two local health organizations in Sichuan, China in 2017. Semi-structured interviews were conducted, and the interview guide included questions about their feelings, experiences, and coping strategies in terms of the serodiscordant relationship and sexual orientation/behavior. Qualitative data were transcribed verbatim and analyzed using content analysis. Two of the authors read all transcripts and selected coding units independently. The identification of sub-categories and categories was discussed and agreed upon among a panel with a multidisciplinary background.

RESULTS: Among the 19 enrolled participants, the median age was 39 years (range: 26-55), all participants had full-time or part-time jobs, and 9 participants attended college or above. We found that these women utilized multiple coping strategies both within the family and externally. Coping strategies within the family included keeping husbands' HIV diagnosis confidential, integrating husband's HIV treatment management into family routines, restoring spousal relationships, protecting themselves from HIV infection, denying, self-blaming, and persuading the husbands to see the psychiatrist due to homosexual behaviors. Coping strategies outside the family included seeking information from multiple sources, peer support, and online support. Participants expressed needs for more information, psychological support, stigma reduction, and special counseling on how to handle their husband's homosexual identity and/or behavior.

CONCLUSIONS: HIV-negative women married to HIV-positive MSM develop both adaptive and maladaptive coping strategies, and the majority of these women's needs are unmet under the current service system in China. A tailored supporting system is needed by considering their attitude and acceptance towards HIV-positive status and homosexual behavior.

DEVELOPMENT AND POVERTY ALLEVIATION

PED1235

PLACEMENT OF TRANSGENDER YOUTH AS CORPORATE EMPLOYEES: HELP TO MAINSTREAM THE COMMUNITY AND REDUCES THE VULNERABILITIES TO HIV & AIDS

Y. Singh[1], V.R. Anand[2], S. Tamanna Gupta[2], M. Sivasubramaian[2]
[1]The Humsafar Trust, Capacity Building, New Delhi, India, [2]The Humsafar Trust, New Delhi, India

BACKGROUND: The Indian Supreme Court's NALSA judgement of 2014 recognized the third gender, and recommended for reservations in jobs and education. Despite this, the enrolment by TG youth in educational institutes and jobs remains suboptimal. The literacy rates continue to remain low among TGs, and the community sustains on begging and sex work, which increases their vulnerability towards HIV and other health issues. The Humsafar Trust, conducted sensitization meetings with corporate's in Delhi NCR to highlight the issues of community and facilitate the process of recruitment.

DESCRIPTION: Under the CONNECT project, we conducted meetings with representatives of corporates e.g VLCC beauty & wellness chain, Lemon tree hotels and Publicis Sapient. The various meetings were attended by 40 corporate representatives . They were sensitized on issues faced by the TG community in general and with regard to employment. The support was provided to develop the TG inclusive HR policies, in subsequent meetings. The suitable candidates were referred and recruitment was done.

LESSONS LEARNED: As a success among our referred candidates, 11 Transgender persons were placed in these corporate houses. The CV pool of candidates was developed by Humsafar and accordingly the suitable candidates were referred to the corporate houses. The soft skill training was imparted to the candidates to face the interviews confidently. The challenges are very basic level positions were offered to candidates, in initial phase.

CONCLUSIONS/NEXT STEPS: The engagement and sensitization with corporate houses in long run will help the corporate's to develop TG friendly HR policies and build confidence to hire managerial level staff from Transgender communities. There is need to organize Job conclaves for community persons at larger level. The policy makers should focus on integration of trans youth into the mainstream society and at workplace.

PED1236

EFFECT OF FINANCIAL COMPENSATION ON SAME-DAY ACCEPTANCE OF VMMC IN ZAMBIA; BREAKING IT DOWN BY AGE AND RISK PROFILE

M. Kabila[1], L. Aladesanmi[1], R. Kamboyi[2], C. Laube[3], O. Chituwo[4], C. Toledo[5]
[1]Jhpiego, Affiliate of Johns Hopkins University, Jhpiego, Lusaka, Zambia, [2]Ministry of Health, Health Services, Lusaka, Zambia, [3]Jhpiego, Affiliate of Johns Hopkins Universisity, Jhpiego, Baltimore, United States, [4]Centers for Disease Prevention and Control, CDC/DDPHSIS/CGH/DGHT, Lusaka, Zambia, [5]Centers for Disease Prevention and Control, CDC/DDPHSIS/CGH/DGHT, Atlanta, United States

BACKGROUND: A well-documented barrier to voluntary medical male circumcision (VMMC) is financial loss due to time taken to undergo and recover from VMMC. We explored whether financial compensation would increase VMMC uptake in Zambia in different age groups and risk segments.

DESCRIPTION: We implemented a 2-phased outcome evaluation of an enhanced demand creation strategy and financial compensation to increase VMMC uptake among high-risk men in two districts. Eligible men were aged ≥18 years, uncircumcised, and self-reported ≥1 HIV risk factor in the past 6 months. The study was in 6 sites, and enrolled 6820 men in Phase 1 and 3734 in Phase 2. In Phase 1, we implemented human-centered design-informed interpersonal communication (IPC) and VMMC referral. In Phase 2 financial compensation of 200 ZMW (~US$17) was added. The VMMC same-day conversion rate (% high-risk men circumcised on same day of enrollment) was calculated by phase, risk segment and age group. Analysis was done using the Cochran–Mantel–Haenszel test with Haldane-Anscombe correction.

A behavioral-psychographic segmentation model by IPSOS was used with priority segments based on risk being Knowledgeable hesitants, Self-reliant and, Socially-supported believers.

LESSONS LEARNED: There is increased uptake of same-day circumcision with financial compensation among clients aged 20 and above. In particular, there is a marked increase in uptake for clients aged 25 to 34-years.

Odds ratios for same-day acceptance of VMMC indicate that clients aged 25-29 years are 12.9 times more likely to go for same-day VMMC when financial compensation is offered, with men in high risk segments aged 20-24, 25-29 and 35-39 being 11 to 38 times more likely.

Risk Segment	18-19	20-24	25-29	30-34	35-39	40-44	45-49	50+
All Clients	3.8 (P<.001)	7.7 (P<.001)	11.9 (P<.001)	7.5 (P<.001)	8.3 (P<.001)	26.4 (P<.001)	32.5 (P<.001)	35.6 (P<.001)
Blue (Self-reliant believers /high Risk)	1.6 (P=.43)	1.9 (P<.001)	15.6 (P<.001)	14.2 (P=.001)	13.7 (P=.002)	8.8 (P=.02)	7.8 (P=.12)	.7 (P=.88)
Brown (Traditional believers/high risk)	4.1 (P=.001)	3.5 (P<.001)	5.1 (P<.001)	4.8 (P=.04)	6 (P=.07)	16.3 (P=.002)	3.1 (P=.51)	7.3 (P=.18)
Green (Friends-driven hesitants / Average risk)	3.9 (P=.01)	11 (P<.001)	7.1 (P<.001)	3 (P=.19)	8.4 (P=.10)	1.8 (P=.76)	4.3 (P=.34)	3 (P=.54)
Grey (Indifferent rejecters /low risk)	4.4 (P<.001)	7.3 (P<.001)	6.2 (P<.001)	7.4 (P<.001)	2.4 (P=.39)	28.7 (P=.001)	46 (P<.001)	11.3 (P=.08)
Orange (Knowledgeable hesitants/high Risk)	3.1 (P=.1)	12.8 (P<.001)	38 (P<.001)	11 (P=.007)	10 (P=.07)	1.3 (P=.90)	2 (P=.73)	2.8 (P=.56)
Purple (Scared rejectors /low risk)	17.6 (P<.001)	6.6 (P<.001)	109.6 (P<.001)	35.6 (P<.001)	5.6 (P=.03)	15.2 (P=.03)	6 (P=.27)	21 (P=.02)
Yellow (Socially-supported/high Risk)	2.9 (P=.23)	15.8 (P<.001)	25.5 (P<.001)	8 (P=.03)	8.3 (P=.03)	2.9 (P=.009)	6.7 (P=.23)	4.5 (P=.38)

[Table]

CONCLUSIONS/NEXT STEPS: There is a marked increase in uptake of VMMC. The high likelihood of same-day acceptance of VMMC by men aged above 20 years indicates this is a viable alternative for mop up strategies targeting the priority age groups, high risk men and to meet ambitious coverage targets.

PED1237

INTEGRATING A MULTI-LEVEL ADHERENCE PROGRAM INTO HIV CARE MANAGEMENT: LESSONS LEARNED FROM THE UNDETECTABLES VIRAL SUPPRESSION PROGRAM IN NEW YORK CITY

G. Gambone[1], A. Thomas-Ferraioli[1], M. Feldman[1], T. Tran[1], A. Kang[1], V. Shubert[2], V. Poitevien[2], G. Wersching[2], N. Harris Tolson[2]
[1]New York City Department of Health and Mental Hygiene, Bureau of HIV, Queens, United States, [2]Housing Works, Brooklyn, United States

BACKGROUND: The Undetectables Viral Load Suppression (VLS) Program is a client-centered model that employs social marketing and a toolkit of evidence-based adherence supports, including collaborative care planning, adherence counseling, and financial incentives (FIs) for VLS. The program aims to improve retention in care and linkage to support services and to increase VLS among vulnerable populations.

DESCRIPTION: The Undetectables was developed and piloted by Housing Works, a NYC-based non-governmental organization, beginning in 2014. The program supports people living with HIV (PLWH) with individual and/or structural barriers to adherence. Clinicians, care managers, and clients collaboratively develop a care plan including strategies from The Undetectables toolkit: case conferencing; Motivational Interviewing-based counseling; adherence support groups; adherence devices; directly observed therapy; and quarterly $100 FIs for lab results showing a viral load <200 copies/mL. The social marketing campaign features superheroes called The Undetectables to engage clients, staff, and the community.

Encouraged by preliminary findings from Housing Works' two-year demonstration project, the New York City Health Department and Housing Works convened stakeholders in mid-2015 to explore program scale-up. In July 2016, over $1.5 million in City-funded contracts were awarded to seven NGOs, community health centers, and hospitals. To date, over 2,700 New Yorkers have been enrolled.

LESSONS LEARNED: As of December 31, 2018, among enrolled clients engaged in care (n=1,870), 87.2% were virally suppressed. Among clients enrolled for the entire 2018 calendar year (n=1,195), 70.4% demonstrated evidence of durable VLS. Based on implementation experience and study of existing research on FIs, recommendations include: identify essential vs. recommended program components; build organization-wide support; leverage existing care management resources; package FIs with other evidence-based strategies; deliver program to individuals with barriers to adherence, including people who have achieved VLS but continue to face barriers; and plan for sustainability.

CONCLUSIONS/NEXT STEPS: Interventions that support durable VLS are needed for individual health, to prevent new HIV infections, and to advance health equity. The Undetectables provides a blueprint for local governments and NGO partners to bring promising interventions to scale.

PED1238

ENHANCING FINANCIAL MANAGEMENT THROUGH COMMUNITY-LED INTERVENTION: A FOCUS ON COMMUNITY ORGANIZATION MANAGED BY FSWS IN INDIA

M. Battala[1], B. Mahapatra[1], S.K. Patel[1], N. George[1], S. Mukherjee[1], N. Saggurti[2]
[1]Population Council, HIV/AIDS Program, New Delhi, India, [2]Population Council, New Delhi, India

BACKGROUND: The majority of female sex workers (FSWs) in India are highly vulnerable in multiple dimensions, which is primarily due to a lack of financial security. This study describes a peer-led community-led intervention on financial management abilities to economically empower FSWs in Andhra Pradesh.

DESCRIPTION: A list of FSWs associated with CO was prepared and screened for consent to participate in the intervention. A total of 218 FSWs gave consent and further divided into 12 groups with 15-20 in each. The leaders from each group received a 3-day classroom training in phase-1 by an external expert. Topics included financial literacy, services from formal financial institutions, loans, business management, networking with stakeholders, risk mitigation, and financial planning. In phase-2, group leaders trained their community members in community settings, which were closely monitored by a subject expert. The entire intervention on financial management delivered in 3 half-day sessions involving both classroom training and participatory approaches. A total of 177 FSWs received in the full intervention in community settings, where FSWs did participate. Lack of time to engage for three days, loss of income and prior commitments were the key reasons cited for non-participation.

LESSONS LEARNED: The evaluation using a quasi-experimental study suggests that there was a gain of eight percentage points (pp) in financial security among FSWs in the intervention area than those in the control area. Further, there was a 27 pp increase in financial autonomy among FSWs in the intervention area as against the control area. Delivery of intervention contents prepared based as per the need of community enhanced their financial capability and confidence in negotiating with clients and other stakeholders. Engaging and community sensitive contents in the training modules along with sensitized trainers make it more acceptable and effective in communicating the messages.

CONCLUSIONS/NEXT STEPS: Financial security and management are critical for a vulnerable population like FSWs. While this intervention clearly demonstrated that short training modules delivered in small sessions can be effective, there needs to be more comprehensive engagement with the communities to address their social, financial and structural vulnerabilities.

PED1239

HEP C TIP: EMPLOYING A COMMUNITY-BASED TREATMENT INCENTIVE PROGRAM TO ENGAGE AND RETAIN VULNERABLE PERSONS IN CURATIVE HEPATITIS C TREATMENT

V. Shubert[1], T. Ghose[2], V. Poitevien[3], G. Saunders[4], B. Hennessey[4], N. Archer[1]
[1]Housing Works, Research and Policy, Brooklyn, United States, [2]University of Pennsylvania, School of Social Policy and Practice, Philadelphia, United States, [3]Housing Works, Community Health Care, Brooklyn, United States, [4]Housing Works, Healthcare Compliance and Special Projects, Brooklyn, United States

BACKGROUND: Social and structural barriers to hepatitis C (HCV) testing, treatment uptake, and cure among marginalized communities include substance use, homelessness, poverty, comorbidities like HIV infection, and complicated insurance protocols. We examine the effectiveness of the Hepatitis C Treatment Incentive Program (TIP) intervention, an 18-month demonstration project at a large U.S. metropolis-based health and social service agency providing primary care (PC) to persons marginalized by experiences of homelessness, behavioral health issues and extreme poverty. TIP's integrated approach includes social marketing, interdisciplinary care planning, care navigation, behavioral health interventions, adherence support groups, and up to five $100 gift card incentives over a one-year period for achieving and maintaining an undetectable HCV RNA viral load (<15 IU/mL). We hypothesized that financial incentives, added to integrated care, can improve HCV identification, treatment engagement and adherence among socially vulnerable persons.

METHODS: We utilized a repeated measures, longitudinal design to compare outcomes for participants in PC during the 18 months pre-TIP implementation (October 1, 2014-March 31, 2016) (n=716) to outcomes for PC participants during the 18-month TIP intervention (April 1, 2016- September 30, 2017) (n=2,870).

RESULTS: Among HCV RNA positive PC clients, 56% were HIV positive; 46% Black; 35% Latinx; 22% cisgender female; and 4% transgender. Compared to non-TIP participants, a significantly higher proportion of TIP participants knew their HCV status (77% vs. 60%, p<0.0001). HCV prevalence was high in both groups: 18% in the intervention, vs 25% in the comparison group, compared to a prevalence of 1.4% in the general population. Among those who knew their status, 43% in the intervention group engaged in treatment, compared to 16% in the comparison group (p<0.0001). Among those engaged in treatment, 90% achieved sustained virologic suppression in the TIP group, compared to 67% in the comparison group (p<0.05).

CONCLUSIONS: The TIP intervention significantly improved HCV outcomes at every point of the treatment cascade among a population with an extremely high prevalence of HCV infection who face multiple barriers to successful HCV care. Our results indicate that an integrative, multidimensional intervention like TIP, implemented in a community-based setting, can improve HCV treatment engagement and outcomes for socially vulnerable communities.

HARM REDUCTION

PED1240

LOW THRESHOLD HARM REDUCTION SERVICES ENGAGE MSM IN DRUG & ALCOHOL TREATMENT

M. Discepola[1], W. Temple[2], R. Andrews[3], R. Lugo[4]
[1]San Francisco AIDS Foundation, Behavioral and Substance Use Health, San Francisco, United States, [2]San Francisco AIDS Foundation, The Stonewall Project, San Francisco, United States, [3]San Francisco AIDS Foundation, The Stonewall Project/PROP, San Francisco, United States, [4]San Francisco AIDS Foundation, The Stonewall Project/Cheers Queers, San Francisco, United States

BACKGROUND: Men who have sex with men (MSM) are more likely than the general population to experience substance use disorder (SUD), which increases HIV/HCV infection risk and leads to poorer HIV medication and PrEP adherence. Yet drug treatment programs--for MSM and others--oftentimes fail to meet the complicated needs of drug users. Most treatment clinics require abstinence, have burdensome enrollment procedures and are expensive--leading to only 1 in 10 people with SUD receiving treatment and a 58% drop-out rate. To engage and retain MSM in substance use treatment, The Stonewall Project (TSP) provides a continuum of harm reduction services that validate the experiences of MSM and provide evidence-based treatment to reduce harms caused by drugs and alcohol.

DESCRIPTION: Founded in 1998 by and for MSM, TSP began as a response to methamphetamine use and HIV transmission in San Francisco, and has expanded to address all forms of substance and alcohol use. Services are free, with many low-threshold access points, including syringe access; an enhanced contingency management program for people using stimulants; brief alcohol counseling; and, walk-in group and individual counseling. In one year, 22% (n=170) of 789 people who used drop-in services entered the formalized "enrolled" program, receiving one-on-one counseling and weekly support groups. Of 237 people who enrolled within the past year, 87% were retained through program "graduation" or left with satisfactory progress.

LESSONS LEARNED: TSP is able to mitigate traditional barriers to care, regardless of substance use status, complexity of client presentation, or ability to pay. Lower-threshold services enable clients to move toward higher levels of engagement, while diminishing risk of HIV/HCV exposure. Best practices include: creating welcoming spaces; providing hospitality and easy-to-eat food; not enforcing rigid group times; supporting harm reduction goals; giving non-judgmental support; allowing programming to evolve to meet clients' changing needs; and, hiring and training staff with diversity of identities and substance use histories.

CONCLUSIONS/NEXT STEPS: By funding and creating lower-threshold services, care providers reduce and sometimes entirely overcome barriers to care that higher-level services demand. A continuum of services allow participants to access services wherever they may be in stages of change.

HIV TESTING (INCLUDING HIV SELF-TESTING)

PED1241

HIV TESTING RECOMMENDATIONS BY BRAZILIAN HEALTHCARE STUDENTS: A CASE VIGNETTES SURVEY

F. Escaleira[1], B. Pousada[1], V. Avelino-Silva[1,2], R. Vasconcelos[2]
[1]Faculdade Israelita de Ciencias da Saude Albert Einstein, Medical School, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de Sao Paulo, Department of Infectious and Parasitic Diseases, Sao Paulo, Brazil

BACKGROUND: Provider-initiated HIV Testing and Counseling (PITC) is a WHO-recommended strategy to increase testing in vulnerable populations. However, provider's initiative for recommending an HIV test may be inadequate. In this study, we investigated patterns and determinants of HIV testing recommendations by healthcare students from Sao Paulo, Brazil.

METHODS: Willingness to recommend HIV testing was evaluated using 3 case vignettes. 2 vignettes presented patients with the same HIV risk profile but varying by a single characteristic (case 1, high vs. low socio-economic status; case 2, MSM vs. heterosexual), randomly assigned to participants. Case 3, describing a patient with no apparent risk factors, was presented to all participants. We explored patients' and participants' characteristics as potential predictors of willingness to recommend HIV testing.

RESULTS: 300 medical and nursing students completed the survey. Most were female (63%), young (median 21yo), white/caucasian (85%), with heterosexual orientation (82%); 48% declared having a religion.

In case 1 (young, female, university student with tuberculosis symptoms), 62% reported they would likely/very likely recommend HIV testing when the patient lived in a poor neighborhood, whereas 54% would do so when the patient lived in a rich neighborhood (p=0.145).

In case 2 (young, asymptomatic male reporting occasional unprotected sex) 68% reported they would likely/very likely recommend HIV testing when the patient was MSM, whereas 47% would do so when the patient was heterosexual (p<0.001).

In case vignette 3, only 40% (95%CI 35-46%) of the participants declared they would likely/very likely recommend HIV testing for a young, female patient without apparent risk factors.

Self-perceived HIV risk, depicted by moderate/high concern with HIV infection in the past year, was significantly associated with HIV test recommendation in case vignette 3 (p=0.040).

	Group A N=147	Group B N=153	p-value
Case 1 A 25-year-old, female, university student presenting with tuberculosis symptoms	Patient lives in a **poor** neighborhood	Patient lives in a **rich** neighborhood	0.145
Likely/very likely to recommend HIV testing (%)	91 (62)	82 (54)	
Case 2 A 22-year-old asymptomatic male patient with a stable partner and reporting occasional unprotected sex, undergoing routine exams prior to a sabbatical leave	Patient is **homosexual**	Patient is **heterosexual**	**<0.001**
Likely/very likely to recommend HIV testing (%)	100 (68)	72 (47)	
Case 3 A 35-year-old asymptomatic female patient undergoing a routine pap-smear test. She reports having sex with casual partners over the past year, always with condoms.			
Likely/very likely to recommend HIV testing	122 (41; 95% CI 35-46%)		
Students with moderate/high concern with HIV infection (N=84)	42 (50; 95% CI 39-61%)		
Students with no/low concern with HIV infection (N=216)	80 (37; 95% CI 31-44%)		

[Table]

CONCLUSIONS: Our findings suggest that healthcare students' willingness to recommend HIV testing is low and recommendations were more frequent to a hypothetical MSM. Moreover, self-perceived HIV risk was associated with more frequent HIV testing recommendations. Educational strategies should be adopted to increase awareness and PITC.

PED1242

TO TELL OR NOT TO TELL: WILLINGNESS TO DISCLOSE A POSITIVE HIV STATUS AMONG INDIVIDUALS PREPARING FOR HIV TESTING DURING ANTENATAL CARE IN TANZANIA

R. Mwamba[1], S. Sao[2], B. Knettel[1], L. Minja[3], H. Osaki[3], G. Kisigo[1,4], J. Ngocho[4,5], J. Renju[5,6], B. Mmbaga[1,5,4,3], M. Watt[1,7]
[1]Duke Global Health Institute, Durham, United States, [2]Duke University, Durham, United States, [3]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of, [4]Kilimanjaro Christian Medical Center, Moshi, Tanzania, United Republic of, [5]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]University of Utah, Salt Lake City, United States

BACKGROUND: Status disclosure among people living with HIV can help individuals attain social support, reduce transmission risks, and improve care engagement. This study assessed willingness to disclose a positive HIV status among pregnant women and their partners preparing for HIV testing in two antenatal care (ANC) clinics in Moshi, Tanzania.

METHODS: Participants included pregnant women (n=624) and male partners (n=295) who were attending a first ANC appointment between April and December 2019. Prior to HIV testing, participants completed a survey using audio computer assisted technology. Willingness to disclose a positive HIV status was measured using a four-item scale with questions about hypothetical disclosure to one's inner circle (partner and/or family member) and outer circle (friend and/or neighbor). Univariable and multivariable regression models were used to examine factors impacting willingness to disclose.

RESULTS: Willingness to disclose a positive HIV status was high, with 95% of participants willing to disclose to at least one person. Participants were more willing to disclose to a member of their inner circle (n= 868; 94%) than outer circle (n=468; 51%). Univariable analysis indicated that participants were more willing to disclose if they had higher education, higher socioeconomic status, and more perceived social support. Participants who were younger were more willing to disclose to their inner circle; those who were older and male were more willing to disclose to their outer circle. In the final multivariable model, having higher levels of education (OR=2.033; 95% CI:1.177, 3.513) and higher perceived social support (OR=1.071; 95% CI:1.017, 1.127) were significantly associated with willingness to disclose to one's inner circle. Being older (OR=1.031; 95% CI: 1.007, 1.056), male (B=1.804; 95% CI: 1.321, 2.462) and having higher levels of perceived social support (OR=1.050; 95% 1.022, 1.080) were significantly associated with willingness to disclose to one's outer circle.

CONCLUSIONS: Among participants preparing to take an HIV test, willingness to disclose a positive HIV status was high. Targeting individuals with lower education and less perceived social support can lead to improvements in disclosure. Pre-test counseling can be a period to develop commitment to HIV disclosure in the event of a positive test result.

PED1243

EVALUATION OF THE AWARENESS, KNOWLEDGE AND USE OF HIV SELF TESTING AMONG MEN WHO HAVE SEX WITH MEN IN SOUTHEAST NIGERIA

E. Onwe[1], E.F. Chukwurah[2], K. Omosigho[3]
[1]Foundation for Better Health and Human Rights (FBHR), Director of Programs, Abakaliki, Nigeria, [2]Ebonyi State University, Department of Medical Laboratory Sciences, Abakaliki, Nigeria, [3]University of Ibadan, Department of Medical Physiology, Ibadan, Nigeria

BACKGROUND: Despite global actions to end AIDS, gaps in HIV testing persist among minority populations which negatively affect our ability to reach 90-90-90. HIV self testing (HIVST) is an innovation that is intended to reduce gaps in HIV testing and could serve men who have sex with men (MSM) who because of privacy concerns, stigma, discrimination, or other barriers do not use facility-based, standard HIV testing. This study purpose is to understand knowledge, availability and uptake of HIVST, in order to maximize testing and especially the use of self-testing among MSM in Southeastern Nigeria.

METHODS: The study was conducted between March and September 2019 among 400 MSM in the 5 states (Abia, Anambra, Ebonyi, Enugu and Imo State) that makeup Southeastern region of Nigeria. Participants were selected through respondent-driven sampling and were interviewed using a standard questionnaire about knowledge and use of HIVST. Data was analyzed using SPSS 23.0. Descriptive statistics were calculated and presented as frequencies and percentages.

RESULTS: Of 400 study participants, 90% had no idea what HIVST is. Only 10% knew what HIVST is all about. Among these, only 6% have actually seen and used the HIVST Kit while 94% had no idea what it looks like. Also, 30% and 23% got the information about HIVST from friends and local NGOs respectively, whereas the remaining 47% were informed through social media.

In terms of willingness to use HIVST kits, 86% were willing to use this innovation because it is simpler and easier. The remaining 14% wouldn't use it because the test might not show the actual result or they would not be able to manage the test result on their own and would need a counselor to support them during the test.

CONCLUSIONS: MSM communities in southeastern Nigeria are not well informed about HIVST and should therefore be the focus of increased awareness to the minority populations. During the study, participants expressed concerns on the need for support at the time of testing. It is important that HIVST interventions also find ways to provide support to participants who test for HIV given their concerns about learning their results alone.

PED1244

WHY EMERGENCY DEPARTMENT PATIENTS AGED 13 - 24 YEARS DECLINE AVAILABLE HIV TESTS, AND HOW CHANGES TO TESTING PROTOCOLS MAY INCREASE UPTAKE

I.D. Aronson[1,2], R. Freeman[1], L. Chernick[3], M. Bugaighis[3], L.A. Marsch[4], A.S. Bennett[1,2], D. Des Jarlais[2]
[1]Digital Health Empowerment, Brooklyn, United States, [2]New York University, School of Global Public Health, New York, United States, [3]Columbia University Irving Medical Center, Department of Emergency Medicine, New York, United States, [4]Dartmouth College, Hanover, United States

BACKGROUND: Youth in the United States face disproportionately high rates of HIV infection, and are far less likely to test for HIV compared to older populations. While federal and some state guidelines

mandate routine HIV testing of patients >= 13 years, many (in particular racial and sexual minority youth) are never offered testing, or are offered tests in ways they overwhelmingly decline. While evaluating a tablet-based intervention designed to increase youth HIV testing, our team interviewed participants about their HIV testing experience in a high-volume New York City emergency department (ED).

METHODS: Research assistants (RAs) enrolled ED patients aged 13 – 24 (N=240), who were randomized to receive HIV test offers via a tablet (n=120) or face-to-face (n=120). RAs conducted semi-structured interviews examining why participants did or did not accept HIV testing when offered. Interviews were audio recorded, then transcribed for later analysis. Two experienced qualitative researchers examined transcripts for themes emerging across interviews.

RESULTS: Approximately 75 percent of participants in both groups declined HIV testing. Interviews analyzed to date show participants declined testing because they: did not want to give blood samples; were ashamed when offered testing in front of other patients; did not want to accept in the company of a parent or guardian. Participants frequently said they would have tested if an oral swab test had been available, if they had been asked in a private space where other patients could not hear the offer or their response, or if they had visited the ED without a parent (in New York State minors can legally test without parental consent).

CONCLUSIONS: Participants expressed clear preferences for how tests are offered (privately as possible), and for particular modes of testing (oral swab rather than blood draw). It may emerge that even slight changes to the way tests are offered (e.g. individually rather than in the presence of others) can increase HIV test rates among highly vulnerable youth populations who frequently do not accept available testing. In settings where private face-to-face test offers are infeasible due to a lack of staff resources, tablet computers can potentially provide increased privacy while also offering HIV prevention education.

PED1245

CLOSING THE GENDER GAP: WHO ARE WE FINDING THROUGH INDEX TESTING IN KENYA?

J. Mwangi[1], F. Miruka[1], H. Muttai[1], M. Mugambi[2], L. Odero[3], V. Ojiambo[3], L. Soo[3], S. Anangwe[4], N. Talam[4], A. Katana[1], E. Wangari[1], A. Waruru[1]
[1]U.S Centers for Disease Control and Prevention (CDC), Division of Global HIV & TB (DGHT), Nairobi, Kenya, [2]Ministry of Health, NASCOP, Nairobi, Kenya, [3]United States Agency for International Development, Health Population and Nutrition (HPN), Nairobi, Kenya, [4]Henry Jackson Foundation Medical Research International, Kisumu, Kenya

BACKGROUND: Identification of HIV-infected persons through HIV testing and counseling services and subsequent linkage to antiretroviral therapy remains a critical step towards achieving HIV epidemic control. While gains have been made, the progress has not been even across subpopulations, with men lagging in knowledge of their HIV status. Index case testing is an efficient case identification approach that follows the chain of HIV transmission to identify HIV-infected individuals across populations. We analyzed HIV testing data from PEPFAR DATIM for the period October 2016-September 2017 (FY 2017) to October 2018-September 2019 (FY 2019) and reviewed impact of index case testing in identifying people living with HIV in Kenya by sex.

METHODS: HIV testing facility-level aggregate data were analyzed, for those aged ≥15 years. We calculated HIV-positive yield from index-testing and other modalities as the number positive/number tested. To compare medians for number of HIV-positive tests and positive diagnoses across reporting period or by sex, we used the Kruskal-Wallis equality-of-populations rank test. To compare positivity by sex and across reporting periods, we used the extended Cochran-Mantel-Haenszel stratified test of association. We standardized identification rates per 100,000 tests.

RESULTS: Among those ≥15-years, the HIV-positive yield for index testing was 11,569 per 100,000 compared to 707 per 100,000 HIV-tests for other modalities. Between FY 2017 to FY 2019, there was an overall increase in the number of tests done through index testing from 119,700 to 215,404, p=0.027. The number of HIV-positive individuals identified through index testing increased significantly from 3,834 to 34,812 in the same period, p<0.001. Standardized HIV-positive yields for index testing were not significantly different by sex; 12,961 for females compared to 10,147 for males per 100,000 index-tests respectively (p=0.326). However, the contribution of index testing to overall positives identified was consistently higher among males than females, p<0.001 (figure).

CONCLUSIONS: We observed increased HIV-positive yield through index testing over time with no differences in proportions identified by sex. There was a higher contribution of index case testing to case identification among males compared to females. Continued scale-up of index-testing provides an opportunity to close the gender gap in case identification to support epidemic control.

PED1246

FACTORS ASSOCIATED WITH LATE PRESENTATION FOR HIV CARE IN UKRAINE, 2010-2018

M. Kornilova[1], Y. Sazonova[2]
[1]Alliance for Public Health, Monitoring and Evaluation, Kyiv, Ukraine, [2]Yale School of Public Health, Albany, United States

BACKGROUND: Late presentation for HIV care is a major issue everywhere across the World. In Europe, almost one-third of individuals infected with HIV do not enter health care until late in the course of their infection. In Ukraine, this proportion is even bigger. It's been increasing in the last 10 years and in 2018 40% of newly diagnosed with HIV had CD4 count <200 cells/mL. Late presentation for care is harmful to the infected person as it's associated with the higher morbidity, mortality and transmission. In this regard, it's critical to identify factors associated with late presentation for HIV care and to include susceptible, but neglected population in the focus of the HIV testing programs. In this study, we conducted an analysis of factors associated with late presentation with the goal to improve HIV screening strategy in Ukraine.

METHODS: For this study we conducted retrospective cohort analysis of 78,679 people registered in HIV care in 12 regions of Ukraine in the period of 2010-2018. Multiple logistic regression was used to identify the impact of the patients' characteristics on late presentation. Additionally, we conducted in-depth interviews with recently diagnosed HIV-positive patients who had CD4<200 cells/mL at the time of diagnosis.

RESULTS: Proportion of late presenters have increased from 31% in 2008 to 41% in 2018. Analysis conducted showed that late presentation was associated with the male gender AOR 1.2(95% CI 1.1-1.4), age 35+ AOR 4.7(95% CI 3.3-6.7), the history of unprotected sex AOR 3.2(95% CI 2.5-3.9) and presence of clinical symptoms of the advanced HIV-infection AOR 4.9(95% CI 3.9-6.1). According to the information obtained through in-depth interviews, late presenters often reported being offered HIV testing late, after already receiving various treatments for their health condition for some time.

CONCLUSIONS: Factors associated with late presentation were age 35+, male gender, unprotected sex. The HIV testing frequently offered late to the people who are likely to be diagnosed and already developed symptoms because they are not considered as key populations. This represents a missed opportunity for HIV diagnosis, highlighting the ongoing need for physician sensitization on HIV testing and education on clinical signs of the disease.

PED1247

IMPROVING UPTAKE OF HIV TESTING SERVICES AMONG SEXUAL PARTNERS OF INDEX CLIENTS THROUGH ASSISTED PARTNER NOTIFICATION: LESSONS FROM BAYLOR-UGANDA COE CLINIC

L. Engurat[1], N. Mukiza[1], R. Nabimba[1], I. Kassozi[1], A. Katawera[1], A. Kekitiinwa[1]
[1]Baylor College of Medicine Children's Foundation, Clinic, Kampala, Uganda

BACKGROUND: Assisted Partner Notification (APN) is an effective approach in identification of new HIV positive individuals whose implementation by Baylor-Uganda commenced in May 2018. By August 2018, only 51% of 312 elicited sexual partners to index clients had received HIV Testing Services (HTS). We share lessons from a quality improvement (QI) project to increase the proportion of elicited sexual partners of index clients at the Baylor-Uganda COE clinic who receive HTS from 51% to 90% between September and November 2018.
DESCRIPTION: A Work Improvement Team (WIT) comprising clinic staff and volunteer expert clients was constituted to address the gap. Root cause analysis using brainstorming, affinity diagram and fishbone techniques revealed reliance on self-notification and counsellor workload as hindrances. Changes tested using the Plan-Do-Study-Act cycle included training and mentorship of lay-testers, involvement of all staff in eliciting sexual partners of index clients following a CME on APN, and mostly weekly visits to the community to notify and test partners compared to Facility based. Progress was monitored using a QI journal updated together with the APN register during weekly data review meetings. Any partner who had not received HTS was included in the denominator for the next month.
LESSONS LEARNED: Between May and August 2018 we elicited 312 sexual partners, 37% being female while between September and November 2018, we elicited 381 of sexual partners, 33% were female and median age was 29 years (IQR: 25-36). All Partner HTS services were 100% in the community. The proportion of sexual partners tested increased from 51% (158/312) between May and August to 90% (381/423) between September and November 2018 (difference=39% (95% CI: 32.8-45.2) p-value <0.001.
CONCLUSIONS/NEXT STEPS: Engaging trained lay-testers, active community-based APN with partner HTS and weekly APN data audits dramatically improved partner HTS. Challenges of access were met with partners outside the catchment area of the Clinic. There is need to explore ways of accessing elicited sexual partners outside the clinic catchment area.

PED1248

IMPROVING ACCESS TO HIV TESTING AND TREATMENT SERVICES FOR MEN IN SOUTH AFRICA: A QUALITATIVE EVALUATION

C. Chinyandura[1,2], F. Buthelezi[2], H.E. Struthers[3], J.A. McIntyre[4], K. Rees[5]
[1]University of the Witwatersrand, Sociology, Johannesburg, South Africa, [2]Anova Health Institute, Public Health, Johannesburg, South Africa, [3]University of Cape Town, Division of Infectious Diseases and HIV Medicine, Department of Medicine, Cape Town, South Africa, [4]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [5]University of the Witwatersrand, Department of Community Health, School of Public Health, Johannesburg, South Africa

BACKGROUND: Data indicate that men in South Africa are less likely than women to test for HIV, have an increased likelihood of delaying and interrupting treatment. To improve testing and treatment initiation in men, the Score4Life project was developed in Johannesburg, an urban South African district. The project clinics/stores offer HIV testing and treatment initiation services to men 21 years and older. These pop-up clinics/stores combine several features to increase service uptake: extended working hours, quick service, male-only waiting areas, convenient locations where men gather (malls, taxi ranks) and an appealing and welcoming store design. This qualitative evaluation aimed to explore men's perceptions of the services and understand how the features of the service impacted on their access to HIV testing and treatment.
METHODS: A qualitative design was adopted to gather rich and in-depth information on the facilitators and barriers affecting men's access to HIV testing and treatment services. We conveniently selected 30 first and repeat service users at four Score4Life clinics/stores spread across Johannesburg. In-depth interviews were conducted using a semi-structured interview guide. NVivo12 software was used to code and categorize data and identify themes. The Socio-Ecological Model and the McIntyre access to health care framework were used to guide data analysis.
RESULTS: Participants were similar demographically: majority were single, unemployed and had matriculated. Participants preferred Score4Life clinics/stores compared to public clinics. Flexible working hours, convenient locations, quick service and positive staff attitudes were found to be key facilitators in men accessing HIV testing and treatment services. Fear, mistrust of service providers and perceived personal risks were cited as key barriers. 'Significant others' (sexual partners, family and friends) had an influential role on men's health outcomes. Gender of the service provider was perceived to be inconsequential to service provision.
CONCLUSIONS: Male focused services should increase the flexibility and options for accessing health services: flexible working hours, "one-stop services", co-location with other services and offering services in non-typical settings (workplaces, sports settings, malls), positive staff attitudes, and providing quick service. The supportive role of significant others to men's health should be harnessed through scaling-up partner notification and testing services.

PED1249

MOTIVATORS AND BARRIERS TOWARD HIV SELF-TESTING AMONG MEN WHO HAVE SEX WITH MEN IN TWO INDIAN CITIES

S. Rawat[1], A. Dange[1], M. Shunmugam[2], D. Baruah[1], V. Chakrapani[2], S.S. Solomon[3], A.K. Krishnan[3], S. Bharat[4], J. Mukherjee[5], B. Mohan[4], N. Singla[5], V. Verma[6], S. Rajan[6], V.R. Anand[1]
[1]The Humsafar Trust, Research, Mumbai, India, [2]Center for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [3]YRG Care, Chennai, India, [4]Tata Institute of Social Sciences, Mumbai, India, [5]International AIDS Vaccine Initiative, Delhi, India, [6]National AIDS Control Organization, Delhi, India

BACKGROUND: HIV self-testing (HIVST) is rapidly gaining prominence for facilitating HIV testing uptake among hard-to-reach communities. Despite recent decriminalization of consensual same-sex relations in India, stigma and lack of social acceptance invisibilizes men who have sex with men (MSM). As a step toward achieving 90-90-90, multiple strategies are needed to bolster HIV testing and linkage to treatment–care services, particularly among MSM, beyond the hotspot-based HIV interventions. This qualitative study thus explored motivators and barriers of HIVST among MSM in two cities (Mumbai and Vijaywada) in India.

METHODS: Eight focus group discussions (FGD), eight in-depth interviews (IDI) and eight key informant interviews (KIIs) were conducted in Hindi/English by trained interviewers, translated/transcribed, and thematically analyzed. FGDs and IDIs were conducted with kothi-, gay-, bisexual-, and versatile-identified MSM while KIIs were conducted with healthcare providers, HIV intervention agencies, and community leaders. All participants provided informed consent, and FGD/IDI participants were compensated INR 500. The study was approved by IRBs of all participating institutions.

RESULTS: The mean age of FGD participants (N=54) was 29.1 years; 41% had college education, with none reporting illiteracy, and 67% were single. In Mumbai, 43% (n=28) reported engagement in part-/full-time sex work. Mean age of IDIs participants (n=8) was 32.7. Two FGD and one IDI participants had prior HIVST awareness. Following motivators were reported: confidentiality; saving time; and convenience. Willingness for HIVST was influenced by several disadvantages of facility-based testing centers: travel costs, longer waiting time, inconvenient operating hours, fear of confidentiality breaches, and hesitation to provide address proof. Following barriers were reported: concerns about HIVST accuracy; lack of pre-/post-test counseling (expressed strongly by Vijaywada participants); and possible outing to family (kit disposal-related concerns). Participants from Mumbai were more willing to access HIVST from online platforms and to pay more (INR 100–200 vs. INR 20–150) for HIVST.

CONCLUSIONS: Overall, MSM reported HIVST as highly acceptable as participants perceived HIVST to offer greater convenience and confidentiality. HIVST can be recommended for Indian MSM with a focus on hard-to-reach MSM such as those on online spaces. Further research is recommended to examine service-delivery models for understanding HIVST uptake among these MSM.

PED1250

MEN'S PERSPECTIVES ON HIV SELF-TESTING STRATEGIES IN UGANDA: A QUALITATIVE STUDY

M. Bulterys[1], A. Mujugira[2], J. Mugisha[2], N.C. Ware[3], J. Fairbanks[1], C. Celum[1], M. Sharma[1]
[1]University of Washington, International Clinical Research Center, Seattle, United States, [2]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [3]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States

BACKGROUND: Men in Africa are less likely than women to test for HIV. HIV self-testing (HIVST) is a convenient and discrete alternative to facility-based HIV testing services (HTS) and could increase testing uptake and knowledge of HIV status among men. The Uganda Ministry of Health is scaling-up delivery of HIVST kits, including secondary distribution from pregnant women to their male partners. Assessing male perspectives on HIVST delivery strategies is critical to designing interventions to optimize uptake.

METHODS: We conducted seven focus group discussions with 45 men whose pregnant female partners were attending antenatal clinics in Kampala, Uganda, to understand men's perspectives on HIVST. Transcripts were transcribed and translated from Luganda to English and analyzed thematically by two coders using NVIVO software.

RESULTS: Men discussed several benefits of HIVST, including increased self-efficacy, time-efficiency and privacy of HIVST compared to HTS, and appeal of oral tests over blood tests. Men reported that HIVST kits allow testing of their non-regular partners before sex. However, they had strong concerns about the absence of counseling ("If you test positive, alone, you will kill yourself") and mistrust about the test's accuracy.

Fears about the impact on their relationship posed barriers if they tested HIV-positive or learned they were in a HIV serodiscordant partnership, leading to blame, accusations of infidelity, or abandonment. Men felt strongly that it is the responsibility of healthcare workers (HCWs) to counsel them about use of HIVST and expressed lack of confidence in their partner's knowledge.

Discussions highlighted prominent gender roles, testing barriers unique to men in this context, and men's strong desire to have a male HCW provide phone counseling with HIVST use and clinic follow-up for confirmatory testing. Men stressed the importance of community sensitization to educate them about the benefits of HIVST, to counteract men's distrust of the test, and distrust of their female partners who deliver the test to them.

CONCLUSIONS: Men expressed high interest in HIVST. Interventions will need to address men's concerns about counseling and HIVST accuracy. Community sensitization and male HCWs can increase men's HIVST uptake and clinic linkage.

PED1251

REASONS FOR SUBOPTIMAL HIV TESTING AMONG YOUNG ADULTS IN THE UNITED STATES: NATIONAL SURVEY OF FAMILY GROWTH, 2015-2017

B. Olakunde[1,2], J. Pharr[1], D. Adeyinka[3]
[1]University of Nevada, School of Public Health, Las Vegas, United States, [2]National Agency for the Control of AIDS, Department of Community Prevention & Care Services, Abuja, Nigeria, [3]University of Saskatchewan, Department of Community Health and Epidemiology, Saskatoon, Canada

BACKGROUND: About 50,900 young adults (15-24 years) are estimated to be living with HIV in the U.S. However, approximately 44% have not been diagnosed. In this study, we examined the main reasons why young adults do not test for HIV in the U.S, and the variation by sociodemographic characteristics and HIV-related risk behaviors.

METHODS: The study used the 2015-2017 National Survey of Family Growth (NSFG). In the nationally-representative survey, participants were asked if they had ever been tested for HIV, and those who had not were asked to identify the main reason why.

We categorized the main reasons into three groups:

(i) Health system-related (never been offered an HIV test and no health insurance coverage),

(ii) Low risk perception (unlikely to be exposed, partner tested negative, and never had sex), and;

(iii) Fear or others (worried about what other people will think, afraid of positive result, don't like needles, tested as part of blood donation, and other reasons).

We performed multivariate multinomial logistic regression with "fear or others" as the reference group. The independent factors included: sex, education, race/ethnicity, poverty level, place of residence, and HIV-related risk behavior. Data analyses were performed using the procedures for complex survey.

RESULTS: Approximately 71.5%(95%CI=68.4-74.7) had never been tested for HIV. Low risk perception accounted for 68.3%(95%CI=65.0-71.5) of the main reasons for never testing for HIV, while health system-related and social or other reasons constituted 26.9%(95%CI=23.6-30.3) and 4.9%(95%CI=3.4-6.1), respectively. Respondents with high school degree had lower odds of indicating low risk perception as the main reason for not testing for HIV (aOR=0.4,95%CI=0.2-0.9). Those with household income of 300% or more of the federal poverty level had higher odds of reporting low risk perception (aOR=3.3,95%CI=1.5-7.0) and access-related reasons (aOR=2.6,95%CI=1.1-5.8). Respondents with low risk behaviors had higher odds of indicating low risk perception (aOR=2.6,95%CI=1.2-6.0).

CONCLUSIONS: Low risk perception accounts for the majority of the reasons for suboptimal HIV testing among young adults in the U.S. Providing health education on the importance of HIV testing and offering HIV testing to young adults regardless of their sociodemographic characteristics and perceived risk may improve its coverage among them.

PED1252

HIV SELF-TESTING IN CAMBODIA INCREASES TESTING RATES AMONG KEY POPULATIONS

P.S. Ly[1], N. Sopha[2], V. Khol[1], S. Samreth[1], B. Ngauv[1], V. Ouk[1], C. Im[2], C. Rang[2], S. Sereyvisith[2], S. Seng[2], W. Steve[2], P. Girault[2], M. Phau[2], S. Tout[3]
[1]National Center for HIV/AIDS, Dermatology and STD (NCHADS), HIV-STI Prevention and Care Tretment, Phnom Penh, Cambodia, [2]FHI360, HIV/AIDS Prevention, Phnom Penh, Cambodia, [3]KHANA, Research, Phnom Penh, Cambodia

BACKGROUND: In Cambodia by the end of 2018, 83% of the people living with HIV knew their status; 97% of those diagnosed were on antiretroviral therapy (ART); and 81% of those were virally suppressed. HIV prevalence among key populations (KPs), however, remains high and uptake of HIV testing is low. In 2019, the national program reported that 33% of men who have sex with men (MSM) and female entertainment workers (FEWs) had never tested, and more than 50% of trans women had not tested in the past 6 months. HIV self-testing (HIVST) was piloted in Cambodia December 2018 – September 2109 in an attempt to improve KP HIV testing rates

METHODS: MSM, FEW, and trans women who declined field-based testing at CBOs or clinic referrals for testing were offered HIVST either by face-to-face (FTF) or online outreach. Eligible clients, after risk assessment, chose assisted or unassisted oral fluid or blood-based testing. Kits were given to clients directly or delivered to or picked up by clients.

Test results were reported online. Clients with reactive results were referred for confirmatory testing and ART initiation. Data were collected from 17 December 2018 to 30 September 2019.

RESULTS: The pilot enrolled 1,235 participants (Figure 1). Most (1,208 or 98%) were enrolled FTF, and of these 1,191 (99%) chose assisted HIVST and 17 (1%) unassisted. Of the 27 participants enrolled online, 22 received an HIVST kit and 7 uploaded their results on the website. Seventy-two percent of participants said they had never previously tested for HIV. Seropositivity was 7.9% of MSM; 10.7% of trans women; and 2.5% of FEWs. Participants with reactive HIVST results had confirmatory testing and initiated ART. A young trans woman attempted suicide after a reactive result from unassisted self-testing but was unharmed. She received a positive confirmatory test and initiated ART.

CONCLUSIONS: HIVST empowers individuals to test even in FTF settings, can reach hidden high-risk populations who have never or infrequently tested, and can achieve high case finding. Online approaches should be simple yet provide complete information on post-test services including online counseling and free ART

PED1253

FROM A DEMONSTRATION STUDY TO NATIONAL ROLLOUT: HIV SELF-TESTING IN NEPAL

R.P. Khanal[1], D.P. Bhandari[1], K. Bam[1], P. Thakur[2], A. Shrestha[1], N. Thapa[1], H. Subhani[1], B. Shrestha[1], K.P. KC[3], M. Cassel[4], A. Bhattachan[5], M.K. Shrestha[5], R. Adhikari[6]
[1]FHI 360, Program-Technical, Kathmandu, Nepal, [2]FHI 360, Strategic Information, Kathmandu, Nepal, [3]FHI 360, Kathmandu, Nepal, [4]FHI 360, Hanoi, Vietnam, [5]Ministry of Health and Population, National Centre for AIDS and STD Control, Kathmandu, Nepal, [6]Tribhuwan University, Kathmandu, Nepal

BACKGROUND: An estimated one in four people living with HIV (PLHIV) globally—and nearly one in three in Nepal—are unaware of their HIV status despite the rapid expansion of standard community- and facility-based HIV testing services. In 2018 HIV case-detection rates

per individual tested were 0.63% nationally. More innovative and impactful HIV testing approaches are needed to close outstanding gaps in HIV diagnosis and treatment.

DESCRIPTION: The USAID- and PEPFAR-supported LINKAGES project collaborated with the Nepal national HIV program and the key population (KP) community to apply the findings of an HIV self-testing (HIVST) demonstration study to accelerate adoption of national policies supporting HIVST and national scale-up. The study, conducted from June to September 2018, enrolled men who have sex with men (MSM), male sex workers (MSWs), and transgender (TG) people—a total of 440 of whom (91%) accepted and participated in HIVST. Among participants, 12 (3%) received reactive results and subsequently received a confirmatory HIV diagnosis through testing in accordance with the national algorithm. Qualitative study findings supported the feasibility and acceptability of HIVST implementation. The study engaged KP community, relevant stakeholders throughout the process of study design, implementation, monitoring and dissemination.

HIVST is now included in national guidelines as an option for HIV screening. Training for lay providers started with three districts to initiate HIVST and will be rolled out in other districts. From August 27 to December 31, 2019, a total of 394 people accepted HIVST and tested as part of routine programming. Of those, 43 people (11%) had reactive results, received confirmatory HIV diagnosis, and were linked to treatment.

LESSONS LEARNED: Continuously seeking and engaging the guidance and participation of a wide range of community, clinical, and policy-level stakeholders may help to accelerate the adoption of evidence-based innovations necessary to fast-track an end to the HIV epidemic.

CONCLUSIONS/NEXT STEPS: The LINKAGES project will support the continued expansion of HIVST across all of the 15 high-HIV burden districts in Nepal, offering individuals a wider range of safe and attractive options to access HIV testing services, and assisting the national program in the achievement of its goals for HIV epidemic control.

PED1254

FAST TRACKING THE FIRST 95 THROUGH FOCUSED TESTING

S. Dwivedi[1], M. Kumar[2], E. Michael[3], V.S. Prasad[4], L. Honig[5]
[1]AIDS Healthcare Foundation - India Cares (AHF - India), Prevention Program, South Delhi, India, [2]AIDS Healthcare Foundation - India Cares (AHF - India), Monitoring & Evaluation, South Delhi, India, [3]AIDS Healthcare Foundation - India Cares, Operations & Partnership, South Delhi, India, [4]AIDS Healthcare Foundation - India Cares, Country Program Director, South Delhi, India, [5]AIDS Healthcare Foundation, Los Angeles, United States

BACKGROUND: In India the access to HIV testing has greatly increased over the past decade due to the scale up of community based rapid testing programs. However, many people at-risk still do not test for HIV. There is now a growing awareness that innovative approaches are needed to increase the numbers of people testing for HIV, particularly in areas where HIV prevalence is high. Programs often test the people who are at risk and do thorough follow up with the HIV positive cases. However, the programs seldom follow-up on people who are in window period.

DESCRIPTION: AHF India Cares through its CSO partners implementing HIV Rapid testing programs populated a list people with contact numbers who are suspected being in the window period. As a result of the analysis of the program data for 2017 and 2018 it was found that this group had higher positivity rates (1.4%) than first time testers (0.8%). In 2019, a focussed intervention was planned to ensure all people in the window period were tested. For the same a refresher training was held for all partners stressing on quality counselling and reporting.

LESSONS LEARNED: In 2019, the second time testers who were in the window period were 13,186 and 348 people were identified with sero-positivity 2.64%. The sero-positivity is nearly 8 times the current national prevalence of 0.22%. They were then counselled to mobilise their partners for testing. Those who are found reactive were referred for a confirmatory test to the nearest HIV testing centre and were linked to the ART Centre for treatment.

This approach has helped in:

1) focussed testing delivering greater yield,

2) return on investment is greater,

3) focussed mobilisation of communities save time, energy and effort.

CONCLUSIONS/NEXT STEPS: Efforts to find the remaining undiagnosed people with HIV will require specific efforts and innovative strategies. This effort to track and follow up people in the window period and further mobilising their partners is an effective strategy. Programs that are fast tracking the last mile need to rely on comprehensive strategies where counselling plays a critical role in social and biomedical response to HIV.

PED1255

CHALLENGES OF HIV SELF-TESTS DISTRIBUTION FOR INDEX TESTING IN A CONTEXT WHERE HIV STATUS DISCLOSURE IS LOW: PRELIMINARY EXPERIENCE OF THE ATLAS PROJECT IN BAMAKO, MALI

S. Boye[1], S. Bouaré[2], O. Ky-Zerbo[3], N. Rouveau[1], R. Silhol[4], A. Keita[5], A. Bekelynck[6], A. Desclaux[3], J. Larmarange[1], D. Pourette[1], ATLAS Team
[1]Ceped, Institut de Recherche pour le Développement, Université de Paris, Inserm, Paris, France, [2]Institut de Pédagogie Universitaire, Bamako, Mali, [3]TransVIHMI (IRD, Université de Montpellier, INSERM), Montpellier, France, [4]Medical Research Council Centre for Global Infectious Disease Analysis, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [5]Institut National de Recherche en Santé Publique, Bamako, Mali, [6]Programme PAC-CI, ANRS Research Site, Treichville University Hospital, Abidjan, Cote D'Ivoire

BACKGROUND: In Côte d'Ivoire, Mali and Senegal, ATLAS project has introduced HIV self-testing (HIVST) as an index testing strategy, distributing HIVST kits to people living with HIV (PLHIV) during consultations for secondary distribution to their partners. Here, we present preliminary results of an ethnographic survey conducted in one HIV clinic in Bamako, Mali, where most HIV patients have not disclosed their HIV status to their partner(s), notably for women for fear of jeopardizing their relationships. In such a context, how non-disclosure affect the distribution of HIVST kits?

METHODS: The study was conducted from September 25 to November 27, 2019, and included individual interviews with 8 health workers; 591 observations of medical consultations; and 7 observations of patient groups discussions led by peer educators.

RESULTS: Three principal barriers to HIVST distribution for index testing were identified. (1) Reluctance of PLHIV to offer HIVST to partners to whom they have not (yet) disclosed their status and desire to learn tactics for offering testing without disclosing their HIV status. (2) Near-universal hesitancy among health workers to offer HIVST to persons who, they believe, have not disclosed their HIV status to

their partner(s). (3) Absence of strategies, among health workers, to support discussion of status disclosure with PLHIV. In the rare cases where HIVST was offered to a PLHIV whose partner did not know their status, either the PLHIV declined the offer or the provider left it to the patient to find a way to deliver the HIVST without disclosing his/her status.

CONCLUSIONS: HIV self-testing distribution could serve as an opportunity for PLHIV to disclose their HIV status to partners. The continuing reluctance of PLHIV to heed advice to share their status and promote secondary HIV self-testing distribution highlights the structural factors (social inequalities and stigma) that limit awareness of HIV status and that favour the persistence of the epidemic.

PED1256

REACHING CHILDREN AND ADOLESCENTS THROUGH TARGETED COMMUNITY TESTING IN RURAL KWAZULU NATAL

S. Bokolo[1], C. Donald[1], T. Msezana[1]
[1]AIDS Foundation of South Africa, HIV Prevention, Durban, South Africa

BACKGROUND: South Africa has made considerable progress in the implementation of HIV testing programmes, thereby making progress in reaching the case finding (HIV positive identification) target of the UNAIDS 95-95-95 targets. Nonetheless, there are still gaps in finding HIV positive children and adolescents. In order to reach more of this population efforts need to be made to improve the HIV testing approach ensuring that more children and adolescents who do not know their status are diagnosed and linked to care. This analysis seeks to explore the high yielding community testing strategies in reaching children and adolescents.

DESCRIPTION: Through the implementation of a community HIV testing programme targeted at children and adolescents between the ages of 2 and 19 years in a predominantly rural community of KwaZulu Natal, data was collected over a period of 12 months (Oct 2018 to Sep 2019). The HIV testing strategies employed were recorded for the different sites. The strategies used included index testing, mobile points testing, OVC and community hotspot testing.

LESSONS LEARNED: Reaching children and adolescents in rural communities required intensified efforts in the adoption of the testing strategies. Over the 12 month period, 3406 children and adolescents were tested and 251 tested HIV positive which gave an overall yield of 7.4%. A closer look on the testing strategies showed greater yields through mobile point testing with 208 new HIV positive children and adolescents identified out of the 2726 that were tested and this gave the highest testing yield of 7.6% compared to other strategies. Furthermore, this strategy represented 83% of all new HIV positive children and adolescents identified in this period. The remainder was identified through other modalities which included index testing, community hotspot testing and the testing of orphans and vulnerable children (OVC).

CONCLUSIONS/NEXT STEPS: The success of reaching children and adolescents in rural communities lies on increasing accessibility by taking services to the community. A number of rural communities do not have fixed health facilities which makes it even more difficult for people to access services. The mobile point testing strategy has the potential to improve case finding of children and adolescents in rural communities.

PED1257

ACCEPTABILITY AND PREFERENCE OF A BLOOD-BASED AND ORAL-FLUID HIV SELF-TEST IN GUATEMALA AND EL SALVADOR

P. Letona[1], J. Wheeler[2], S. Lungo[1]
[1]Pan American Social Marketing Organization (PASMO), Guatemala, Guatemala, [2]Population Services International (PSI), Washington, DC, United States

BACKGROUND: The HIV epidemic in Central America is concentrated in vulnerable populations, such as men who have sex with men (MSM) and transgender women (TGW). HIV self-testing (HIVST) has been proposed to increase the uptake of HIV testing but has yet to be incorporated to national policy or made available on the market. In 2019, PASMO assessed the acceptability of a blood-based (BB) (INSTI, Biolyticals) and an oral-fluid (OF) HIVST kit (OraQuick, OraSure), and identified preference for both tests among MSM, TGW and heterosexual men.

METHODS: A convenience sample of individuals in Guatemala and El Salvador who reported being HIV-negative or with unknown status was recruited through Facebook and asked to attend the local PASMO office. In the presence of an observer, each participant self-administered both tests consecutively (random order) following the manufacturer´s instructions. User errors, constructs of acceptability (e.g., perceived effectiveness, affective attitude, self-efficacy), willingness to pay, and testing preference were assessed through a structured observation questionnaire and a quantitative survey.

RESULTS: Forty-one individuals (63.4% MSM, 17.1% TGW, 19.5% men), ages 21-44, were enrolled. During the OF HIVST, most participants conducted all steps appropriately without assistance, except for swabbing along the gums (56.1% did it correctly). More than half (60.0%) considered this test capable of detecting HIV, 95.0% felt comfortable performing the test, 100.0% considered it easy to conduct, and 92.5% felt capable of conducting it again. Participants had greater difficulty during the BB HIVST, particularly with the use of the lancet and placement of the drop of blood in Bottle 1 (70.7% and 39.0% did it correctly, respectively). All respondents considered this test capable of detecting HIV, 92.5% felt comfortable using it, 82.5% considered it easy to conduct, and 100.0% felt capable of conducting it again. Most participants (87.5%) preferred the BB HIVST and were willing to pay more for it (13.84 USD) than the OF HIVST (10.13 USD).

CONCLUSIONS: Both BB and OF HIVST were considered acceptable. BB performance had more user errors; however, acceptability and preference were stronger. These findings can guide the development of instructional resources, introduction and scaling-up of HIVST in Guatemala and El Salvador.

PED1258

THE REALITY OF INDEX TESTING IN THE COMMUNITY: NAVIGATING INDEX TESTING CHALLENGES IN A RURAL COMMUNITY OF KWAZULU NATAL, SOUTH AFRICA

S. Bokolo[1], C. Donald[1], T. Msezana[1]
[1]AIDS Foundation of South Africa, HIV Prevention, Durban, South Africa

BACKGROUND: With the shift towards targeted approaches of finding new HIV positive individuals in an attempt to reach the UNAIDS 95-95-95 targets of case finding, ART initiation and retention in care, index testing that prioritises offering HIV testing to the children and sexual partners of HIV positive individuals has increased, with few

guidelines on sensitivity or how to manage confidentiality. This approach has been proved to be effective in finding new HIV positive cases, however, beyond its success in improving case finding, index testing is associated with a range of challenges, such as increasing stigma when testing is offered to specific individuals considered to be at high risk, it is also criticised for undermining the confidentiality of the partners linked to the index cases as well as increasing incidences of intimate partner violence.

DESCRIPTION: An index testing programme was implemented in a predominantly rural community of KwaZulu Natal. HIV positive clients (referred to as cases) were requested to disclose the names of their sexual partners (referred to as contacts) in the past 12 months and home-visits were conducted to offer testing. The cases were not mentioned to the contacts, all contacts were offered HIV testing which was also extended to other individuals in the household and/or the neighbourhood.

LESSONS LEARNED: Maintaining the anonymity of the index cases during the home-visits ensured that they were protected from any form of violence that might arise as a consequence of disclosing the contacts' details. Further to this was avoiding disclosure of HIV status on behalf of a case. While indexing as prescribed requires finding the identified contact, in the community it was necessary to test others in the neighbourhood in order to diffuse stigma. Proper recording to separate the index contacts from other tested individuals was key to ensure accurate reporting.

CONCLUSIONS/NEXT STEPS: While index testing is evidently yielding great results in identifying new HIV positives, there is great need to manage the unintended consequences of this testing approach. Therefore great sensitivity is needed in managing the potential challenges that may arise from index testing protecting both the case and the contact.

PED1259

OPTIMIZING HIV CASE FINDING THROUGH INDEX TESTING

O. Petrash[1]
[1]100% Life, Kyiv, Ukraine

BACKGROUND: Ukraine has adopted the UNAIDS 90-90-90 Fast-Track targets as part of the National Strategic Plan for reducing the HIV epidemic by 2020. However, almost half of the estimated number of people living with HIV are not aware of their status. In order to achieve the first 90, the HealthLink project piloted index testing (IT) approach in the 12 PEPFAR priority regions starting from March 2018.

DESCRIPTION: HIV-service providers, both medical staff and social workers were trained on the index testing approach, motivational interviewing, stigma and discrimination issues, and HIV testing. Facility- and community-based index testing strategy is focused on biological children, sexual and needle-sharing partners of newly detected HIV-positive person involvement in testing and treatment.

The project developed standard operating procedures for 460 project health care facilities, as well as the data-collection and partner notification tools for use by providers during counseling of HIV index clients and meeting their partners. 5599 HIV-infected clients, newly detected within the PITC and community-based testing model, were screened and out of them, 88% reported untested sexual or needle-sharing partners. Among the exposed contacts of HIV-positive persons, 12195 clients were tested, out of them – 1222 received positive results.

[Figure]

LESSONS LEARNED: Index testing model showed the highest testing yield (10%) in comparison with other project modalities (PITC – 2.2%, community – 3%). Since the sexual transmitting of HIV has been driving the epidemic in Ukraine, the IT model is the most effective HIV-case finding strategy.

CONCLUSIONS/NEXT STEPS:

- IT model needs to be further expanded to more facilities.
- Talking points and scripts for IT services are obligatory for usage by any provider within HIV testing and treatment.
- IT model should be optimized through the enhanced management of testing sites.
- For the IT model strengthening and index partners' involvement, targeted informational materials should be developed and disseminated to all testing points.

INTERVENTIONS TO REDUCE STIGMA AND DISCRIMINATION

PED1260

PSYCHOLOGICAL AND STIGMA PROFILES OF HIV PATIENTS IN A NORTH-CENTRAL CITY OF NIGERIA

M. Osinubi[1], A. Ahmed[1], M. Uthman[2], A. Aderibigbe[2], A. Adesina[1]
[1]Federal Medical Center, Community Medicine & Primary Care, Abeokuta, Nigeria, [2]University of Ilorin, Epidemiology & Community Health, Ilorin, Nigeria

BACKGROUND: The World Health Organization defines health as a state of complete physical, mental, and social well-being and not merely the absence of infirmity and disease. Researchers and clinicians have focused on health outcomes that are physically or laboratory measured such as symptoms, viral load and efficacy of treatment. Biomedical measures, however, do not reflect how the affected individual feels and functions in daily life. This study therefore, assessed the psychological and stigma profiles of these patients which in essence defined the individual's self-evaluation of their well-being.

METHODS: The study was a descriptive cross sectional study of 384 HIV positive patients who were systematically recruited at 5 public service delivery sites in Ilorin- a North-central State, Nigeria. Data was analyzed using SPSS software version 23.0. Level of significance was pre-determined at p-value < 0.05 at a confidence level of 95%.

RESULTS: Female respondents constituted 222 (58.0%) while males were 162(42.0%). Respondents experienced varying proportions of psychological characteristics. As many as 228 (59.4%) reported being anxious about their condition, 98 (25.5%) feel depressed, 134 (34.5%) experienced rejection, 163 (41.4%) reported self-criticism/ poor sleep. Over two-thirds 258 (67.2%) of the respondents expressed strong concern regarding disclosure, about three-quarters 298 (77.6%) of them reported poor social relationship compared to 86 (22.4%) that reported good social relationship, while up to 155 (40.4%) reported poor self-acceptance of their health condition.

Variables	Frequency N=384	%
Anxiety	228	59.4
Depression	98	25.5
Feel rejected	134	34.9
Self-criticism/ poor sleep	163	41.4

[Table 1: Psychological characteristics of respondents.]

Multiple responses:

Domains	Poor (%)	Good (%)
Stereotype	101 (26.3)	283 (73.7)
Disclosure concern	126 (32.8)	258 (67.2)
Social relationship	298 (77.6)	86 (22.4)
Acceptance	155 (40.4)	229 (59.6)

[Table 2: Reported level of stigma experienced by respondents (N=384).]

CONCLUSIONS: Continued efforts should be sustained to further improve on the well-being of people living with HIV (PLHIV) such as campaign against stigmatization as well as enactment of laws against stigmatization.

PED1261

ASSESSING THE IMPACT OF SCHOOL-BASED INNOVATIVE INTERVENTION PROGRAM IN COMBATING HIV STIGMA AND DISCRIMINATION AMONG ADOLESCENT FEMALE STUDENTS

A. Malek[1], H. Ismail[2]
[1]High Institute of Public Health, Epidemiology, Alexandria, Egypt, [2]High Institute of Public Health, Family Health, Alexandria, Egypt

BACKGROUND: HIV stigma and discrimination can pose complex barriers to prevention, testing, treatment and support for people living with or at risk of HIV, their resilience and reintegration. The study aims to assess the impact of innovative stigma-reduction intervention program on reducing HIV stigma and discrimination among adolescent female students.

METHODS: 1000 student girls were enrolled from randomly selected 20 secondary girl schools in Alexandria – 50 per school. Based on identified gaps, Misconceptions and barriers fuel HIV stigma from focus group discussion with a sample of enrolled students, an HIV-stigma-reduction program was developed and implemented using a combination of innovative interactive multi-approaches, including; school wall magazines, local cast, debates and funfairs. Anti-stigma team „AST" was established from among student cadres in each school. The program was assessed at the 20 schools among the enrolled students, using a comprehensive pretested self-administered questionnaire in a pre /post and post-post tests. Data entered into computer, processed and analyzed, using SPSS.

RESULTS: The mean age of enrolled students was 15.7 ± 0.60. Four-fifth (84.7%) ranked their knowledge as very little. half (52.6%) had misconception regarding modes of HIV transmission. Their base-line mean knowledge score was one-third of the high (11.0 ±5.7 of 30 – 35.5%). Three-quarter (77.5%) considered HIV a „shameful" disease, and (77.8%) had conservation to deal with persons living with HIV „PLWH". three quarter (71.7%) scared from being infected through daily activity with PLWH. Half (52.6%) had blame towards them and (50.9%) wanted to isolate them. The overall mean attitude score was (5.9± 2.1 of 18 - 32.9%). Post intervention, significant changes were observed in HIV transmission knowledge score (27.5±4.8 of 30 – 91.6%) with improvement in attitude score (14.8±2.1 of 18 – 79.4%). In testing for sustainability, both; knowledge and attitude scores declined (23.8±5.1 of 30 – 79.3%) and (10.7±2.4 of 18 – 59.4%) consecutively, but both remained above the base line.

CONCLUSIONS: Misconceptions about HIV continue to drive stigma and discrimination. Combination of innovative interactive multi-approaches proved to be effective in shifting adolescent female students' level of HIV stigma and alleviating attitudinal barriers. Boosters are recommended to sustain the gain in attitude.

PED1262

HIV/AIDS-RELATED STIGMA AND DISCRIMINATION IN GAZA-STRIP (OF PALESTINE): HEALTH STAFF ATTITUDES AND PERCEPTIONS CHANGE AFTER 3 YEARS OF ACTIVE INTERVENTION

M. AlAfifi[1], M. Shehada[1], R. Afifi[1]
[1]Substance Abuse Research Center (SARC), Community Research, Gaza, Palestine

BACKGROUND: Substance Abuse Research Centre (SARC) in Palestine was the winner of the Red Ribbon Award 2010 (UNAIDS and UNDP),. The stigma of HIV/AIDS remains a major barrier to achieve active treatment and harm reduction. The stigma was also spreading among health professionals. We carried an active program to change their attitude and reduce their stigmatizing behavior towards HIV/AIDS patients. This paper reports our intervention and its results.

METHODS: The intervention with the medical professionals continued for 3 years with the participation of an HIV positive trainer member. A pre and post-test was carried, and after another two years, we carried this. a cross-sectional survey among doctors, nurses, and social workers, n = 615. Participants were interviewed using a questionnaire including questions on demographic characteristics, knowledge of HIV/AIDS infection, prevention and harm reduction, Stigma and discriminating behaviors. The results were analyzed by the SPSS statistical package.

RESULTS: The results compare this study and the pre-test. 95% compared to (82%) have knowledge of HIV/AIDS and of harm reduction. 42% (compared to 11%) agreed to shake-hand a positive HIV case. 34% (compared to 21%) agreed to work with HIV+ cases. 26% (compared to 18%) agreed to have a social relationship with HIV+ cases as visiting and have a company socially. 20% (compared ton18%) agreed to share swimming, using the same bathroom, and sporting together. 38% (compared to 23%) agreed to have a marriage with brothers or sisters of HIV+ cases.

CONCLUSIONS: The study revealed effective intervention and improved situation among the medical professionals, but still need more active intervention to fight the stigma and related behaviors among medical professionals to help for better control of HIV/AIDS. It is recommended to continue the intervention with the participation of active and/or HIV positive members

PED1263

COMMUNITY HEALTH WORKERS' EMPATHY AND NEGATIVE ATTITUDE TOWARD PEOPLE WHO USE DRUGS IN VIETNAM

D.B. Nguyen[1,2], C. Lin[1], T.A. Nguyen[3], L. Li[1]
[1]University of California, Los Angeles, United States, [2]Hanoi Medical University, Hanoi, Vietnam, [3]National Institute of Hygiene and Epidemiology, Hanoi, Vietnam

BACKGROUND: Community health workers (CHW) serve as a critical bridge between people who use drugs (PWUD) and their needed healthcare services in the community. This study aims to investigate CHW's negative attitude towards PWUD, empathy, and associated factors.

METHODS: We used data from a cross-sectional assessment of 300 CHW in 60 communities in Vietnam. The assessment was administered using the computer-assisted self-interview method. CHW's levels of negative attitude towards PWUD and empathy were measured by multi-item scales. Participant characteristics such as gender, age, job position, education, working experience, and perceived occupational risk were included. Multilevel regression analyses were performed to explore the relationship among CHW's negative attitude, empathy, and background characteristics.

RESULTS: Of all participants, 75.7% were female, and 16.7% were doctors. The average age was 39.3 (SD 10.3) years. More than half (55.7%) have worked in the medical field for more than 10 years. After controlling for other covariates, CHW's empathy was associated with their negative attitude towards PWUD (β = -0.078, 95% CL: -0.144; -0.011). Higher perceived occupational risk was associated with a lower level of empathy (β = -0.639, 95% CL: -0.850; -0.429) and a higher level of negative attitude (β = 0.223, 95% CL: 0.103; 0.350). Other characteristics, including gender, job position, monthly contact with PWUD, years of education and in the medical field, were not associated with either empathy or negative attitude towards PWUD.

CONCLUSIONS: Our findings suggest that training on medical safety in community health settings could be a useful strategy to improve the provider's empathy and reduce their negative attitude towards PWUD. Promoting occupational safety in healthcare settings should be included in future stigma reduction intervention programs.

PED1264

REDUCING HIV-RELATED STIGMA AND DISCRIMINATION IN HEALTHCARE SETTINGS IN VIETNAM

P. Do[1], V. Dang Thi Nhat[1], H. Duong Thi[1], P. Vu Ngoc[1], L. Nguyen Ly[1], N. Vo Thi Tuyet[1], A. Nguyen[2], U. Nguyen Kieu[3], C. Nguyen Nhat[4], T. Nguyen Van[5], T. Do Huu[6], L. Cosimi[7,8], T. M.Pollack[1]
[1]The Partnership for Health Advancement in Vietnam, Hanoi, Vietnam, [2]US Centers for Disease Control and Prevention, Hanoi, Vietnam, [3]Binh Duong Provincial AIDS Center, Binh Duong, Vietnam, [4]Hanoi Center for Disease Control, Hanoi, Vietnam, [5]Thai Nguyen Center for Disease Control, Thai Nguyen, Vietnam, [6]Vietnam Administration of HIV/AIDS Control, Hanoi, Vietnam, [7]The Partnership for Health Advancement in Vietnam, Boston, United States, [8]Brigham and Women's Hospital and Beth Israel Deaconess Medical Center, Boston, United States

BACKGROUND: HIV-related stigma and discrimination (S&D) are major barriers to achieving 90-90-90 in Vietnam. Decreasing S&D at healthcare settings is a critical component of the HIV response.

METHODS: We surveyed healthcare workers (HCWs) and patients living with HIV (PLHIV) before and after a 9-month intervention to reduce HIV-related S&D at 10 facilities across 3 provinces in Vietnam (from 8/2018 to 6/2019). Interventions included HCW training, policy development, facility collaboration with clients, communication materials, and targeted quality improvement projects. HCWs completed self-administered questionnaires covering 5 domains (fear of infection, use of unnecessary precautions, observed discrimination, attitude towards PLHIV, and attitude toward co-workers with HIV). PLHIV were interviewed by trained peers using a structured questionnaire covering 4 domains (experienced discrimination, self-stigma, disclosure of HIV status, reproductive health). McNemar's test was used to analyze differences in paired proportions among HCWs and Chi-square test was used to analyze differences in proportions among PLHIV before and after the intervention.

RESULTS: Of 672 HCWs who completed baseline and post-intervention questionnaires, 75% were female and mean age was 35. Participants were physicians (20%), nurses (57%), other staff (23%) and 66% reported caring for or interacting with PLHIV. 649 and 652 PLHIVs were interviewed at baseline and post-intervention respectively. Mean age was 40, 62% were male and 100% were on ART for a mean duration of 6.5 years. At baseline, reported S&D was high with 81.2% of HCW reporting fear of HIV infection, 69.2% reporting use of unnecessary precautions, and 43.6% reporting observation of discrimination toward PLHIV. Among PLHIV, 21% reported experiencing discrimination in healthcare settings. Following the intervention, S&D was significantly reduced in all domains (table).

Healthcare staff survey	Before	After	P-value*	PLHIV survey	Before N=649	After N=652	P-value**
1. Fear of infection, n=626	508 (81.2%)	324 (51.8%)	<0.001	1. Experienced discrimination in the last 12/9*** months	139 (21.4%)	100 (15.4%)	0.005
2. Report of using unnecessary precautions, n=569	394 (69.2%)	196 (34.4%)	<0.001	2. Self-stigma	106 (16.4%)	80 (11.3%)	0.008
3. Observed discriminatory practices made by hospital staff, n=672	293 (43.6%)	214 (31.8%)	<0.001	3. Disclosure of HIV status by HCW	91 (14.0%)	48 (7.4%)	<0.001
4. Negative attitude and opinion of hospital staff towards PLHIV, n=672	364 (54.2%)	238 (35.4%)	<0.001	4. Experienced discrimination around reproductive health^	44 (6.8%)	23 (3.5%)	0.008
5. Negative attitude of hospital staff towards co-workers living with HIV, n=670	273 (40.7%)	158 (23.6%)	<0.001	***PLHIV were asked about their experience during previous 12 months on baseline survey and previous 9 months on post-intervention survey			
*McNemar's test **Chi-square test							

[Table. Prevalence of stigma and discrimination among healthcare staff and PLHIV before and after interventions to reduce HIV-related S&D, % (95% CI)]

CONCLUSIONS: HIV-related S&D is common in healthcare settings in Vietnam. Our results demonstrated the effectiveness of a multi-pronged intervention. Nonetheless, S&D remained high post-intervention. Additional effort is needed to achieve the goal of zero discrimination.

PED1265

TRAINING IN HEALTHCARE SETTINGS TO REDUCE STIGMA AND DISCRIMINATION TOWARDS KEY POPULATIONS: COVERAGE AND OPPORTUNITIES FOR IMPROVEMENT

C. Wells[1], A. Aidala[2], T. Harris[1], K. Hartsough[1], J. Frieze[1], V. Nightingale[3], K. Klindera[4], H. Gardi[5], M.H. Razak[6], T. Gantt[6], E. Rodriguez[7]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [2]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States, [3]US Department of Defense, HIV/AIDS Prevention Program, Defense Health Agency, Washington, D.C., United States, [4]US Agency for International Development, Washington, D.C., United States, [5]US Peace Corps, Washington, D.C., United States, [6]US Health Resources and Services Administration, Rockville, United States, [7]US Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV and TB, Atlanta, United States

BACKGROUND: Key population (KP) groups often experience substantial stigma, which can be a barrier to accessing HIV-related services. Globally, HIV disproportionately affects KP, even in generalized epidemic settings, making access to HIV services for this population critical for epidemic control. While KP-competency training among healthcare staff is a key intervention to reduce stigma and discrimination (SD) in healthcare settings, and improve KP engagement in HIV services, there is limited knowledge as to how widely it is implemented.

METHODS: From December 2018-March 2019, key informants from 403 PEPFAR-funded implementers, across five U.S. Government agencies, were asked to complete an online reporting tool. Questions assessed HIV-related SD reduction activities that implementers directly supported, as well as general practices at facilities or community-based sites supported by implementing partners (IP). We present findings on KP-competency training and compare responses to general anti-HIV SD training.

RESULTS: Overall, 244 implementers from 50 countries responded. Fewer implementers reported direct support for KP-competency training (156/244, 64%) than anti-HIV SD training (186/244, 76%). Of those supporting KP-competency training, lay workers (136/156, 87%) and clinical professionals (133/156, 85%) were most commonly trained; least common were administrative support staff (93/156, 60%) and clinical support workers (91/156, 58%). Among IP reporting KP-competency training at supported sites, it was more common in primary health facilities (84/115, 73%) and community-based settings (83/115, 72%), than secondary (66/115, 57%) or tertiary (54/115, 47%) facilities. Onsite training was the most common modality (124/156, 79%), and 87% (136/156) provided repeated training using varying modalities for at least one cadre. KP-competency training was more common, with less of a difference compared to anti-HIV SD training, in regions with KP-centered epidemics than in regions with generalized epidemics (Table 1).

	KP-centered epidemics: Central America, Caribbean, and Asia/Pacific N=59 (%)	Generalized epidemics: West, East and Southern Africa N=165 (%)	Total N=224 (%)
Number of IP reporting anti-HIV SD training at supported sites	46 (78%)	110 (67%)	156 (70%)
Number of IP reporting KP-competency training at supported sites	41 (69%)	74 (45%)	115 (51%)

[Table 1. Training activities at IP-supported sites by regional HIV epidemic characteristics (based on UNAIDS 2019 epidemic data)]

CONCLUSIONS: While most PEPFAR-implementers supported KP-competency training, it was less common than general anti-HIV SD training and there were variations by cadre, healthcare setting, and HIV epidemic characteristics. Opportunities exist to improve coverage across all cadres and settings, especially in regions with generalized epidemics, where reaching KP for HIV-related services is crucial for epidemic control.

PED1266

A CAMPAIGN FOR TO SUPPORT RE-ENGAGEMENT IN HIV CARE AND RE-INITIATION OF ANTIRETROVIRAL THERAPY IN AN URBAN SOUTH AFRICAN DISTRICT: PERSPECTIVES OF HEALTHCARE WORKERS

M. Bisnauth[1], S. Monareng[2], N. Davies[3], H. Struthers[4], J. McIntyre[5], K. Rees[6]
[1]University of Witwatersrand/Anova Health Institute, Public Health, Johannesburg, South Africa, [2]Anova Health Institute, Johannesburg, South Africa, [3]Anova Health Institute, Clinical Research, Johannesburg, South Africa, [4]University of Cape Town, Division of Infectious Diseases and HIV Medicine, Johannesburg, South Africa, [5]University of Cape Town, School of Public Health and Family Medicine, Johannesburg, South Africa, [6]University of Witwatersrand, Community Health, Johannesburg, South Africa

BACKGROUND: People who interrupt their antiretroviral therapy (ART) experience poor health outcomes and on a population level their HIV transmission risk increases.

Anova Health Institute and the Johannesburg Health District Departments of Health developed a two-part campaign to encourage clients to return to ART care. Part 1 involved health care worker (HCW) training on how to manage patients restarting ART and Part 2 comprised mass media messaging about the importance of returning to care. The study objective was to assess campaign implementation and analyse fidelity of campaign components from the HCW's perspective.

METHODS: Six months after implementation (June-August 2019), semi-structured interviews were conducted with HCWs in six healthcare facilities located in Johannesburg. The interview covered staff attitudes as well as facility management of clients reinitiating ART. HCWs also completed a questionnaire about their own and their facility management of clients reinitiating ART. Interview data was analysed using a content analysis approach and questionnaire data using descriptive statistics.

RESULTS: After campaign implementation, the facilities had a 92% increase in people returning to care. A total of 36 nurses and counsellors were interviewed. Most participants answered positively regarding how clients returning to care were managed citing differentiated care, plans for treatment, and adherence support. Staff highlighted the importance of clients voicing their adherence challenges to enable better understanding about how to help clients overcome adherence barriers. Many (28, 85%) believed that the campaign helped improve client-provider relationships.

However, staff didn't successfully implement all campaign components, 25% (from 3 different facilities) responded that patients are sent to the back of the queue and that staff insist on transfer letters, and 69% (25) responded that they have seen/heard other staff act negatively toward returning clients. Many participants expressed that these negative behaviours result from working within highly demanding and rigid work environments.

CONCLUSIONS: The campaign improved HCWs approach to clients restarting ART. However, negative attitudes and flawed clinic management remain. A more comprehensive approach to consistently improving behaviours and attitudes at facility level is needed to support HCWs to provide better care.

PED1267

THEIR STORY, YOUR CHOICE – A SERIES OF INTERACTIVE FILMS AIMED AT TARGETING HIV STIGMA IN BLACK AFRICAN COMMUNITIES IN THE UK. FUNDED BY COMIC RELIEF AND THE MAC AIDS FUND

T. Mukiwa[1], G. Halfin[1], D. Edwardes[1], L. Lopez[2]
[1]Terrence Higgins Trust, London, United Kingdom, [2]Brown Boys Productions, London, United Kingdom

BACKGROUND: Black Africans (BA) are disproportionately affected by HIV in England, making up 41% of heterosexuals diagnosed in 2018, 54% of whom were diagnosed late.

This project aimed to reduce HIV stigma among black African communities in the UK through storytelling, a strong tradition in many BA cultures.

Stigma significantly limits uptake of HIV prevention and testing tools and services (NICE, 2017). Research shows that effective stigma interventions "allow the exploration of the personal experience through a story" (NAT, 2016).

DESCRIPTION: Terrence Higgins Trust (THT) and Brown Boys Productions held interviews and focus groups with BA PLWHIV about their experiences of stigma and how it affected their life and relationships.

Based on these experiences, we produced three interactive films where viewers choose the characters' actions which influences the outcomes of each story, Themes covered include disclosure in relationships, late diagnosis, dating, and abuse.

To ensure they were realistic, culturally appropriate, appealing, and medically accurate we:

- User tested during production with BA PLWHIV and other BA
- Engaged a BA writer living with HIV as a consultant
- Conducted medical peer reviews.

Films were hosted on the THT website and YouTube, with additional information on HIV and referral to testing services.

Targeted social media advertising was used to promote the videos.

LESSONS LEARNED: The films were effective at reaching BAs and started conversations on themes explored in the films. 87,661 people landed on the first scene of a film with about 27% watching to the end of a story. There were 3,565 social media reactions, comments and shares.

Providing additional information alongside the videos was effective as it resulted in;

- 101 HIV self tests kits ordered – (59-BA)
- 6,971 looking at other information website pages

CONCLUSIONS/NEXT STEPS: Using interactive videos storytelling and drama can be effective to reach and engage people disproportionately affected by HIV stigma.

Advertising is essential to maximise reach and engagement.

People reflected that the interactive nature of the films made them reflect more on the themes than if the films had not been interactive. While storytelling approaches can be useful, practitioners need to think of ways to engage viewers more than just passively.

PED1268

STIGMA AND MENTAL HEALTH AMONG PEOPLE LIVING WITH HIV IN UGANDA

V. Kiwanuka[1]
[1]National Forum of PLHIV Networks in Uganda, Programs, Kampala, Uganda

BACKGROUND: People living with HIV are greatly impacted by mental health challenges which may become a structural barrier and drive the epidemic underground due to non disclosure arising from stigma. Mental health conditions explored include feeling nervous, anxious or on the edge, not being able to stop or control worrying, little interest or pleasure in doing things and feeling depressed or hopeless.

METHODS: With support from the Embassy of Ireland, the National Forum of PLHIV Networks in Uganda (NAFOPHANU) conducted the 2nd national PLHIV stigma index survey in 2019 targeting 1,400 PLHIV from 21 districts of Uganda. The PLHIV stigma index survey adopted a one-group post only cross-sectional design. The design was based on PLHIV empowerment principles and therefore conceptualized as a project. The study largely used quantitative research methods for data collection and analysis while the qualitative picked on stories/scenarios of PLHIV lived experiences.

RESULTS:

- Approximately 540 (39%) out of 1398 respondents reported forms of feeling nervous, anxious or on the edge over the last two weeks before the survey.
- 538 respondents (39%) reported not being able to stop or control worrying.
- 432 (31%) reported having little interest or pleasure in doing things
- 453 (33%) reported feelings of depression or hopelessness.
- Only 301 (39.71%) had received any type of support such as counseling or other types.

CONCLUSIONS: Focus on mental health conditions among PLHIV remains very pivotal in addressing issues of stigma to ensure that all PLHIV get the necessary support like counseling. Therefore, there is need to design programs that specifically address mental health as a mechanism to fight stigma and discrimination.

PED1269

WHAT MATTERS MOST ENABLES RESISTANCE OF HIV STIGMA: SUSTAINED EFFECTS OF A NOVEL, CULTURALLY-TAILORED PRENATAL HIV STIGMA-REDUCTION INTERVENTION ON STIGMA AND DEPRESSION IN BOTSWANA

A. Ho-Foster[1,2], M. Goodman[3], P. Entaile[4], S. Rampa[5], V. Jackson[6], G. Manyeagae[7], O.B. Poku[8], S. Misra[3], P. Opondo[9], T. Arscott-Mills[4,10], H. Mehta[11], T. Becker[12], T.M. Benti[13], M.B. Blank[14], L.H. Yang[3]
[1]University of Botswana, Faculty of Medicine Office of Research and Graduate Studies, Gaborone, Botswana, [2]University of Pennsylvania Perelman School of Medicine, Department of Medicine, Philadelphia, United States, [3]New York University, School of Global Public Health, New York, United States, [4]Botswana-UPenn Partnership, Gaborone, Botswana, [5]University of Botswana, Department of Psychology, Gaborone, Botswana, [6]University of California, Department of Anesthesia and Perioperative Care, San Francisco, United States, [7]University of Botswana, Department of Statistics, Gaborone, Botswana, [8]Johns Hopkins University, Department of Mental Health, Baltimore, United States, [9]University of Botswana, Department of Psychiatry, Gaborone, Botswana, [10]University of Pennsylvania Perelman School of Medicine, Department of Pediatrics, Philadelphia, United States, [11]Columbia University, Teachers College, New York, United States, [12]Icahn School of Medicine at Mount Sinai, Department of Psychiatry, New York, United States, [13]University of Botswana, Department of Obstetrics and Gynecology, Gaborone, Botswana, [14]University of Pennsylvania Perelman School of Medicine, Department of Psychiatry, Philadelphia, United States

BACKGROUND: Botswana has among the highest HIV prevalence rates worldwide (24% infected). Despite a strong national HIV treatment program that includes initiation of life-long antiretroviral therapy (ART) for women diagnosed during prenatal care, severe stigma persists, impeding adherence to ART in the postpartum (PP) period. To date, only a few studies conducted in sub-Saharan Africa have shown prenatal interventions can reduce stigma in the PP period.
METHODS: We tested Mothers Moving towards Empowerment (MME), a novel, culturally-tailored intervention developed using the What Matters Most (WMM) framework. Contact with peer-co-leaders (i.e., mothers with HIV) was part of this intervention. Pregnant women with HIV enrolled at 28 weeks pregnancy were assigned to receive MME or treatment as usual (control). We used median score (M) to assess severity of stigma (Berger Stigma Scale) and depressive symptoms (CES-D) at baseline, after the intervention (MME only), and at four months PP (4mPP). Qualitative data, as monitored via fidelity assessments, captured participant perceptions throughout the intervention.
RESULTS: Interim analyses (n=34) show a monotonic decrease in stigma from pre-intervention (M=88.0) to post-intervention (M=78.0), and to 4-month PP (M=72.0): a 20% decline from baseline. Depressive symptoms (CES-D) reflected an even more substantial decrease from pre-intervention (M=30.0) to post-intervention (M=19.0), and to 4-month PP (M=12.0): a 60% decline from baseline. In contrast, we observed increases in the severity of stigma and depressive symptoms from baseline to 4mPP (+25.0 change or 39.4% increase in stigma; +7.5 change or 48.4% increase in depression) among the control group (n=12). These results are consistent with qualitative findings via fidelity assessments that suggested dramatic changes in some participants' disclosed attitudes and behaviors at onset (e.g., fearing familial rejection if HIV status were disclosed, thus jeopardizing ART adherence), compared with after the intervention (e.g., successful disclosure of HIV status to family, eliciting greater social support).
CONCLUSIONS: While ongoing, these initial results suggest that the WMM framework-based, prenatal HIV stigma intervention holds promise in improving stigma and related adverse psychosocial outcomes for HIV-positive mothers in the PP period. Further development for implementation scale up and testing for viral suppression is recommended.

PED1270

IDENTIFYING RISKS, REMOVING BARRIERS TO ACCESS TO CARE: MAPPING OF VIOLENCE BASED ON GENDER AND SEXUAL ORIENTATION IN THE CITY OF DOUALA, CAMEROON

J. Mandeng[1]
[1]Alternatives-Cameroun, Management, Douala, Cameroon

BACKGROUND: Violence based on gender and sexual orientation is on the increase in the city of Douala. A community study conducted by Alternatives-Cameroon in 2017 revealed that 12% of MSM and 19% of WSW had already been raped. The 2016 IBBS study found that 13% of MSM had already been discriminated against by their families. The same study found that key victims of violence are twice as infected with HIV as people who have not experienced any violence. Alternatives therefore thought of identifying risk areas in order to prevent violence against LGBTI people, help reduce their vulnerability, and increase their access to care.
DESCRIPTION: We listed all the violence events we documented since 2014. There were 293 events of violence which have been classified by type and place of occurrence. A map of the city of Douala has been printed in very large format. Each event of violence was then marked on the card with a sticker, in the place where it took place. The violence was classified into 6 types, and each type had a label color. We then used this card to educate our beneficiaries about their personal safety. It was also used for our sensitizations with certain social actors such as traditional chiefs or nursing staff.
LESSONS LEARNED: The map which is now pasted in the waiting room of our Community Center, quickly proved to be a powerful communication tool on security and advocacy for LGBTI people in Douala. It is a very practical way to visualize the situation and draw the consequences. This mapping is used, for example, as a compass for LGBTI people in the neighborhood of residence. Visitors to the Center quickly realize the evidence and risky locations in the city, and feel encouraged to use the Center more to receive more information and services.
CONCLUSIONS/NEXT STEPS: We plan to exhibit this mapping at advocacy workshops with social actors. We plan to expand the mapping nationwide. To this end, the documentation of the violence will now cover the entire national territory, with the focal points that we have recruited in all regions of Cameroon.

IMPACT OF THE TOBACCO USE REDUCTION PROGRAM IN PEOPLE LIVING WITH HIV ON THEIR SMOKING BEHAVIOR: A PRE AND POST COMPARISON STUDY IN MICHIGAN, 2018

B. Thomas[1], S. Watson[1], F. Shamo[2], J. Hitchingham[1]
[1]Michigan Department of Health & Human Services, Division of Chronic Disease & Injury Control Division: Tobacco Section - Tobacco Use Reduction for People Living with HIV Program, Lansing, United States, [2]Michigan Deparmtent of Health & Human Services, Division of Chronic Disease & Injury Control Division: Tobacco Section - Tobacco Use Reduction for People Living with HIV Program, Lansing, United States

BACKGROUND: Cigarette smoking is the leading preventable cause of death in the United States. Advances in treatment and control of the HIV disease, as a chronic disease, is extending the life span of

people who are HIV positive. However, people living with HIV (PLWH) are dying 12 years sooner from tobacco related illness than from complications of HIV. In order to address tobacco health disparities among PLWH, the Michigan Tobacco Control Program (TCP) partnered with the HIV Care and Prevention section to fund the Tobacco Use Reduction Program for PLWH.

METHODS: Major components of the project include, gaining better information of tobacco use behaviors through an ASO staff survey, a comprehensive HIV client survey, and HIV client focus groups. Two surveys provided detailed information regarding tobacco use and current staff and client tobacco knowledge. Following the completion of the surveys and focus groups, the project continued with 15 contractors being trained and certified as Tobacco Treatment Specialists. Within second and third fiscal years, contractors were funded to implement the 5As intervention (Ask, Advise, Assess, Assist, Arrange), provide tobacco dependence treatment counseling, implemented peer to peer specialist, and other resources to reduce tobacco use among PLWH.

RESULTS: According to our first study in 2015, the smoking rate among PLWH was 49.5%. Concentrated training that focused on tobacco treatment and motivational interviewing was provided to staff of the ASOs to build internal agency capacity to treat their PLWH who smoke. A second HIV client survey was conducted to assess the impact of the implementation of almost 3 years of the project on the smoking and quitting behavior, knowledge, and attitude of the clients, data was collected at the end of 2017. Findings from the 2017 client surveys showed a great reduction in the cigarette smoking prevalence in 2017 study (41%) compared to (49.5%) in 2015, this reduction is highly significant (P < 0.05).

CONCLUSIONS: Due to the compelling data, the Tobacco Use Reduction Project for People Living with HIV moved from a demonstration project to a sustainable program funding 18 contractors throughout the state of Michigan to offer tobacco cessation services.

BREASTFEEDING DURATION AND CORRELATES OF BREASTFEEDING CESSATION IN ESWATINI

N.J. Gama[1], C. Ngcamphalala[2], N. Gwebu[2], M. Ndlangamandla[2], M.C. Shongwe[3,4], R. Sahabo[2], Z. Mnisi[5], Y. Wu[6], H. Nuwagaba-Biribonwoha[2,6]
[1]Health Research Training Program (HRTP) Fellow, ICAP in Eswatini, Mbabane, Eswatini, [2]ICAP at Columbia University, Mailman School of Public Health, Mailman School of Public Health, Mbabane, Eswatini, [3]Health Research Training Program (HRTP) Mentor, ICAP in Eswatini, Mbabane, Eswatini, [4]University of Eswatini, Department of Midwifery Science, Faculty of Health Sciences, Mbabane, Eswatini, [5]Ministry of Health, Mbabane, Eswatini, [6]Columbia University, Department of Epidemiology, Mailman School of Public Health, Department of Epidemiology, Mailman School of Public Health, New York, United States

BACKGROUND: Eswatini began transition to lifelong antiretroviral therapy(ART) for pregnant and breastfeeding women living with HIV(WLHIV) in 2013. National guidelines recommended that WLHIV breastfeed for 6-12 months while taking ART (in-line with 2013 World Health Organization guidelines). Among HIV-negative women, breastfeeding can continue up to 24 months and beyond. We assessed breastfeeding practices among women 15+ years in Eswatini during this transition period.

METHODS: We conducted a secondary analysis of the second Swaziland/Eswatini HIV Incidence Measurement Survey(SHIMS2) dataset. SHIMS2, conducted in 2016-2017, collected self-reported data on HIV status, ART use and breastfeeding in the three years prior to the survey (approximately 2013-2015). We analyzed time to stopping breastfeeding, censored at date of survey (for women still breastfeeding during the survey). We used Kaplan-Meier methods to compare time to breastfeeding cessation between WLHIV and HIV-negative women, and multivariate Cox regression analysis to examine the correlates of time to breastfeeding cessation.

RESULTS: Of 1258 women reporting a live birth, nearly one third (32%; n=404) reported living with HIV, of whom 32%(n=132) reported ART use during breastfeeding. Median duration of breastfeeding was 7 months (interquartile range [IQR]=4-12 months) among WLHIV, and 12 months (IQR 6-17) among HIV-negative women. At 6 months, breastfeeding survival using Kaplan-Meier analysis was 60%(n=280) among WLHIV and 82%(n=672) among HIV-negative women. At 12 months it was 22%(n=149) among WLHIV and 55%(n=460) among HIV-negative women.

In adjusted analyses, earlier breastfeeding cessation was associated with HIV-positive status: (adjusted hazard ratio [AHR]=2.03, 95% confidence interval [95% CI]: 1.69-2.43). Compared to 2013, women who gave birth in 2014 (AHR=1.19, 95% CI 1.02-1.37), and 2016 (AHR=1.74, 95% CI: 1.32-2.30) were more likely to stop breastfeeding earlier, but not 2015 (AHR=1.01, 95% CI 0.86-1.17). Other factors significantly associated with breastfeeding cessation were tertiary education (reference: no education, AHR=1.30, 95% CI 1.07-1.58), and employment (reference: unemployed, AHR=1.14, 95% CI 1.02-1.27).

CONCLUSIONS: Earlier breastfeeding cessation was more likely among WLHIV, and two-thirds of breastfeeding WHLIV were not on ART. Our analysis suggests low rates of breastfeeding which could impact infant morbidity and mortality. Targeted interventions to support ART use and breastfeeding continuation among lactating WLHIV are needed.

PED1273

A SOCIAL NETWORK ANALYSIS OF PEOPLE LIVING WITH HIV AND THEIR TREATMENT PARTNERS IN BOTSWANA: SUPPORT RECIPROCITY AND HIV VIRAL SUPPRESSION

N. Phaladze[1], L. Bogart[2], M. Mosepele[3], H.D. Green[4], B. Lekoko[5]
[1]University of Botswana, School of Nursing, Gaborone, Botswana, [2]Rand Corporation, Santa Monica, United States, [3]University of Botswana, Faculty of Medicine, Gaborone, United States, [4]University of Indianapolis, Indianapolis, United States, [5]Botswana Harvard AIDS Institute Partnerships, Gaborone, Botswana

BACKGROUND: To examine whether social support, including reciprocity of support between people living with HIV (PLWH) and their treatment partners (social network members selected by PLWH when starting antiretroviral therapy, to support adherence), is associated with viral suppression. Support reciprocity (extent to which people exchange mutual support) is an indication of relationship quality and associated with long-term physical and mental health.

METHODS: A total of 131 patients and their treatment partners were recruited from one HIV clinic in Gaborone, Botswana. Participants completed surveys assessing socio-demographic, social network, and psychosocial characteristics. They listed 20 social network members with whom they interacted frequently (including the treatment partner) and reported on network members' characteristics. Participants were asked how close they were emotionally to each social network member, including their treatment partner (not at all close=0, somewhat close=1, very close=2), and rated how likely each social network member would be to show them love and support (not likely=1, somewhat likely=2, very likely=3).

RESULTS: Multivariate logistic regressions indicated a higher likelihood of viral suppression among patients who reported greater average emotional closeness to their network members [OR (95% CI)=3.8 (1.3-11.5), p=.02]. Lower relationship reciprocity (an asymmetric relationship) was associated with lack of viral suppression: viral suppression was less likely when patients felt closer to their treatment partner than their treatment partner felt to them [OR=0.55, p=.01] and when the patient's estimation of their treatment partner's likelihood to show love and support to him/her was greater than their treatment partner's estimation of the likelihood that the patient would show love and support to him/her [OR=0.53, p=.05].

CONCLUSIONS: Treatment partners' reciprocity matters as much as overall closeness in relationships between PLWH and their treatment partners. Interventions to improve the support of informal caregivers could help to increase relationship quality, quality of life, and health outcomes among PLWH.

PED1274

TOBACCO USE BEHAVIORS AMONG PEOPLE LIVING WITH HIV (PLWH) IN NAIROBI, KENYA

E. Koech[1], J. Shuter[2], S. Ojoo[3], S. Himelhoch[4], W. Potts[5], P. Oduor[6], M. Ondire[7], L. Khakali[6], A. Achieng[7], T. Masai[6], D. Medoff[8], M. Bennett[5]
[1]University of Maryland, Centers for International Health, Education and Biosecurity (CIHEB) Kenya Programs, Nairobi, Kenya, [2]Albert Einstein College of Medicine, Department of Medicine, New York, United States, [3]Georgetown University, Medical Center, Washington, United States, [4]University of Kentucky, Department of Psychiatry, Lexington, United States, [5]University of Maryland, Department of Psychiatry, Baltimore, United States, [6]University of Maryland, CIHEB-Kenya Program, Nairobi, Kenya, [7]University of Maryland, CIHEB-Kenya Programs, Nairobi, Kenya, [8]University of Maryland, Department of Psychiatry, Baltimore, Kenya

BACKGROUND: Tobacco use remains the most important preventable cause of mortality worldwide, with >1 billion projected deaths in the 21st century, and the largest predicted regional increases occurring in Africa. There are 1.6 million persons living with HIV (PLWH) in Kenya, and reported smoking prevalences among them vary from 16% to 100% depending on the population surveyed, with particularly high rates in past/present substance users. Few details are known about tobacco use behaviors in Kenyan PLWH.

METHODS: With the goal of culturally tailoring a tobacco treatment intervention for Kenyan PLWH in an upcoming trial, in fall 2019 trained staff administered structured interviews about tobacco use to PLWH smokers recruited from 4 HIV Care clinics and 2 methadone maintenance facilities in Nairobi.

RESULTS: 50 PLWH completed interviews. LANGUAGE: 72% Swahili, 14% English, 14% Swahili+English. DEMOGRAPHICS: Mean age=38.5±9.6 (range: 20-57); 68% M/32% F; 18% single, 48% married, 34% separated/divorced/widowed. EDUCATION: 32% some primary, 20% completed primary, 22% some secondary, 18% completed secondary, 8% post-secondary. EMPLOYMENT: 62% fulltime, 24% parttime, 14% unemployed. HOUSING: 94% stable, 6% transitional. HIV: A mean of 6.5±4.4 years had elapsed since HIV diagnosis, and 100% were on ART. SUBSTANCE USE (in past 30 days): 34% alcohol, 44% marijuana, 0% cocaine, 8% heroin, 72% methadone. TOBACCO USE: 100% cigarette smokers, 4% chewing tobacco, 4% nasal snuff. 74% started smoking at age≤20. Mean cigs/day=14.9±12.4. 92% regular cigarettes, 6% menthol, 18% non-daily smokers. 100% purchased cigarettes as individual "sticks," none purchased full packs. 40% lived with another smoker. NICOTINE DEPENDENCE (FTND), 20.9% low, 25.6% medium, 53.6% high. READINESS TO QUIT (Abrams-Biener ladder), 44% precontemplation, 2% contemplation, 46% preparation, 8% action. QUIT HISTORY: 69.4% had made ≥1 quit attempt in the past. Of these 90% were unassisted ("cold turkey"), 8% with nicotine replacement, 2% with counseling, and none had ever tried bupropion or varenicline.

CONCLUSIONS: In this sample of Kenyan PLWH smokers, cigarettes were always purchased individually, never in packs, there were high levels of nicotine dependence but also high motivation to quit. Almost all prior quit attempts were unassisted with virtually no usage of counseling or pharmacotherapy.

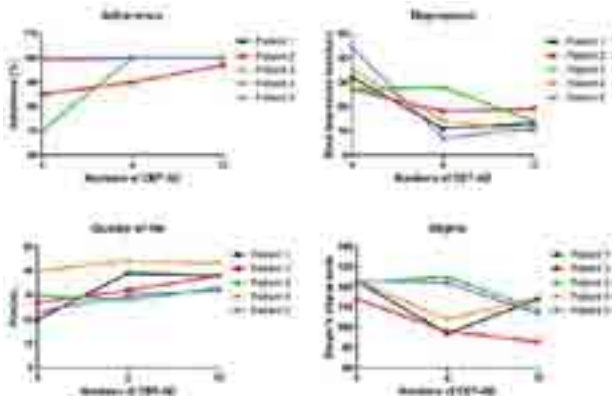
PED1275

EFFECTS OF A NURSE-DELIVERED COGNITIVE BEHAVIORAL THERAPY ON ADHERENCE AND DEPRESSIVE SYMPTOMS OF PEOPLE LIVING WITH HIV IN SOUTH KOREA

J.H. Kim[1], J.M. Kim[2], M. Ye[3], J.I. Lee[2], S. Na[1], Y. Lee[4], D. Short[5], J.Y. Choi[1]
[1]Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Republic of, [2]Severance Hospital, Seoul, Korea, Republic of, [3]Yeoji Mind Clinic, Seoul, Korea, Republic of, [4]Yonsei University College of Medicine, Medical Education, Seoul, Korea, Republic of, [5]ViiV Healthcare, London, United Kingdom

BACKGROUND: Cognitive behavioral therapy focusing on adherence and depression (CBT-AD) performed by clinical psychologists has been found to be an effective treatment for improving depressive symptoms and ART adherence of people living with HIV (PLWH). However, because access to clinical psychologists is limited in most clinics, CBT-AD is rarely performed for PLWH. This study evaluates whether CBT-AD can be effectively performed by a nurse trained and supervised by a clinical psychologist, with a view to wider provision of CBT-AD.

DESCRIPTION: For conducting nurse-delivered CBT-AD, a clinical psychologist developed manuals, educated and supervised a nurse. PLWH with depressive symptoms or adherence <90% were enrolled, and CBT-AD was conducted once weekly for 12 sessions. PLWH were assessed with an adherence by visual analog scale (ranges 0-100%), Beck depression inventory for depressive symptoms (ranges 0-63, higher score means more depressed), PozQoL for quality of life (ranges 13-65, higher score means higher quality of life), and Berger's 40-item stigma scale for stigma (ranges 40-160, the higher the score, the worse the stigma) at baseline, and after the 6th and 12th sessions. In addition, acceptability and feasibility were evaluated by PLWH and providers through surveys.



[Figure]

LESSONS LEARNED: Five male PLWH have completed 12 sessions of CBT-AD. Two of them had <90% adherence before CBT-AD, but nearly 100% adherence after CBT-AD. All study participants showed im-

proved depressive symptoms and quality of life after CBT-AD. As for stigma, overall stigma of participants also showed improving trends. In a survey regarding acceptability, all study participants received great help from CBT-AD and expressed their desire to continue.

CONCLUSIONS/NEXT STEPS: Our findings suggest that a nurse-delivered CBT-AD was effective and acceptable for improving depressive symptoms, quality of life, stigma and ART adherence of PLWH. The implementation of this nurse-delivered intervention should be applied more widely in clinical practice to understand its value.

PED1276

FACTORS MITIGATING RETENTION IN ANTIRETROVIRAL TREATMENT SERVICES IN NIGERIA: NEED FOR EFFECTIVE COMMUNICATION CAMPAIGNS

W. Agbim[1], I. Ndolo[2], I. Atta[3], N.J. Egwuonwu[4]
[1]National Agency for the Control of AIDS (NACA), Corporate Communications/ Public Relations, Abuja, Nigeria, [2]Enugu State University of Science and Technology, Mass Communication, Enugu, Nigeria, [3]National Agency for the Control of AIDS, Special Duties, Abuja, Nigeria, [4]National Agency for the Control of AIDS, Research, Monitoring and Evaluation, Abuja, Nigeria

BACKGROUND: The study seeks to evaluate factors mitigating retention in care services among patients on ART. Lost to follow up (LTFU) arising from poor retention has become a challenge to ART program implementation in most developing countries with rates of 16% to 40% within the first year of treatment.

The study was anchored on Health Belief Model (HBM) for sustained virologic control of HIV by providing a forum of discussion and communication on ART, creating supportive environment for positive behavior change, increasing knowledge about the services, and putting follow up of patients on ART on the news agenda. High levels of awareness campaigns are required towards enhancing retention in care services.

METHODS: A total of 4133 participants were used for the study. Key Informant Interviews (KII) using in depth interviews were conducted among Health Care Workers and PLHIV currently on ART. The study was conducted in 6 health facilities in five states and F.C.T. Participants were randomly selected using computer generated random numbers. Quantitative data obtained were analysed using STATA while the qualitative data was by thematic analysis. The study process and tools were tested for reliability and replicability.

RESULTS: Findings revealed that effective communication campaigns plays significant roles in enhancing retention in care. Out of 1818 (44%) PLHIVs who stopped ART for reasons ranging from drug side effect, preference for herbal medications, health workers poor attitude, non-disclosure of status to family members, poverty, fear of stigma, religious belief, cultural belief etc said they had little or no exposure to health communication messages. It also showed that majority of the clients 2314 (56%) who were regular on ART were exposed to different kinds of communication messages.

CONCLUSIONS: Recommendations includes: Integrating communication through various means like adherence to individual and group counselling, within and outside clinical settings to enhance continued engagement in treatment/care. Provision of incentives to PLHIVs on ART and attitudinal change training for HCWs. There should be a network of trained community accompagnateurs who provide education, counseling, psychosocial support, supervision across the treatment/care and retention continuum. Mobile technologies should be deployed to track and encourage patients in homes and communities.

PED1277

MODIFYING POLICE BEHAVIOR TO PREVENT NEEDLE STICK INJURIES AND REDUCE COMMUNITY HIV RISK: DUAL PUBLIC HEALTH BENEFITS OF SHIELD POLICE TRAINING IN TIJUANA, MEXICO

P. Baker[1,2], L. Beletsky[1,3], D. Abramovitz[1], J. Arredondo[1,4,5], G. Rangel[6], I. Artamonova[1], P. Marotta[7], M.L. Mittal[1,8], T. Rocha-Jimenez[1,2,9], M. Morales[1,10], E. Clairgue[1], S. Kang[1,3], A. Banuelos[11], J.A. Cepeda[1], T.A. Patterson[1], S.A. Strathdee[1]
[1]University of California, Division of Infectious Disease and Global Public Health, San Diego, United States, [2]San Diego State University, Graduate School of Public Health, San Diego, United States, [3]Northeastern University, Bouvé College of Health Sciences, Boston, United States, [4]Centro de Investigacion y Docencia Economica, Programa de Politica de Drogas, Aguascalientes, Mexico, [5]British Columbia Centre on Substance Use, Vancouver, Canada, [6]U.S.-Mexico Border Health Commission, Mexico Section, Tijuana, Mexico, [7]Yale University School of Medicine, Department of Psychiatry, New Haven, United States, [8]Universidad Xochicalco, School of Medicine, Tijuana, Mexico, [9]Universidad Mayor, Society and Health Research Center, Santiago, Chile, [10]The University of Arizona, School of Government and Public Policy, Tucson, United States, [11]Secretaria de Seguridad Publica Municipal, Department of Planning and Special Projects, Tijuana, Mexico

BACKGROUND: Drug law enforcement elevates risk of accidental needlestick injury (NSI) among police, especially as injection drug use spreads globally. Syringe-related policing practices (e.g. confiscation) also drive HIV risk among people who inject drugs (PWID) via syringe sharing. Police training seldom addresses police NSI or HIV risk among PWID, resulting in avoidable harm to officers and PWID. We assessed the longitudinal impact of a SHIELD-based police training intervention to reduce syringe-related occupational risk and deleterious behaviors related to PWID health among Mexican officers.

METHODS: Tijuana police (N=1,788) received instruction linking NSI prevention with HIV and health among PWID (2015-2017). A randomly selected follow-up cohort (n=771) was followed for 24 months. We conducted longitudinal analysis with Generalized Linear Mixed Models to evaluate training impact on occupational NSI risk, measured by the previously validated STIC (Syringe Threat and Injury Correlates) score, and HIV risk to PWID using a composite score of police behaviors negatively impacting PWID health (PWIDH score). [BP1] Both composite scores integrate self-reported syringe-related police practices (e.g. syringe confiscation, breaking) with the PWIDH indicator also accounting for PWID arrest.

RESULTS: We observed significant immediate reductions in police NSI risk (16.2% drop in STIC score) at three months, with sustained decrease of 17.8% through 24mo, compared to pre-training. Police assignment (patrol vs. admin) moderated the training effect on NSI risk (p=0.012). Younger age, male gender, lower rank, and previous NSI were independently associated with higher NSI risk overtime, although all groups demonstrated significant reductions post-training. Regarding behaviors related to HIV risk among PWID, the total effect of the intervention significantly (p<0.0001) reduced the mean PWIDH score by 0.35. This accounts for the indirect effects of mediating police factors such as intent to prevent NSIs (accounted for 13.0% of indirect effects), stigma towards PWID (9.6%), and negative opinions regarding SEPs (8.6%), decriminalization of drugs (5.7%) and the perceived role of police in PWID health (8.5%).

CONCLUSIONS: Police training utilizing the SHIELD model holds promise for sustained improvement in occupational NSI risk and HIV risk among PWID. This warrants scale-up and tailoring to other settings, especially in view of potential simultaneous public health benefits.

PRE-EXPOSURE PROPHYLAXIS

PED1278

HIGH PREP DEMAND AMONG MSM AND TRANSGENDER ADOLESCENTS IN THAILAND AMIDST SYSTEMIC MULTISECTORAL BARRIERS TO IMPLEMENTATION

P.A. Newman[1], K. Fongkaew[2], J.W. de Lind van Wijngaarden[3], S. Tepjan[4], N. Chonwanarat[2]
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]Burapha University, Humanities and Social Sciences, Chonburi, Thailand, [3]Burapha University, Public Health, Chonburi, Thailand, [4]VOICES-Thailand Foundation, Chiang Mai, Thailand

BACKGROUND: Young men who have sex with men (MSM) and transgender people in Thailand continue to face a high burden of HIV infection. With median age of sexual debut at 17-years-old and higher HIV incidence among adolescent versus young adult MSM, adolescent-specific interventions are needed. Thai-government guidelines support provision of federally subsidized pre-exposure prophylaxis (PrEP) for MSM and transgender persons at high risk of HIV acquisition; but with existing interventions targeting urban, adult gay entertainment venues, PrEP has largely failed to reach adolescents and uptake remains low. We explored PrEP awareness, demand, and implementation challenges among MSM and transgender adolescents in semi-urban communities to inform targeted preventive interventions.

METHODS: Focus group discussions (FGDs) were conducted using a semi-structured Thai-language topic guide with 16–20-year-old MSM and transgender persons recruited from high-schools, vocational schools, and universities in three Thai provinces. Youth <18-years-old provided parental consent. Key informant (KI) interviews were conducted in Thai or English with healthcare providers (HCP), nongovernmental organization (NGO) leaders, and youth advocates. FGDs and interviews were transcribed verbatim (in Thai or English) and reviewed using thematic analysis in Atlas.ti by a bilingual team, with coding discrepancies resolved by consensus.

RESULTS: From May-July 2018 we conducted four FGDs (n=20 MSM, 5 transgender adolescents; mean age=18.0 years, SD=1.3) and 17 KI interviews (7 HCPs, 5 NGO-leaders, 5 youth-advocates). A minority of adolescents reported experimenting with anal sex; most didn't use condoms. Most reported no school-based HIV/sexual health education inclusive of young MSM and transgender persons, and very limited PrEP awareness and knowledge; a few heard about PrEP through Facebook/other social media. Once explained, most adolescents expressed high interest if PrEP were provided for free. KIs corroborated adolescents' sexual risk, lack of adolescent MSM/transgender-specific HIV/sexual health education, and articulated barriers in PrEP implementation due to adolescents' low awareness and access, and HCP resistance amidst reported concerns about negative parental reactions, lower condom use, and high public health costs.

CONCLUSIONS: Despite low PrEP awareness, most MSM and transgender adolescents indicated interest in PrEP once explained. However, pervasive barriers across school, parental, and healthcare system domains impede implementation despite enabling government policies and individual demand.

PED1279

SEXUAL BEHAVIOR CHANGE IN PEOPLE USING HIV PRE-EXPOSURE PROHYLAXIS

U. Koppe[1], U. Marcus[1], S. Albrecht[2], K. Jansen[1], H. Jessen[3], B. Gunsenheimer-Bartmeyer[1], V. Bremer[1]
[1]Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany, [2]Robert Koch Institute, Department of Epidemiology and Health Monitoring, Berlin, Germany, [3]Praxis Jessen[2] + Kollegen, Berlin, Germany

BACKGROUND: Use of HIV pre-exposure prophylaxis (PrEP) might be accompanied by changed sexual behavior. We investigated self-reported sexual behavior change in a large sample of German PrEP users.

METHODS: From April to June 2019 we recruited PrEP users in Germany on MSM dating apps, community-based HIV testing sites, and a community website for an anonymous online survey. We defined increased sexual activity as reporting more partners and/or more sexual contacts since starting PrEP. Risk factors for increased sexual activity were assessed with logistic regression models adjusting for age, gender identity, and duration of PrEP use.

RESULTS: We recruited 3,071 PrEP users with a median age of 37 (IQR 30-45) and with 94.7% identifying as cisgender male (missing: 3.5%). More than 3 partners for anal/vaginal sex within the last 6 months were reported by 83.3% (Table 1) and 77.7% of the participants indicated they reduced or stopped condom use.

Of 2,564 participants providing information on the development of sexual behavior since starting PrEP, 43.6% indicated having more partners and/or more contacts (Table 1). Participants with more partners and/or more contacts were more likely to report >20 partners within the last 6 months than participants with stable partner/contact numbers (OR = 2.1, 95% CI 1.7 – 2.4). In addition, participants indicating increased partner/contact numbers since starting PrEP were more likely to use condoms less often as before (OR = 2.7, 95%CI 2.1 – 3.4) or stopped using condoms altogether (OR = 4.8, 95% CI 3.6 – 6.3).

Partner numbers within the last 6 months	No change in partner/contact numbers after start of PrEP (n = 1,447)	Increase in partner/contact numbers after start of PrEP (n = 1,117)	Overall (n = 2,564)
0-3	273 (18.9%)	103 (9.2%)	376 (14.7%)
4-5	239 (16.5%)	137 (12.3%)	376 (14.7%)
6-10	312 (21.6%)	178 (15.9%)	490 (19.1%)
11-20	238 (16.4%)	215 (19.2%)	453 (17.7%)
>20	363 (25.1%)	455 (40.7%)	818 (31.9%)
Missing	22 (1.5%)	29 (2.6%)	51 (2.0%)

[Table 1: Partner numbers within the last 6 months in PrEP users]

CONCLUSIONS: PrEP users in Germany had high partner numbers and were using condoms less often regardless of their sexual behavior change during PrEP use. PrEP is important for HIV prevention in this group. Because of lower condom use, PrEP users have a higher probability of acquiring and passing on sexually transmitted infections (STI) which should be considered when providing PrEP.

PED1280

CHALLENGES AND UNMET NEEDS AFFECTING PREP ACCESS AND UPTAKE AMONG BLACK AND LATINX MSM AND TRANSGENDER WOMEN

S. Wang[1], S. Philip[2], T. Packer[2], J. McCright[2], C. Boyer[3]
[1]Santa Clara University, Counseling Psychology, Santa Clara, United States, [2]San Francisco Department of Public Health, NA, San Francisco, United States, [3]University of San Francisco, Pediatrics, San Francisco, United States

BACKGROUND: Oral pre-exposure prophylaxis (PrEP) has been shown to significantly reduce the acquisition of HIV infection. Despite the availability of PrEP in the U.S., Black and Latinx men who have sex with men (MSM) and transgender women experience the greatest disparities in PrEP uptake. Consequently, there is an urgent need to better understand factors related to PrEP awareness, access, and uptake in communities most disproportionately affected by the epidemic. San Francisco provides an opportunity to examine challenges and unmet needs in these groups given the abundance of resources and availability of PrEP.

METHODS: A qualitative case study funded by the San Francisco Department of Public Health solicited input from a diverse group of healthcare providers and Black and Latinx MSM and transgender women in San Francisco. Fourteen individual in-person interviews were conducted with six healthcare providers and eight Black and Latinx MSM and transgender women, aged 18-25 years, who were recruited through snowball sampling strategies.

RESULTS: Results of content analysis identified challenges and unmet needs due to: resource distribution (where services are located and concentrated), stigma within and outside of health care settings (medical mistrust, fear of being seen in particular clinics), lack of linguistically-sensitive services, an over-emphasis on sexual risk in healthcare settings, and non-inclusive PrEP awareness campaigns. Given the multi-level barriers impeding PrEP access, participants provided recommendations across different levels of the socioecological system, including alternative venues for HIV screening (pop-up clinics, mobile vans) and other methods to reduce stigma and medical mistrust, providing bilingual Spanish-speaking services, using terminologies that focus on “wellness” instead of “risk”, and incorporating trauma and violence history to assess comprehensive health needs, not just sexual health. Participants also underscored the need for simplified and inclusive PrEP awareness campaigns to showcase strength-based images of people of color that also target women and heterosexual community members.

CONCLUSIONS: The findings describe challenges and unmet needs affecting PrEP access and uptake among Black and Latinx MSM and transgender women in San Francisco, which underscore the need for multi-level contextual considerations for development of culturally congruent outreach campaigns and healthcare services to enhance PrEP awareness and uptake.

BACKGROUND: Non-oral pre-exposure prophylaxis (PrEP) delivery modalities are viable HIV prevention tools for female sex workers experiencing adherence challenges to widely available daily oral PrEP. We compare acceptability of various PrEP delivery modalities/schedules and correlates in a prospective cohort of street-based cisgender (CFSW) and transgender female sex workers (TFSW) in the United States.

METHODS: Women aged 15 and older who recently (past 3 months) sold/traded sex to clients picked up in public places 3+ times were recruited via targeted sampling in Baltimore, Maryland. During five study visits over 12 months, participants completed interviewer-administered surveys assessing sex work history and police encounters, proceeded by HIV/STI testing. Among HIV-negative CFSW (n=236) and TFSW (n=36) at baseline, multivariable Poisson regression with robust variance estimation cross-sectionally identified factors associated with interest in two non-daily, non-oral PrEP modalities: quarterly arm injections and microbicidal topical gels (applied vaginally or rectally before sex). Due to the small sample of TFSW, regression models only converged for CFSW.

RESULTS: Compared to interest in daily oral PrEP among CFSW (73%) and TFSW (66%), over half (CFSW: 56%, TFSW: 61%) and one-fourth (CFSW: 25%, TFSW: 22%) of participants expressed interest in injectable PrEP and topical gels, respectively. Among CFSW, condom coercion by clients (Adjusted Prevalence Ratio [APR] = 1.23, 95% Confidence Interval [CI]: 1.00–1.52), not carrying condoms to avert police encounters (APR=1.35, CI: 1.07–1.71), and injection drug use with (APR=1.59, CI: 1.13–2.25) and without (APR=1.63, CI: 1.18–2.26) syringe sharing, respectively, were significantly associated with interest in injectable PrEP. By comparison, syringe sharing during injection drug use was inversely associated with interest in topical gels (APR=0.41, CI: 0.21–0.81). CFSW reporting condomless vaginal sex with clients (APR=1.61, CI: 1.04–2.49) and physical violence perpetration by non-paying partners (APR=2.20, CI: 1.32–3.67) exhibited higher interest in topical gels.

CONCLUSIONS: Acceptability of non-oral PrEP modalities varied, with over half of both CFSW and TFSW expressing interest in injectable PrEP and one quarter in topical gels. Our findings identify unique interpersonal, behavioral, and structural profiles of at-risk women whose HIV prevention preferences and needs warrant highly differentiated alternatives to daily oral PrEP.

PED1282

UNDERSTANDING PREP INTEREST AMONG SOUTH AFRICAN ADOLESCENTS: THE IMPACT OF PERCEIVED PARENTAL SUPPORT AND PREP-RELATED STIGMA

D. Giovenco[1,2], A. Pettifor[1], L.-G. Bekker[2,3], L. Filiatreau[1], M. Atujuna[2], K. Gill[2], M. Akande[4], D. Stein[5], C. Kuo[4,5]

[1]University of North Carolina at Chapel Hill, Epidemiology, Chapel Hill, United States, [2]Desmond Tutu HIV Center, Cape Town, South Africa, [3]University of Cape Town, Medicine, Cape Town, South Africa, [4]Brown University, Behavioral and Social Sciences, Providence, United States, [5]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa

BACKGROUND: As PrEP rollout expands to include adolescents in high-prevalence settings, parental support and perceived stigma have emerged as barriers to PrEP use in qualitative research. The parent-child interaction around PrEP, however, remains largely unexplored. We examined perceptions of PrEP-related stigma among adolescent-parent dyads to determine if PrEP-related stigma is associated with interest in and support for adolescent PrEP uptake.

METHODS: This cross-sectional data was collected in a peri-urban settlement near Cape Town, South Africa during baseline procedures of the Our Family Our Future intervention efficacy trial (R01MH114843). Adolescents (14-16 years) at disproportionate risk for acquiring HIV and their parents were recruited via systematic door-to-door sampling in 2018-2019. Eligible dyad members were invited to complete an ACASI-administered survey evaluating oral PrEP awareness, interest in/support for adolescent oral PrEP use, and perceptions of PrEP-related stigma. Stigma was assessed using 7-items with average scores dichotomized at the median. Prevalence ratios (PRs) were computed using log-binomial regression.

RESULTS: Adolescents (n=305) were 56% female. Over half (54%) had engaged in vaginal or anal intercourse, of whom 24% reported never having used a condom. Parents were 88% female. Among adolescents, 36% had heard about PrEP and 69% reported they would "definitely" or "probably" want to use PrEP. Further, 62% thought their parent would support their PrEP use. Among parents, 29% had heard about PrEP and 84% reported they would support their adolescent using PrEP. Adolescents who thought their parents would support their PrEP use were 1.72 times as likely to be interested in PrEP (95%CI:1.38-2.15, p<.001). Adolescents reported higher PrEP-related stigma scores (mean=2.41) than parents (mean=2.08), p<.001. Adolescents reporting lower stigma were more likely to be interested in PrEP than adolescents reporting higher stigma (adjusted-PR=1.24, 95%CI:1.04-1.47, p=.014). The same association was observed for parents (adjusted-PR=1.21, 95%CI:1.05-1.36, p=.007).

CONCLUSIONS: Overall PrEP awareness was low, but interest among adolescents and support among parents were high. Parents were more supportive of their adolescents using PrEP than adolescents perceived, and low perceptions of parental support and PrEP-related stigma were associated with reduced PrEP interest among adolescents. Future PrEP implementation efforts should consider parents as important allies in supporting adolescent PrEP uptake and use.

PERCEPTIONS OF PRE-EXPOSURE PROPHYLAXIS FOR HIV PREVENTION IN A HIGH-BURDEN SETTING IN KWAZULU-NATAL, SOUTH AFRICA

C. Laxmeshwar[1], P. Isaakidis[2], J. Furin[3], C.K. Molokoe[1], L. Dlamini[1], K. Hlophe[4], N. Gcwensa[1], A. Shigayeva[1], A. Nelson[1], S.J. Steele[2], G. Van Cutsem[2], L. Ohler[1]

[1]Médecins Sans Frontières, Eshowe, South Africa, [2]Southern Africa Medical Unit, Médecins Sans Frontières, Cape Town, South Africa, [3]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States, [4]Department of Health, Eshowe, South Africa

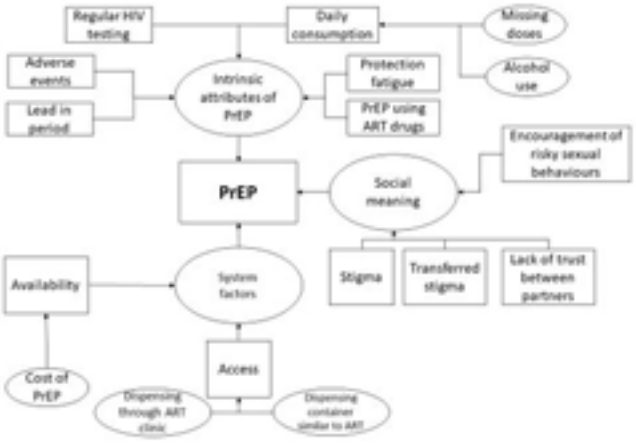
BACKGROUND: Pre-exposure prophylaxis (PrEP) is a reliable HIV prevention option for young adults in countries with high HIV prevalence. However, little is known about the perceptions of young adults about benefits and challenges of taking PrEP. This study was conducted to understand the perceived barriers and facilitators of PrEP among young men and women (18-35 years) in KwaZulu-Natal, South Africa.

METHODS: This qualitative study using in-depth interviews and focus group discussions (FGD) was conducted between February and April 2018. Young adults testing HIV negative at MSF supported community testing sites were invited to participate in the study. Key informant interviews were conducted with community leaders, religious leaders, traditional chiefs and community health promoters.

RESULTS: Sixteen FGDs (6 with females, 10 with males and 6-10 persons per group), 22 in-depth interviews (9 with males and 13 with females) and 6 key informant interviews were conducted. Thematic network of reported barriers have been described in the figure. Themes affecting the acceptability of PrEP were categorised as the intrinsic attributes of PrEP, system factors and the social meaning attached to PrEP.

Important intrinsic factor affecting PrEP acceptability was having to use multiple prevention methods leading to 'protection fatigue'. Accessing PrEP through ART clinics was an important system factor affecting acceptability. The perception that the partner of the PrEP recipient is HIV-positive, termed 'transferred stigma' was an interesting social meaning.

Facilitators for taking PrEP included, stressing the "value of life" and participation of community leaders in awareness campaigns. Peer support groups and decentralised delivery of PrEP outside ART clinics were mentioned as motivators.



[Figure]

CONCLUSIONS: This study shows that PrEP is an acceptable method of HIV prevention for the youth. Perceived barriers were mainly related to PrEP delivery methods and the meaning assigned to taking PrEP by the community. Provision of adequate support is essential.

PED1284

END-USER PERSPECTIVES ON THEIR ABILITY, MOTIVATION AND OPPORTUNITY TO USE THE DAPIVIRINE VAGINAL RING

K. Schwartz[1], N. Bhavaraju[2], K. Ridgeway[1], A. Gomez[3]
[1]FHI 360, Durham, United States, [2]FSG, Washington, United States, [3]AVAC, New York, United States

BACKGROUND: In preparation for the potential launch of the dapivirine ring in Africa, the OPTIONS Consortium, in collaboration with the International Partnership for Microbicides, consolidated evidence representing end-user insights from relevant dapivirine ring research. The objective was to create a comprehensive compendium of insights to inform demand creation efforts post-approval and identify areas for further exploration needed to support ring introduction.

METHODS: From September-November 2019, we reviewed published and grey literature to identify insights that may influence women's uptake and continued use of the dapivirine ring. Thirty-seven resources across 21 studies were reviewed, including results from clinical trials, qualitative or market research, discrete choice experiments and human centered design studies published between January 1, 2014 and November 30, 2019 focused on women of any age. Sub-Saharan Africa was the primary geographic focus.

Key insights across the resources were summarized thematically and categorized according to the ability, motivation, and opportunity (A-M-O) framework1. Specific factors contributing toward product uptake and continued use included: knowledge, self-efficacy, social support (categorized as Ability); risk perception, willingness, norms (Motivation); and availability, accessibility, and affordability (Opportunity).

RESULTS: Twenty-nine end-user insights were identified from the literature. There was high coverage in the Ability category, with 45% of insights falling into this area. Eleven insights (38%) had moderate coverage - risk perception, willingness, and accessibility. Only five insights (17%) were related to norms, availability, and affordability. Examples of insights garnered from this analysis include:

- Effective use and replacement of the ring improves with experience (self-efficacy)
- Young women may consider their personal HIV risk low, even while recognizing high levels of general risk (risk perception)
- Stigma against sexual activity, especially for young people, has significant influence on product choice (norms)
- Women largely seek to access the ring in clinical settings at the outset (accessibility)

CONCLUSIONS: The A-M-O Framework provides a helpful structure for organizing end-user research in a way that contributes to demand creation efforts for HIV prevention products. This analysis shows a paucity of known end-user perspectives on norms, availability, and affordability. Using this compendium, program managers, researchers, and communications/marketing teams can determine what information exists and what areas need further exploration.

PED1285

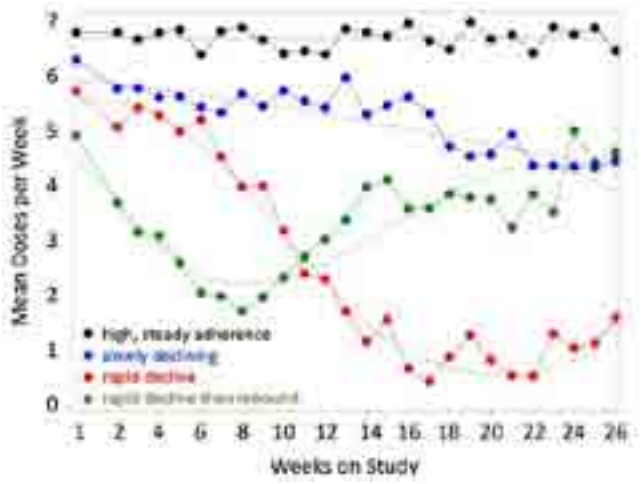
ADHERENCE TO DAILY, ORAL TDF/FTC PREP DURING PERICONCEPTION AMONG HIV-EXPOSED SOUTH AFRICAN WOMEN

L.T. Matthews[1], M. Jaggernath[2], Y. Kriel[2], P.M. Smith[1], M. Mathenjwa[2], K. Bennett[3], C. Psaros[4], K.E. Wirth[5], C.W. Hendrix[6], J.M. Baeten[7], D.R. Bangsberg[8], J.E. Haberer[4], J.A. Smit[2]
[1]University of Alabama at Birmingham, Medicine, Birmingham, United States, [2]University of the Witwatersrand, MRU (Maternal, Adolescent and Child Health Research Unit), Durban, South Africa, [3]Bennett Statistical Consulting, Ballston Lake, United States, [4]Massachusetts General Hospital, Boston, United States, [5]Harvard T.H. Chan School of Public Health, Boston, United States, [6]Johns Hopkins University, Baltimore, United States, [7]University of Washington, Seattle, United States, [8]Oregon Health Sciences University/ Portland State University, Portland, United States

BACKGROUND: Women who conceive while exposed to HIV need strategies to mitigate HIV acquisition risks. We are conducting a longitudinal study in Durban, South Africa to evaluate use of TDF/FTC as PrEP among HIV-exposed women planning for pregnancy.

METHODS: We enroll HIV-uninfected, 18-35 year old women with plans for pregnancy with a stable partner living with HIV or of unknown-serostatus. Safer conception counseling including PrEP is offered at each study visit. PrEP is supplied with an electronic pill cap and quarterly adherence counseling. Plasma tenofovir is collected quarterly. We follow women for one year; those who become pregnant are followed through pregnancy outcome. Adherence is defined as the number of electronic pill cap openings divided by number of days of expected PrEP use. We present data for the first 307 participants. Group-based trajectory models were used to identify 26-week adherence patterns for 156 periconception participants.

RESULTS:



[Figure. Periconception PrEP adherence trajectories for 156 participants.]

Between October 2017 and December 2019 we enrolled 307 women with median age 24 (range 18-35) years. Partner HIV-serostatus was unknown by 293 (96%). Among 296 women completing safer conception counseling, 62% (N=183) chose to initiate PrEP. During periconception follow-up overall median (IQR) adherence was 73% (51%-86%). In trajectory analyses, four adherence patterns emerged: high steady adherence (19% of women), slowly declining (39%), rapid decline (19%), and rapid decline then recovery (24%) (Figure). Women aged 18-24 years were more likely to follow either of the rapidly declining adherence patterns compared to older women (p=0.03). Detectable tenofovir was significantly associated with pill cap openings (p<0.0001).

CONCLUSIONS: Among women at-risk for HIV acquisition and planning pregnancy, most choose PrEP as a safer conception strategy. These data indicate high demand for and acceptability of periconception PrEP in South Africa. Trajectories identify groups who may require different types of support to optimize adherence behavior.

FEASIBILITY AND ACCEPTABILITY OF JUST4US, A WOMAN-FOCUSED INTERVENTION TO INCREASE PREP UPTAKE AND ADHERENCE AMONG PREP-ELIGIBLE WOMEN IN NYC AND PHILADELPHIA

H.V. Tieu[1], B. Koblin[1], A. Davis[2], V. Frye[3], G. Ortiz[1], D. Lucy[1], N. Englert[1], K. Stewart[1], D. Fiore[2], V. Nandi[4], B. Brawner[5], E. Iwu[6], A. Teitelman[7], Just4Us Study Team

[1]Lindsley F. Kimball Research Institute, New York Blood Center, Lab of Infectious Disease Prevention, New York, United States, [2]University of Pennsylvania Perelman School of Medicine, HIV/AIDS Prevention Research Division, Philadelphia, United States, [3]City College of New York, CUNY School of Medicine, Department of Community Health and Social Medicine, New York, United States, [4]Lindsley F. Kimball Research Institute, New York Blood Center, Lab of Data Analytics, New York, United States, [5]University of Pennsylvania School of Nursing, New York, United States, [6]Rutgers University, New Brunswick, United States, [7]University of Pennsylvania School of Nursing, Department of Family and Community Health, Philadelphia, United States

BACKGROUND: Women comprise 21% of new HIV infections in the US. Many women vulnerable to HIV acquisition are not aware of and thus cannot access oral PrEP. We conducted a pilot randomized controlled trial to assess acceptability and feasibility of a theory-based, contextually relevant, technology-enhanced behavioral intervention, Just4Us, to promote PrEP initiation and adherence among women in NYC and Philadelphia.

METHODS: Eligibility criteria included: cisgender women, aged 18-55 years, HIV-negative, not currently taking PrEP, and meeting US guidelines for PrEP eligibility. Participants were recruited from venues (e.g., homeless shelters, drug treatment), online, and via referrals. They were randomized 3:1 to intervention (education and activities) or control (information only) arms.

All participants were provided with PrEP information and list of local PrEP clinics. Intervention arm participants also received a 1-1.5 hour individually-delivered baseline session with a counselor/navigator; the session involved 12 mini-modules related to providing information (video), motivation enhancement, skills-building, problem-solving, and referrals. Between baseline and 3-month follow-up, they received post-visit phone calls to support linkage to care and text-messaging program to promote adherence. All participants completed baseline, immediate post-intervention and 3-month online follow-up surveys.

Feasibility was assessed by: number of women eligible relative to number screened, number enrolled relative to number eligible, and number enrolled relative to target sample size. Acceptability was assessed by: intervention completion rate, 3-month visit retention rate, and satisfaction level based on survey responses.

RESULTS: Eighty-three women were enrolled (61 intervention; 22 control), exceeding target enrollment. Mean age was 37 years; 79% were Black, 26% Latina. Of 255 screened, 104 (41%) were eligible and 83 (80%) enrolled. Nearly 100% of the intervention mini-modules were completed. Retention rate was high at 90%. Intervention arm participants reported the following "very satisfied/satisfied" levels: overall session, 95%; discussion with counselor/navigator, 97%; tablet activities, 95%; text-messaging set-up, 93%; and video, 90%. Among control and intervention arms, 78% felt the session length was just right.

CONCLUSIONS: The pilot study demonstrated feasibility and acceptability of the Just4Us intervention, a promising woman-focused intervention to increase uptake of daily oral PrEP among women. These findings will be used to refine and test the adapted intervention in a larger trial.

PED1287

"I HAVE NO REASON TO TAKE IT, I KEEP MYSELF SAFE": ACCEPTABILITY AND PERSPECTIVES ON HIV PRE-EXPOSURE PROPHYLAXIS AMONG PEOPLE WHO INJECT DRUGS IN VANCOUVER, CANADA

C. Ng[1], P.-J. Coulaud[2,1], W. Small[1], R. Knight[2,1]

[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada

BACKGROUND: Despite Pre-Exposure Prophylaxis (PrEP) being highly efficacious for HIV prevention among marginalized populations, levels of PrEP awareness and uptake remain low among people who inject drugs (PWID). The objective of this study is to identify the individual, social, and structural factors that influence the acceptability of PrEP among PWID.

METHODS: From February to September 2017, we conducted in-depth, semi-structured interviews with 30 HIV-negative PWID (ages 33-73, 13 women, 17 men) from a prospective cohort in Vancouver, Canada. Interviews were coded and analyzed in NVIVO using thematic analysis which focused on examining PrEP acceptability and perceived barriers to use.

RESULTS: Three primary themes emerged from the interviews.

First, individual-level knowledge and awareness about PrEP was generally low and shaped by very low levels of HIV risk perception and concerns about PrEP (e.g. effectiveness, mistrust, side effects). While many felt PrEP would be suitable for others, only a small number considered themselves to be appropriate candidates for the intervention. Some participants also expressed unwillingness to use PrEP in the future, while others did not rule it out completely.

Second, participants described a set of social barriers to PrEP uptake. For example, a few discussed how HIV-related stigma (e.g. having to disclose being in a relationship with someone living with HIV) represents a significant barrier to PrEP use.

Third, a sub-set emphasized social and structural determinants with regards to PrEP access. Their discussions suggested the need to develop PrEP interventions through free, nonjudgmental, non-stigmatizing, and easy access to PrEP. They described that people who experience HIV-related anxiety, those who inject drugs, sex workers, and serodiscordant couples should be priority populations for future PrEP interventions.

CONCLUSIONS: Our findings suggest that HIV prevention messages related to PrEP have yet to reach PWID. Future HIV interventions and research should focus on health promotion strategies to ensure PWID who will benefit from PrEP both know about and have easy and free access to PrEP.

PED1288

#IYKWIM... WHAT AGYW REALLY THINK ABOUT PREP, HIV SERVICES AND HOW WE TALK TO THEM (#IYKWIM - IF YOU KNOW WHAT I MEAN)

E. Briedenhann[1], D. Pillay[1], N. Vundamina[1], N. Sheobalak[1], M. Lanham[2], G. Morales[2], S. Mullick[1]
[1]Wits Reproductive Health and HIV Institute, Implementation Science, Johannesburg, South Africa, [2]FHI 360, Durham, United States

BACKGROUND: Adolescent girls and young women (AGYW) are a priority group for oral pre-exposure prophylaxis (PrEP) in South Africa (SA). Limited insights exist regarding their decision-making to use PrEP, and what role information, education and communication (IEC) materials play in this process.

DESCRIPTION: Between August 2018-August 2019, the WitsRHI OPTIONS team conducted six youth dialogues facilitated by a communications expert. Participants were selected through peer educators, age 18 or older, and categorized as PrEP current, past or never users. Dialogues, conducted in a semi-structured discussion, explored PrEP knowledge, barriers to testing, intent to access services, social mobilization and the National Department of Health IEC materials.

LESSONS LEARNED: Sixty-one youth participated, 50 AGYW, 10 young men and one transgender woman. Youth showed excellent knowledge on PrEP and HIV but did not endorse good health as a primary motivator for uptake, "It's so difficult because I don't like taking pills, knowing well that this is something that will keep me negative." However, feeling part of a movement, like We Are The Generation That Will End HIV (which features on all SA IEC materials), encouraged feelings of ownership and stimulated interest in PrEP. Materials were reported as an asset for navigating issues like PrEP side-effects, continuation, stigma and misinformation. Peer-led social mobilization was highly ranked but should include a digital approach: "Capitalise on Twitter, Instagram, Facebook and YouTube! On all these things that we're forever on." Youth showed resilience using innovative strategies to facilitate continuation and manage side-effects. HIV testing is a barrier to accessing PrEP due to fear and stigma associated with a positive result. The benefit of self-screening was noted but youth had concerns about receiving a positive result in the absence of support. Convenient services were a consistent theme, highlighting desire for mobile and youth-friendly clinics, and PrEP courier delivery.

CONCLUSIONS/NEXT STEPS: The biomedical benefit of PrEP isn't a motivator for uptake, rather positive emotional communication paired with convenient/supportive services and the reward of "being part of something bigger than myself" resonates with youth. Communication across digital platforms is valued; in response, these platforms have been established: www.myprep.co.za and @myPrEP_SouthAfrica on social media.

PED1289

U.S. PHYSICIAN INTENTIONS TO RECOMMEND AND PRESCRIBE HIV PRE-EXPOSURE TO ADOLESCENTS AND YOUNG ADULTS

B. Spicer[1], J. Kahn[1,2], G. Zimet[3], T. Qiu[4], B. Huang[4,2], T. Mullins[1,2]
[1]Cincinnati Children's Hospital Medical Center, Division of Adolescent Medicine, Cincinnati, United States, [2]University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States, [3]Indiana University, Division of Adolescent Medicine, Indianapolis, United States, [4]Cincinnati Children's Hospital Medical Center, Division of Biostatistics and Epidemiology, Cincinnati, United States

BACKGROUND: In the U.S., 21% of new HIV infections occurred in 13-24-year-olds; thus, pre-exposure prophylaxis (PrEP) is a promising intervention to prevent HIV in youth. However, PrEP's effectiveness depends upon clinicians' willingness to recommend and prescribe it. We examined physician intentions to recommend and prescribe PrEP, factors associated with these intentions, and experiences providing PrEP to youth.

METHODS: Surveys (n=2556) were physically mailed (May-December, 2018) to a random sample of physicians stratified by geographic region and specialty, drawn from the American Medical Association Physician Database (family practice, internal medicine, obstetrics/gynecology, pediatrics, adolescent medicine). Respondents caring for youth under age 18 were included. Surveys, informed by the Theory of Planned Behavior, Diffusion of Innovations, and a prior qualitative study, assessed demographics, knowledge, attitudes, benefits of, and barriers to, providing PrEP to youth, characteristics of PrEP impacting uptake, and experiences with PrEP. Outcomes - intention to recommend PrEP and intention to prescribe PrEP to 13-21-year-olds - were measured on 5-point Likert-type scales and dichotomized into high intention vs. other responses. Separate logistic regression models were generated for each outcome. Predictors associated with outcomes at p< 0.10 in unadjusted models were included in multivariable stepwise logistic regression models.

RESULTS: Of 414 responses, 375 were from physicians caring for youth and included in analyses. Most respondents were white (77.3%) and female (71%). Mean age was 48.3 years (SD10.7). Practice type was primarily private practice (38.4%) and academic (31.2%); 55% (SD38.6) of patients in the physician's practice were under age 18 years. Among respondents, 41% had discussed PrEP and 20% had prescribed PrEP to youth ages 13-21. Results of multivariable regression models are shown in the Table.

	Predictor	Adjusted Odds Ratio (95% Confidence Interval)
Intention to Recommend PrEP to Youth Ages 13-21 Years	U.S. region in which residency training was completed	
	Northeast vs. West	2.32 (1.08-4.98)
	Midwest vs. West	1.16 (0.55-2.47)
	South vs. West	1.45 (0.66-3.19)
	Physician specialty	
	Obstetrics/gynecology vs. Pediatrics	0.15 (0.05-0.41)
	Internal medicine/family practice vs. Pediatrics	2.15 (1.03-4.47)
	Adolescent medicine vs. Pediatrics	1.47 (0.74-2.90)
	Confidence in providing current HIV prevention methods	0.64 (0.41-1.01)
	Perceived ease of incorporating PrEP into practice	1.57 (1.24-1.99)
Intention to Prescribe PrEP to Youth Ages 13-21 Years	Physician specialty	
	Obstetrics/gynecology vs. Pediatrics	0.07 (0.02-0.21)
	Internal medicine/family practice vs. Pediatrics	2.74 (1.26-5.97)
	Adolescent medicine vs. Pediatrics	1.96 (0.91-4.21)
	Familiarity with PrEP	0.43 (0.28-0.65)
	Comfort with prescribing PrEP to patients under age 18 years	1.55 (1.18-2.04)
	Perceived ease of incorporating PrEP into practice	2.05 (1.54-2.72)

[Table: Factors Associated with Intention to Recommend and Prescribe PrEP to Youth Ages 13-21 Years]

CONCLUSIONS: Strategies to improve physician comfort with prescribing PrEP and ease of incorporating PrEP into practice may improve clinician intentions to prescribe and actual prescription of PrEP to at-risk youth.

PED1290

INDIVIDUAL AND CONTEXTUAL FACTORS ASSOCIATED WITH PREP ADHERENCE AMONG KENYAN ADOLESCENT GIRLS AND YOUNG WOMEN

J. Cover[1], C. Obong'o[2], R. Obanda[2], E. Kariithi[2], O. Madiang[2], J. Mukabi[2], M. Brady[1], S. Zobrist[1], P. Drain[3], J.D.D. Tapsoba[4], Y. Chen[4]
[1]PATH, Seattle, United States, [2]PATH, Kisumu, Kenya, [3]University of Washington, Seattle, United States, [4]Fred Hutchinson Cancer Research Center, Seattle, United States

BACKGROUND: Adolescent girls and young women (AGYW) bear a disproportionate burden of new HIV infections in Kenya. Since March 2017, AGYW enrolled in DREAMS are offered PrEP for HIV prevention. Our objectives were to measure biomarker and self-reported levels of PrEP adherence and identify factors associated with poor adherence.

METHODS: We enrolled 343 randomly-selected AGYW ages 18-24 years from Kisumu and Homabay counties in Kenya who were taking PrEP for 2-9 months. Participants engaged in interviews and provided a dried blood spot (DBS) biomarker sample for testing of tenofovir-diphosphate drug levels. Interviews were repeated three months later, and if the participant continued PrEP, a second DBS sample was collected. First round interviews and DBS collection took place from June to September, 2019, with follow up from September 2019 to January 2020. AGYW are PrEP adherent if their tenofovir-diphosphate drug levels exceed 30f/molx106.

We used bivariate and multivariate regression analyses to identify associations with PrEP adherence. Because the study is currently underway, results shown are descriptive and derived from the first round of interviews; full results, including for biomarker testing, will be presented at the conference.

RESULTS: For self-reported adherence, 85% of participants reported taking PrEP most or all of the time; 82% reported taking PrEP is very or somewhat easy. In the week prior, 89% reported taking PrEP 4 or more days. The most common explanations for missed pills were not having pills when needed (41%) and privacy concerns (33%). Participants reported high levels of social support among friends, moderate support from family and low support from partners. Among those whose partner was unaware of her PrEP use, more than half indicated intimate partner violence was somewhat or very likely if he were to learn of it. One-quarter never use condoms, and half indicate their condom use has declined since initiating PrEP. Married AGYW report lower condom self-efficacy than unmarried AGYW.

CONCLUSIONS: In this cohort of AGYW, self-reported adherence was high, social support was strongest among peers, and condom use has declined. Our results will help determine patterns of PrEP adherence among AGYW, informing the structure of HIV prevention programs in resource-limited settings.

PED1291

AWARENESS, WILLINGNESS TO USE, AND WILLINGNESS TO PAY FOR DIFFERENT PREP SCHEMES AMONG MSM IN MEXICO

D. Cerecero-Garcia[1], H. Vermandere[1], J. Gomez-Castro[1], L.A. Moreno-Aguilar[1], A. Colchero-Aragonés[1], G. Martinez-Silva[1], A. Martínez-Dávalos[1], I. Huerta-Icelo[1], S. Bautista-Arredondo[1]
[1]National Institute of Public Health, Cuernavaca, Mexico

BACKGROUND: PrEP roll-out has been slow, especially in low-and-middle-income countries, partly because of its high costs. Since PrEP programs are currently being designed, alternatives to make it available to as much people at risk as possible need to be considered: understanding willingness to use (WTU) and to pay (WTP) for different PrEP schemes among eligible individuals is essential.

METHODS: Between November and December 2019, a survey was conducted among men who have sex with men (MSM) and transgender women (TGW) in venues for meeting sexual partners. Information was collected on sociodemographics, sexual behavior, PrEP awareness, as well as WTU and WTP for different PrEP schemes: daily and event-driven PrEP, implants, and injections. We explored the demand curves for all PrEP schemes. To assess the predictors of awareness, WTU, and WTP, multivariate regression models were used.

RESULTS: We collected data from 166 MSM and 34 TGW. On average participants were 31 years old and 60% reported having a university degree or higher. 70% of the participants had heard of PrEP. The WTU was 88%, 66%, 72%, and 77% and the average monthly WTP was 66, 71, 84, and 173 USD for daily PrEP, event-driven, injections, and implant, respectively. Among TGW, the average WTP for daily PrEP was 67 USD. Participants with high school and university or higher degree were more likely to be aware of PrEP (OR 8.5 95%CI 2.1-34.7; OR 13.8 95% CI 3.7-50.9 respectively) than those with no education. Riskier sexual behaviors were significantly associated with lower PrEP awareness. WTP was predicted by income: being in the higher income tercile increases in 7.3% the WTP compared to the lower tercile. Those with university or higher degree had a higher WTP for long-active PrEP types versus those with lower education.

CONCLUSIONS: In this study we documented the awareness, WTU, and WTP for PrEP in Mexico. Our results highlight the need to roll out national PrEP programs among MSM and TGW. We also identified individual characteristics associated with higher WTP. These findings should be taken into account when planning and estimating the costs for PrEP scale-up at a national level.

PREVENTION OF VERTICAL TRANSMISSION

PED1292

QUALITY MATTERS: ACTIVE CASE MONITORING RESULTED IN IMPROVEMENT OF CARE CASCADE FOR HIV POSITIVE MOTHERS AND EXPOSED INFANTS: INTERVENTION FROM PLAN INDIA'S GLOBAL FUND SUPPORTED AHANA PROJECT IN INDIA

R. Kochukudiyil Balanpillai[1], K. Biswas[1], R. Mitra[1], S.K. Kanoujia[1], M.K. Singh[1], D. Nirwal[1]
[1]Plan International (India Chapter), Programme Implementation - GFATM, New Delhi, India

BACKGROUND: The global community has committed itself to accelerating progress for prevention of vertical HIV transmission with the goal of eliminating new HIV infections in infants by 2020. Plan India implements Global Fund-supported PPTCT program (AHANA) in 357 priority districts of 14 States in India to achieve the goal of EMTCT through providing quality home based care and support services. To understand the effectiveness of the programme intervention, Plan India carried out an assessment in the intervention states.

METHODS: The study involved a mixed research method where both qualitative and quantitative methods of data collection and analysis were used. In-depth direct interviews (IDI) were carried out with 102 positive pregnant women, state and district level officials and Focused Group Discussions (FGDs) were carried out with ASHAs and ANMs . Altogether 232 In-depth interviews were carried out in 14 States of India. Data from a prospective cohort of positive pregnant women & exposed babies was triangulated to corroborate the findings.

RESULTS: Regular outreach activities and concurrent follow up 78% pregnant women found positive initiated on ART during 2017-18 has increased to 96% in Sept.19.Out of 5081 live birth, 94% babies initiated on ARV prophylaxis. DBS collection at 6 weeks was increased from 48% to 94% due to active monitoring. Out of PPW interaction (IDI) 82% were aware about the transmission of HIV, 96% PPWs were regularly taking ART. 75% PPWs faced side effect while taking ART. All spouse and 45% family members were aware about HIV Status of PPW. All PPWs were orientated on breastfeeding and out of 96% following breast feeding protocol. Primary health care providers were oriented on PPTCT towards greater convergence. Study suggests that the active case follow-up has resulted a positive improvement in the care cascade.

CONCLUSIONS: Multipronged programme strategy resulted in improved CD4 count of PPWs, positivity rate of infant and Stigma & Discrimination has reduced considerably through the efforts of Ahana. 87% PPW confirmed that their quality of life,as their position in the family and in the neighbourhood, has improved considerably. Managing care-cascade and timed intervention has catalysed reduced infant morbidity and mortality due to HIV infection.

PED1293

MULTIPLE HEALTH FACILITY ATTENDANCE FOR ANTENATAL AND POSTNATAL CARE AMONG WOMEN IN ZIMBABWE AND THE ASSOCIATION WITH MTCT

I. Anyene[1], S. McCoy[1], M.-S. Kang-Dufour[1], A. Mushavi[2], N. Padian[1], F. Cowan[3,4]
[1]University of California, Berkeley, United States, [2]Ministry of Health and Child Care, Harare, Zimbabwe, [3]Centre for Sexual Health and HIV Research, Harare, Zimbabwe, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

BACKGROUND: Multiple facility attendance may impact prevention of mother-to-child HIV transmission (PMTCT) and the continuity of antenatal (ANC), postnatal (PNC), and HIV care, but its prevalence and associated factors are not well understood. Among women with a recent birth in Zimbabwe, we evaluated the prevalence of multiple facility attendance and its association with various dimensions of healthcare access, utilization of services in the PMTCT cascade, and mother-to-child HIV transmission (MTCT).

METHODS: We analyzed 2018 cross-sectional serosurvey data from randomly sampled mother-infant pairs from five provinces in Zimbabwe. Eligible women were ≥16 years and biological mothers of infants born 9-18 months prior to the survey. We assessed the prevalence of reported multiple facility attendance and utilized robust Poisson regression to determine the association between multiple facility attendance and: 1) characteristics related to ANC and PNC access, affordability, and the mother's personal characteristics, and 2) the initiation of infant antiretroviral (ARV) prophylaxis, early infant HIV testing, and MTCT among HIV-exposed infants.

RESULTS: Overall, 2,979 (43.1%) of 6,937 women visited multiple facilities for ANC, delivery, or PNC. Women who reported that they were the dominant decision maker in the household/family (adjusted PR: 1.31, 95% CI: 1.31, 1.31) and those in the highest wealth quartile (adjusted PR: 1.84, 95% CI: 1.83, 1.84) were more likely to report multiple facility attendance. Multiple facility attendance was associated with a lower prevalence of HIV-exposed infants initiating infant ARV prophylaxis (58.68% vs. 69.9%, adjusted PR: 0.92, 95% CI: 0.91, 0.92), a slightly higher prevalence of i) early infant HIV testing (26.53% vs. 24.24%, adjusted PR: 1.14, 95% CI: 1.12, 1.16), and ii) higher MTCT at 9-18 months (7.3% vs. 1.81%, adjusted PR: 3.1, 95% CI: 2.53, 3.8).

CONCLUSIONS: Multiple facility attendance for maternal care services is common amongst women with a recent birth in Zimbabwe. Although multiple facility attendance is associated with higher SES and empowerment, it is also paradoxically associated with lower rates of infant prophylaxis and higher prevalence of MTCT. Future research is needed to understand the drivers of this and to inform the design of interventions.

PED1294

MTCT KNOWLEDGE GAPS AMONG BIOLOGICAL MOTHERS OF INFANTS ATTENDING IMMUNIZATION CLINICS IN UGANDA (PMTCT IMPACT STUDY 2017/19)

M. Achom Okwero[1,1], R. Nakityo Bosa[1], M. Adler[1], L. Nabitaka[2], J. Kasule[3], P. Mayambala Namukanja[1], P. Mudiope[2]
[1]Centers for Disease Control and Prevention, Kampala, Uganda, [2]Ministry of Health, Kampala, Uganda, [3]Rakai Health Sciences Project, Kampala, Uganda

BACKGROUND: Comprehensive knowledge on MTCT improves uptake of PMTCT services and Viral Load (VL) suppression among HIV positive (HIV+) mothers. In Uganda PMTCT services are offered in high-level health facilities that provide maternity services and a few immunization clinics. Within the PMTCT Impact Study, we assessed the level of MTCT knowledge among Biological mothers of infants attending immunization clinics to understand critical gaps for optimizing PMTCT interventions for HIV Epidemic control.

METHODS: The PMTCT Impact study prospectively enrolled HIV+ and HIV Negative (HIV-) Mother-Infant pairs from 206 immunization clinics across the country during September 2017-March 2018. We interviewed a total of 12,054 Biological mothers (1,290 HIV+ and 10,764 HIV-); and assessed their knowledge on MTCT (can baby get HIV from infected mother? MTCT modes and PMTCT interventions).

RESULTS: The majority (88%) of HIV negative and HIV+ (96%) mothers knew that a baby can get HIV from infected mother. However, over half (54%) of HIV+ mothers and two-thirds (62%) of HIV- mothers did not know that MTCT can occur during Pregnancy. Similarly, a quarter (26%) of HIV+ mothers and over a third (35%) of HIV- mothers did not know that a baby can get HIV from infected mother during Child birth. High proportions (90%) of HIV+ mothers and HIV- mothers (86%) knew that MTCT can occur during breast feeding.
A few HIV+ mothers (3%) did not know that ART can protect baby from getting HIV.

Characteristics	HIV Negative n=10,764 (89.3%)	HIV Positive n=1,290 (10.7%)
Baby can get HIV from infected mother (Yes)	9,469 (88.0%)	1,237 (95.9%)
Mother's knowledge on MTCT modes		
Breastfeeding (Yes)	8,188 (86.5%)	1,116 (90.2%)
Pregnancy (Yes)	3,606 (38.1%)	566 (45.8%)
Childbirth (Yes)	6,151 (65.0%)	910 (73.6%)
Heard that HIV+ mother can take HAART for life to prevent MTCT (Yes)	8,939 (83.1%)	1,244 (96.4)

[Table 1: MTCT Knowledge among HIV Positive and negative mothers.]

CONCLUSIONS: Both HIV positive and negative women had major knowledge gaps regarding MTCT. Interventions to improve PMTCT knowledge and VL suppression should target Mothers' understanding of MTCT risks during pregnancy, childbirth and breastfeeding. Additional efforts needed to support Mothers adopt safe Infant feeding practices. Immunization Clinics offer a good platform for education, counselling and identification of HIV+ mothers for PMTCT.

PED1295

MULTI-COUNTRY REVIEW ON FINAL OUTCOME IN ELIMINATION OF MOTHER TO CHILD TRANSMISSION OF HIV IN M2M COUNTRIES

K. Schmitz[1], A.M... Mbule[1], N. Kwendeni[1], J. Igumbor[1], C. Hofmeyr[1], F. Burtt[1], F. Mpungu[1], E. Scheepers[1]
[1]mothers2mothers, Cape Town, South Africa

BACKGROUND: Early access and retention on treatment has been a game changer in the fight to eMTCT. This approach includes early treatment initiation, monitoring the effectiveness of treatment, and supporting clients to provide preventative ARVs to their children while adhering to the recommended infant feeding practices. mothers2mothers (m2m) Mentor Mothers robust tracking of client appointments, timely follow-up of lost to care clients, support for early treatment uptake and retention in care, infant prophylaxis and HIV testing and safer infant feeding are methods used to reduce vertical transmission of HIV among mother-baby cohorts for up to 24 months of HIV exposure.

METHODS: A stratified, representative sample of 2957 pregnant women and new mothers enrolled from January – June 2016 from 69 sites in Eswatini, Kenya, Lesotho, Malawi, South Africa and Uganda. A cohort final outcome analysis based on Mother Baby Pairs (MBP) followed from the time of enrollment until December June 2018.

RESULTS:

[Figure. m2m multicountry PMTCT cascade]

Rates of maternal ART initiation and infant prophylaxis among this sample were 97% for and 93% respectively while uptake of CTX was documented at 86%. Uptake of infant testing registered at 91%; 75% of infants had a final test outcome documented at 18-24 months. Combining the two reports 73% of the sample had a final infant status, with a vertical MTCT rate of 1.9% less than the anticipated 5% MTCT rate among breastfeeding children. 93% of the HIV positive children were initiated on ART

CONCLUSIONS: Access to infant HIV tests continues to grow with increased fragmentation of service delivery in health facilities despite limitations. m2m peer interventions can be used to support service integration as part of the change care package in reaching the final outcomes results.

PED1296

THE ROLE OF PEER LAY HEALTH WORKERS PROGRAMMES AND INNOVATIVE SCALABLE QUALITY IMPROVEMENT SOLUTIONS TO IMPROVE FINAL HIV DIAGNOSTIC TEST UPTAKE AMONG HIV EXPOSED INFANTS

K. Schmitz[1], A.M.N. Mbule[1], N. Kwendeni[1], C. Hofmeyr[1], J. Igumbor[1], F. Burtt[1], E. Scheepers[1]
[1]mothers2mothers, Cape Town, South Africa

BACKGROUND: m2m's peer-led integrated service platform employs HIV positive women 'Mentor Mothers' to deliver innovative and proactive approaches for uptake of PMTCT cascade services. These include HIV testing among HIV exposed infants (HEIs); those born to HIV positive women and babies of unknown HIV status. Final HIV test outcome must be established among all HEIs at 18-24 months. Lack of a final test outcome among all HEIs creates a key challenge to governments to accurately monitor our progress towards virtual eMTCT.
METHODS: As part of m2m's routine services at facility-community, HEIs are followed up and linked to a continuum of care including EID and 18-24 months rapid diagnostic HIV testing. m2m deployed a quality improvement change package that included Mentor Mothers' review of monthly data on infant tests done versus scheduled; m2m's electronic active tracking system was instrumental. Mentor Mothers also participated in static and mobile immunization clinics to ascertain infant exposure status, proactive linked 18-24 months infants to rapid partner-led community-based HIV testing and provided household follow up integrated with early childhood development interventions.
The analysis of uptake of HIV services among HIV-exposed infants (aged 0-2 years) draws on a stratified, representative sample of 69 sites in Eswatini, Kenya, Lesotho, Malawi, South Africa and Uganda. The sample included all HIV-positive index clients enrolled between January - June 2016.
RESULTS: Uptake of the first DNA PCR test among HIV exposed infants averaged at 69 implementing sites averaged at 87% ranging between 83% in Malawi and 98% in South Africa. Seventy-three (73%) of the HIV exposed infants had a final HIV test at 18-24 months (Eswatini at 68%, Kenya 61%, Lesotho 73%, Malawi 65%, Uganda 79% and South Africa 89%). Although not ideal, the final HIV test and results achieved are above reported national averages.
CONCLUSIONS: Peer lay health workers play a positive role in supporting infant testing and final outcomes of HEIs. However, there is a need to strengthen QA/QI approaches that allow for client-centered service delivery and maximize services integration in resource-limited settings.

PED1297

PROTECTING BABIES OF HIV-POSITIVE MOTHERS FROM MOTHER-TO-CHILD TRANSMISSION (MTCT) IN VENEZUELA IN THE FACE OF A COMPLEX HUMANITARIAN EMERGENCY

L. Aguais[1], M. Osio[1], C. Sotelo[1]
[1]AID FOR AIDS International, New York, United States

BACKGROUND: The Healing Venezuela Program was launched in response to the complex humanitarian emergency in Venezuela, when AID FOR AIDS was distributing ART to people with HIV and identified 1,000 women without treatment who were at risk of transmitting the virus to their babies through breastfeeding. This program aims to contribute with the nutrition of Venezuelan babies aged between 0 and 12 months, babies of mothers with HIV without access to treatment, by providing them with infant formulas to prevent their malnutrition.
DESCRIPTION: The Healing Venezuela program involves five (5) key steps: 1) AFA secures funding to purchases infant formula. 2) AFA purchases formula already registered in Venezuela with health certificate, this to avoid possible confiscations from the government. 3) AFA partners with pediatricians nationwide to determine needing population. 4) The partner doctors select babies born to mothers with HIV. 5) AFA Venezuela and civil society implement a surveillance system to monitor the delivery and distribution of infant formula.
LESSONS LEARNED: AFA has developed a pioneering mechanism to surpass governmental obstacles and address infant malnutrition in Venezuela. AFA's mechanism entails a continued surveillance of the monthly delivery of the infant formula through the weight and height indicators, turning AFA in one of the largest suppliers of formula nationwide benefiting 2,400 babies exposed to HIV during 2018 and 2019 in 20 states, 24 cities, involving 33 partner doctors, 28 assistance centers, 12 NGOs, 3 Catholic institutions, 6 volunteers and 2 private companies.
CONCLUSIONS/NEXT STEPS: AFA managed to avoid mother-to-child transmission (MTCT) through breastfeeding to the babies benefiting from the Healing Venezuela programme, achieving a satisfactory nutritional evolution in 80% of the babies. Going forward, AFA aims to provide infant formula to 3,000 babies of mothers with HIV while the shortage of ART, viral load and CD4 keeps going.

RISK COMPENSATION: CONCEPTUALIZATION, ASSESSMENT AND MITIGATION

PED1298

PREP OR CONDOMS, OR BOTH? INSIGHTS ON RISK COMPENSATION THROUGH A DISCRETE CHOICE EXPERIMENT ON PREP PREFERENCES AMONG GAY, BISEXUAL, AND OTHER MEN WHO HAVE SEX WITH MEN

R.K.J. Tan[1], Y. Wang[1], K. Prem[1,2], J. Harrison-Quintana[3], A.K.J. Teo[1], N. Kaur[1], A.R. Cook[1], M.I.-C. Chen[1,4], C.S. Wong[4,5]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Grindr for Equality, Los Angeles, United States, [4]National Centre for Infectious Diseases, Singapore, Singapore, [5]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

BACKGROUND: HIV pre-exposure prophylaxis (PrEP) is effective in preventing HIV acquisition among gay, bisexual, and other men who have sex with men (GBMSM). While evidence for risk compensation has been mixed, less work has considered how individuals make decisions around PrEP use vis-a-vis real world considerations, including the availability and accessibility of PrEP vis-à-vis condoms.
METHODS: A discrete choice experiment (DCE) was disseminated through Grindr® among a sample of GBMSM. Participants were asked to select their preferred basket of PrEP attributes relating to cost and accessibility of medication and follow-up visits, and compared this choice to a condoms-only option, and later, an option to add on condoms over and above PrEP (PrEP+condoms). Latent class models were employed to ascertain preferences across classes of GBMSM.

RESULTS: A three-class model was selected based on an assessment of both information criteria and preliminary data collected by the study team. 'PrEP moderates' had no significant preference for PrEP only compared to condoms only, but were more likely to prefer PrEP+condoms compared to PrEP only. Their utilities for PrEP were not associated with their risk perceptions of HIV and other sexually transmitted infections (STI). 'PrEP conservatives' were more likely to have greater utility when using condoms only compared to PrEP only, as well as PrEP+condoms compared to PrEP only. Their utilities for PrEP were sensitive to changing perceptions of HIV risk when considering PrEP only. 'PrEP liberals' were more likely to choose PrEP only compared to condoms only, as well as PrEP only compared to PrEP+condoms. They had greater disutility as perceptions of HIV and other STI risks increased, compared to PrEP moderates, but less so than PrEP conservatives. PrEP liberals were also more likely to perceive themselves to be good candidates for PrEP in the demographic survey prior to the DCE, compared to moderates and conservatives.

CONCLUSIONS: There is evidence for potential risk compensation among PrEP liberals who perceived themselves to be good candidates for PrEP prior to the DCE. PrEP remains an effective means of HIV prevention in GBMSM as PrEP liberals may benefit from enhanced STI screening and treatment through the course of PrEP follow-up.

SCHOOL-BASED SEXUAL EDUCATION, LIFE SKILLS AND GENDER EQUALITY EDUCATION

PED1299

EFFECTS OF SOCIAL MEDIA-DELIVERED INTERVENTION ON HIV RISK PERCEPTION AND WILLINGNESS TO GET TESTED AMONG STUDENTS OF SELECTED TERTIARY INSTITUTIONS IN SOUTH-WESTERN NIGERIA

O. Olaleye[1]
[1]University of Ibadan, Health Promotion and Education, Ibadan, Nigeria

BACKGROUND: Persistent new HIV infections especially among young people underscores the need for enhanced prevention. In Nigeria, young people are ardent users of social media (SM) and these media have been understudied in terms it relevance to HIV prevention. This study investigated the effects social media-delivered intervention on HIV risk perception (HRP) and willingness to get tested (WgT) among students of selected tertiary institutions in south-western Nigeria.

METHODS: The quasi-experimental study was conducted in two selected public polytechnics which were randomly allocated into Experimental (EG) and Control Groups (CG). A total of 101 in EG and 99 in CG were selected through a four-stage simple random sampling technique. Baseline data collected using pre-tested self-administered questionnaire included; respondents' socio-demographic characteristics, HRP and WgT. Scores ≤6, 7-12, >12 were categorised as low, average and high HRP. Baseline findings were used to design and implement a four-month educational intervention using a created social media group platform; WhatsApp. A post-intervention survey was conducted after one-month follow-up using same instrument at the baseline. Data were analysed using descriptive statistics, Chi-square and t-test at $\alpha 0.05$.

RESULTS: Respondents' ages were 21.3±2.7 and 21.4±2.7 years, while males included 61.4% and 70.7% in EG and CG, respectively. At the baseline, 31.7% and 35.5% has ever been tested for HIV in EG and CG respectively. WgT for HIV among those who have never been tested was 82.6% (EG) and 87.5% (CG). At the post-intervention, significantly, all participants (100%) who were yet to be tested for HIV were willing to undergo the test in EG while 67.5% were willing in CG. With reference to the baseline, there was a significant increase in HRP in EG at the post-intervention from 11.5±2.8 to 12.6±2.4, compared with CG which increased from 11.7±2.4 to 11.5±2.7 with no significant difference. High HRP was 42.6% (EG) and 42.5% (CG) at the baseline, at the post-intervention, high HRP significantly increased in EG (75.3%) and compared with 43.6% in CG.

CONCLUSIONS: Social media-delivered intervention increased HRP and WgT among the respondents. Social media interventions are therefore recommended to reach young persons on HIV preventive related matters.

PED1300

PREVENTING HIV AND SCHOOL DROPOUT IN UGANDAN GIRLS THROUGH AN ADOLESCENT-LED, SCHOOL-COMMUNITY EARLY WARNING SYSTEM

J. DeSoto[1], A. Belsan[1], R. Laura Lulua[2], G. Ekpo[1], V. Ochaya[2], S. Benson[1], R. Wamala[3]
[1]World Vision, Inc., Washington, United States, [2]World Vision Uganda, Kampala, Uganda, [3]Makerere University, Kampala, Uganda

BACKGROUND: According to the Uganda Violence Against Children Survey (2018), 20% of girls experienced forced sex before age 18, of whom 28% become pregnant. 75% acquired sexually transmitted infections including HIV, and 25% missed school due to violence, all of which increase the risk of acquiring HIV (UNAIDS, 2018). Uganda has one of the highest global HIV prevalence rates (6%), and the HIV prevalence of adolescent girls (AGs) aged 15-19 is approximately 2.5% - almost four times higher than boys aged 15-19 (UPHIA 2016-2017). Previous research recommends programming for adolescents using the socio-ecological theory that comprehensively engages schools, communities, individuals, and families. The School-Community Accountability for Girls Education (SAGE) program in Uganda was an integrated school-based HIV prevention program for AGs that used an Early Warning System to track school attendance and incorporated social and behavior interventions to change social norms around girls' education.

METHODS: A longitudinal study was conducted in 13 districts of Uganda using cross-sectional baseline and endline surveys. The sample size was 1,310 AGs (950 intervention; 360 control) and 672 parents/caregivers (420 intervention; 252 control). The study assessed the intervention's impact in reducing secondary school dropout and the associated risk of HIV among 38,750 girls aged 13 to 19 in 151 schools.

RESULTS: The data indicated AGs who experienced school-related gender-based violence decreased by 7% in the last six months of the project, the number of AGs who took an HIV test increased by 10.8%, the number of AGs who had sexual intercourse decreased by 7.2%, and rates of corporal punishment in intervention schools decreased by 17.5%. SAGE's innovative combination approach helped shift social norms and practices around girls' education, violence against children, reproductive health, and positive discipline. Further, SAGE monitoring data reported an increase in girls retained in school at the end of the project - 99.7% (2019) compared to 88.5% (2016).

CONCLUSIONS: Findings suggest that the integrated approach is a potentially effective way to identify AGs at risk of dropping out of school and mitigate the causes of dropout (thus decreasing risk of HIV). Scaling up similar interventions to reduce HIV-related vulnerabilities can be considered.

STRATEGIES TO RECRUIT AND RETAIN POPULATIONS (E.G., FROM HOT SPOTS)

PED1301

BARRIERS AND MOTIVATORS TO PARTICIPATION AND RETENTION IN HIV/HCV COHORT STUDIES AMONG PEOPLE WHO INJECT DRUGS: A COMMUNITY CONSULTATION IN IRAN

S. Hosseini Hooshyar[1,2], A. Mirzazadeh[1,3], A. Shahesmaeili[1], A. Bahramnejad[4], A. Barsham[4], G. Moosavian[1], I. Najafi[1], H. Sharifi[1], A.-A. Haghdoost[1], A. Briceno[5], W. McFarland[3,5], K. Page[6]
[1]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [2]The Kirby Institute, UNSW Sydney, Sydney, Australia, [3]Institute for Global Health Sciences, University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [5]University of California, San Francisco, United States, [6]Epidemiology, Biostatistics and Preventive Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, United States

BACKGROUND: The lack of robust estimates of HIV/HCV incidence among people who inject drugs (PWID) in Iran calls for well-designed prospective cohort studies. Successful recruitment and follow-up of PWID in cohort studies require formative assessment of barriers PWID are faced with in participation and retention in cohort studies and motivators they think may enhance this engagement. Using a focus group discussion (FGD) format, we conducted a consultation with PWID in southeast Iran to recognize those barriers and motivators.

METHODS: Using targeted sampling, we recruited PWID (aged≥18, injected in last 6 months) from community-based drop-in centers (DICs), homeless shelters, and through outreach efforts to participate in four FGDs (one women-only). Socio-demographic characteristics, injection behaviors and self-reported HCV/HIV testing and diagnosis history were obtained. Then, a semi-structured FGD guide was applied to explore barriers and motivators to participation and retention in cohort studies among study participants. All FGD sessions were recorded and transcribed verbatim, removing any identifying information. The content of FGDs were analyzed by thematic analysis using an inductive approach.

RESULTS: In total, 30 individuals (10 women) participated in the study. The mean age of participants was 35.4 years (SD 7.6), with majority (73.3%) reporting injecting drug use within the last month. Only 40.0% reported ever being tested for HCV whereas a larger proportion (63.4%) reported ever being tested for HIV. With most willing to participate in cohort studies, breach of confidentiality, fear of positive test results, perceived high commitment required, and marginalization were reported as barriers to participation and retention in such studies. Monetary incentive, the thought of a better life, protection from police interventions and trust between health workers and PWID were addressed as motivators of engagement in cohort studies among PWID.

CONCLUSIONS: Strategies to enhance data security and reduce stigma associated with injecting drug use along with involving peer workers in research, providing pre and post-test counselling and education and addressing the needs of more marginalized groups potentially through integrated healthcare programs and housing support are among few approaches that may help address barriers and strengthen the motivators for successful cohort studies among this population.

PED1302

FEMALES LEADING THE WAY FOR VOLUNTEER MOBILIZATION TO REACH VMMC CLIENTS

J. Berg[1], A. Rozario[1], P. Motsoari[1], I. Malitsane[1]
[1]Jhpiego, Maseru, Lesotho

BACKGROUND: In Lesotho, only thirty-eight percent of males aged 15-49 years reported being medically circumcised (LePHIA, 2017). With funding from PEPFAR/USAID, Jhpiego has supported over 210,000 voluntary medical male circumcisions (VMMCs) since 2012. Despite low saturation of medical circumcision, uptake of VMMC remains suboptimal, presenting a challenging opportunity for strengthening demand creation.

DESCRIPTION: In response to low VMMC uptake from October 2017 – September 2018, the mobilization program was redesigned from an informal volunteer based system to a structured, incentive-based, system engaging Volunteer Community Advocates (VCAs). VCAs are recruited through local health facilities, VMMC registers of satisfied clients, and other motivated individuals interested in mobilizing for VMMC. A formal three-day training is conducted, basic branded uniforms and ID cards are provided, and data is collected from each VCA through paper-based forms collected monthly. VCA-specific data was entered into excel from January – September 2019 to track performance. Basic VCA demographics were also collected to allow performance to be disaggregated by gender, age and district.

LESSONS LEARNED: During the scale-up 274 VCAs were trained and deployed for VMMC community mobilization directly resulting in over 9,100 clients receiving VMMC services from October-September 2019, while the program as a whole saw a 31% increase in performance. On average 81 VCAs were active each month depending on where services were being offered, and the availability of the VCA. Of the trained VCAs, 56% were female and 44% were male; however 70% of VCA-mobilized clients were brought by female VCAs and only 30% of VCA-mobilized clients were brought by male VCAs. Female VCAs were more likely to be active each month and the productivity per VCA was also slightly higher among females. While males were originally targeted for VCA recruitment, this performance has resulted in a programmatic shift towards a balance of both male and female VCAs as we better understand the important role female mobilizers play in men's health and the ability for women to motivate and encourage men to receive VMMC services.

CONCLUSIONS/NEXT STEPS: While VMMC mobilization is targeting men, female VCAs play a key role in mobilizing men for health services, and encouraging behavior change for health seeking behaviors.

PED1303

ONLINE AND VENUE-BASED RECRUITMENT STRATEGIES ARE COMPLEMENTARY TO REACH HIGH RISK MSM FOR A LARGE PREP SERVICE IN RIO DE JANEIRO, BRAZIL

D.R.B. Bezerra[1], T.S. Torres[1], L.E. Coelho[1], C. Jalil[1], E. Carvalheira[1], J.R. Grangeiro[1], D. Waite[1], T. Araujo[1], J. Freitas[1], C. Cerqueira[1], L. Monteiro[1], C. Oliveira[1], L. Kamel[1], N.M. Fernandes[1], S.w. Cardoso[1], B. Hoagland[1], V.G. Veloso[1], B. Grinsztejn[1]
[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

BACKGROUND: New cases of HIV infections continue to increase among young MSM in Brazil. In order to mitigate the HIV epidemic, it is crucial to reach and engage young vulnerable MSM in PrEP services. This study compares online and venue-based strategies to recruit MSM to HIV prevention service in Rio de Janeiro, Brazil.

METHODS: MSM at high risk for HIV infection were recruited through venue-based and online strategies. Venue-based strategies consisted in peer educators recruitment in gay venues, referral by friends or health professionals and self-referral. Online strategies included advertisements on GSN dating apps (Hornet and Grindr) and social media (Facebook/Instagram) to increase PrEP and HIV awareness. We used chi-square test to compare the characteristics of MSM who attended the service through online and offline strategies.

RESULTS: From Mar-2018 to Oct-2019, 2246 MSM attended the service looking for HIV testing, HIV counseling and HIV prevention strategies (PEP and PrEP): 649(28.9%) recruited online and 1597(71.1%) through venue-based strategies. MSM recruited online were older (age median 28[IQR:24-35] vs. 27[IQR:23-34] years old, p=0.041), white (39.7% vs 35.6%, p=0.071) and of higher education (53.2% vs 36.0%, p<0.001) compared to MSM recruited through venue-based strategies. (Table). HIV prevalence was 10.7%(IQR:9.5-12.1%), higher among MSM recruited through venue-based strategies (12.0% vs. 7.7%, p=0.03). Among HIV-uninfected MSM, 74.6%(1496/2005) were eligible for PrEP, and the proportion was higher among MSM recruited online (77.8% vs. 73.3%, p=0.033). Among PrEP eligibles, PrEP uptake was 56.4% (844/1496), higher among those recruited online (62.9% vs. 53.5%, p<0.001). PEP initiation was higher among MSM recruited offline (18.3% vs. 8.2%, p<0.001).

		Venue-based 1597(71.1)	Online 649(28.9)	Total 2246(100)	p-value
Median age (years)		27 (IQR:23-34)	28 (IQR:24-35)	27 (IQR:23-34)	0.041
Age (years)	18-24 25-34 ≥35	545(34.3) 729(45.9) 315(19.8)	187(28.9) 312(48.2) 148(22.9)	732(32.7) 1041(46.6) 463(20.7)	0.003
Race	White Non-white	550(35.6) 995(64.4)	246(39.7) 373(60.3)	796(36.8) 1368(63.2)	0.071
Education	≤ Secondary school > Secondary school	998(64.0) 561(36.0)	297(46.8) 337(53.2)	1295(59.1) 898(40.9)	<.001

[Table]

CONCLUSIONS: Online and venue-based strategies are complementary to reach high risk MSM. While online strategies reached more MSM at higher HIV risk, venue-based strategies reached younger, non-white and lower educated MSM.

PED1304

PEER NAVIGATION IS IMPORTANT TO IMPROVE CARE PRACTICES OF ADOLESCENTS MSM AND TGW WHO ARE TAKING PREP: LESSONS LEARNED FROM BRAZIL

R. Lúcia e Silva e Oliveira[1], L.A. Vasconcelos da Silva[1], M. Castellanos[1], S. Assis Brasil[2], L. Pedrana[1], L. Silva[1], B. Santana[1], D. Freire[1], P.R. Costa[1], R. Ribeiro[2], L. Fideles[1], L. Magno[2], I. Dourado[1]
[1]Universidade Federal da Bahia, Salvador, Brazil, [2]Universidade do Estado da Bahia, Salvador, Brazil

BACKGROUND: In many countries including Brazil, adolescent and youth men who have sex with men (MSM) and transgender women (TGW) (AYKP) are at high risk for HIV infection. PrEP is an effective HIV prevention tool in high-risk populations. However, there are still gaps in PrEP enrolment among adolescents. Our goal is to explore care practices of Peers Navigators (PN) with participants in PrEP1519 study.

METHODS: Data are from PrEP1519, the first demonstration study among AMSM and ATGW aged 15-19, ongoing in three Brazilian cities: Salvador, Belo Horizonte e São Paulo. Data was collected between April-July, 2019 in Salvador site. After PrEP initiation, a PN is assigned to follow-up the needs of each participant and reinforce PrEP adherence. Fifteen field notes describing PN interactions with the participants were reviewed, and main themes categorized. In addition, transcription of a focus group with three PN, and first author field observations analyzed.

RESULTS: PN highlighted the importance of their efforts to create a narrow bond between the project and participants, once their follow-up reduces participants' anxiety and fear of the repercussions of prolonged medication use. The LGBT belonging of PN and their emotional and operational support on PrEP use, facilitated the emergence of sensitive topics such as affective-sexual experiences, self-image, daily life experiences, and access to work. The navigation includes care and support on various aspects such as: use of PrEP and its difficulties (side effects, drug interaction - especially hormone use in TGW, forgetfulness, appropriate storage), sexual health care, combined prevention and the multidisciplinary care offered in the PrEP clinic, following-up them at public services in order to facilitate access to health and care, and social support to overcome TGW vulnerabilities (financial, family and emotional).

CONCLUSIONS: PN is an important bonding and retention strategy for AYKP, considering the various social vulnerabilities they face. The navigation has been developing as a holistic care process and beyond PrEP adherence maintenance. It has been molded and reformulated according to the needs of each participant.

PED1305

REDUCING ATTRITION AMONG PERSONS LIVING WITH HIV IN RESOURCE-POOR SETTINGS: LESSONS LEARNED IN A RETURN-TO-CARE CAMPAIGN IN RURAL HAITI

J.-A. Pretanvil[1], A. Beckett[2], S. Philippe[1], M.C. Maura[1], S. Augustin[1], F. Leandre[1]
[1]Zanmi Lasante, Port au Prince, Haiti, [2]Partners In Health, Boston, United States

BACKGROUND: Despite remarkable reductions in HIV prevalence and mortality in Haiti over the past decade, high rates of attrition remain a serious challenge in progress toward epidemic control. PEPFAR estimates that almost half of the PLHIV newly enrolled in the

past three years have been lost to follow-up (LTFU). Factors contributing to attrition include socioeconomic barriers, migration, stigma, poor health, perceptions of good health, and death.

DESCRIPTION: Partners In Health / Zanmi Lasante support comprehensive HIV treatment for over 15,000 PLHIV in 11 Ministry of Health clinics in rural Haiti. In October 2018, the number of patients lost to follow-up in the prior three years was more than 2,000. In order to address this problem, a new system was designed to return patients to care that: 1) shifted coordination of patient tracking activities from nurses, who were overburdened by clinical and reporting requirements, to social workers, 2) harnessed a cadre of trained and compensated community health workers to track patients, and 3) updated the electronic medical record to identify patients meeting LTFU criteria.

LESSONS LEARNED: Between October 2018 and April 2019, 2,244 patients were identified as LTFU and referred into the redesigned tracking process. Among these, 27% were returned to care and 51% were not able to be located, with tracking activities ongoing at the time of reporting (Table).

Status	Number	Percent
Returned to care	602	27%
Contacted, planned to return to care	107	5%
Contacted, declined to return to care	73	3%
Deceased	117	5%
Relocated out of catchment area	162	7%
Transferred care to another provider	37	2%
Not located, tracking ongoing	1,146	51%

[Table: Patient status in return-to-care campaign]

CONCLUSIONS/NEXT STEPS: This return-to-care campaign demonstrated that with efficient systems for tracking patients LTFU, powered by established community health workers, large numbers of LTFU could be re-engaged in care in a short time period. A significant number of LTFU could not be located, suggesting the need for better documentation of transfers between providers, more study of migration patterns, and improved death registries. Re-engaging patients previously LTFU highlighted the need to expand patient-centered approaches to prevent attrition, including rapid pathways to reduce clinic wait times and multi-month and community drug distribution.

PED1306

CONTRIBUTION OF TRADITIONAL MEDICINE PRACTITIONERS AND RELIGIOUS LEADERS IN THE FIGHT AGAINST TUBERCULOSIS AND AIDS IN CENTRAL AND NORTHERN CÔTE D'IVOIRE FROM JANUARY 2018 TO JUNE 2019

O. Abdoulaye Fougnigue[1], T. Penda Diagola[1]
[1]NGO Centre Solidarite Action Sociale, Bouake, Bouake, Cote D'Ivoire

BACKGROUND: In Côte d'Ivoire, the prevalence of HIV / AIDS is 3.4% (EDS 2012) and for Tuberculosis (TB) the incidence is 153 per 100,000 Hbts. Ivory Coast benefits from Global Fund grants since 2009, with CI Alliance as Principal Recipient Community to run from 2018 to 2020 the New Project Financing Model for HIV / AIDS and Tuberculosis. It is within this framework that the SAS Center intervenes in six health regions in the Center and North of Cote d'Ivoire, ie 30% of the regions of the country. To achieve the objectives of these projects, one strategy was to involve practitioners of traditional medicine and community religious leaders in the notification process of Tb, early detection of HIV and retention ARV and TB care of patients.

DESCRIPTION: Mapping traditional medicine practitioners and religious leaders in the project intervention areas Organize meetings to explain objectives, and project activities related to the three 90s of HIV / AIDS and Tuberculosis Plead for the referral and counter referral of cases of lost sight of or positive screened in denial Awareness raising and case reference by religious leaders (pastors-priests-imams) during their sermons and preaches Awareness raising and case referral for performing HIV test and sputum examination by traditional medicine practitioners during their consultations.

LESSONS LEARNED: 96 advocacy meetings were organized
1414 suspected tuberculosis cases referred
663 cases Tuberculosis suspects detected positive out of the 1414 referred
169 cases referred for HIV testing
160 cases referred for the HIV / AIDS screening test screened positive out of the 169 referred
119 of 135 Loss of Sight under Antiretroviral treatment and 07 out of 10 Loss of Sight under treatment of Tuberculosis were found by leaders of prayer camps and practitioners of traditional medicine and reintegrated into careintegrated into care.

CONCLUSIONS/NEXT STEPS: The referral and counter referral system put in place between traditional medicine practitioners, religious leaders, prayer camp officials, non-governmental community organizations, and state health providers contributes to ensuring that patients are referred early for screening, retention in care and thus lead to the 3rd 90 for HIV and cure for Tuberculosis.

PED1307

STRATEGIES FOR REACHING AND ENGAGING YOUNG MEN WHO HAVE SEX WITH MEN IN A DIRECT-TO-CONSUMER MODEL OF KEEP IT UP!, AN EHEALTH HIV PREVENTION INTERVENTION

K. Macapagal[1], K. Madkins[1], D. Li[2], B. Mustanski[1]
[1]Northwestern University, Department of Medical Social Sciences & Institute for Sexual and Gender Minority Health and Wellbeing, Chicago, United States, [2]Northwestern University, Department of Psychiatry and Behavioral Sciences & Institute for Sexual and Gender Minority Health and Wellbeing, Chicago, United States

BACKGROUND: Keep It Up (KIU) is a CDC best-evidence, brief online HIV prevention program for young men who have sex with men (YMSM) in the U.S. In nationwide research trials, KIU was delivered 1) via community-based organizations (CBOs) and 2) direct-to-consumer (DTC), where centralized staff recruited YMSM through online advertising, shipped them HIV/STI test kits, and upon testing HIV-negative granted them intervention access. Yet little is known about how to implement eHealth HIV prevention interventions in real-world settings. As it eHealth DTC interventions' success in the real world relies on the ability to reach, engage, and retain the target population, we describe lessons learned from early stages of implementing KIU to inform future eHealth HIV prevention implementation.

DESCRIPTION: In October 2019, we began testing KIU in a hybrid type III effectiveness-implementation RCT comparing CBO versus DTC delivery in 44 U.S. counties (22 counties per strategy). The 4-person DTC staff is implementing a county-by-county recruitment strategy including ZIP-code-based paid online advertising; outreach to CBOs and stakeholders in DTC counties; and direct outreach to YMSM.

LESSONS LEARNED: After 3 months, 1124 individuals accessed our eligibility screener, 49 were eligible, and 14 participants have enrolled. Most eligibles came from paid online ads and participant registries, and primary reason for ineligibility was county of residence. Enrollment patterns and participant feedback suggest that the free HIV/STI tests motivate some to enroll, but the lack of monetary incentives lead to significant attrition. Additional barriers to enrollment include a limited recruitment budget, and lack of on-the-ground presence in the DTC counties. Our YMSM advisory council suggested offering coupon codes and sexual health products to compensate for lack of monetary incentives, and networking with LGBT social groups in each county to increase reach.

CONCLUSIONS/NEXT STEPS: DTC delivery of eHealth HIV prevention interventions promises to reach YMSM more effectively than traditional in-person approaches, yet this has not been studied empirically. Our early challenges suggest that strategies effective in a research context may not be pragmatic in a real-world service implementation of KIU. Our team is brainstorming novel approaches to reaching, engaging, and retaining YMSM in KIU within project constraints.

PED1308

REACHING AND ENGAGING TRANSWOMEN: A SUCCESSFUL RECRUITMENT CASCADE IN AN HIV PREVENTION SERVICE IN RIO DE JANEIRO, BRAZIL

C. Jalil[1], D. Bezerra[1], T. Torres[1], L. Coelho[1], E. Jalil[1], E. Carvalheira[1], C. Souza[1], L. Monteiro[1], T. Santos[1], J. Freitas[1], D. Waite[1], L. Kamel[1], J.R. Grangeiro[1], E. Bastos[1], A. Nabor[1], N. Fernandes[1], S. Cardoso[1], B. Hoagland[1], V. Veloso[1], B. Grinsztejn[1]
[1]*FIOCRUZ, Rio de Janeiro, Brazil*

BACKGROUND: Transwomen are disproportionately affected by HIV epidemic worldwide. However, stigma, social marginalization and transphobia hinder transwomen from accessing HIV prevention and care services. We describe the recruitment cascade among transwomen at a large research and care center for HIV prevention in Rio de Janeiro, Brasil.

METHODS: Since 2015, Fiocruz, a major public health institution in Brasil has implemented a transgender health clinic and has been developing HIV prevention and treatment studies for transwomen. Transwomen diagnosed with HIV infection are offered care and immediate ART initiation, and high-risk HIV negative transwomen are offered HIV prevention services including PrEP and PEP. Clinical care including mental health and endocrinology are offered at no cost. Trans community educators were hired, gender-neutral spaces were created, and support activities and services such as art workshops, dance classes, legal assistance were implemented. Peer referral, peer-educator outreach activities in trans venues and sex work hot spots, and social media campaigns are the main recruitment strategies. Information on demographics, HIV testing, and PrEP were collected by semi-structured interviews.

RESULTS: From Oct-2018 to Nov-2019, 467 transwomen were assessed. The majority were referred by peers (65%) and 15% by outreach activities performed by the trans community educators part of our team. Only 1% was referred by social media advertisements. Median age was 26 years (IQR:22-33), 73% were non-white, and 49% had elementary school or less. 90 transwomen were HIV-infected (19.3% prevalence; 95%CI:16.0-22.1). Among the 377 HIV-uninfected transwomen, 370 (98%) were eligible for PrEP according to CDC criteria, 349 (92.6%) were referred for PrEP, and PrEP uptake was 33.8% (125/370); 21 had criteria for PEP use and initiated PEP in the same day. A hot line was made available for them to call if any adverse events or concerns about PrEP and PEP use.

CONCLUSIONS: A strong partnership with trans communities and the establishment of a gender-affirming setting led to successful recruitment of young and vulnerable transwomen for prevention and care services and research projects. Inclusion of peers is of utmost importance to reach and recruit transwomen. Use of social media has not proven yet as a useful strategy to recruit transwomen in our setting.

ENGAGING TRADITIONAL BIRTH ATTENDANTS FOR IMPROVED ACCESS TO PMTCT SERVICES BY PREGNANT WOMEN

O. Augusta Ngozi[1], G. Owhonda[2], E. Jennifer[3]
[1]*Rivers State Ministry of Health, Department of Public Health, Port Harcourt, Nigeria,* [2]*Rivers State Ministry of Health, Director Department of Public Health, Port Harcourt, Nigeria,* [3]*Institute of Human Virology, Port Harcourt, Nigeria*

BACKGROUND: Prevention of mother-to-child transmission of HIV (PMTCT) programs in Nigeria faces challenges in achieving service uptake. One important reason is because of the significant preference for traditional birth attendants (TBAs) which have not routinely been included in national PMTCT programs. We examined the benefits of incorporating TBAs in PMTCT program.

METHODS: We conducted a retrospective review of PMTCT data in 128 facilities linked to 190 TBAs in three local government areas (LGAs) of Rivers State between January 2018 and March 2019 A 7-step TBA engagement intervention model was implemented ;1 Advocacy and stakeholder management: PMTCT gap analysis discussions were held with stakeholders. 2. Mapping of TBAs: We mapped TBAs around existing PMTCT health facilities, 3. Knowledge assessment and capacity building: A baseline knowledge assessment and capacity building on SOPs for HIV counselling and testing, 4. Roll out of PMTCT services by TBAs: HIV counselling, testing and documentation were supported with supply of commodities and technical assistance, 5. TBA-Health facilities Referral system: Each TBA was linked to PMTCT sites with protocols for referral and linkage services, 6. Performance based incentives: High performing TBAs were provided with incentives such as communication allowances and souvenirs for clients.7.Monitoring and Evaluation: Documentation and reporting of testing, delivery, ARV prophylaxis and referral services.

RESULTS: 580 HIV positive pregnant women delivered their babies at the health facilities within the period of review, and 20.7% (120) were unbooked pregnant women referred from TBAs. Similarly, 463 HIV exposed infants received ARV prophylaxis within 72 hours of delivery, of which 11.0% (84) were HIV exposed infants delivered outside the health facilities but referred by the TBAs for EID and prophylaxis. Another 52 exposed infants received ARV prophylaxis after 72 hours, of which 65.4% (34) were from TBA referrals of HEIs delivered outside health facilities.

CONCLUSIONS: The involvement of TBAs in PMTCT reflects an opportunity to improve PMTCT outcomes. It can help bridge access gap between the communities and health facilities.

PED1310

USE OF CHATBOT FOR ADDRESSING ADOLESCENT'S QUERIES ON SRH AND HIV RELATED ISSUES – FINDINGS FROM A PILOT INITIATIVE IN MADHYA PRADESH, INDIA

R. Prasad[1], S. Badgujar[2]
[1]IIHMR University, Jaipur, India, [2]Independent Consultant, Jaipur, India

BACKGROUND: As per the Census of 2011, adolescent (10 – 19 years of age) constitute around 20% of the population. Because of taboos around sexual health, many adolescents lack the correct information and at times even spread false information among their peers. Without access to reliable channels for providing accurate information on sex and sexual health, young people get incorrect or incomplete information. A study done by Population Council in two states in India highlighted adolescents' limited awareness on sexual and reproductive matters including HIV/AIDS.
DESCRIPTION: In order to provide correct information to adolescent, while ensuring their privacy and confidentiality, a chatbot was developed. The chatbot had access to more than 9000 question and answers including audio and video materials. A helpline was also developed, which can be accessed both online and through phones, to answer any further questions. The helpline was manned by trained counselor. A study was done with 480 adolescents (240 boys and 240 girls) in two districts of Madhya Pradesh to assess its relevance and usefulness.
LESSONS LEARNED: The concept of chatbot was appreciated by 93% of the respondents and they prefer it instead of having face-to-face conversation with counselor or health care providers for information on SRH and HIV/AIDS related issues. 89% respondents appreciated that it is easily accessible, 74% respondents appreciated that it has comprehensive information and 72% respondents found chat messages appropriate. 31% respondents also called up on helpline to get more information after chatting with the chatbot. 27% respondents were also worried that as their family members may see their chats. 38% respondents also expressed the need of making it multilingual and support some regional languages.
CONCLUSIONS/NEXT STEPS: Chatbot can be very powerful medium to address adolescent's queries on SRH and HIV related issues as it is easily accessible and adolescent feel more comfortable. At the same time, it need to be backed with service provision and create enabling environment for adolescent to avail services like condoms from health facilities. Besides that, not all adolescent has access to internet and also there may be risk that other family members can access the chat violating the privacy.

PED1311

GEOSOCIAL NETWORKING APPLICATION USAGE IS ASSOCIATED WITH INCREASED HIV SEXUAL RISK BEHAVIOR AND PREP AWARENESS AMONG NIGERIAN GAY, BISEXUAL AND OTHER MEN WHO HAVE SEX WITH MEN

A. Ogunbajo[1], W. Lodge II[1], A. Restar[1], O. Oginni[2], S. Iwuagwu[3], R. Williams[4], K. Biello[1], M. Mimiaga[1]
[1]Brown University School of Public Health, Behavioral & Social Sciences, Providence, United States, [2]Obafemi Awolowo University, Department of Mental Health, Ile-Ife, Nigeria, [3]Centre for Right to Health, Abuja, Nigeria, [4]Equality Triangle for Health and Peoples Development Initiative, Delta, Nigeria

BACKGROUND: Nigerian gay, bisexual, and other men who have sex with men (GBMSM) bear a disproportionately higher burden of HIV compared to the general population. In countries where same-sex attractions and sexual activity are stigmatized and criminalized, GBMSM may seek social and sexual networking through geosocial networking applications (GSN apps). We investigated prevalence of GSN app usage and its association with sexual behaviors, mental health, minority stress factors and PrEP awareness in a sample of community-recruited, multisite sample of GBMSM in Nigeria.
METHODS: Between March and Jun 2019, we recruited 406 GBMSM from Abuja, Delta, Lagos, and Plateau to complete a quantitative assessment at local community-based organizations. Bivariate and multivariable logistic regression were used to examine factors associated with GSN app usage.
RESULTS: More than half (52.6%) of participants reported using GSN apps to find male partners for sexual activity in the previous 3 months. In the multivariable model, factors significantly associated with increased odds of higher frequency of GSN app usage included: being single [adjusted odds ratio (aOR) 1.62; 95% confidence interval (CI): 1.04 to 2.51] compared to not being single, having a university degree or higher (aOR 1.81; 95% CI: 1.07 to 3.07) compared to senior secondary school or lower, reporting 4-5 receptive anal sexual acts (aOR 2.32; 95% CI: 1.23 to 4.40) and 6 or more receptive anal sex acts (aOR 3.18; 95% CI: 1.42 to 7.12) in the previous 3 months compared to none, reporting awareness of PrEP (aOR 2.58; 95% CI: 1.54 to 4.33), reporting having a primary care provider (aOR 1.62; 95% CI: 1.06 to 2.46), and higher levels of identity concealment (aOR 1.09; 95% CI: 1.04 to 1.14).
CONCLUSIONS: Our results suggests that GSN apps might be a effective medium to disseminate health information, specially related to HIV prevention and treatment services and harm reduction strategies to a high-risk population, especially due to the highly stigmatized nature of GBMSM individuals in Nigeria. While GSN apps might be an effective mechanism to reach a subset of the GBMSM community in Nigeria; it might overlook a far more vulnerable population (less educated and lower socioeconomic status).

PED1312

CORRELATES OF ENGAGEMENT WITHIN AN ONLINE HIV PREVENTION INTERVENTION FOR SINGLE YOUNG MEN WHO HAVE SEX WITH MEN: THE MYDEX PROJECT

S.K. Choi[1], M. Michna[2], D. Connochie[1], J.A. Bauermeister[1]
[1]University of Pennsylvania, Family and Community Health, Philadelphia, United States, [2]University of Pennsylvania, College of Arts & Sciences, Philadelphia, United States

BACKGROUND: My Desires & Expectations (myDEx), is an online intervention to promote HIV prevention behaviors among single young men who have sex with men (YMSM; ages 18-24) seeking partners online. Previous mHealth intervention studies showed effectiveness in reducing sexual risk behaviors among sexual minority populations, but challenges in promoting engagement in mHealth interventions remain. Therefore, we examined whether YMSM's psychosocial characteristics were associated with their intervention usage.

METHODS: 180 YGBMSM were randomized into either myDEx arm or attention-control arm using a stratified 2:1 block randomization. 120 YMSM randomized into the myDEx arm after completing a baseline survey and granted access to the 6-session intervention content over a three-month period. Six sessions within intervention condition include: introduction, relationship and sexual decision-making, sex education, reduction in HIV risk-taking behaviors, sexual communication, and summary. Participants are allowed to view the same sessions multiple times. We used Poisson regressions to assess the association between engagement outcomes (defined as the number of sessions viewed and logins, respectively) and YMSM's sexual behaviors, partner-seeking behaviors and psychological well-being. Multivariable models were fit based on significant variables in bivariable models ($p<0.05$).

RESULTS: The mean number of sessions viewed was 6.93 (range 0-22) and number of logins was 5.44 (range 2-14). In multivariable model, number of sessions viewed was lower among Latino YMSM (estimated Poisson regression coefficients [b]=-0.27, p=0.002), and negatively associated with lower education (b=-0.19, p=0.002), limerence (b=-0.02, p=0.004), and online discrimination (b=-0.01, p=0.007). In addition, number of sessions viewed was positively associated with perceived utility of online apps for hookups (b=0.13, p=0.002) and loneliness (b=0.06, p=0.004). However, we found no association between number of logins and the aforementioned variables in multivariable model.

CONCLUSIONS: YMSM's engagement with session visits is linked to their psychosocial profile, yet not linked to their likelihood of login multiple times into the app. Given the importance of dose receive and fidelity in long-term intervention effectiveness, engagement strategies should be personalized using YMSM's psychosocial characteristics to increase continued intervention exposure and usage and maximize the effect of mHealth interventions among YMSM.

PED1313

A MOBILE PHOTO VERIFICATION APP FOR HIV SELF-TESTING: A MIXED-METHOD STUDY OF USER EXPERIENCES

D. Oladele[1], O. Ezechi[1], T. Gbaja-biamila[1], C. Obiezu-umeh[2], J. Okwuzu[1], U. Nwaozuru[2], A. Musa[1], I. Idigbe[1], B. Kapogiannis[3], J. Tucker[4], J. Iwelunmor[2]
[1]Nigerian Institute of Medical Research, Lagos, Nigeria, [2]Saint Louis University, College for Public Health and Social Justice, Saint Louis, United States, [3]National Institutes of Health, National Institute of Child Health and Human Development, Bethesda, United States, [4]University of North Carolina at Chapel Hill, Chapel Hill,, United States

BACKGROUND: Despite the expansion of HIV self-testing (HIVST) around the world, many research studies rely on self-reported outcomes. New methods for verification of HIVST are needed, especially in resource-limited settings. The purpose of this study was to evaluate the usability of a mobile health application to enhance self-testing results reporting and verification.

METHODS: A sequential mixed-method approach was used to evaluate usability in three core areas: effectiveness, efficiency, and usefulness. Participants used a think-aloud approach while performing usability tasks and subsequently completed a qualitative exit interview. The app included educational resources on HIV, step-by-step video instructions for performing HIVST, a 20-minute timer, a guide on interpreting results, and a photo-verification system. Demographic characteristics were descriptively reported. Qualitative data were analyzed using thematic analysis.

Variable considered	Beta Test 1 [01/08/2019]	Beta Test 2 [24/09/2019]	Beta Test 3 [29/09/2019]
Appearance of the App	"The App could be more attractive, with regard to colour"	"The App should be more colorful/ attractive" "There is a need to improve on the resolution of the videos"	"The App background should be more attractive" "There is a need to use more phrases that will catch Nigerian youth attention"
Ease of use of the App	"It is easy to use the App. The picture/ videos were helpful even for a layman" "It is simple and straight forward" "Basic HIV information on the App was useful"	"The information about HIV on the App was quite educational" "The instruction on HIV self-testing on the App is adequate to safely conduct the test" "The App instruction on how to setup the test needs a little more work" "I would prefer if the language of the App could also be pidgin English" "The App contains all the information I will need to do HIV self-testing on my own"	"The App is self-explanatory" "The video made it easy to understand the test process" "I wonder if the App can be used offline" "It was easy to take the photo evidence of my test" "The explanation of the test result is adequate to educate users on their test result, its significance and next steps to be taken"
App usage and privacy	"It does encourage privacy"	"The App will promote privacy because many young people want to keep their health issues private" "The App is convenient especially for someone who does not want to go to a health center or who live far away from a health center"	"Am happy that no one can have access to my result by looking at the App on my phone"
Linkage to Care after checking result	"After reading my result, I will prefer to call the health facility with the number provided"	"The feature on the App to request a call or call a youth counselor is great, though I would prefer to make the call myself after seeing my result"	"Yes I will request a call from the youth counselor if my result is positive"
Recommend the App to peers			"I will recommend the App to my friends because it is simple and easy to use"
Timer countdown to result	"The time of waiting to read the result is too long" "I would prefer an alert/buzz when the 20 minutes waiting time elapses"		"The buzz at the end of 20 minutes is important. I also like the fact that the App can function in the background while I wait for my result"

[Table]

RESULTS: Nineteen users (12 female, 7 male) participated with mean age of 22 years. Ninety-five percent completed the usability tasks on first attempt. All participants successfully uploaded a photo of their test result using the app. Three main themes were identified in the data:

1)"Design" described how providing an offline version and/or low data usage app was integral to the level of usability;
2)"Ease of use" described how participants felt that the app was self-explanatory and the instructions made it easy to understand the test process;and
3)"Linkage to care" referred to the ability to request a call from trained counselors upon completion of the test, and was highlighted as a key feature of the app.
A majority of the participants noted that the app provides a convenient and private means of verifying HIV test results.
CONCLUSIONS: Our study demonstrated the importance of engaging end-users at the development phase of technological innovation targeted for youth health action. Future trials are needed to determine the feasibility and acceptability of using a mobile health app to verify HIVST results among young people.

PED1314

TECHNOLOGY-DELIVERED HIV SELF-TESTING SERVICE – WHAT USERS FROM A UGANDA PILOT LIKE AND DISLIKE

J.M. Bwanika[1], A. Kiragga[2], H. Banonya[1], D. Musinguzi[1], L. Kamulegeya[1], S. Lammert[3], K. Horvath[4]
[1]The Medical Concierge Group Limited, Research, Kampala, Uganda, [2]Infectious Diseases Institute Limited, Research, Kampala, Uganda, [3]University of Minnesota, Minneapolis, United States, [4]San Diego State University, San Diego, United States

BACKGROUND: National healthcare programs have been scaling up HIV Testing Services to include the roll out of HIV Self Testing (HIVST). However, there remains significant contextual barriers to the successful implementation of HIVST. In this study, we assess qualitative feedback from study participants regarding what they liked and disliked about their experience in a novel HIVST intervention that leveraged SMS and voice (telehealth) platforms to facilitate information provision and HIVST kit access.
METHODS: Between May and June 2019, we enrolled participants at community event locations in Kampala, Uganda for a telehealth HIVST intervention. For 90 days following enrollment, participants received (and could respond to) theoretically-grounded (Information, Motivation, Behavioral) HIVST messages through either SMS, Facebook messenger, or Twitter direct messaging. They also had access to an existing medical call-in center from where they could order free HIVST kits via voice calls or the messaging platforms above. Kits would then be delivered to them at a location of their choice. Assessments occurred at months 1 and 3 through telephone-administered questionnaires, including asking participants what they liked and disliked about HIVST. Qualitative data were double-coded for themes and disagreements were resolved through discussion.
RESULTS: 100 participants were recruited for the study and complete data was available for 99 participants; Mean age-26 years (standard deviation-6); 49% women and 60% were young adults (18-24years). There were 4 prominent themes for what participants liked most about HIVST: 1) usability: HIVST was easy to use and did not require technical knowledge (23% of statements); 2) HIVST was painless (24% of statements); 3) confidentiality: HIVST was private and confidential (25% of statements); and 4) convenience: the HIVST saves time and avoid hospital queues (20% of statements). Among the dislikes were: 1) the geographical limitation of pilot to one district (52% of statements); 2) design: too long of a wait and bulky packaging (26% of statements); 3) fear of an HIV-positive test result (12% of statements).
CONCLUSIONS: HIVST roll out with technology-assisted ordering, delivery and follow up is feasible and received predominantly positive user reviews for its confidentiality, easy-of-use and convenience. Further effort is needed to address the packaging design and results-anxiety.

PED1315

OUTCOMES OF THE KIDZALIVE MOBILE APP CAPACITY-BUILDING INTERVENTION IN 45 COMMUNITY AND PRIMARY HEALTHCARE FACILITIES IN GAUTENG AND KWAZULU-NATAL, SOUTH AFRICA

N. des Fontaine[1], N. Heath[1], D. Heath[1], C. Mutambo[1], S. Thomas[1]
[1]Zoë-Life Innovative Solutions, KidzAlive, Durban, South Africa

BACKGROUND: Digital application-based job aids are increasing in popularity in low resource settings where they are being leveraged to improve the knowledge, skills and confidence of frontline healthcare workers (HCWs) delivering HIV services. The KidzAlive Talk Tool, originally a paper-based child-friendly job-aid widely used by the National Department of Health of South Africa to improve the quality of care for children living with HIV (CLWHIV), was developed into a novel mobile application for android devices.
The KidzAlive Talk Tool app was successfully pilot-tested between 2018 and 2019 where it received positive reviews from frontline healthcare workers, children, primary caregivers and primary healthcare managers. The next stage of testing has led to its scale-up in 45 community and primary healthcare facilities in Gauteng and KwaZulu-Natal since November 2019. Part of this scale-up involved capacity building (one-one training, mentorship and a training video) of HCWs on how to use the mobile app during HIV care for CLWHIV. We evaluated the outcome of this capacity building process using Kirkpatrick's four-level model for evaluating training.
METHODS: We conducted a pragmatic mixed-methods study. A mix of 45 community organisations and primary healthcare facilities from Gauteng and KwaZulu-Natal were purposively selected to participate in the scale-up process. HCWs (nurses and HIV counsellors) from each of these organisations/facilities were trained and mentored between November and December 2019 using a training video (loaded on tablet devices). We measured the outcomes of each stage of training including a Knowledge test, Confidence questionnaire, Training/Mentorship evaluation form and a Mentorship assessment form. We analysed the quantitative data generated from this process using means and two-sample t-test for proportions and thematic analysis for qualitative data.
RESULTS: The results of this study suggest positive participant reactions to the training, high knowledge and skills retention (p=0.01), increased confidence over time p=(0.00) and improved quality of care (based on qualitative data).
CONCLUSIONS: This study makes a case to support the value of training and mentoring frontline HCWs on digital innovations to increase their acceptability, sustained usage over time and quality of care for children living with HIV in low resource settings.

PED1316

DEVELOPING AN MHEALTH INTERVENTION FOR IMPROVED TREATMENT LITERACY AND MEDICATION ADHERENCE AMONG PEOPLE LIVING WITH HIV/AIDS IN MUMBAI, INDIA

P. Patankar[1], S. Acharya[2], N. Apte[1], S. Saharan[1]
[1]Avegen Pvt Ltd, Mumbai, India, [2]Mumbai District AIDS Control Society, Mumbai, India

BACKGROUND: Antiretroviral therapy (ART) adherence is a principal predictor for the success of 90-90-90 goals. Digital interventions offer a potential cost-saving solution for overburdened health systems with high service delivery costs to improve patient outreach & support. We evaluated the feasibility of a mobile application for improving treatment literacy & medication adherence among People Living with HIV/AIDS (PLHAs) in Mumbai India.

DESCRIPTION: We analysed treatment & counselling patterns at select ART centres through focused group discussions & interviews. Based on these inputs, we developed a mobile application containing videos, infographics & quizzes in the local language & piloted the application at 6 ART centres. The application uses story-telling with relatable PLHA personas in familiar community settings to help build a personal connection. The video themes include information on treatment initiation and adherence, misconceptions and stigma around HIV, safe behaviour & nutrition. PLHAs receive points & badges for content consumption & understanding. Additionally, it also has a self-reported mood tracker to gauge PLHAs' emotional wellbeing.

LESSONS LEARNED: Since enrolment, the app has been used by 450 PLHAs. On an average, 20% users are active on the app every week. The videos belonging to themes Nutrition and wellbeing, Treatment literacy and Emotional health received highest views. Most watched infographic themes included Healthy living and Community support. During qualitative feedback sessions, many PLHAs reported that the video duration was helpful for watching in short time & they were able to connect with the personas represented in the videos. PLHAs who have been on ART for longer duration felt the need for more detailed videos on special interest topics such as sex education, ongoing diet & exercise counselling.

CONCLUSIONS/NEXT STEPS: The usage behaviours & patterns demonstrate that PLHAs are interested in seeking information about various aspects of the disease, medications & lifestyle changes. This mHealth intervention can be effective in ensuring personalised treatment literacy and address behaviour change to effect improved ART adherence. The mHealth intervention can be replicated and upscaled to other parts of the country.

VOLUNTARY MEDICAL MALE CIRCUMCISION

PED1317

ACCELERATED SCALE UP OF VOLUNTARY MEDICAL MALE CIRCUMCISION WITHIN THE MILITARY HEALTH SERVICES IN UGANDA: THE RACE TOWARDS 2020 HIV EPIDEMIC CONTROL

E. Lugada[1], A. Nyanzi[1], G. Seruwagi[2], V. Kasujja[3], B. Kikaire[4], N. Kak[5], H. AlMossawi[5], D. Bwayo[1], B. Lutimba[1], T. Rwegyema[1], J. Akao[6], C. Wamundu[3], A. Musinguzi[3], S. Lawoko[7]
[1]University Research Co., LLC - Department of Defense HIV/AIDS Prevention Program, Kampala, Uganda, [2]Makerere University, Kampala, Uganda, [3]Uganda Peoples Defense Forces (UPDF), Directorate of HIV/AIDS, Bombo, Uganda, [4]Uganda Virus Research Institute (UVRI), Entebbe, Uganda, [5]University Research Co., LLC, Washington D.C, United States, [6]U.S. Department of Defense (DoD), Kampala, Uganda, [7]Gulu University, Gulu, Uganda

BACKGROUND: Scaling up Voluntary Medical Male Circumcision (VMMC) is a critical ingredient in achieving HIV epidemic control by 2020. However, documentation of programmatic interventions to improve VMMC uptake among military populations, an HIV high-risk population is lacking. URC - Department of Defense HIV/AIDS Prevention Program implemented a novel approach to accelerate VMMC uptake in the Ugandan military. We describe trends and operational cost associated with VMMC uptake following the intervention contrasted between military and civilian facilities.

DESCRIPTION: We implemented monthly mobile VMMC services throughout the country targeting soldiers, their families and surrounding communities. Records gathered during implementation were used to describe the intervention. Quantitative methods were applied to compare VMMC post intervention rates with set targets and monthly VMMC trends country-wide between military and civilian facilities over a five months period. An operational VMMC service cost analysis was applied to determine per male circumcision unit cost excluding cost of consumables.

LESSONS LEARNED: Command-driven mobilization, multiple stakeholder engagement, use of mobile VMMC teams and data-driven planning increased demand for and uptake of VMMC services among the military. By the first month of intervention, VMMC performance had surpassed set monthly targets of 1,474 by 199% (n=2,931 circumcisions) from 31% to 62% uptake. Overall VMMC performance achieved within the military was 132% in excess of set targets (n=7408) at six months. The scaled-up operational VMMC cost per circumcision performed dropped from $15 to $7, a 47%-unit cost saving within six months. While a positive trend in VMMC uptake was observed in the military facilities, the opposite was exhibited in civilian facilities over the observation period.

CONCLUSIONS/NEXT STEPS: It is feasible to rapidly scale up circumcision coverage in military populations through mobile short term episodic VMMC services optimizing volume and efficiency. Invoking command-led mobilization and multiple stakeholder involvement is critical in demand creation and overcoming the mobile nature of the military.

PED1318

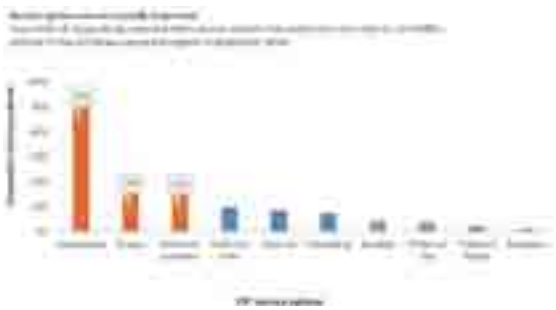
WHAT INFLUENCES ADULT MEN TO USE HIV PREVENTION SERVICES: LESSONS FROM A PROMISING MALE-FRIENDLY 'VIP' INITIATIVE TO PROMOTE VOLUNTARY MEDICAL MALE CIRCUMCISION (VMMC) SERVICES IN TANZANIA

M. Makokha[1], P. Massawe[1], M. Machaku[1], A. Christensen[1], E. Msafiri[1], C. George[1], H. Mpunza[1], G. Malisa[1], N. Tegile[1], S. Tesha[1], V. Mushi[2], Z. Mwandi[3], S. Subira[4], B. Mpora[4], M. Carrasco[5], F. Rwegerera[6]
[1]Jhpiego, AIDSFree Project, Dar es Salaam, Tanzania, United Republic of, [2]FHI 360, Tulonge Afya Project, Dar es Salaam, Tanzania, United Republic of, [3]Jhpiego, AIDSFree Project, Nairobi, Kenya, [4]Ministry of Health, Community Development, Gender, Elderly and Children (MOHCDGEC), National AIDS Control Program (NACP), Dodoma, Tanzania, United Republic of, [5]United States Agency for International Development, Office of Family Planning and Reproductive Health, Washington DC, United States, [6]United States Agency for International Development, Community-Based Services, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Reaching adult men with evidence-based HIV prevention interventions is a global priority to achieve epidemic control. The AIDSFree Project has successfully supported VMMC services in five regions in Tanzania since 2014 reaching 563,139 men 10 years and older since inception. However, VMMC utilization among 25-29 year-old men has been problematic. AIDSFree reached 26% (5,477) of the annual target for this age group from January to December 2018.

DESCRIPTION: AIDSFree developed a menu of 10 'VIP' options to improve declining VMMC service utilization among adult men. Produced as a 'VIP' card, the menu incorporated local volunteers' intimate knowledge of their communities and barriers to VMMC services reported by adult men. AIDSFree pretested the 'VIP' card among 164 men, providers and volunteers at nine government health facilities in early 2019 and scaled up its use to all 71 AIDSFree-supported facilities in August 2019. Volunteers recruited 'VIPs', assisted them to check off desired options on their 'VIP' cards and pre-arranged clinic visits with providers.

LESSONS LEARNED: From August to December 2019, AIDSFree served 4,983 adult men compared to 1,864 men from January to July 2019. The 'VIP' intervention improved utilization among by 267% between the two periods, achieving 55% of annual target. Extrapolating same levels of VMMC service utilization after 'VIP' inception, the project would have served 11,959 men during the year compared to 3,195 men without 'VIP' services, equivalent to 374% higher utilization. In September 2019, AIDSFree asked 160 'VIP' clients for their feedback. 97% of respondents reported satisfaction with 'VIP' services. 81% of respondents favored three options (Figure 1).



[Figure 1. How 'VIP' options influenced men to use VMMC services]

CONCLUSIONS/NEXT STEPS: The 'VIP' model addressed barriers to men accessing VMMC services from their perspective, substantially improving uptake. Pre-arranged support for clinic visits can help men move from longstanding intention to use VMMC services to actual use by assuring them that their needs will be met.

PED1319

70% MALE CIRCUMCISION CONVERSION RATES IN KATETE DISTRICT: DEMAND CREATION FOOTBALLERS

F. Kaira[1], J. Makupa[1], F. Luwita[1], L. Aladesanmi[1], O. Chituwo[2], P. Simwanza[3]
[1]Jhpiego, an Affiliate to Johns Hopkins University, Jhpiego, Lusaka, Zambia, [2]Centers for Disease Prevention and Control, CDC/DDPHSIS/CGH/DGHT, Lusaka, Zambia, [3]Ministry of Health, Health services, Chipata, Zambia

BACKGROUND: Voluntary Medical Male Circumcision (VMMC) has been provided in Zambia since 2007, however uptake is still insufficient to meet targets and uptake of the procedure is expected to decline as early adopters have already been circumcised. VMMC prevalence has plateaued in the past 5 years at 22% as seen in both the 2013/14 ZDHS and the 2016 ZAMPHIA, there is therefore an urgent need to improve the quality and precision of demand creation strategies to convert hard to reach men.
In response to this, Jhpiego Zambia has implemented various interventions to scale up VMMC for HIV prevention in its areas of work with a priority of reaching both young and adult men aged 15 to 29.

DESCRIPTION: Jhpiego, funded by PEPFAR through CDC, supports 40 facilities in five provinces to provide VMMC services. The project's overall objective is to increase VMMC coverage to 80% in supported locations. To scale up services, the project introduced an innovative and targeted demand creation strategy in Katete district which combines "soccer galas with complimentary IPC conducted before and during the galas". The participating football teams were oriented on VMMC messaging and were tasked to mobilize a minimum of 15 clients per team as an entry requirement into the tournament. Mobilization continued during the tournament with a general orientation of the entire stadium, with mobilizers stationed throughout the arena to provide information to spectators one-on-one.

LESSONS LEARNED: In a space of three weeks, football teams booked 630 prospective clients of which 427 people were circumcised and during the games there was an additional 250 bookings with 190 circumcised. In the previous month the health facility covering this catchment only mobilized 507 clients and only 264 clients were circumcised. The gala increased the circumcision number by 62% and these improvements have been sustained with clients referring to the soccer gala as their information source for MC.

	People Booked	Circumcised	Conversion Rate
Soccer Gala Teams	630	427	67%
Mobilizers during gala	250	190	76%
Total	880	617	70%

[Table]

CONCLUSIONS/NEXT STEPS: The soccer gala plus IPC demand creation strategy created more awareness for VMMC than the other approaches at reaching and converting men. The project is scaling up this approach to other districts with low circumcision coverage.

PED1320

CONSTRUCTIONS OF SEXUALITY AND RISK IN THE SIX WEEK PERIOD POST VOLUNTARY MALE MEDICAL CIRCUMCISION IN SOUTH AFRICA

D. Skinner[1,2], Y. Toefy[2], L. Marais[3], J. Cloete[3], V. Diwan[4], S. Thomsen[4]
[1]Human Sciences Research Council, Social Aspects of Public Health, Cape Town, South Africa, [2]Stellenbosch University, Dept. of Public Health, Cape Town, South Africa, [3]Free State University, Center for Development Support, Bloemfontein, South Africa, [4]Karolinska Institutet, Department of Global Public Health, Stockholm, South Africa

BACKGROUND: Voluntary male medical circumcision (VMMC) is a key interventions to reduce HIV transmission, but during the six week period post VMMC, risks of HIV infection for men who have unprotected sex are raised. This paper seeks to understand how men interpret and practice their sexuality, and understand risk over the six week period post VMMC.

METHODS: Six focus groups from Cape Town and 25 semi-structured interviews from Mangaung, South Africa, were conducted with men who have been through VMMC. These interviews were done as part of larger studies to assess the use of voice messaging to encourage abstinence during the six week healing period. The interviewees were recruited from the VMMC clinics, and were purposively selected to obtain a wide range of experiences. A descriptive phenomenological analysis approach was applied using Atlas ti.8.

RESULTS: The men knew that they should not have sex during the six week period, but had a poor grasp of the risks over the latter weeks once the pain had remitted. For the men in any sexual relationships, sex was felt an essential part of life; including enjoyment, satisfaction of their desire, support of identity, and to maintain relationships. Key was the influence of triggers especially with partners or going out with friends. Men were uncertain of their capacity to resist having sex once aroused.

During first two weeks the penis is too painful, but once the pain reduced the men reported their desire returned. Men had to decide between satisfying desire and their own safety. The approaches were dominantly to:

Balance their risk, including condom use and reduced sexual frequency

Avoid temptation, including drawing on partner support and sleeping and dressing separately, and staying at home, one man hid at home.

CONCLUSIONS: Men showed great care is trying to balance their awareness of risk with their desire to have sex, using their own knowledge and beliefs about HIV to reduce the risk. Many felt they had to take additional measures to avoid having sex, including some level of social isolation. Greater education is required on the nature of the additional risk over the latter weeks.

PED1321

BARRIERS, BENEFITS, AND BEHAVIORAL BELIEFS: A THEORY-DRIVEN ANALYSIS TO INFORM DEMAND-CREATION STRATEGIES THAT FACILITATE IDEATION FOR VOLUNTARY MEDICAL MALE CIRCUMCISION UPTAKE IN ZAMBIA

J.G. Rosen[1], M.A. Carrasco[2], B. Olapeju[3], E.'. Kumoji[3]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]United States Agency for International Development, Washington, United States, [3]Johns Hopkins Center for Communication Programs, Baltimore, United States

BACKGROUND: With high voluntary medical male circumcision (VMMC) coverage (22.2%) and sustained investment to offer 400,000 boys and men VMMC in 2020, Zambia is well-positioned to reach high VMMC coverage and curb HIV transmission. Efforts to scale services, however, are threatened by competing benefits and barriers to service uptake. Applying Kincaid's Behavioral Ideation Model, we sought to identify cognitive and social determinants of circumcision intention in a nationally representative sample of Zambian men in order to inform VMMC demand-creation efforts.

METHODS: Two-stage sampling proportional to population size was used to identify households across residence types (urban/rural) in 14 districts. Circumcision intent was ascertained dichotomously in uncircumcised men aged 15-59 years through self-reported intention to access VMMC services in the future. Bivariate and multivariable Poisson regression with robust error variance modeled relationships between ideational determinants (e.g., perceived benefits, barriers, susceptibility, and self-efficacy) and VMMC intent. Survey weights adjusted for clustering and stratification.

RESULTS: Among uncircumcised men (N=1,204), 40.0% expressed future intent to access VMMC services. Men declaring intent to circumcise were more likely to perceive circumcision to increase sexual satisfaction/pleasure (Adjusted Prevalence Ratio [APR] = 1.45, 95% Confidence Interval [CI]: 1.11–1.89) and endorse distance to services as a barrier to VMMC uptake (APR=1.54, CI: 1.27–1.87). Conversely, these men endorsed the following barriers to VMMC at significantly lower proportions than men with no intention to circumcise: reduced sexual satisfaction (APR=0.10, CI: 0.02–0.94), incompatibility with local customs (APR=0.41, CI: 0.18–0.94), and perceived unimportance (APR=0.71, CI: 0.51–0.98).

CONCLUSIONS: Demand-creation strategies seeking to bolster VMMC uptake should address salient barriers to uptake, particularly concerns around sexual pleasure, distance to services, and perceptions that VMMC is incompatible with local customs. The barrier around perceived unimportance should be addressed by ongoing awareness-raising efforts while respecting that for some men, notably those with low HIV risk, VMMC may indeed be unimportant.

PED1322

DEMAND FOR MEDICAL CIRCUMCISION SERVICES BY OLDER MEN IN A MATURE PROGRAM IN WESTERN KENYA: WHERE MEN ARE IN THE DECISION-MAKING PROCESS TOWARDS CIRCUMCISION

K. Agot[1], E. Mboya[1], F.O. Okeyo[2], J. Okore[1], M. Ochillo[1], S. Ohaga[1], E. Omanga[1]
[1]Impact Research and Development Organization, Kisumu, Kenya, [2]Nyanza Initiative for Girls' Education & Empowerment, Kisumu, Kenya

BACKGROUND: Most medical male circumcision (MMC) programs in Africa face challenges with getting older men above 25 years to take up MMC services, yet this is the age at highest risk of sexually acquired HIV. About 90% of those circumcised in Kenya (n=2,256,396) were <20 years, and only 5% were above 25 years. Using Transtheoretical Model (TTM) of behaviour change, we explored with uncircumcised men in western Kenya the stage at which they were in making a decision to seek MMC services.

METHODS: We conducted household listing in 3 locations (urban, peri-urban and rural) of Kisumu County, and identified households with men aged 20-49 and uncircumcised. We administered a survey to determine circumcision status of those who met the eligibility criteria. Those reporting being uncircumcised were asked for the likelihood of getting circumcised. We used TTM framework to place men at various stages of decision-making towards circumcision: pre-contemplation (operationally defined as 'not considering MMC'), contemplation ('weighing options) and preparation (planning to go 'soon'). (Action, maintenance and termination stages were deemed irrelevant.)

RESULTS: We enrolled 1,200 uncircumcised men, median age 33 [IQR 28-39], 73% completed ≥primary school, 92% were married/living together, and 21% reported condom use in the last one month. Likelihood of getting circumcised was 55% 'definitely', 35% 'maybe' and 9% 'unlikely'. This is equated to 9% being in pre-contemplation stage, 35% in contemplation stage, and 55% in preparation stage. However, when asked directly to self-classify in the TTM Model, 25.1% put themselves under pre-contemplation (not planning for MMC ever or within 6 month), 46.7% contemplation (planning within 6 months) and 27.9% preparation stage (planning within one month). However, only 1.3% actually went for MMC within three months. Ninety-seven percent believed circumcision reduces HIV risk, but only 39.4% believed they are at moderate-to-high risk of acquiring HIV.

CONCLUSIONS: Uncircumcised men in Kenya know that MMC reduces HIV risk yet are unprepared to go for MMC possibly due to low risk perception. Interventions to boost demand for VMMC should be tailored to increase risk perception and support men to progressively move from one stage of change to the next.

PED1323

COMMUNITY MOBILIZATION AS STRATEGIC TOOL FOR HIV TESTING, A STUDY OF LARKANA DISTRICT OF SINDH PROVINCE OF PAKISTAN

F. Ahamd[1]
[1]Shaheed Zulfikar Ali Bhutto Institute of Science and Technology (SZABIST), Management Sciences, Larkana, Pakistan

BACKGROUND: Pakistan become fastest growing AIDS epidemic in the south Asian, as 20,000 AIDS cases were reported in 2017. HIV various is affecting mostly poor and marginalized segment of the population in Larkana, city of Pakistan is affected badly with HIV virus. In July 2019, WHO declares HIV outbreak as grade 2 emergencies in Larkana district. The current study aimed to measure the association between community mobilization efforts and HIV testing to seek whether communication mobilization is good strategy to engage Larkan distircts's people in testing.

METHODS: Data from individuals aged 16-45 from Larkana. In this study, social mobilization variable was measured on 5-point scale using on its four dimensions: community participation, social cohesion, collective efficacy, and leadership. Bivariate and multivariate regression model was used to measure the association between HIV testing and community mobilization. Furthermore, multivariable models were stratified in term of sex and residence.

RESULTS: Among 400 respondents, 10% (n=40) previously gone for HIV testing, with female (9% vs. 8%, p< 0.001) and married (7% vs. 6%, p< 0.001) respondents reporting HIV testing at significantly higher proportions than male and never-married respondents, respectively. People aged 116-23 years reporting significantly lower proportion when compared with respondents aged 24-33 years (8% vs. 10 %, p< 0.001) and 34 to 45 years (8% vs. 11%, p< 0.001). The results also revealed that, in multivariable analysis, community mobilization (mean: 51.48, range: 28 to 88) was significantly associated with HIV testing (AOR=1.02, CI: 1.00 to 1.02). on account of gender, and living area -stratified models, the odds of HIV testing were higher and significant among males (AOR=1.02, CI: 1.01 to 1.04), in rural areas people (AOR=1.03, CI: 1.01 to 1.06), but not among females or urban residents, for each additional unit increase in community mobilization.

CONCLUSIONS: The findings shows community mobilization is linked with HIV testing HIV testing among those respondents who participated in survey. The finding highlights that, among male segment of the society living in rural and remote areas. Social mobilization is very effective tool to reach remote and hard to reach areas, especially men who are living in remote and rural areas.

PED1325

INITIATING HIV SERO STATUS DISCLOSURE TO REGULAR PARTNERS AMONG WOMEN LIVING WITH HIV (WLHIV) AT A CLINIC FOR A HIGH RISK KEY POPULATION IN KAMPALA

A. Ssali[1], S. Nakate[1], C. Nankabirwa[1], D. Bagiire[1], P. Odongo[1], J. Seeley[1,2]
[1]Medical Research Council/Uganda Virus Research Institute & London School of Hygiene and Tropical Medicine Uganda Research Unit, Kampala, Uganda, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

BACKGROUND: Disclosing HIV sero-status to regular sexual partners is a challenge among women living with HIV(WLHIV). The Good Health for Women project clinic in Kampala offers PEPFAR supported services that include HIV testing and counselling, provision of condoms, STI care, gender-based violence prevention education and ART treatment and care to women at high risk of HIV who include self-identified sex workers. Services are offered to women and their regular sexual partners. Women are encouraged by the facility counsellors to share their HIV results in order to broaden their support network. WLHIV are invited in small groups to discuss areas of concern in the disclosure process. Expert peers who have disclosed to partners provide support to their peers by sharing their personal testimonies.

DESCRIPTION: One hundred WLHIV in care have received counsellor- and peer-supported counselling sessions at the clinic between April and September 2019. Mean age was 33.8 years; 49% reported

to regularly use alcohol; 13% reported smoking tobacco and/or other substances. Only 27% were able to share their HIV positive results with their regular partner, seven of whom experienced some form of gender-based violence. In spite of their revealed sero discordancy, 13/27 (48%) reported not to be using condoms with their regular partner.

LESSONS LEARNED: HIV is still highly stigmatized in the community. Peer-supported counselling is a useful model to foster sero-status disclosure by WLHIV to their regular sexual partners. Some WLHIV have been able to share their test results with regular sexual partners. Condom use is a challenge with spouse or regular partners even among high-risk women who disclose their sero status. Gender based violence, alcohol and substance use may be affecting the disclosure process.

CONCLUSIONS/NEXT STEPS: Disclosure of HIV sero-status to regular sexual partners is key in reducing HIV transmission. A model to encourage group sharing and use of expert peers working with professional counsellors is a worthwhile strategy in this population.

DOMESTIC CONTRIBUTION TO THE HIV/AIDS RESPONSE AMONG COUNTRIES CLOSER TO EPIDEMIC CONTROL

V. Vasireddy[1], M. Ruffner[1], J. Palen[1], M. Wollmers[1], A. Bush[2], S. Harmon[1], N. Allyala[1]
[1]President's Emergency Plan for AIDS Relief (PEPFAR), US Department of State, Washington, United States, [2]USDA Food and Nutrition Service, Washington, United States

BACKGROUND: UNAIDS estimates that US$26.2 billion is required for the global HIV response in 2020 alone. UNAIDS data from 112 countries shows domestic public spending on HIV increased by 60% from 2006 to 2016 exceeding international donor funding. Despite a flat-lined budget since 2010, the President's Emergency Plan for AIDS Relief (PEPFAR) remains the world's largest donor fighting HIV/AIDS. Countries are expected to increase their HIV/AIDS budgets and implement efficient and cost-effective methods due to shrinking donor funding.

METHODS: We analyze trends in Domestic Resource Mobilization (DRM) from 2017 to 2019 across select countries at or near epidemic control. Epidemic control is attained when the incidence mortality ratio (IMR) is less than one. Countries selected for this analysis have IMR between 0.32 and 1.5. The Sustainability Index Dashboard (SID) is a tool developed by PEPFAR and UNAIDS and implemented by partner countries every two years to measure progress towards sustainable epidemic control. DRM is an element in the SID and analyzes multiple factors specific to HIV/AIDS on a scale of 0-10: long-term financing strategy, HIV targets in the national budget, and the share of domestic funding within the national response.

RESULTS: While 70% of countries in this abstract show a positive trend towards increasing DRM, Cambodia, Ethiopia, and Zimbabwe declined from 2017. Significant increases in DRM score are seen in Kenya, Lesotho, and Namibia (chart below).

[Chart]

CONCLUSIONS: While countries have shown progress towards mobilizing resources, a common factor across countries showing a decline in DRM score is budget execution, which leads to less than efficient program implementation. In comparison, the common factors across countries with increased DRM score are budget execution and improvement in long-term HIV financing strategy. Going forward, PEPFAR will focus on strengthening budget execution in select countries in order to maximize available resources and sustain the HIV/AIDS response.

PEE1324

DECLINING INVESTMENT IN HUMAN RIGHTS AND GENDER (HR/GESI) IN SOUTH ASIAN (SA) COUNTRIES AFFECTING THE 90-90-90 TARGETS

M. Sharma[1], K. Badal[2]
[1]Birat Nepal Medical Trust, Kathmandu, Nepal, [2]UNAIDS, M and E, Kathmandu, Nepal

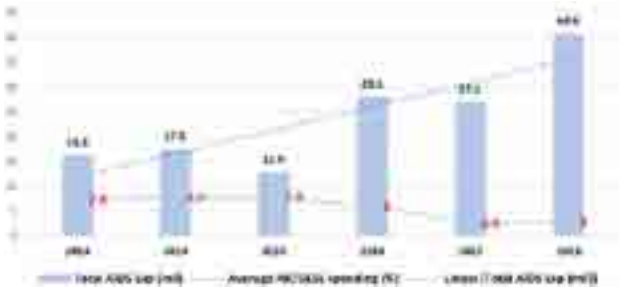
BACKGROUND: Many countries are lagging behind in achieving 90-90-90 targets. It has been ostensibly highlighted globally that HR/GESI (GBV, stigma, discrimination) are major barriers for KPs in accessing HIV services; therefore emphasised for increased investment. Clearly, exploring the investment made in HR/GESI is pertinent

METHODS: We reviewed the Global AIDS Monitoring data (2013-2018) for SA countries for spending on HR/GESI activities. Four country's data were available (we excluded India), that we grouped into three,

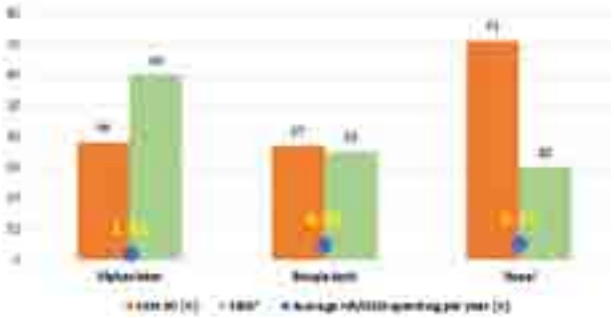
1. HR/GESI:
2. KP interventions; and,
3. Other.

To get the total investments, along with direct spending, we also arbitrarily considered 10% as HR/GESI spending from KP interventions where HR/GESI activities are often inbuilt. We analysed HR/GESI spending against selected indicators (Global AIDS updates 2019), first 90 and S&D (...would not buy vegetables from a PLHIV shopkeeper).

RESULTS:



[Figure 1. HR/GESI spending (%) in three South Asian countries]



[Figure 2. HR/GESI spending (2013 - 2018), 90-90 targets, S & D]

Average spending on HR/GESI was recorded at 7.4% (2013) and 3% in 2018 peaking at 7.9% (2015). Total AIDS spending in the same period more than doubled from 16.3 mil to 40.8 mil (figure 1). In the same period Afghanistan has 1.9%, average spending/year on HR/GESI Bangladesh 4.8% and Nepal 5.15%. The first 90 targets in those countries was noted at 38%, 37% and 71%; and S&D was recorded at 60%, 35%, and 30% respectively (figure 2)

CONCLUSIONS: While overall AIDS spending has increased over the period, percentage of HR/GESI spending has declined in the same period (figure 1). A clear pattern and relationship of HR/GESI spending with first 90 target and S&D was observed. This calls for increased investment and further study on HR/GESI

PEE1325

ASSESSING INVESTMENT IN HIV PROGRAMMES FOR PEOPLE WHO USE DRUGS AND OPPORTUNITIES FOR A REDIRECTION OF DRUG-RELATED LAW ENFORCEMENT SPEND IN SEVEN COUNTRIES IN ASIA

E. Rowe[1], C. Cook[1]
[1]*Harm Reduction International, Sustainable Financing Team, London, United Kingdom*

BACKGROUND: New HIV infections among people who use drugs continue to rise globally. In order to meet commitments within the 2016 Political Declaration on HIV/AIDS of reducing new HIV infections to less than 500,000 per year, it is critical that access to harm reduction services is dramatically increased. Although challenging, critically assessing investment in HIV programmes for people who use drugs is crucial for informing advocacy for responsible donor transition and sustainable harm reduction financing.

METHODS: Harm Reduction International (HRI) developed research tools which were adopted by civil society partners to assess harm reduction investment in India, Thailand, Nepal, Cambodia, Vietnam, the Philippines and Indonesia. Applying pre-developed criteria, countries were ranked on four categories: harm reduction service coverage; accessibility of spending data; government investment; and sustainability of funding. An instrument to capture drug-related law enforcement expenditure was also developed and data collected in Thailand, Indonesia, Nepal and India.

RESULTS: Harm reduction service coverage varied with Thailand, India, Nepal and the Philippines ranking most poorly and Indonesia ranking most favourably. Accessibility and validity of spending data was a concern across all countries. Government investment in needle and syringe programmes was minimal; with any substantive funding allocated to opioid substitution therapy or ART. Overall there was a paucity of investment in HIV services specifically targeted at people who use drugs. In several countries, community and civil society representatives reported concerns relating to poor political will to ensure financing for HIV services for people who use drugs. Furthermore, researchers identified an exorbitant amount of public funds being channeled into punitive drug control in the four country study sites.

CONCLUSIONS: Study indicated that harm reduction funding in all sites is precarious or already in crisis, and that increased government investment into and mainstreaming of harm reduction services will be crucial for sustaining national responses. Greater accessibility around harm reduction, HIV and law enforcement spending data is necessary to inform strategic investment in public health responses to HIV and drug use. HRI modeling projections demonstrate that redirecting a small proportion of drug control funds to harm reduction could end injecting-related HIV infections by 2030.

PEE1326

ACHIEVING EFFICIENCY IN EXPENDITURE ON HIV TREATMENT IN NIGERIA

O. Adebanjo[1], M. Yanet[1], I. Ezirim[1], R. Aguolu[1]
[1]*National Agency for the Control of AIDS (NACA), Research, Monitoring and Evaluation, Abuja, Nigeria*

BACKGROUND: The 90-90-90 strategy is central towards ending AIDS. Investment in HIV treatment is critical to this following the adoption of test and treat policy and treatment as prevention (TasP) approach in Nigeria. The country needs to implement HIV treatment programs at higher efficiency to achieve the second 90.

METHODS: Data for this paper was extracted from the National AIDS Spending Assessment (NASA) and National aggregated HIV treatment program. NASA collects expenditure amounts on mutually exclusive HIV and AIDS activity categories (treatment, prevention, etc) from program implementers, donors and government agencies using a top-down and bottom-up approach that prevents double counting. HIV treatment expenditure data was collated for 2012 to 2018.

The national HIV treatment program collects routine facility-level data using the ART monthly summary form which is aggregated to obtain annual data for the country. HIV treatment data for 2012 to 2018 was collated. Simple average was calculated with HIV treatment expenditure amount and number of PLHIV on treatment to obtain expenditure per PLHIV on treatment for each year.

RESULTS: As shown in table below, expenditure on HIV treatment was highest in 2015 at USD308, 609,485 and lowest in 2012 at USD191,463,353. Number of persons on treatment rose gradually from 491,021 in 2012 to peak at 1,066,223 in 2017 before a decline to 1,049,019. HIV treatment expenditure per person ranged between USD227 in 2018 to USD390 in 2012.

Year	Expenditure on HIV Treatment (USD)	Persons on HIV Treatment	Expenditure/Person (USD)
2012	191,463,353	491,021	390
2013	211,994,657	639,397	332
2014	190,766,855	747,382	255
2015	308,609,485	853,992	361
2016	302,808,349	983,980	308
2017	304,376,381	1,066,223	285
2018	238,447,440	1,049,019	227

[Table 1: Expenditure on HIV Treatment in Nigeria 2012 - 2018]

CONCLUSIONS: This study shows annual variability in expenditure per person on treatment which indicates opportunities to reduce waste and maximize efficiency. Therefore, Nigeria needs to improve in the number of people covered per unit of expenditure in order to reach more PLHIVs with treatment and end HIV by 2030.

PEE1327

GENERATING ADDITIONAL RESOURCES FOR HIV RESPONSE THROUGH MAINSTREAMING HIV&AIDS IN NATIONAL PROCESSES: THE CASE OF UGANDA

S. Khanakwa Bwayo[1], V. Bagambe[1], N. Musoba[2], J. Mwesigwa[3]
[1]Uganda AIDS Commission, Planning and Strategic Information, Kampala, Uganda, [2]Uganda AIDS Commission, Kampala, Uganda, [3]Ministry of Finance Planning and Economic Development, Kampala, Uganda

BACKGROUND: Mainstreaming HIV into national processes is a key approach to generating additional domestic resources for HIV and addressing the behavioral and structural risk factors of the HIV epidemic. Through integration of HIV interventions within the sector programs, mainstreaming enables a multisectoral and multi-stakeholder response. In Uganda, HIV Mainstreaming is enshrined in the Presidential Fast Track Initiative for Ending AIDS as a Public Health Threat in Uganda by 2030 – launched in June 2017. Guidelines for an effective and standardized HIV&AIDS mainstreaming approach for public and non-public sectors in Uganda were developed in 2019. The Ministry of Finance Planning and Economic Development in its Budget Call Circulars for Financial Years 2018/2019 & 2019/2020 instructed all government Ministries, Departments, Agencies (MDAs) and District Local Governments (DLG) to allocate 0.1% of the budgets (excluding Pensions, Gratuity & Transfers) to HIV activities. We assessed the extent to which Uganda has generated additional domestic resources towards HIV response through Mainstreaming HIV&AIDS into national programs.

METHODS: In October 2019, we conducted a rapid assessment of Ministerial Policy Statements for all the 19 Government of Uganda Sectors to generate sector allocations and expenditures to HIV&AIDS for 2019/2020.

RESULTS: A total of 146 entities from 19 Sectors were analyzed. 136 entities had evidence of allocating at least 0.1% of their budget to HIV and AIDS Mainstreaming activities. 8/19 sectors had allocated >0.1% of their total budget, with an average allocation of 0.2%. Only 4 sectors allocated <0.1%. A total USD 10.5 Million was allocated to HIV interventions through the HIV mainstreaming approach in the respective sectors. HIV interventions financed included; HIV Counseling & testing, HIV Awareness campaign, social support, care and treatment, and workplace policies.

CONCLUSIONS: This study demonstrates that HIV mainstreaming can creatively avail additional domestic resources to the National HIV response. To optimize this opportunity further, it will require the Government of Uganda to create a vote output to track resources and expenditures to sector HIV specific outputs. This will ensure efficient and effective use of public resources mobilized through HIV&AIDS mainstreaming.

PEE1328

A TIME TO ACT: PROSPECTS FOR RE-COMMITMENT TO EPIDEMIC CONTROL AND SUSTAINABILITY IN INDONESIA'S LAGGING PROGRAM

C. Cantelmo[1], S. Prabhakaran[1], R. Soehoed[2], A. Wardhana[3], A. Dutta[1]
[1]Palladium, Washington, United States, [2]Palladium, Jakarta, Indonesia, [3]Indonesia AIDS Coalition, Jakarta, Indonesia

BACKGROUND: Indonesia is far from HIV epidemic control with a high ratio of incidence to prevalence and only 16% ART coverage (December 2018). In 2019, the government launched the ART Acceleration Plan, targeting 40% ART coverage by December 2020 and epidemic control by 2027. However, to become reality this requires political will, strengthened coordination and collaboration across institutions, transparency and efficiency in procurement practices (tenders for vital drugs fail and the country pays much more per regimen than neighbors), efficient service delivery, and revised provider payments to incentivize outcomes.

DESCRIPTION: Since 2017, the USAID- and PEPFAR-funded Health Policy Plus (HP+) project partnered with the Ministry of Health, National Health Insurance, local governments, and civil society organizations (CSOs) like the Indonesia AIDS Coalition to generate evidence on HIV costs, epidemic trajectory, financing options, etc., to inform HIV policy formulation. In 2020, HP+ is supporting a pilot of HIV service purchasing reforms.

LESSONS LEARNED: Consistent engagement at national and subnational levels is needed to implement the government's strategy to identify, link, initiate and retain ART patients. With mentoring, local governments in Jakarta and Papua, two high-burden provinces, have developed capacity to generate and use costing and modelling evidence for decision-making. Local governments must also mandatorily fund HIV case-finding under a minimum package of services. CSOs are now using new tools and cost data to develop outcome-linked budgets to access government grants for HIV. Overall, key program priorities include: optimize HIV case-finding based on cost-efficiency analysis of current testing methods, stratified by risk groups; improve referral and down-referral systems to ensure stable ART patients are seen at the appropriate level; implement performance-based payment at primary care to incentivize retention in care; support more efficient procurement of ARVs and improved reimbursement for the scale-up of viral load testing, and introduce new and effective service delivery models for high-cost interventions, such as ART support groups and lost-to-follow-up tracking.

CONCLUSIONS/NEXT STEPS: Indonesia's program must institutionalize routine, country-led analyses and adaptive policymaking; differentiated service delivery models, de-medicalizing and making more accessible HIV care to reach the majority of people living with HIV are needed, which better leverage the existing financing schemes.

PEE1329

CALCULATING THE COST OF PREVENTION AND EARLY INTERVENTION SERVICES TO ADDRESS THE SOCIAL DRIVERS OF HIV IN SOUTH AFRICA: A COSTING ANALYSIS OF THE CORE PACKAGE OF SERVICES

M. Mmolai[1], W. Botes[2]
[1]South African Government, Department of Social Development, Pretoria, South Africa, [2]Pact South Africa, Government Capacity Building and Support Programme, Pretoria, South Africa

BACKGROUND: South Africa has 2 800 000 orphans, 12.2 million children receiving social assistance, and carries an HIV population of around 500 000 HIV positive children. Providing social services to such a large population is hampered by the limited ability of the Department of Social Development (DSD) to secure appropriate funding. DSD developed a prevention/early intervention-based Core Package of Services (CPS) for orphaned and vulnerable children (OVC) and embarked on a costing exercise of the program.

DESCRIPTION: An economic evaluation of the CPS was conducted. The CPS was converted into a logic- model. Then, field research was conducted to determine the true cost of services across that logic model; state of resources; and staffing available. Subsequently,, the

data were reworked into the logic model and usable costing model with provincial budgeting and planning. Lastly, the costing gap between currently available funding and CPS implementation were calculated. Public and private sector representatives then collaborated on developing a finance strategy aligned with the legal and policy environment.

LESSONS LEARNED: The costing enables DSD to calculate and assign the cost of services for an individual child across risk level within a standardised intervention framework. The costing model tool enables service cost projection which factors in variables of coverage and adjustable timeframes for service reach. The model allows provincial planners to isolate priority districts with the highest HIV prevalence, predicting service demand indicating gaps in budgeting. The financing strategy highlights resource gaps in the country to fund OVC services. It calls for a platform for public/private investment in common and sustainable objectives to improve the lives of Orphans and Vulnerable Children.

CONCLUSIONS/NEXT STEPS: The costing of the CPS was beneficial for understanding current service costs and anticipating future expenses. It also provides a broader baseline calculation of Government's investment into prevention and early intervention program. It is anticipated that the implementation of the program and the ability to calculate costs more effectively across South Africa by both the private and public sector, will deliver on the anticipated long-term social returns and enable a more system better able to sustain gains and mitigate setbacks related to national financing.

PEE1330

COUNTRY-LEVEL COSTS FOR VOLUNTARY MEDICAL MALE CIRCUMCISION PROGRAMS IN 14 PRIORITY SUB-SAHARAN AFRICAN COUNTRIES: AN ECONOMETRIC APPROACH USING MICRODATA FROM SEVERAL COSTING STUDIES

C. Pineda Antunez[1], D. Cerecero Garcia[1], S. Bautista-Arredondo[1]
[1]*National Institute of Public Health, Health Economics, Cuernavaca, Mexico*

BACKGROUND: Costing studies are expensive and slow to implement, and mathematical modeling is often the only viable and timely option for informing decision-making. Most of the studies using mathematical modeling to assess the costs and impacts of scaling-up voluntary medical male circumcision (VMMC) programs rely on two assumptions: that costs remain constant across different levels of scale and coverage and do not vary regardless of other service delivery platform (SDP) characteristics. In this work we presented an alternative approach to estimate total costs of VMMC programs based on econometric analysis taking into account the effects of scale, national coverage and SDP characteristics.

METHODS: We estimated VMMC total costs using primary data from eight African countries. First, we identified VMMC costing studies that collected primary data and contacted authors to request the underlying data. All datasets were standardized to create a pooled dataset for analysis. We modeled VMMC unit cost costs to explore and identify the effects of scale, national VMMC coverage and SDP on unit costs. Based on historical data, we projected the change in the number of circumcisions and national levels of coverage. We estimated unit and total costs of VMMC for priority countries from 2018 to 2022.

RESULTS: We estimated VMMC unit cost for the 14 priority countries. We observed a negative and significant association between unit cost and scale --for every 10% increase in the annual number of male circumcisions, the unit cost decrease on average 1.5% – and a significant association with VMMC coverage --for every percentual point increase in coverage the unit cost increases in two percent. Other predictors of unit cost variation were: ownership and service delivery model (outreach vs fix). We estimated the total annual investment needed to achieve or keep the 80% VMMC coverage target ranging from 4 billion USD in Ethiopia to 338 billion USD in South Africa.

CONCLUSIONS: This work presented an alternative econometric empirical approach to model total costs of VMMC programs accounting for variations in facility-level costs resulted from evidence based factors such as economies of scale, increase of coverage and SDP characteristics specific to each country.

TRANSITIONAL FINANCING

PEE1331

FROM THE GROUND UP: LOCAL ADVOCACY INTERVENTIONS AS A BASIS FOR A SMOOTH AND SUSTAINABLE TRANSITION OF HIV PROGRAMS FINANCING FROM THE GLOBAL FUND TO STATE BUDGETS IN UKRAINE

I. Kovalchuk[1], R. Drozd[2], Y. Kononchuk[1]
[1]*All-Ukrainian Network of PLHIV, Kyiv, Ukraine,* [2]*CO "Light of Hope", Poltava, Ukraine*

BACKGROUND: Before 2018 Ukrainian government financed only healthcare and ART purchasing, while the rest of social care and prevention services for more than 250,000 people living with HIV (PLHIV) and Key populations had been provided via HIV programs funded by Global Fund to Fight AIDS, Tuberculosis and Malaria (GF). Such services became under threat of discontinuation after the GF budget had been planned to decrease by 80% during 2018-2020.

In 2017, CO "All-Ukrainian Network of PLHIV" (the Network) supported by USAID and GF started to implement advocacy initiatives on transitional financing to support sustainability of social services.

DESCRIPTION: Due to decentralization processes in Ukraine, a set of advocacy interventions at state and local levels was conducted with the aim of developing local sustainability policies, obtaining funds from local budgets and introducing mechanisms of direct purchases of social care services from NGOs.

Under the program framework, 27 local NGOs had been trained by partner CO "Light of Hope" to advocate local policies changes and transitional financing.

LESSONS LEARNED: Transitioning of financial responsibility for HIV programs from GF to Ukrainian authorities started after execution of a set of advocacy interventions by NGOs at local level. In 2017, after deployment of first initiatives approx. $60K in total were allocated from regional budgets for direct purchases of social care services delivered by regional NGOs. In 2018 total amount reached approx. $70K and in 2019 – approx. $110K.

Based on successful local pilot programs, an amount of $3.6M was allocated in national budget in 2019 to cover 50% of all expenses to provide social care services for PLHIV. Furthermore, approx. $6.8M are planned in 2020 to cover 100% of needs.

Local experience became a basis for development of most of national standards of cost, description and budget planning of HIV social care and prevention services.

CONCLUSIONS/NEXT STEPS: Successful local advocacy interventions helped to develop mechanisms for a smooth transition from GF to Ukrainian national budget funding in 2018-2020.
In 2019 the Network in partnership with Alliance for public health started pilot projects in Eastern Europe and Central Asia aimed to implement best practices in 7 countries with similar political and economic backgrounds.

PEE1332

KEY DRIVERS OF SUSTAINABILITY IN HIV/TB RESPONSES IN EASTERN EUROPE AND CENTRAL ASIA (EECA)

T. Deshko[1]
[1]*Alliance for Public Health, International Programs, Kyiv, Ukraine*

BACKGROUND: EECA is the region of donor exiting despite being one of the two regions globally with reported increase in the incidence of HIV, at the level of 30% between 2010 and 2018. Drug use remains the main driver of HIV/HCV epidemics. Current policies to control drugs contribute to disease progression and over-incarceration for mainly nonviolent offences such as possession for personal use. Successful transition to national funding will be key in controlling HIV epidemic in EECA.
DESCRIPTION: ART most successfully transited to national funding; major areas at risk are key populations programs. Different transition focus was made for these interventions. The largest Global Fund HIV prevention program transition happened in Ukraine in 2019 and prioritized national CSO contracting through open tender process. Similar approach was taken in Bulgaria. North Macedonia, Montenegro and Serbia have followed national grant scheme. In Russian Federation and in Belarus regional financing is the major source. Engaging cities to fund programs has been successful in Ukraine and Moldova, more progress expected in Kazakhstan and Serbia in 2020.
The main challenges of transition in EECA are: lack of understanding and systems for civil and community services delivery; replacing outreach civil society services with medical institution-based ones; very skinny packages of services for key populations with limited attention to quality and quality control; low allocations for key population services; political dynamics and government change containing risk in allocation for next period; difficult to engage officials to support transition in low prevalence HIV settings.
LESSONS LEARNED: Optimization of expenditure (e.g. on ART) is a trigger to prevention domestic financing. The most sustainable responses involve multiple funding sources and modalities, e.g. financing procurement and medical interventions through insurance package (ART, OST, PrEP), basic package of HIV prevention and linkage services through national granting or service procurement scheme, city specific packages and information campaigns - through municipal budgets.
Where strong, civil society and communities played key role during transition and further programs implementation.
CONCLUSIONS/NEXT STEPS: ART procurement should be optimized. Diverse financing modalities and sources should be prioritized in EECA countries. EECA drug policy commission should be established and address the regional drug use criminalizing approaches.

PEE1333

ACHIEVING SUSTAINABLE HIV FINANCING: A NOVEL FRAMEWORK TO MEASURE AND MONITOR PROGRESS

P. Loh[1], J. Xia[2], R. Gupta-Lawrence[2], P. Tanguay[2], G. Gray[1]
[1]*Australian Federation of AIDS Organisations (AFAO), NSW, Australia,*
[2]*Independent Affiliation, Bangkok, Thailand*

BACKGROUND: As countries approach middle-income status and transition out of international donor support, a critical issue of sustainability faces the HIV response, especially the continued investments in programs for the most affected key populations (KP). The Sustainable HIV Financing in Transition (SHIFT) Program, was a 2-year Global Fund grant (2017-2018) aimed at enabling and empowering civil society, including KP communities to advocate for sustainable HIV-financing. The program was implemented by the Australian Federation of AIDS Organisations (AFAO) in four countries – Indonesia, Malaysia, Philippines and Thailand.
METHODS: A new monitoring and evaluation framework was developed to measure progress towards enhancing meaningful participation of civil society organizations (CSOs) in financing discussions, and towards achieving sustainable financing. This framework consists of 23-indicators across domains of fiscal space, allocative efficiency, transitioning, domestic funding mechanisms, and sustainable financing for CSOs, and can be used as a tool to track and monitor government and/or donor budget and spending. Primary and secondary data for these indicators was collected through literature reviews, KII and FGDs at the start (07/2017) and end (01/ 019) of the program and compared to measure progress.
RESULTS: SHIFT implemented 47 national and regional advocacy activities that mobilized 1,165 people; 22 training activities that reached a total of 422 individuals, and produced a total of 50 information products. Achievements of the program include: development of sustainable CSO coalitions; formation of strategic partnerships; allocation of official seats for CSO and key population representatives in domestic funding mechanisms; development of city-level investment plans; integration of SHIFT project activities in national grants and strategic plans; and development of funding proposals for organizations and coalitions.
CONCLUSIONS: SHIFT developed a novel framework to quantify meaningful participation of CSO in financing discussions and progress towards sustainable financing of national HIV responses. This framework is one of the first attempts at methodologically evaluating progress in HIV financing and sustainability advocacy and can also serve as a tool to monitor government/donor budgeting and spending. SHIFT's indicators can be adapted to fit the needs of different stakeholders across most geographical contexts and can thus readily support future projects involving financial sustainability of the HIV response.

PEE1334

COSTING OF HIV PREVENTION SERVICES AS ELEMENT IN THE ADVOCACY FOR A MORE SUSTAINABLE CONTRACTING AND FUNDING MECHANISM THROUGH THE GOVERNMENTAL FINANCING

K. Boiko[1], P. Smyrnov[1], T. Deshko[1]
[1]ICF Alliance for Public Health, Kyiv, Ukraine

BACKGROUND: A steady decline in funding for HIV programs from the Global Fund has been observed in recent years in many countries. In order to insure the sustainability of HIV prevention program among key population advocacy of funds in governmental budgets is the essential task. Instruments that are needed for this advocacy is good communication and clear understanding of the amount of funds, which should be allocated by Government. Calculating of the costs per client per budget period and multiplying it by coverage targets can be the easiest way for the requested funds calculation, which also allow for direct linkage between coverage targets and funds allocated to the program.

DESCRIPTION: An electronic costing tool developed in Microsoft Excel helps can help to calculate both the cost of preventive services and goods per one unique client reached in the program as well as the budget per service provider organization. The tool requires following easy steps: decide which services should be included to the primary (essential) and secondary packages; updating prices of health products and salaries of social workers or other service providers, updating time per one service provision, frequency of visits and number of health products per client per budget period.

LESSONS LEARNED: This tool was used for unit cots calculation in Balkan countries and following results have been received. Level of salary of social and outreach workers are the most important factors influencing unit costs while time per client per service are almost the same in countries. Other factor is coverage per one service provider - in organization with small coverage overhead costs (which usually are fixed) can be more than 50%.

Country	KP	Primary services and commodities, EUR	Secondary services and commodities, EUR
Romania	PWID	70.73	15.36
	SW	62.19	15.61
	MSM	83.23	11.60
Bosnia and Herzegovina	PWID	117.40	7.75
	MSM	76.77	53.37
North Macedonia	PWID	114.74	13.40
	SW	129.49	22.25
	MSM	62.57	33.63

[Table]

CONCLUSIONS/NEXT STEPS: We recommend the usage of Costing Tool for countries under the transition period as it can help in the advocacy for developing a more sustainable contracting and adequate funding of the prevention services.

INTERNATIONAL ASSISTANCE, FRAMEWORKS AND FUNDING MECHANISMS

PEE1335

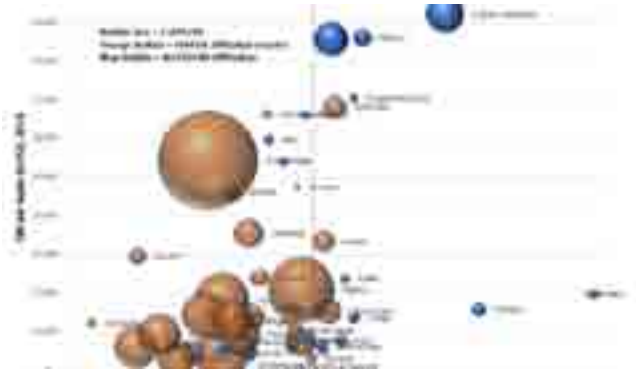
IMPACT OF ECONOMIC STATUS, HEALTH SYSTEMS, AND ADOPTION OF WHO ART POLICIES ON ART COVERAGE AND REDUCTIONS IN NEW HIV CASES AMONG PEPFAR AND SELECT NON-PEPFAR COUNTRIES

J. Palen[1], M. Wollmer[2], M. Ruffner[2], V. Vasireddy[2]
[1]U.S. Department of State, Office of the Global AIDS Coordinator, Washington, United States, [2]US Department of State, Office of the Global AIDS Coordinator, Washington, United States

BACKGROUND: Significant progress towards control of the HIV/AIDS epidemic has been made in low resource countries. Factors may include the national economy, the strength of the health system, and/or the political will of national governments, measured by the timeliness of adoption and implementation of key ART delivery policies. The purpose of this analysis is to assess to what degree these factors impact progress towards reaching epidemic control, especially among low income countries.

DESCRIPTION: This analysis compares three system factors, (1) national economic (GNI), (2) health system status (Health Systems Efficiency Index - HSI), and (3) rapid ART policy adoption to level of ART coverage and changes in new infections among PEPFAR and non-PEPFAR countries.

LESSONS LEARNED: As shown in Figure 1, the economic status (GNI) is positively correlated (Pearson's r=0.34) with the percent change in new infections from 2010 to 2017; specifically, the lower a country's GNI per capita, the greater the reduction in infections over time. Affiliation with PEPFAR has been associated with fewer new infections over time, which may offer an explanation for this finding.



[Figure 1]

HSI was not correlated to percent change in new infections or ART coverage for either PEPFAR or non-PEPFAR countries. Finally, countries demonstrating early adoption of priority ART guidelines, defined as the adoption of WHO-Consolidated ART Guidelines within 12 months of their release, have considerably higher levels of ART coverage and a greater reduction in new infections than comparison countries. For example, ‚early' adopters such as Namibia, Eswatini, Lesotho, and Zimbabwe progressed more rapidly to epidemic control than ‚late' adopters, such as Cameroon, Cote d'Ivoire, and Tanzania. Further analysis is warranted to better understand these findings.

CONCLUSIONS/NEXT STEPS: PEPFAR resources and the rapid adoption of WHO HIV treatment guidelines was associated with significant progress in reaching HIV/AID epidemic control, regardless of current economic or health system status.

PEE1336

PILOTING THE SUSTAINABILITY BRIDGE FUNDING APPROACH TO SUSTAIN NGO-BASED HARM REDUCTION SERVICES WITHIN THE TRANSITION CONTEXT IN SOUTHEASTERN EUROPE

I. Varentsov[1], L. Serebryakova[1]
[1]Eurasian Harm Reduction Network, Vilnius, Lithuania

BACKGROUND: Some donor and civil society stakeholders believe that a special mechanism - the Sustainability Bridge Fund (SBF) — should be introduced to ensure that countries have the required capacity to maintain and scale-up their response to end the three epidemics after they are no longer eligible for international funding and to mitigate the damage of improperly planned transitions from donors' support if and when they arise. In 2018 - 2019 the Eurasian Harm Reduction Association (EHRA) with support of OSF piloted the SBF approach in 3 Balkan countries (Bosnia and Herzegovina, Montenegro and Serbia), analyzed the strengths and weaknesses of this approach and developed the suggestions for its improvement in future.

DESCRIPTION: The project was implemented between June 2018 and September 2019 through one sub-regional level sub-recipient and three national level sub-sub recipients. It served the purpose of ensuring the sustainability of harm reduction services in 3 countries after the transition from Global Fund support until national funding becomes available and was also considered as a demonstration of the SBF approach in the region.

A desk review and interviews with implementing partners were conducted. Besides exploration of the applicability of a particular modality of SBF approach, the results of the project have been evaluated from two perspectives: (I) the sustainability of regional/national NGOs and their contribution to activities within this project to (II) ensure sustainability of harm reduction services at national/local levels using government funds.

LESSONS LEARNED: The application of SBF approach in 3 countries as well as its organizational model were considered as highly relevant to the context although the implementation period of the project was short and the sufficiency of budget available within the project is disputable. Donors should engage national counterparts, especially from NGO sector, in the process of selecting the focus of the SBF mechanism. SBF mechanism should ensure the provision of continuous funding to civil society advocacy efforts which are less likely to be supported by national governments within the transition, but also should be responsive to ad-hoc demands.

CONCLUSIONS/NEXT STEPS: Although SBF is still a concept and not yet fully defined its piloted modality can be transferred to many settings.

PEE1337

THE DREAMS INNOVATION CHALLENGE: FINDING NEW SOLUTIONS TO HIV PREVENTION AMONG ADOLESCENT GIRLS AND YOUNG WOMEN

N. Bhandari[1], L. Marks[1], J. Saul[1], F. Harris[2]
[1]U.S. Department of State, Office of the U.S. Global AIDS Coordinator (PEPFAR), Washington, D.C., United States, [2]Formerly JSI Training & Research Institute, Inc., Boston, United States

BACKGROUND: HIV prevalence rates among females ages 15-24 are consistently higher than among their male peers, with adolescent girls and young women (AGYW) being up to 14 times more likely to become HIV-infected than their male counterparts. PEPFAR announced the DREAMS (Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe) public-private partnership to provide a comprehensive package of core interventions to address many of the factors that make AGYW particularly vulnerable to HIV.

DESCRIPTION: PEPFAR launched the DREAMS Innovation Challenge in 2016 to:

1) identify innovative solutions for HIV prevention among AGYW;

2) engage new partners that have never received PEPFAR funding; and,

3) support funding for small local community-based organizations (CBOs).

The Challenge covered six focus areas: strengthening the capacity of communities for service delivery; keeping girls in secondary school; linking men to services; supporting pre-exposure prophylaxis (PrEP); providing a bridge to employment; and applying data to increase impact. Through a competitive process, 55 organizations were selected to implement innovative solutions.

LESSONS LEARNED: Innovative solutions that were implemented include: combining PrEP services to AGYW with distribution of self-testing kits to their male partners; instituting an early warning system to improve retention in secondary school; training AGYW in skills such as mechanics, financial literacy, and coding linked to employment; utilizing community libraries as safe spaces to provide mentorship and HIV prevention information; using celebrities and musicians to create demand for PrEP services; and building CBOs capacity to integrate gender-equity promotion strategies in institutional culture. 40% of the organizations selected for the Challenge had never received PEPFAR funding, and nearly two-thirds were small CBOs of less than $1 million annual revenue.

50% of the grantees funded by PEPFAR were indigenous organizations and 52% secured additional funding to continue their programs beyond the Challenge. 90% had a gender policy in place, compared to 16% at baseline.

CONCLUSIONS/NEXT STEPS: Utilizing an innovation challenge can help bring new ideas, solutions, and partners to the response to HIV/AIDS. The Challenge was able to support innovative solutions to addressing the complex needs of AGYW and strengthen the ability of indigenous and community-based organizations to effectively deliver HIV/AIDS services to AGYW.

PEE1338

SUPPORTING HIV TESTING, ART INITIATION AND ADHERENCE IN MALAWI IN A HIGH BURDEN DISTRICT THROUGH FELLOWSHIPS TO FILL GAPS AND INCREASE HUMAN RESOURCES FOR HEALTH

E. Schell[1,2], E. Geoffroy[1], K. Nash[1], C. Mwangonde[3], L. Nyirenda[3], J. Jere[3], C. Brown[4]
[1]Global AIDS Interfaith Alliance, Programs, San Rafael, United States, [2]University of California, San Francisco, United States, [3]Global AIDS Interfaith Alliance, Limbe, Malawi, [4]The Elizabeth Taylor AIDS Foundation, Beverly Hills, United States

BACKGROUND: Malawi suffers a shortage of nurses: over 60% of government positions are vacant. Malawi has made substantial efforts to increase the production of new nurses and Global AIDS Interfaith Alliance (GAIA) has partnered in this effort through a health worker training program that supports disadvantaged students. However since 2015, shortfalls in the government budget have delayed the deployment of newly graduated and licensed nurses. In 2017, GAIA

worked with the Mulanje District Health Office (DHO) to create fellowship positions at clinics and health centers for new graduates awaiting permanent deployment.

DESCRIPTION: With fellowship salaries and training costs provided by The Elizabeth Taylor AIDS Foundation, GAIA recruited new graduates awaiting formal deployment to serve as fellows to work in a variety of clinical settings including mobile HIV testing (HTS) programs, antiretroviral therapy (ART) clinics, and high HIV burden fixed facilities. Fellows received HTS and ART training according to Malawi Ministry of Health and Population (MoHP) guidelines and provided compensation commensurate with MoHP rates for new graduates. While in the program, GAIA supported fellows to create resumes and practice interviewing skills for permanent employment. Once a fellow secured a permanent deployment, another recent graduate awaiting deployment was recruited, trained and employed.

LESSONS LEARNED: Thirty positions were available at a time, increasing Mulanje's health workforce by 11%. A total of 45 new graduates were supported through the program for an average of 14 months each with a range of 3 to 22 months. At the end of 2019, 34 fellows had attained permanent deployment and the remaining 11 are expecting permanent deployment by q1 2020. During the two year program, the number of people living with HIV (PLHIV) initiated on treatment in Mulanje increased by 23% from 47,337 to 58,293.

CONCLUSIONS/NEXT STEPS: The program addressed the lag in deployment by keeping new graduates working in their chosen field, helping them both maintain and gain new skills. At the same time, it addressed workforce shortages, especially in HIV services when Malawi adopted universal treatment, expanding DHO capacity to serve PLHIV when there was a spike in the number eligible for and seeking ART.

PEE1339

ACHIEVING PEPFAR'S FUNDING LEVEL FOR LOCAL ORGANIZATIONS: CHALLENGES AND SUCCESSES TO GETTING TO 70% IN ETHIOPIA

C. Brokenshire-Scott[1], A. Balcha[2], G. Esubalew[1], Y. Asfaw[1], C. Mejia[1], S. Oli[3], D. Arbuckle[3], C. Raulfs-Wang[4], D. Kaliel[4]
[1]IntraHealth International, Washington, DC, United States, [2]IntraHealth International, Addis Ababa, Ethiopia, [3]USAID/Ethiopia, Addis Ababa, Ethiopia, [4]Office of HIV/AIDS, USAID, Washington, DC, United States

BACKGROUND: Local NGOs are pivotal for sustainable epidemic control, providing essential services to meet national and global targets, but have had limited organizational growth opportunities primarily working as subs to international NGOs. Accelerating Support to Advanced Local Partners (ASAP) rapidly develops organizations to have essential capabilities to serve as prime recipients for USAID/PEPFAR. This new and developing program has seen the common challenges local organizations face and the required remedial action for organizational growth and compliance with donor requirements.

DESCRIPTION: ASAP's approach starts with baseline assessments of local NGOs. ASAP expanded NUPAS (Non-US Pre-Award Survey) to develop NUPAS Plus, which includes: 1) compliance management with donor's legal provisions; 2) effective leadership and governance; 3) financial management and segregation of duties; 4) early fraud detection and mitigation; 5) talent management; 6) gender equity; 7) IT security; and 8) business development and sustainability.

ASAP has conducted baseline assessments in Tanzania, Uganda, Nigeria, and Ethiopia to identify capacity development needs. Assessments form the basis for on-going short-term locally-embedded technical assistance, including capacity-building in financial management and compliance; audit readiness; sub-award and grants management; human resources; business development/sustainability; program management and performance monitoring.

In Ethiopia, ASAP is working with 10 local organizations with identified needs in 1) financial management and compliance; 2) administration and procurement systems and 3) human resource systems. All organizations were successful at achieving previous targets for orphans and vulnerable children but lacked the full skill set to do robust monitoring and evaluation.

LESSONS LEARNED: External assessments are a learning opportunity when administered collaboratively. Organizations managed budgets but were unaware of accounting cost principles and needed training followed by on-site support and peer learning. Performance monitoring was heavily reliant on prime recipients and required support in quality assurance and data use. Gender equity is challenging at the highest levels and requires active change management internally.

Carefully selected embedded TA provides quick and responsive support to organizations.

CONCLUSIONS/NEXT STEPS: For PEPFAR to achieve the target of 70% of funding going to local organizations, it is critical to have external assessments and provide individually responsive support to strengthen organizations.

FINANCING HIV WITHIN UHC FRAMEWORKS

PEE1340

"FLEX" YOUR MUSCLES: WHAT GOVERNMENTS REALLY NEED TO DO TO ACHIEVE UHC

K. Bhardwaj[1]
[1]N/A, New Delhi, India

BACKGROUND: In 2019, governments pledged at the UN to achieve Universal Health Coverage (UHC). While debates on UHC have focussed on financial risk protection and service delivery, the third component i.e. access to safe, effective, quality and affordable essential medicines has yet to be properly addressed. According to the WHO, essential medicines are those that, "satisfy the priority health care needs of the population." Internationally, the WHO's Model EML is used as a guide by countries. For several decades, patented medicines accounted for only a small number of medicines on the WHO's EML. In the 2002 WHO EML, several patented anti-retrovirals for the treatment of HIV were included. The more recent WHO EMLs have seen steady inclusions of patented medicines across disease areas.

DESCRIPTION: The 2019 EML addresses the issue of cost in detail and highlights the importance of the use of TRIPS flexibilities in ensuring access to medicines. This paper examines multiple case studies of the use of TRIPS flexibilities by governments for the procurement and sustainable supply of affordable medicines including:

1. Government Use Licenses for HIV, heart disease and cancer: Sustainability of Thailand's Universal Coverage Scheme:
2. Rigorous patentability criteria: Opening generic supply of ARVs in India
3. Transition period: A critical procurement tool for least developed countries (LDCs)
4. First government use license for hepatitis: Supporting access and innovation in Malaysia

LESSONS LEARNED: It is evident from the case studies, that the use of TRIPS flexibilities by low and middle income countries will be critical to the success of implementing UHC. Yet countries often face barriers in using TRIPS flexibilities. Some hurdles arise from a lack of technical expertise in the use of these flexibilities or their absence from national or regional patent laws or take the form of pressure either from the pharmaceutical industry or at times from developed countries.

CONCLUSIONS/NEXT STEPS: There is still considerable debate on how UHC should be achieved; ensuring access to essential medicines requires specific commitments and a clear intent from the global community in using every legal and regulatory tool in this regard, particularly the full use of TRIPS flexibilities.

APPROACHES TO ACHIEVING SUSTAINABILITY

PEE1341

ENABLERS AND BARRIERS TO SUSTAINABILITY OF HIV&AIDS CONTROL PROGRAMS IN UGANDA: A QUALITATIVE EXPLORATION OF THE DREAMS AND CHAI PROGRAMS

S. Khanakwa Bwayo[1,2], J. Mbonigaba[3], N. Poku[3], D. Byamukama[4]
[1]University of Kwazulu Natal, Health Economics and HIV and AIDS Division Department, Durban, South Africa, [2]Uganda AIDS Commission, Planning and Strategic Information, Kampala, Uganda, [3]University of Kwazulu Natal, Durban, South Africa, [4]Uganda AIDS Commission, Policy, Research and Programs, Kampala, Uganda

BACKGROUND: Uganda is one of the HIV high burden countries in the world that has recently made impressive progress towards controlling the HIV epidemic. Sustaining the country's progress is currently gaining attention in the country given the changing trend in global health priorities. However, there is an inadequate knowledge base about the enablers and barriers to sustainability of HIV&AIDS programs in the current setting. This study explored the technical and structural enablers and barriers to sustainability of HIV&AIDS programs in Uganda, based on the PEPFAR funded DREAMS program and the World Bank funded Community HIV&AIDS Initiative – CHAI.

METHODS: We conducted 19 key informant interviews and 6 focus group discussions from October to December 2019. Data were collected in 3 purposively selected districts and at national level. The participants included decision-makers from government, donors, and NGO involved in the planning and implementation of the DREAMS and CHAI HIV&AIDS programmes. Data was analyzed thematically using both inductive and deductive approaches based on theoretical constructs combining Williamson's Transaction Cost Economics theory (Williamson, 2010) and Ostrom's Institutional Analysis and Development framework (Ostrom, 2011).

RESULTS: A total of 69 participants were interviewed. The thematic analysis identified the perceived level of seriousness of the epidemic (i.e. level of emergency of the problem) in particular as a key enabler prominently among government decision-makers. Other enablers identified were social commitment, strength of 'community voices', and legal responsibility. The decline in the value of social capital, technically controlled approach to project implementation, lack of legally binding enforcement mechanisms, and failure of the decentralization policy were the most commonly mentioned barriers.

CONCLUSIONS: This study found that decision-makers' perception of the seriousness of the epidemic is critical in planning for and sustaining HIV interventions. Efforts towards sustaining HIV&AIDS control programs will require dedicated efforts to keep the public and decision-makers informed on public health burden of HIV, as well as optimizing the enablers and addressing the barriers identified in this study.

PEE1342

ASSESSING THE ECONOMIC IMPACT OF TB MORTALITY IN HIGH HIV/TB BURDEN COUNTRIES: WHAT IT WILL COST IF WE DON'T ACHIEVE THE END TB TARGETS

S. Silva[1], E. Goosby[2], D. Jamison[2], M. Reid[3]
[1]Harvard University, Harvard T.H. Chan School of Public Health, Boston, United States, [2]University of California, Institute for Global Health Sciences, CA, United States, [3]University of California, Institute for Global Health Sciences, Medicine, CA, United States

BACKGROUND: Despite declines in mortality over the last decade, TB remains the leading cause of death among people with HIV (PLHIV). We examined the economic value of reducing premature mortality from TB in high TB/HIV burden countries - specifically, if a 90% reduction in mortality, compared to 2015, was achievable in 2030, as proposed in the End TB strategy.

METHODS: We estimated the change in life expectancy in 165 countries from 2020 to 2050, if TB deaths among PLHIV were to fall by 90% (of 2015 rates), by 2030. We monetized the changes in life expectancy by transforming life expectancy gains to standardized mortality units, scaling them to each age (interval) and then multiplying by the density of age distribution, the per capita income for each year, and the value of a statistical life in each country, which we adjusted for country income. To calculate the population value of the gains, we multiplied the per capita value by the projected population in each year, which was available from the World Population Prospects database.

RESULTS: The total economic value of reducing TB mortality in PLHIV in the 30 highest TB/HIV burden countries by 90% (of 2015 rates), by 2030 would be US$47.8 billion. If reductions were delayed until 2045, an additional US$32 billion (to total US$79.8 billion) would be lost. If the End TB targets were achieved by 2030 and TB deaths were to remain steady through 2050, the highest economic gains would accrue to South Africa (US$15.7 billion total, US$84.3 million annually), Nigeria (US$8.2 billion), and Zimbabwe's (US$7.96 billion). We estimated that in countries in sub-Saharan Africa, the economic losses will be 13-fold higher, compared to the next highest region (East Asia & Pacific; US$3.5 billion compared to US$43.6 billion).

CONCLUSIONS: Failure to achieve the End TB targets by 2030 will have a devastating and disproportionate economic impact on countries with a high prevalence of both HIV and TB, especially those in sub-Saharan Africa. These results highlight the urgent need for increased funding for TB research in strategies that will lead to rapid declines in mortality among PLHIV in high TB/HIV burden countries.

PEE1343

COSTS, BENEFITS AND EFFICIENCY GAINS FROM INTEGRATION OF HIV SERVICES WITH OTHER HEALTH SERVICES: A SYSTEMATIC REVIEW

C.A. Bulstra[1,2], M. Otto[2], A. Stepanova[2], E. Lamontagne[3,4], A. Yakusik[3], R. Atun[5], J.A. Hontelez[1,2], T. Bärnighausen[2,5,6]
[1]Erasmus Medical Center, Department of Public Health, Rotterdam, Netherlands, [2]Heidelberg University, Heidelberg Institute of Global Health, Heidelberg, Germany, [3]UNAIDS, Geneva, Switzerland, [4]Aix-Marseille University, Aix-Marseille School of Economics, CNRS, EHESS, Les Milles, France, [5]Harvard University, Harvard T.H. Chan School of Public Health, Boston, United States, [6]Africa Health Research Center (AHRI), KwaZulu-Natal, South Africa

BACKGROUND: From its inception, the HIV response was a unique undertaking and often separate from the broader health system. Nowadays, there is a widespread recognition that the future of a sustainable HIV response will depend on finding opportunities for strategic integration between HIV and other health services, boosted in recent years by the Sustainable Development Goals (SDGs), strengthened movement towards Universal Health Coverage, and rising double burden of HIV/AIDS and non-communicable/chronic diseases/conditions. We systematically reviewed the literature on potential benefits and efficiency synergies to be gained through integrated HIV service delivery with other health services; including well-known integration types as well as more innovative integrations such as with chronic-disease-platforms, human papilloma virus screen-and-treat, and mental health.

METHODS: We included peer-reviewed studies published after 2010 that present empirical evidence on economic, health, utility and quality indicators related to HIV services integration and synthesised the findings from previous reviews within our scope. Following the review, we developed a conceptual framework to guide policy on finding suitable integration strategies for different contexts.

RESULTS: Of the over 4,000 reviewed articles, 105 articles were finally included. Most studies were conducted in sub-Saharan Africa, followed by Asia and the United States. Overall, most commonly evaluated integration types were HIV services integration with family planning or sexual-and-reproductive-health, followed by primary healthcare, maternal-and-child-healthcare and tuberculosis care. Evidence on potential benefits of newer integration strategies remains scarce. A range of integrated services were found to lead to benefits and efficiency gains. Magnitude of synergies gained depended on (i) the target population; reachability and (type of) end-users, (ii) which types of services are integrated; such as prevention, testing and counselling or treatment adherence, and (iii) degree of integration; solely at service-level or beyond.

CONCLUSIONS: Our systematic review provides a comprehensive up-to-date overview of the existing evidence on HIV services integration, and our framework can help guiding decision making for a sustainable HIV response in the light of the SDGs. Although current evidence supports service integration in most contexts, there is no 'one-size-fits-all' integration strategy, and optimal integration strategies depend on the local epidemiological and health system context.

PEE1344

THE PEPFAR RESPONSIBILITY MATRIX: CHANGING THE FINANCING DISCUSSION FROM TOTAL DOLLARS SPENT TO FULFILLING RESPONSIBILITY FOR HIV SERVICES, PROVIDING A ROADMAP FOR TRANSITION

M. Ruffner[1], V. Vasireddy[1], J. Palen[1], M. Wollmers[1], E. Reuben[2], A. Bush[3]
[1]U.S. Department of State, Office of the Global AIDS Coordinator, Washington DC, United States, [2]USAID, Office HIV/AIDS, Washington, United States, [3]U.S. Department of Agriculture, FNS, Washington, United States

BACKGROUND: The international community focuses on Domestic Resource Mobilization as the main sustainable financing source. While funding is important, early transition experience shows that overall health funding is less important than actually continuing specific elements of the HIV response.

DESCRIPTION: PEPFAR created the responsibility matrix (https://www.state.gov/where-we-work-pepfar/) to chart elements of the HIV response that are fulfilled by donors or domestic sources. In a focus session, in country stakeholders determined the level of responsibility for the HIV response between PEPFAR, the Global Fund or other domestic sources.

LESSONS LEARNED: Despite spending that is nominally low compared to international donors, there is no country where the HIIV response is solely the responsibility of the international community. 81% of PEFPAR supported countries have primary responsibility for service delivery elements of HIV care whereas donors generally have primary responsibility for non-service delivery elements (eg training.) Only 39% of countries are categorized as primarily responsible for non-service delivery elements. Within service delivery, there is a mutual primary responsibility for service delivery with 30% of PEPFAR countries with both domestic and international sources listed as primary. In other words if either side did not fulfill their responsibility, service delivery would end. In general, Facility Level workers (93%) are more likely to be domestic responsibility while Community Health Care Workers are international responsibility (67%) which accounts for some of the dual responsibility.

	Care and Treatment Service Delivery	Care and Treatment Non Service Delivery	Facility Level Staff	Community Health Care Workers	KP Program Service Delivery	KP Program Non Svc Delivery
% Domestic Primary Responsibility	81%	39%	93%	48%	33%	26%
% International Primary Responsibility	30%	59%	15%	67%	89%	89%
% Domestic Secondary Responsibility	15%	33%	4%	22%	30%	44%
% International Secondary Responsibility	70%	41%	81%	33%	11%	11%

[Table 1: Select measures from the Responsibility Matrix]

CONCLUSIONS/NEXT STEPS: Charting responsibility avoids the problem of equating spending with importance to the response which, in turn, undervalues domestic contributions. Charting responsibility creates a roadmap to transition. With the roadmap, the focus can evolve away from general budget commitments for health, to a targeted discussion elements required for sustainability. Given the shared nature of service delivery, PEPFAR will be more

focused on country capabilities. Without ending support, countries can be encouraged to take on primary responsibility while the international community is still available to provide a safety net of secondary responsibility.

PEE1345

PEPFAR'S SUSTAINABILITY INDEX AND DASHBOARD: RESULTS FROM SID 2019

M. Wollmers[1], M. Ruffner[1], V. Vasireddy[1], J. Palen[1], A. Nandakumar[1], A. Bush[2], E. Reuben[1]
[1]U.S. Department of State/PEPFAR, Washington, United States, [2]U.S. Department of Agriculture, Washington, United States

BACKGROUND: The achievement of sustainable control of the HIV epidemic is a critical goal for individuals, communities, and governments. PEPFAR's Sustainability Index and Dashboard (SID) defines critical elements that contribute to sustainability, and enables its users to assess the current state of national HIV/AIDS responses while identifying strengths and vulnerabilities over time. The latest iteration, "SID 2019," provides results that reveal insights into advances and common challenges across countries.

DESCRIPTION: SID 2019 was implemented in more than 30 countries through a participatory process. PEPFAR country teams worked with UNAIDS to convene key stakeholders who collaborated to complete the SID tool, enabling them to assess sustainability across 17 elements organized into four domains. This cycle, two new elements were added: *market openness* and *data for decision-making ecosystem*.

LESSONS LEARNED: The results of SID 2019 show that while PEPFAR-affiliated countries continue to make progress towards a more sustainable response to the epidemic, the pace of improvements has slowed—i.e., from 2015 to 2017, among PEPFAR's 23 standard countries, there was an average increase of 0.58 points across elements (from 5.75 to 6.33 on a 0.00-10.00 scale), but from 2017 to 2019 there was just a 0.30 increase. Average scores improved across 14 of the 15 elements that were in place both SID cycles, although many showed very modest increases. From 2017 to 2019, the three elements with the highest average gains were *public access to information*, *private sector engagement*, and *performance data*. The average SID element scores of 17 of the 23 standard countries rose while 6 fell, with Tanzania's average score increasing the most and Ethiopia's falling the most.

CONCLUSIONS/NEXT STEPS: PEPFAR has designed an original index that enables important cross-country comparisons that highlight what critical variables support advancement of sustainable programs. The SID provides essential data used to determine health systems investments and metrics to track the impact of those investments over time. At the country level, the SID framework continues to orient national stakeholders to their sustainability strengths and challenges, and facilitate informed decisions about where to target efforts and resources to respond to the HIV epidemic more efficiently.

PEE1346

THE ROLE OF CIVIL SOCIETY IN PRICE REDUCTION OF HCV TREATMENT IN MOROCCO

Z. Bahtout[1], A. Hajji[1], O. Mellouk[1], A. El Geddari[1], M. El Harrar[1]
[1]ITPC MENA, Advocacy, Marrakech, Morocco

BACKGROUND: Direct-acting antivirals (DAAs) have revolutionized the treatment of HCV infection. However, the exorbitant price of their launch made them inaccessible in resource-limited countries. This price is largely linked to the market monopoly of originator products most often protected by patents.
Since the launch of this new therapeutic class, Moroccan civil society organizations under the coordination of ITPC-MENA joined their advocacy efforts to make treatment affordable in the country and scale-up free access to all people.

METHODS: During three years, civil society organizations have developed, adapted and implemented an advocacy strategy for price reduction based on several components:
- Raising awareness of decision-makers and media campaign
- Research on the status of patent protection, assessment of the quality of patents,
- Dialogue with the patent office about quality of patents
- Dialogue with the pharmaceutical industry within the framework of Community Advisory Board (CABs) and advocacy for inclusion in voluntary licenses
- Use of the competition authority to improve competitiveness in the context of procurement tenders.

RESULTS: Thanks to the action of civil society, the monopoly on the market for originator products has been broken. The country has been included in the main voluntary licenses covering the pan genotypic combinations SOF / VEL and SOF / DCV paving the way for the entry into the market of generic versions. Local production initially reduced the cost of the cure by 90% to $ 1,250. Increased competition between suppliers during calls for tenders reduced the cost of the cure (SOF / DCV) to $ 216 according to the last call for tenders, which represents a reduction of 83%.

CONCLUSIONS: Removing barriers to entry into the generic drug market and putting several suppliers under competition are key elements to reduce drug prices. The efforts of civil society in Morocco will contribute to the generalization of access to treatment and the acceleration of the plan to eradicate hepatitis C by 2030 in accordance with the commitment of the Ministry of Health. Despite this significant price reduction, NGOs are continuing their efforts and hope to reach the target of $ 100 per cure with increased competition and increased volumes.

PEE1347

COST SHARING FOR THE SUSTAINABILITY OF THE HIV RESPONSE IN THE DOMINICAN REPUBLIC: INCLUSION OF ARVS IN THE COUNTRY'S SOCIAL SECURITY HEALTH INSURANCE

N. Diaz[1], C. Valdez[2], J. Cali[3], E. Barillas[4], M. Castillo[5], L. Martinez[6], J.J. Elenes[7], C. Pina[7]

[1]Abt Associate, Program Manager, Santo Domingo, Dominican Republic, [2]Abt Associate, Consultant, Santo Domingo, Dominican Republic, [3]Abt Associate, Program Manager, Washington, United States, [4]GIS Grupo Consultor EIRL, Medicines, Washington, United States, [5]National HIV and AIDS Council, Medicines, Santo Domingo, Dominican Republic, [6]Superintendencia de Salud y Riesgos Laborales, Actuarial, Santo Domingo, Dominican Republic, [7]USAID, Health, Santo Domingo, Dominican Republic

BACKGROUND: Although the Ministry of Health (MoH) has financed the procurement of antiretrovirals (ARV) and laboratory reagents, the Dominican Social Insurance System (DSIS) does not cover the costs of ARV to patients with HIV insured by a subsidized or pre-paid insurance plan. This constitutes an unfair public subsidy to the better-off. The National HIV Strategic Plan (NHSP) specifies that services, including ARV, must be covered by the DSIS. The National HIV and AIDS Council (CONAVIHSIDA) and the Superintendence of Health and Labor Risks (SISALRIL) were instructed to implement this directive but they confronted a challenge: ARV are procured internationally within a joint mechanism in one annual order to reduce costs, and DSIS's decentralized design does not cover drugs or supplies purchased centrally from foreign suppliers.

DESCRIPTION: To tackle this issue, USAID's Health Financing and Governance Project (HFG) provided technical assistance to establish a national technical group (NTG) to develop an operational model that identified the legal and institutional reforms required for allowing ARV to be financed by DSIS while maintaining the MoH international pooled procurement at the central level. The NTG proposed the creation of a unified special fund for disease control programs (FONSAP, Spanish acronym) to facilitate the DSIS financing of ARV. FONSAP was designed to receive funds from the Social Security Treasury (insured population) and withholds from the MoH to cover the uninsured population. The NTG proposed a model and it was presented and approved by the MoH in 2019 and will be presented to the DSIS for final approval in 2020.

LESSONS LEARNED: The evidence-based analysis of HIV financial challenges by a multi-institutional team and the proposal of a feasible model were key pieces in the decision-making and approval of the model by the MoH.

CONCLUSIONS/NEXT STEPS: DSIS coverage of ARV will increase the sustainability of the HIV national response and free MoH resources for prevention programs, also providing a model for integrating other disease programs, and reduce reliance on international donors. FONSAP charts a path for DR's HIV program financial sustainability and provides a model for other countries for covering HIV services through the social insurance

PEE1348

FINALIZING ETHIOPIA'S FIRST-EVER HIV DOMESTIC RESOURCE MOBILIZATION AND SUSTAINABILITY STRATEGY, 2020–2025: ACHIEVING MULTISECTORAL CONSENSUS AND WHAT IT MEANS FOR A SCALED-UP AND SUSTAINABLE HIV RESPONSE

Z. Gizachew[1], H. Assefa[1], A. Abie[2], T. Fagan[3], A. Haile[4], E. Lang[3]

[1]Ethiopia Federal HIV/AIDS Prevention and Control Office, Projects and Grant Management Coordination Directorate, Addis Ababa, Ethiopia, [2]Ethiopia Ministry of Health, Partnership and Cooperation Directorate, Addis Ababa, Ethiopia, [3]Palladium/Health Policy Plus, Washington, DC, United States, [4]Health Policy Plus, Addis Ababa, Ethiopia

BACKGROUND: Over the past decade, 90% or more of funding for Ethiopia's HIV program was external. External funding declined by more than 60% over this period, even as the program needs to sustain and further scale up antiretroviral treatment and deliver high-impact prevention interventions critical for epidemic control. The government of Ethiopia has committed to ensuring sustainability of the program and to mobilize new domestic resources to continue progress toward national and international targets.

DESCRIPTION: The Federal HIV/AIDS Prevention and Control Office and Ministry of Health, with support from the USAID-funded Health Policy Plus project, led a consultative process with stakeholders from government, development partners, private sector, and civil society to develop a five-year HIV Domestic Resource Mobilization and Sustainability Strategy. The decision-making process was informed by a first-ever assessment of domestic HIV financing. Stakeholders achieved consensus on best practices for resource mobilization and allocation adaptable to the Ethiopian context and aligned with the country's universal health coverage schemes. The final strategy includes five initiatives:

- Increasing budget allocations from federal and regional governments
- Institutionalizing participation in and use of AIDS Fund contributions for formal sector employees
- Improving targeting of cross-sectoral HIV budget mainstreaming
- Mobilizing voluntary community-level resources
- Implementing an HIV-earmarked tax on corporate profits

By 2025, the strategy aims to mobilize 30% of the cost of the national HIV/AIDS Strategic Plan from domestic sources, with targets and roles for each initiative.

LESSONS LEARNED: Often the policy process for HIV resource mobilization has been driven only by HIV program stakeholders. Ethiopia's approach of engaging high-level government officials and multi-sectoral stakeholders—including the Ministry of Finance and Ministry of Revenue—led to a consensus on (a) the need to increase domestic financing for the HIV program and (b) how, and to what extent, this can be accomplished.

CONCLUSIONS/NEXT STEPS: Ethiopia's experience presents a best practice for developing an HIV domestic resource mobilization strategy based on a recent assessment of the baseline performance of the system, and then thorough, iterative engagement of actors within and outside the HIV and health sector to develop consensus on actions needed.

PEE1349

ACHIEVING SUSTAINED EPIDEMIC CONTROL FOR HIV/AIDS: LESSONS LEARNED FROM THE SUSTAINABLE FINANCING INITIATIVE

H. Marqusee[1], S. Baker[1], C. Mann[1], E. Reuben[1], J. Chang[1], M. Jordan[1], J. Tayag[2], A. Nandakumar[3], M. Hijazi[1]
[1]USAID, Office of HIV/AIDS, Washington, DC, United States, [2]USAID, South Africa, Pretoria, South Africa, [3]Office of the Global AIDS Coordinator, Department of State, Washington, DC, United States

BACKGROUND: Per UNAIDS estimates, countries will require an investment of around $26.2 billion by 2020 to meet the demand for HIV/AIDS services. At least $14.6 billion, or 55 percent, of the total should come from domestic sources. If fully-funded, the AIDS response could avert an estimated 17.6 million new infections and 11 million premature deaths between 2016 and 2030.

DESCRIPTION: The Sustainable Financing Initiative for HIV/AIDS (SFI) is a PEPFAR-funded, USAID-led initiative to encourage domestic financial participation in the HIV response in PEPFAR-supported countries. SFI works with ministries of health and finance, donors, the private sector, and other critical stakeholders to improve efficiencies in the HIV response through data-driven resource allocation for HIV/AIDS at the national and subnational levels. Three core areas of assistance are emphasized: improved public financial management, integration of HIV services into social health insurance schemes, and leveraging the private sector. Much of this work cuts across three key themes of increasing the efficiency of the HIV response, advocacy and analytics to generate political will for shared responsibility, and securing a sustainable supply of HIV commodities into the future.

LESSONS LEARNED: Over a four year period, SFI invested $48 million across eighteen countries to leverage domestic resources for HIV/AIDS and improve approaches to health financing. SFI interventions have yielded significant results globally. For example:

- In Vietnam, SFI supported the inclusion of over 80 PEPFAR-supported clinics to be contracted with Vietnam's Social Health Insurance Scheme (SHI). Currently 97% of HIV facilities nationally have enrolled.
- In Kenya, advocacy for increased allocations to health and HIV resulted in a $26 million allocation for ARVs and test kits, $6 million allocated to HIV, and $98 million allocated to health at the county level.
- In Nigeria, SFI decongested public hospitals by decanting patients into decentralized private sector outlets. As of 2019, 18,000 patients were picking up their medication from private pharmacies and hospitals.

CONCLUSIONS/NEXT STEPS: By investing in financing interventions, PEPFAR funding can leverage additional resources from host-country governments and the private sector to increase the sustainability of the HIV response.

ECONOMIC EVALUATION AND AFFORDABILITY ASSESSMENTS

PEE1350

ASSESSING THE WILLINGNESS TO PAY FOR HIV COUNSELLING AND TESTING SERVICE: A CONTINGENT VALUATION SURVEY IN LAGOS STATE, NIGERIA

F.O. Adekunjo[1], R. Rasiah[2], M. Dahlui[3], C.W. Ng[3]
[1]Lagos State University, Department of Economics, Faculty of Social Sciences, Lagos, Nigeria, [2]University of Malaya, Asia Europe Institute, Kuala Lumpur, Malaysia, [3]University of Malaya, Department of Social and Preventive Medicine, Kuala Lumpur, Malaysia

BACKGROUND: One of the major health concerns facing the world and in particular sub-Saharan Africa for some decades is HIV and AIDS. Presently, Nigeria ranks third by a number of people living with HIV/AIDS in the world. HIV Counselling and Testing (HCT) is prominent among the continuum of HIV/AIDS intervention programmes because of its strategic role as a gateway between prevention and care. However, HCT service in Nigeria is faced with many challenges among whom is inadequate funding which threatens its sustainability. There has been a paucity of research into these area leading to inadequate evidence to support policy decision-making. This study was carried out to assess the quantum of payment and determining factors associated with people's willingness to pay (WTP) for HCT services in Nigeria.

METHODS: The study employed a cross-sectional survey to examine the contingent valuation method of economic evaluation using data from 768 individuals collected through convenience sampling in three Local Government Areas -Alimosho, Ikorodu, and Surulere in Lagos State, Nigeria, between May - July, 2015. Data were analysed using descriptive statistics, chi-square, Mann-Whitney, Kruskal-wallis, and GLM regression analysis.

RESULTS: The results revealed that 75% of the respondents were willing to pay on the average N1291 (~$4.22) amount for HCT service. The amount is much lower than the reported $7.4 mean cost per client. Individuals who were male, less than 50 years of age, and married were willing to pay more. Furthermore, the significant determinants of WTP were, income, knowledge of someone living with HIV or died of AIDS, worry about HIV infection, and fear of HIV-related stigma.

CONCLUSIONS: The findings of this study accentuate high rate of willingness to pay for HCT service. The findings suggest feasibility of partial cost recovery from potential users of HCT service. The findings offer vital information germane to future implementation of co-payment schemes aimed at financial sustainability of HCT services in Nigeria.

PEE1351

HEALTH CARE EXPENDITURES OF PLHIV IN SOUTH WEST OF FRANCE: MATCHING ANRS CO3 COHORT AND SOCIAL SECURITY SYSTEM DATA

P. Morlat[1,2], E. Verpillot[3,4], R. Kabore[4], O. Leleux[5], F. Daniel[4], A. Perrier[4], F. Saillour[6,4], F. Bonnet[1,7,5], J. Wittwer[3,4]
[1]Bordeaux University Hospital, Internal Medicine and Infectious Diseases, Bordeaux, France, [2]Bordeaux University, Faculty of Medicine, Bordeaux, France, [3]Bordeaux University, Public Health School, Bordeaux, France, [4]INSERM U 1219, EMOS Team, Bordeaux, France, [5]INSERM U 1219, Morpheus Team, Bordeaux, France, [6]Bordeaux University Hospital, Medical Information Department, Bordeaux, France, [7]Bordeaux University, Faculty of Medicine, Bordeaux, France

BACKGROUND: A good knowledge of the distribution of healthcare expenditures among people living with HIV (PLHIV) is needed to optimize their care pathways. The objectives of our study were to estimate the annual total cost of healthcare by any sources of funding in PLHIV followed in Aquitaine (South West of France) and to analyze its determinants in 2014.

METHODS: A retrospective cohort study was carried out by matching the hospital-based Aquitaine ANRS CO3 cohort database with that of the French national health insurance while respecting the anonymity of individuals. Patients seen at least once in 2014 in one of the 16 participating centers were included. A step-by-step multivariate analysis was carried out to identify the determinants of healthcare cost of the 25% highest and of the 25% lowest consumers.

RESULTS: 4145 PLHIV were included (M/F= 2.54; median age = 50 years; median time since diagnosis = 17 years). 17.2% lived in rural areas. HIV-related expenditures were fully covered by the national health insurance for 94.6% of the patients. 9.4% benefited from a health insurance program (CMU-C) allocated to the poorest persons. 49.8% had at least one comorbidity. 67.8% were current or former smokers. 97.5% received antiretroviral drugs. Total annual healthcare expenditures were € 67,095,047 (median per person = € 12,650) of which 85.8% were for ambulatory care (antiretroviral drugs = 63.3% of the total) and 14.2% for hospitalization. The determinants of high consumption were: length of time since diagnosis, CD4+ < 500/mm3, 50 c/mL ≤ viral load (VL) < 400 c/mL, ≥ 1 comorbidities, smoking, contracting HIV by intravenous drug use (IVDU), women infected through heterosexual contact. Determinants of low consumption were: CD4+ ≥ 500/mm3, VL ≥ 400 c/mL, no comorbidity, contracting HIV by IVDU, men infected through heterosexual contact, university hospital follow-up, CMU-C.

CONCLUSIONS: Antiretroviral drugs account for two-thirds of healthcare expenditures for PLHIV. Healthcare consumptions are mainly driven by epidemiological, clinical, and biological factors. The effects of history of IVDU and of VL level are non-monotonous. Further, residential location has no impact and PLHIV who benefit from CMU-C are more likely to be low healthcare consumers. Next step will be studying the relevance of differences in healthcare consumptions.

PEE1352

GLOBAL EVIDENCE ON HEALTH-ECONOMIC EVALUATIONS OF PROVIDING DIFFERENTIATED SERVICE DELIVERY FOR HIV: A SYSTEMATIC REVIEW

P.N. Perez-Guzman[1], L. Stackpool-Moore[2], A. Grimsrud[3], L. Golob[2], N. Bazarova[2], H. Prudden[2], T. Roberts[2], M. Smit[1]
[1]Imperial College London, London, United Kingdom, [2]International AIDS Society, Geneva, Switzerland, [3]International AIDS Society, Cape Town, South Africa

BACKGROUND: Differentiated Service Delivery (DSD) is a client-centred model of care, focused on simplifying and adapting health services to meet the needs and expectations of people living with HIV across their continuum of care, whilst reducing the burden on health systems. To identify available evidence and gaps regarding health-economic evaluations of DSD provision, we conducted a global systematic review.

METHODS: We searched Medline and Embase from 1 January 2010 to 21 November 2019 and ClinicalTrial.gov (ongoing trials only) for studies reporting original health-economic outcomes of DSD models. We classified studies by geo-economic region, HIV care continuum stage targeted, DSD model type (facility-based individual, out-of-facility individual, healthworker-led group or client-led group), and whether it evaluated cost-effectiveness (CE).

RESULTS: We identified 5,595 studies, with 161 meeting inclusion criteria. Most (n=113) were from low- and middle-income countries (LMICs), including 91 from sub-Saharan Africa. The review identified two important trends. First, whilst peer-reviewed publications from LMICs have predominantly focused on individual-centred DSD models strengthening all stages of the HIV care continuum, those from high-income countries mainly reported on individual-centred DSD models targeting early stages (e.g. prevention, screening). Few studies reported on health worker-led or client-led group models. Secondly, more recent publications and ongoing trials are increasingly focusing on later stages of the HIV care continuum (e.g. adherence, viral suppression) across settings, and also evaluating group-centred models. Overall, 78 studies included a CE evaluation, including 37 peer-reviewed publications with healthcare perspective valuations and 41 ongoing trials. The rest solely summarised DSD costs (e.g. cost-per-client-year, program costs), mainly from the provider perspective.

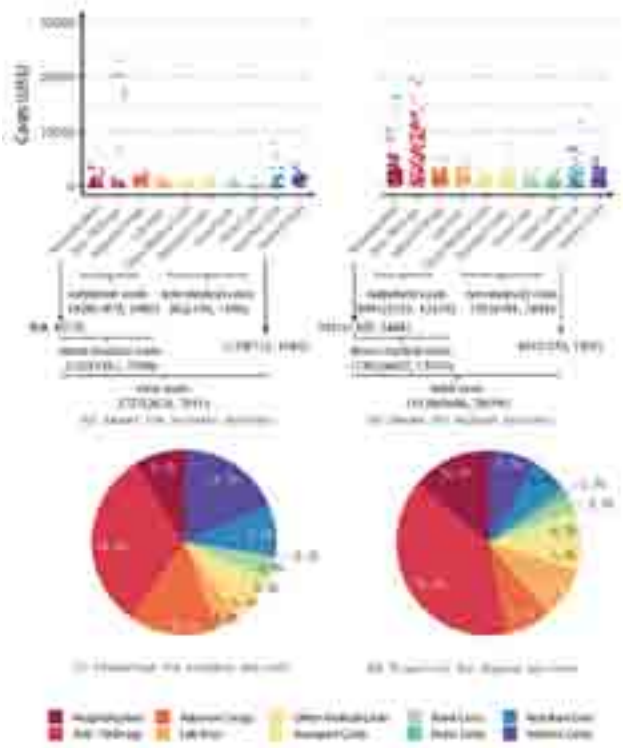
CONCLUSIONS: Although our review identified a wealth of economic evaluations of DSD provision, crucial evidence gaps remain. These include economic evaluations of models focusing on groups and social engagement, beyond individual-level health, and on the scale-up, sustainability and optimisation of DSD models. Data emerging from ongoing trials should, at least in part, address these gaps (e.g. combining individual- and group-centred models). Further studies, combining primary data collection and economic decision models, are needed to optimize economic and health-related benefits from DSD.

PEE1353

THE ECONOMIC BURDEN AND THE DETERMINANTS FOR BOTH NATIVE AND TRANS-REGIONAL MULTIDRUG-RESISTANT TUBERCULOSIS PATIENTS

J. Ye[1], X. Zou[2], H. Wu[3], L. Chen[3], F. Zhou[3], H. Kuang[4], L. Zhou[3], L. Ling[1]
[1]Sun Yat-sen University, Faculty of Medical Statistics, School of Public Health, Guangzhou, China, [2]Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China, [3]Center for Tuberculosis Control of Guangdong Province, Guangzhou, China, [4]Guangzhou Chest Hospital, Guangzhou, China

BACKGROUND: The financial barrier impeded multidrug-resistant tuberculosis (MDR-TB) patients from effective treatment. The World health Organization (WHO) aims to eliminate the catastrophic costs of caused by TB by 2020. For seeking better health care service, trans-regional treatment is common for MDR-TB patients in China. However, the trans-regional movements bring extra expense. The financial burden for trans-regional MDR-TB patients is unknown.
METHODS: A questionnaire for MDR-TB patients was conducted in Guangzhou chest hospital to investigate the basic information, non-medical expenses and work absence. Medical expenses and reimbursement information of patients were collected from the hospital information system. The determinants of total expenses of MDR-TB patients were analyzed by hierarchical multiple linear regression model.



[Figure]

RESULTS: A total of 162 MDR-TB patients were included in this study, with 59 native patients and 103 trans-regional patients. The total cost of trans-regional patients was significantly higher than that of native patients, which was USD $3727(2638, 7541) and USD $15138(9646, 20199), respectively. Anti-TB drugs contributed to the largest proportion of total costs (native patients: 30.4%, trans-regional patients: 39.2%). MDR-TB treatment resulted in 29/59 (49.1%) of native patients, and 93/103 (90.3%) of trans-regional patients suffering from catastrophic total cost, respectively. The results of the hierarchical regression model showed that trans-regional movements, unemployment, the use of cycloserine and linezolid, hospitalization and family accompanying would increase the economic burden of MDR-TB patients. After adjusted, the basic health insurance has no association with the total costs of MDR-TB patients.
CONCLUSIONS: MDR-TB patients face heavy economic burden. In order to reduce the economic burden of MDR-TB patients, the access of treatment and diagnose for MDR-TB should be improved. The coverage of the subsidy policy should be further expanded to cover trans-regional patients. Meanwhile, the reimbursement ratio and limit of the basic medical insurance should be improved to reduce the economic burden of MDR-TB patients.

FINANCING HIV DRUG ACCESS: THE ECONOMICS OF GENERICS AND DIFFERENTIAL PRICING STRUCTURES

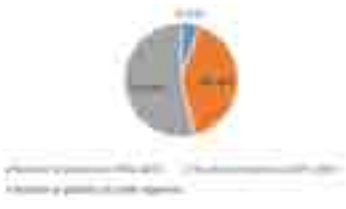
PEE1354

IMPACT OF PATENT MONOPOLIES ON INCREASING ACCESS TO DOLUTEGRAVIR IN EASTERN EUROPE AND CENTRAL ASIA: SNAPSHOT ANALYSIS AND GENERIC ACCESS SCENARIO

D. Godlevskiy[1], S. Golovin[1], A. Mikhailov[1], N. Egorova[1], T. Khan[1], M. Shibaeva[1], G. Vergus[1], K. Babikhina[1]
[1]International Treatment Preparedness Coalition in EECA, Saint Petersburg, Russian Federation

BACKGROUND: WHO-2018 HIV treatment guidelines introduced dolutegravir (DTG) as a preffered first-line option. Several countries in Eastern Europe and Central Asia introduced DTG proactively thanks to generic access under the licensing agreement. Excluded countries do not have access to generic DTG because of the patent protection (e.g. Belarus, Kazakhstan, Russia).
Our aim was to asses access to DTG in Russia as a country with the largest epidemic in EECA and to draft a DTG generic access scenario.
Objectives:
1) identify per patient per year (PPY) DTG cost
2) estimate a number of people receiving DTG, including percentage of total PLWH on ART
3) draft a generic access scenario for increasing DTG access
DESCRIPTION: Methodology included:
1) Analysis of tender document;
2) Calculation of total ART budget, including regimen breakdown;
3) Calculation of all ART cost PPY;
4) Calculation of total number of patients on ART;
5) Calculation of number of patients for each medication (with focus on DTG and EFV).

[Table]



[Figure. Comparison of DTG and EFV coverage in Russia, 2019]

LESSONS LEARNED: In 2019, DTG cost in Russia was 1842 USD PPY. In countries with generic access the cost ranged from 60 to 73 USD PPY.
The DTG budget in Russia was over 45 mln. USD. The number of people receiving DTG was 25 211 (5% of PLWH on ART), as opposed to 205 400 on EFV (40%).
With generic price the number of people on DTG can be increased to 636 146 with the same budget.
CONCLUSIONS/NEXT STEPS: Patent monopoly is a barrier for access to DTG. It is observed in other countries without generic access. Proportion of PLWH on DTG ranges from below 1% in Belarus, to around 10% in Kazakhstan with the price range USD 1300-2000 PPY.
Price reduction measures are needed for better access to WHO-recommended regimens, e.g. compulsory licensing (discussed for Kazakhstan and Russia) or voluntary license.

PEE1355

MARKET DYNAMICS OF ANTI-RETROVIRAL DRUGS: ESTIMATING THE MARKET SIZE AND PRICE VARIATIONS IN GENERIC ACCESSIBLE LOW- AND MIDDLE-INCOME COUNTRIES USING DATA REPORTED TO UNAIDS AND TO GOVERNMENT CUSTOMS AGENCIES

D. Mattur[1], J.A. Izazola Licea[1], P. Indravudh[2]
[1]UNAIDS, Strategic Information, Geneva, Switzerland, [2]LSHTM, Global Health and Development, London, United Kingdom

BACKGROUND: By end of 2018, 37.8[32.7 million–44.0] million people were living with HIV and 24.5 million [21.6 million–25.5] people were accessing antiretroviral therapy by mid-2019.
METHODS: Data from Global AIDS Monitoring (average ARV unit prices) and India government customs were analyzed to estimate the market size, price trends & variations for generic ARVs (exported between 2016 and 2019) in generic accessible low-and-middle-income countries (LMIC). .
Estimates for person-years on treatment and unit costs per person-years were calculated from the volume and price of ARV exports in LMICs. Analyses were stratified by year, regimen, income group and region.
RESULTS: The value of the market size for ARVs in generic accessible low-and-middle-income countries was estimated at US$ 1.9Bn (US$ 1.8Bn – US$ 2Bn) in 2019.
Between 2016 and 2019, the unit cost per person-year on treatment decreased from US$89.01 to US$75.76 for lamivudine-based regimens and from US$117.11 to US$100.85 for emtricitabine-based regimens. For combinations including lamivudine or emtricitabine, unit costs were lowest for lower middle-income (US$72.57) and low-income countries (US$73.65), respectively. Unit prices varied from US$68.12 in West and Central Africa to 264.82 in Eastern Europe and Central Asia for lamivudine-based regimens; US$61.13 in Asia and the Pacific to 166.31 for emtricitabine-based regimens.
The average unit prices for Zidovudine-Lamivudine-Nevirapine regimens came down in Sub Saharan Africa from US$ 91 per person year on treatment in 2016 to US$ 73 in 2019. During the same period, Tenofovir-Lamivudine-Efavirenz based regimens witnessed a price drop from US$98 per person year to US$ 73.5. The average price per dose for Tenofovir-Lamivudine based regimens which could be administered for PrEP was US$ 47 in Sub Saharan Africa in 2019. It witnessed a price reduction of US$ 4 per dose in the last 3 years.
CONCLUSIONS: There were declines in unit prices between 2016 and 2019 in most income level groups of countries and in regions. There still are large variations in average procurement prices.
In the current environment of flat-lined international resources for HIV, countries must look for options to optimize their procurement cost and thereby reallocate the resources saved through supply chain optimization to other program needs.

FUNDING FOR HIV PROGRAMMES AND SERVICES

PEE1356

INTERNATIONAL DONORS MORE LIKELY TO HAVE RESPONSIBILITY FOR KEY POPULATION PROGRAMMING: SUSTAINABILITY OF KP PROGRAMMING AT RISK

M. Ruffner[1], V. Vasireddy[1], J. Palen[1], M. Wollmers[1], E. Reuben[2], A. Bush[3]
[1]U.S. Department of State, Office of the Global AIDS Coordinator, Washington DC, United States, [2]USAID, Office HIV/AIDS, Washington, United States, [3]U.S. Department of Agriculture, FNS, Washington, United States

BACKGROUND: As countries achieve epidemic control in their general population groups, Key Population (KP) groups will still need additional work to achieve and maintain epidemic control. Today, the international community only uses total spending converted into dollars to understand KP programming at the country level.
DESCRIPTION: PEPFAR created the responsibility matrix (https://www.state.gov/where-we-work-pepfar/) to chart elements of the HIV response that are fulfilled by donors or domestic sources. The Sustainability Index and Dashboard (SID) is a tool developed by PEPFAR and UNAIDS to assess the sustainability of a country's HIV response. In a focus session during the summer of 2019, in country stakeholders determined the level of responsibility for the HIV response between PEPFAR, the Global Fund or other domestic sources and also updated the SID.
LESSONS LEARNED:

	Care and Treatment Service Delivery	Care and Treatment Non Service Delivery	Facility Level Staff	Community Health Care Workers	KP Program Service Delivery	KP Program Non Svc Delivery
% Domestic Primary Responsibility	81%	39%	93%	48%	33%	26%
% International Primary Responsibility	30%	59%	15%	67%	89%	89%
% Domestic Secondary Responsibility	15%	33%	4%	22%	30%	44%
% International Secondary Responsibility	70%	41%	81%	33%	11%	11%

[Table]

While general service delivery for HIV programming is often the responsibility of the host government, the international community has higher rates of responsibility for Key Population programs. As is shown in table 1, only 33% of countries take primary service delivery responsibility for KP programs. Even fewer countries, 26%, take responsibility for non-service delivery components. Also since KP program are more heavily dependent on community workers,

many countries will have a significant challenges maintaining KP programs without policy changes that enable the use of community health care workers.

CONCLUSIONS/NEXT STEPS: While domestic responsibility for elements of HIV care has increased, or has been under estimated, it is clear that there is a much further ways to go when it comes to key populations programming. In general, where there are separate focused efforts, KP programming is more often the responsibility of the international community. Building the political will and creating domestic funded and operated KP programs will be a more significant task to assure sustained epidemic control. Ensuring that Community Health Care Workers are recognized cadres within a national system will be an important part of KP programming sustainability. Focusing on social contracting for KP services or creating social enterprises are key sustainability efforts.

PEE1357

THE FUNDING FOR THE PREVENTION AND TREATMENT OF HIV CAN SAVE LIVES! THE MECHANISMS FOR FUNDING PROGRAMS IN THE AREA OF HIV, THROUGH LOCAL BUDGETS!

R. Mazhitov[1]
[1]*NGO Plus Centre, Osh, Kyrgyzstan*

BACKGROUND: At the moment, the situation in the Kyrgyz Republic with the financing of programs to overcome HIV infection, is not for the better. We can see that since the beginning of the 2000s, the activities were carried out by the Global Fund, and 90% of the funding in the Republic was carried out at the expense of donors. Since 2014, the country has moved into the category of a country with an income below the average in the world Bank category, and until today there is a steady trend of reduction of funds. The commitments made by the country to achieve the goals set out in the UNAIDS 90-90-90 strategy to save lives and stop the HIV epidemic **can be met by increasing public funding and spending efficiency.**

DESCRIPTION: NGO "Plus Center", in 2018, was active in the field of Advocacy for Public funding and the rights of vulnerable groups. The project, together with the city hall of Osh, created a working group that developed and presented to the deputies of the city Council - a social program, the Project conducted research on the needs of vulnerable groups and missing services. The project protected a Social program worth 2 million soms for 2 years, and the deputies approved the city budget with services for vulnerable groups, including PLHIV.

LESSONS LEARNED: Osh city Hall has signed a document to Fund services for vulnerable groups. Five NGOs in the city received funding from the Osh city budget. 2000 representatives of vulnerable groups were covered. Training was conducted for city hall employees on rights, laws and stigma of discrimination.

CONCLUSIONS/NEXT STEPS: A City-wide HIV Coordination Council has been Established in Osh. Osh city hall, signed the Paris Declaration on HIV, Osh City hall is preparing to adopt a new city plan on HIV for two years, with funding for services for PLHIV and other target groups. HIV services will be Monitored at the city level. Vulnerable groups receive political support from the mayor's office. Communities have been involved in the research, development and implementation of local, national, and international instruments for HIV treatment, care, and support programs.

PEE1358

HOW MUCH ARE WE INVESTING IN THE RESPONSE TO HIV? RESOURCE AVAILABILITY FOR THE HIV RESPONSE IN LOW- AND MIDDLE-INCOME COUNTRIES 2010-2018 AND CHANGES FROM 2017 TO 2018

J.A. Izazola Licea[1], D. Mattur[1]
[1]*UNAIDS, Strategic Information, Geneva, Switzerland*

BACKGROUND: A target to mobilize at least $26.2 Billion (at constant 2016 dollars) by 2020 for an effective response to HIV in low- and middle-income countries was adopted in 2016. This target assumed efficiency gains of 40% and increased program effectiveness..

METHODS: The international sources were based on annual reports for bilateral contributions, and disbursement reports by multilaterals. The domestic public resources were estimated by panel data regression analysis using the 2000 to 2018 annual reports to the Global AIDS Monitoring; domestic private estimates used data from NASA.

RESULTS: The resource availability from all sources for low- and middle-income countries increased from $15 Bn in 2010 to $19.0 Bn in 2018 (26% increase) expressed in 2016 constant dollars (to make it comparable to the 2020 target set in 2016). The peak value was in 2017 at $19.9 Bn.

The domestic resources increased from 2010 to 2018 by 50% (or by $3.6 Bn) to reach $10.7Bn in 2018. Similarly, bilateral contributions from the US-government increased by 47% or $1.6 Bn. Bilateral's contributions (other than the USG) decreased by 57% (from $1.9 Bn to $0.8 Bn).

Multilateral institutions other than GFATM and UNITAID decreased by 37% down to $217 million in 2018. The share for HIV from UNITAID decreased by -36% (from $200 to $132 million). The resources disbursed by the GFATM to LMIC for HIV in 2010 were almost at the same level as in 2018.

There was a reduction in the resource availability in 2018 compared to 2017 of $920 million constant 2016 dollars equivalent to a 5% decrease. This would be the second time since 2000 that there had been reductions on the total availability for same countries on a year-to-year basis, i.e. from 2013 to 2014 ($400 million reduction, or -2%).

In 2018, domestic resources (public and private) constitute 56% of the global AIDS resources

CONCLUSIONS: The resource availability for HIV has flattened in recent years and efficiencies have not yet been fully realized thus risking meaningful change in the epidemic trend.The funding gap to reach the 2020 target of $26.2 Billion (in 2016 dollars) is not being reduced.

PEE1359

WHEN THE POLITICS IS IN THE WAY; UNDERSTANDING BARRIERS TO EFFECTIVE DOMESTIC FINANCING OF HIV/AIDS THROUGH THE LENS OF GOVERNMENT'S PUBLIC FINANCIAL MANAGEMENT (PFM) SYSTEM

F. Ilika[1], G. Alawode[1], A. Chidozie[2], H. Edumoh[1]
[1]*Health Policy Plus, International Health, Abuja, Nigeria,* [2]*Nnamdi Azikiwe University Teaching Hospital, Community Medicine, Nnewi, Nigeria*

BACKGROUND: There is a high dependence on donor funding and inadequate domestic spending on HIV/AIDS in Nigeria. With decreases and changes in prioritization of donor funding for HIV/AIDs control, domestic revenue mobilization (DRM) is a vital step for sus-

tainability of HIV control efforts. The government is not meeting this challenge and therefore, it was imperative to examine the obstacles to government funding through a closer examination of the Public Financial Management(PFM) system. An effective PFM system is essential to ensuring adequate public spending on HIV/AIDS.

METHODS: We conducted a PFM assessment in 4 Nigerian states with the highest HIV burden in the country, to understand the system, identify roadblocks to government spending on HIV/AIDS, and devise solutions. The assessment examined the financial planning, budgeting, releases, and spending and was based on the Health Finance and Governance Project's 'Guided Self-Assessment of Public Financial Management Performance (PFMP-SA), and the USAID's Public Financial Management Risk Assessment Framework (PFM-RAF) methodology. We conducted key informant interviews and reviewed government financial documents to obtain required information.

RESULTS: Common obstacles were found in the four states. Budget credibility is low as evidenced by a lack of accurate costing and unavailability of accurate budget ceilings or envelops for departments during the planning process. Budgets are unrealistic when compared to available or potential revenues, and changes in political priorities affect expenditures; as prioritization is political and not evidence based. Missing links and wide variances exist between budgeted and actual expenditure. Health actors have inadequate understanding of the PFM process and are not proactive in requesting for funds allocated to them. Disbursement decisions are made at the highest executive level requiring strong political advocacy and lobbying, leading to delays and often non-release of funds for HIV/AIDS activities.

CONCLUSIONS: For effective government spending on HIV/AIDS control efforts, PFM reforms are vital. Health stakeholders should employ political engagement to address PFM obstacles and promulgate use of evidence-based, realistic and program based budgets. To increase government HIV spending, capacity building of HIV sector actors on the PFM system, and fostering of inter-sectorial collaboration and partnerships with finance ministries and high level advocates is essential.

PEE1360

ALIGNING RESOURCES TO MAXIMIZE EFFICIENCY, ACCOUNTABILITY, AND IMPACT OF THE GLOBAL HIV RESPONSE

E. Reuben[1], M. Ruffner[1], A. Birikorang[2], V. Agueci[2], A. Ibrahim[2], A. Faye[2]
[1]US Department of State, Office of the US Global AIDS Coordinator, Washington DC, United States, [2]The Global Fund, Geneva, Switzerland

BACKGROUND: PEPFAR and the Global Fund in partnership with host country governments form the cornerstone in combating the HIV/AIDS epidemic. To achieve a sustained response, it is essential to synergize efforts and ensure optimal alignment and allocation of resources between stakeholders. Availability of routine harmonized financial data enables increased collaboration between donors and partner governments during planning and budgeting processes ensuring investments are strategically aligned for maximum impact.

DESCRIPTION: Collaborative planning between stakeholders is critical to ensuring that prioritized interventions are scaled, geographic priorities are shared, and that all available resources for HIV/AIDS in the country are utilized optimally. Every year PEPFAR country teams in close collaboration with host country and Global Fund ensure that dollars strategically align to address gaps and solutions for impact while maximizing transparency, efficiency, and accountability of resources.

LESSONS LEARNED: The Resource Alignment collaboration between PEPFAR and the Global Fund has enabled efforts to better align resources, avoid duplication, drive efficiency, and improve the cost analysis and resource estimations of HIV treatment and prevention programming. Harmonizing budgets and expenditures for the two largest donors in the HIV response have enhanced strategic collaboration and coordination during program cycle planning and budgeting. Examining actual expenditures against planned investments by specific program areas help identify areas of low absorptive capacities, investigate possible causes, and develop strategies to address it. Triangulating resource alignment data with national program data will provide a better understanding of total funding against results; whether investments are adequately targeted to address issues along the clinical cascade; assess possible gaps in funding and pockets of inefficiencies; identify areas where agency/host country government can prioritize resources based on competitive advantages.

CONCLUSIONS/NEXT STEPS: As donor funding continues to plateau or decline in some cases amidst an accelerated pursuit of epidemic control, resource alignment efforts become an invaluable tool to engage with partner governments to advance efforts around domestic responsibility and resource mobilization to ultimately ensure financial sustainability of HIV programs.

EVIDENCE FROM INTEGRATION OF HEALTH SERVICES

PEE1361

HPV TESTING ON SELF-COLLECTED VAGINAL SAMPLES AS A CERVICAL CANCER SCREENING METHOD AMONG HIV-POSITIVE WOMEN: A STUDY IN UGANDA

J. Joseph[1], M. Lubega[2], A. Abala[2], O. Demke[1], S. Khan[1], C. Boeke[1], Y. Kamuntu[2], G. Senyama[2], A. Musoke[2], S. Ndidde[3]
[1]Clinton Health Access Initiative, Global Health Sciences, Boston, United States, [2]Clinton Health Access Initiative, Kampala, Uganda, [3]Uganda National Health Laboratory Services, Kampala, Uganda

BACKGROUND: Cervical cancer incidence and mortality is highest among women living with HIV (WLHIV) in low-income countries with limited access to cervical cancer screening and treatment. The World Health Organization currently recommends HPV testing as part of cervical cancer screening programs. In Uganda, cervical cancer is the leading cause of cancer death but only 10% of women are screened annually through visual inspection with acetic acid (VIA). A study is being conducted in Uganda to assess the acceptability and feasibility of HPV testing using self-collected samples for WLHIV.

METHODS: In this observational pilot (September 2019-March 2020) in seven Ugandan hospitals, self-collected vaginal samples from WLHIV are tested using GeneXpert. Data is extracted from facility registers. Descriptive analyses are presented here for data through December 2019.

RESULTS: 1021 women were tested for HPV; 991 (97%) had a valid result and 349 (35%) tested HPV+. 175 (50%) HPV+ women were linked to care and received VIA, of whom 54 were VIA+ and 2 suspected

of cancer. Among these women, 35 (63%) were treated with either thermocoagulation or cryotherapy, 16 (29%) referred for specialized treatment, and 5 (9%) deferred for treatment. In sub-population analysis among women with minimum of 30-day follow-up, the proportion linked to VIA was 72%. Median turnaround time (TAT) for sample collection to patient result receipt was 12 days (IQR: 3-27), with TATs being faster for HPV+ (9 days) versus HPV- women (14 days). For HPV+ women, TAT from patient result receipt to VIA was 0 days (IQR: 0-1).

CONCLUSIONS: HPV prevalence in this population was 35%. Preliminary data from the pilot indicate that HPV testing in WLHIV was acceptable and feasible with the majority of HPV+ women linking to care and receiving treatment on the same day they received their results. As this study is ongoing, we expect linkage rates to increase with additional follow-up. Additionally, in resource-limited settings, thermocoagulation and cryotherapy are practical approaches for prompt on-site treatment of VIA+ women. The pilot results are expected to inform the National Cervical Cancer Control Programme in Uganda in the adoption and implementation of HPV testing as the primary cervical cancer screening method nationally.

PEE1362

PEER SUPPORT INTEGRATION: CREATING SAFE SPACES FOR ADOLESCENTS LIVING WITH HIV

G. Makota[1], L. Phillips[1], D. Mark[1], M. Wallace[1], T. Burdock[1], L. Hatane[1]
[1]Paediatric - Adolescent Treatment Africa, Cape Town, South Africa

BACKGROUND: HIV is the leading cause of mortality amongst adolescents in Africa, who remain under-served in the HIV response.

DESCRIPTION: The Re-Engaging Adolescents and Children with HIV (REACH) programme is a health facility-based, low-cost adolescent peer support model building the capacity, agency and resilience of lay providers age 18-24 years living with HIV to deliver psycho-social support services for their peers. Implemented at 15 health facilities across Cameroon, Kenya, Malawi, Uganda and Zambia, peer supporters work alongside health providers to improve service quality through task-shifting and an expanded package of psycho-social support services. The programme provides peer supporters with training, mentorship, peer engagement, livelihood strengthening and skills--building to improve job performance, career prospects and well-being. Embedded mixed methods monitoring and evaluation is being used to assess the model's feasibility, acceptability and effectiveness, while developing a user-friendly package of tools to support its scale-up in the region.

LESSONS LEARNED: In the past year, REACH facilities tested 54% more adolescents and young people (AYP) for HIV than they had the year before REACH was initiated. Across sites, the 66,699 tested yielded an HIV positivity rate of 3%. Remarkably, 99% of that tested positive were initiated on antiretroviral therapy (ART). Looking at the total population of AYP on ART within the programme, 95% were retained in care and 95% virally suppressed.

While preliminary results have demonstrated that REACH is feasible, acceptable and can result in improved service delivery and client outcomes, data have also revealed challenges, such as peer supporters being required to perform tasks for which they are not equipped, and insufficiently recognised and respected by health providers. In partnership with peer supporters and health providers within the programme, a suite of guidelines and tools was developed covering peer supporter recruitment to integration.

CONCLUSIONS/NEXT STEPS: Looking ahead, the prospect of mainstreaming REACH using mobile technology to establish virtual safe spaces will be explored, as will differentiating the model and its tools to reach marginalised groups of young people living with HIV. These efforts will assist health facilities to set standards for peer support services and build greater uniformity in service quality for all AYP.

APPROACHES TO FINANCING ACROSS SECTORS

JOY OF GIVING AND RECEIVING: GRASSROOT FUNDRAISING IN MBEYA, TANZANIA

N.A. Jiwa[1], D. Mwenisongole[1], E. Masuka[1], J. Bacha[2], K. McKenzie[2], B. Kasambala[3], L. Mwita[3]
[1]Baylor College of Medicine Children's Foundation, Pharmacy, Mbeya, Tanzania, United Republic of, [2]Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Baylor College of Medicine, Mbeya, Tanzania, United Republic of, [3]Baylor College of Medicine Children's Foundation, Mbeya, Tanzania, United Republic of

BACKGROUND: Recent budgetary challenges have adversely affected our ability to purchase life-saving medicines, provide important social support packages (such as transport, clothes, blankets, basic necessities), and offer food packages for the most vulnerable children living with HIV/AIDS. To address these shortcomings, the Mbeya COE Pharmacy, Social Work and Nutrition departments created and implemented a fundraising event on World AIDS Day 2018.

DESCRIPTION: The event targeted the local community by inviting guests to the COE for a celebratory day, viewing of short inspiration HIV/AIDS videos, and discussions with COE staff about the program in hopes of soliciting local donations. As staff, we organized ourselves into two teams. One team handled internal logistics and event agenda, and the second team helped to deliver invitation letters and initiate mobilization amongst people to attend our event. Children from our clinic were not invited to curb disclosure of status in public and risk of unintended stigmatization.

This event gathered a grand total of cash and auctions worth of USD 3,730. Donated products (e.g. sugar, flour, clothes, powdered soap) are being stored for distribution through Social Work department to eligible children. Perishable items such as eggs were distributed to around 60 families to celebrate Christmas before the holidays. Donated gallons of liquid soap is auctioned to raise additional money to support COE patients.

LESSONS LEARNED: This event brought to light kindness that community bears in relation to giving for children living with HIV/AIDS. As three departments, we have also learnt to form a committee and formal processes for accessing and using the products and money accumulated from this cause. It is also important to clearly depict processes of accessing the accumulated products and funding since delays as well as uncertainties would disable motivation for this exercise.

CONCLUSIONS/NEXT STEPS: We hope to continue these community level fundraising efforts on annual basis in Mbeya. We hope to collaborate through other community partners, civil society organizations and commercial business sector in the community to further mobilize our cause and keep receiving community support for future.

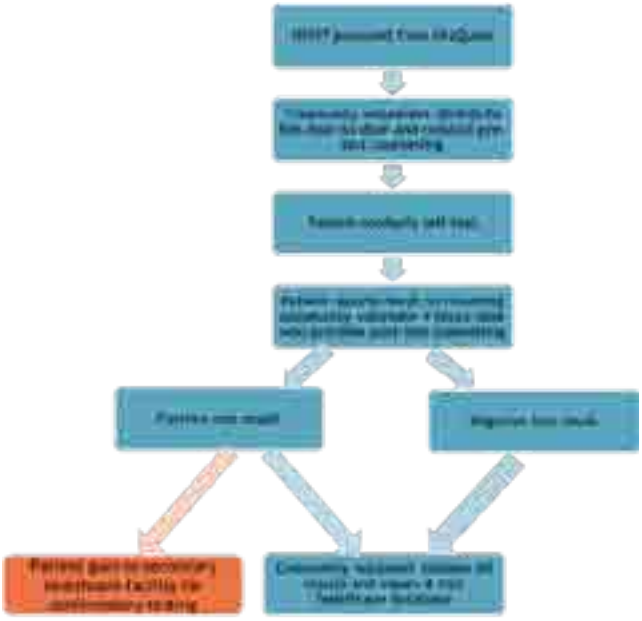
ASSESSMENTS OF COST EFFECTIVENESS: PROVIDER AND COMMUNITY PERSPECTIVES

PEE1364

ARE HIV SELF-TESTS A COST-EFFECTIVE ALTERNATIVE FOR INCREASING THE NUMBER OF HIV TESTS CONDUCTED IN AN ADULT RURAL NIGERIAN COMMUNITY COMPARED TO EXPANDING PRIMARY HEALTHCARE SERVICES?

P. Cecula[1], R. Singh[2], O. Sikdar[2]
[1]Imperial College London, Medicine, London, United Kingdom, [2]Imperial College London, London, United Kingdom

BACKGROUND: Nigeria has the second-largest HIV epidemic in the world with 3.2 million people living with HIV. 2016 World Health Organisation (WHO) guidelines recommended HIV Self-Tests (HIVST) as an additional approach to testing.
In 2012 EFMC conducted their 1 year Reaching All with Care and Support Services in HIV/AIDS (REACH) initiative which involved expanding HIV services in primary healthcare facilities (PHC). The aim of the research was to evaluate current testing practice (expanding HIV services in primary healthcare facilities) and HIVST, as well as to conduct a cost-effectiveness evaluation of those.
METHODS: Cost-effectiveness was determined by comparing the social cost per test of REACH and an HIVST model based on WHO guidelines. Primary data was collected via a survey conducted in Bwari general hospital outpatient department and HIV clinic (n=50). Secondary data on the REACH program was obtained from EFMC and CFHI.
Sensitivity analysis was conducted on each estimated cost, this showed the extent to which our assumptions could vary the cost of the model. If the range of possible total costs didn't overlap, the results would be significant. The HIV self-test model was created based on a literature review and information gathered from patients, doctors and EFMC:



[Figure]

RESULTS: Results showed that one self-test would cost $11.13 (9.79-12.79) per person, while in REACH the price was $21.14 (19.66-22.62). Overall, sensitivity analysis shows that the HIVST model is more cost-effective than the REACH program. At a critical value of $12 a kit HIV self-testing becomes more expensive than current PHC based practice.
CONCLUSIONS: Apart from the cost of HIVST kits, no single cost has a large enough variation to make the range of total cost of both methods overlap. Sensitivity analysis of the HIVST model shows the price of kits is the only significant variable. Limitations and future directions have been identified.

PEE1365

EVALUATING THE EFFECTS AND COST-EFFECTIVENESS OF A FAMILY ECONOMIC EMPOWERMENT INTERVENTION TO INCREASE ADHERENCE TO ANTIRETROVIRAL THERAPY AMONG HIV+ ADOLESCENTS IN UGANDA

Y. Tozan[1], A. Capasso[1], S. Sun[2], T. Neilands[3], O. Sensoy Bahar[2], C. Damulira[2], F. Namuwonge[2], W. Byansi[2], P. Nabunya[2], F.M. Ssewamala[2]
[1]New York University, School of Global Public Health, New York, United States, [2]Washington University in Saint Louis, Brown School, Saint Louis, United States, [3]University of California in San Francisco, School of Medicine, San Francisco, United States

BACKGROUND: Economic insecurity is associated with poor adherence to antiretroviral therapy (ART) among HIV-infected youth. Family-based economic empowerment (FEE) interventions, which aim to increase household financial stability, have the potential to mitigate the challenges in accessing treatment due to economic insecurity and improve adherence in this vulnerable population. We present efficacy and cost-effectiveness analyses of the Suubi Adherence study, a FEE intervention aiming to improve ART adherence among HIV-positive adolescents in southern Uganda.
METHODS: Intent-to-treat analyses using multilevel logistic regressions compared the effect of the intervention on participants receiving economic incentives and medical and psychosocial support-bolstered standard of care to those only receiving bolstered standard of care. The primary outcome was viral load suppression (< 40 copies/ml) at 24 months. Per-participant costs for each arm were calculated conservatively using the treatment-on-the-treated sample. Intervention effects and per-participant costs were used to compute incremental cost-effectiveness ratios from a provider perspective.
RESULTS: At 24 months, participants in the intervention arm exhibited higher odds of being virally suppressed (OR 2.15; 95% CI 1.12, 4.15; p = 0.022) and had higher mean difference in viral suppression compared to baseline (Percent change: 10.0% versus 1.1%; p = 0.032). Per-participant cost was US$109 for the intervention group, and US$27 for the control group. While the estimated cost of achieving 10% increase in the probability of being virally suppressed was US$71 (95% CI $30, $680), the cost per virally suppressed adolescent was estimated at $923 (95% CI $474, $2982).
CONCLUSIONS: Our findings indicate that the family-based economic empowerment intervention was effective in improving ART adherence among HIV-positive adolescents in Uganda. There is limited evidence regarding the cost-effectiveness of medication adherence for HIV in particular, and for chronic diseases in general. This study contributes with findings on ART adherence from low resource settings, that can aid policymakers in developing guidelines and programming for HIV care in such contexts.

PEE1366

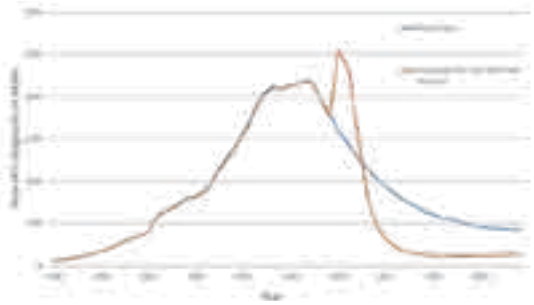
COST-EFFECTIVENESS OF "UNIVERSAL HIV TEST-AND-TREAT" STRATEGY TO ELIMINATE HIV EPIDEMIC AMONG MEN WHO HAVE SEX WITH MEN IN TAIWAN: A MODELLING STUDY

Y.-Y. Lee[1], H.-J. Wu[2], Y.-H. Chen[1], C.-T. Fang[1]
[1]Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan, Province of China, [2]National Cheng Kung University Hospital, Department of Public Health, College of Medicine, Tainan, Taiwan, Province of China

BACKGROUND: In Taiwan, HIV epidemic concentrates in men who have sex with men (MSM). Despite a universal access to antiretroviral therapy, social stigma and discrimination associated with current MSM-targeted HIV testing program discouraged potential clients. In 2018, up to 33% of newly diagnosed HIV clients developed AIDS within 3 months. A "Universal HIV Test-and-Treat" program for all sexually active young men and women might greatly improve timing of HIV diagnosis. We aimed to provide the first economic evaluation for such strategy to eliminate HIV epidemic in MSM.

METHODS: We conducted a modelling study on the effect of a universal annual-HIV-test-and-immediate-treat program (scaling up from status quo to targeted level over a 3-year period) for all sexually active unmarried young men and women in Taiwan, using Taiwan MSM-HIV Model which was calibrated to actual HIV epidemic data from 1986 to 2019. Lifetime medical cost per new MSM HIV case was based on Taiwan National Health Insurance data, with extrapolation of survival and cost to 50 years after diagnosis, taking a 3% annual discount rate from a payer's perspective. To obtain a conservative cost-effectiveness estimate, averted heterosexual transmission was not considered.

RESULTS: Over a 20-year time horizon, universal HIV test-and-treat strategy will avert 26% cases, lead to 100,275 QALYs gained, and eliminate HIV epidemic by 2027. This strategy will cost 76 million US dollars per year, but is highly cost-effective (US$2,442/QALY gained). Sensitivity analysis shows that if we restrict testing to only sexually active young men or MSM, the program will become cost-saving with a ratio of 5.6 and 71.5, respectively (Table).



[Figure. Impact of universal HIV-test-and-treat strategy in Taiwan (eliminate HIV epidemic defined as an HIV incidence lower than 0.001/ year by World Health Organization)]

Strategy	Annual HIV testing costs	Incremental cost-effectiveness ratio (USD/QALY)	Cost-saving ratio
Universal HIV test-and-treat for sexually active young men and women	76,461,768 USD	2,442 (2019 GDP per capita in Taiwan: 25,932 USD)	–
HIV test-and-treat for sexually active young men	40,046,006 USD	dominated	5.6
HIV test-and-treat for MSM	3,108,845 USD	dominated	71.5

[Table. Cost-effectiveness of Universal HIV Test-and-Treat Strategy in Taiwan]

CONCLUSIONS: Universal HIV test-and-treat is a highly cost-effective strategy to eliminate the HIV epidemic among MSM in Taiwan.

PEE1367

SOCIAL RETURN ON INVESTING IN A COMMUNITY-BASED HIV PROGRAM IN INDIA: LESSONS LEARNED FROM THE AVAHAN PROGRAM

S. Mukherjee[1], B. Mahapatra[1], S.K. Patel[1]
[1]Population Council, HIV and AIDS Program, New Delhi, India

BACKGROUND: The Bill & Melinda Gates Foundation has invested USD 7 million in 2014 to strengthen community-led organizations (COs) across five states of India: Tamil Nadu, Andhra Pradesh, Telangana, Karnataka and Maharashtra. Through this investment, it was expected to reduce structural barriers faced by female sex workers (FSWs), men having sex with men (MSM), and transgenders (TGs) and hence, reduce vulnerabilities related to financial security, social protection and crisis response over three years. This study uses social return on investment (SROI) methods to evaluate social, economic and health values resulting from the investment of the Avahan-III program.

METHODS: The SROI methodology is a social cost-benefit analysis that measures and accounts for the values created by a program by adopting the multi-stage approach. Data to carry out the SROI for this study was collected from the program monitoring data and the end line survey data conducted during 2017-2018. SROI involves reviewing the theory of change of the project i.e. inputs, outputs, outcomes and impacts experienced by the beneficiaries of the program during the consultation workshop. Five stages were used to calculate the SROI: establishing scope and identifying key stakeholders, mapping project outcomes, assigning a financial value to project outcomes, establishing project impact, and calculating inputs.

RESULTS: SROI estimation of Avahan Phase-III program described that the program over its 4 years of implementation had delivered a positive return to investment ratio of 16.7:1. This means an investment of 1 USD resulted to 16.7 USD after 4 years of the program and suggested that investments made to reduce social, financial and crisis response related vulnerabilities among the key population can generate "value for money". Beneficiaries gained large share of returns (62%) from financial, social and crisis response components. Return on financial security dimensions was the highest (59%), followed by crisis response (28%).

CONCLUSIONS: The findings suggest that the investment was highly successful, particularly, in ensuring financial security. Given the intervention was community-led, the investment made would be sustainable and the return is likely to continue in future.

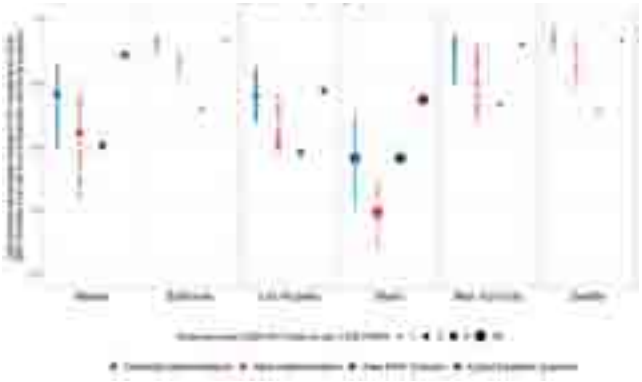
REDUCING HIV INCIDENCE AMONG PEOPLE WHO INJECT DRUGS WITH LOCALIZED COMBINATION IMPLEMENTATION STRATEGIES IN SIX U.S. CITIES

E. Krebs[1], X. Zang[1], B. Enns[1], J.E. Min[1], C.N. Behrends[2], C. Del Rio[3], J.C. Dombrowski[4], D.J. Feaster[5], K.A. Gebo[6], B.D. Marshall[7], S.H. Mehta[6], L.R. Metsch[8], A. Pandya[9], B.R. Schackman[2], S.A. Strathdee[10], B. Nosyk[1], on behalf of the localized economic modeling study group
[1]British Columbia Centre for Excellence in HIV/AIDS, Health Economic Research Unit, Vancouver, Canada, [2]Weill Cornell Medical College, Department of Healthcare Policy and Research, New York City, United States, [3]Rollins School of Public Health and Emory University School of Medicine, Atlanta, United States, [4]University of Washington, Department of Medicine, Division of Allergy and Infectious Disease, Seattle, United States, [5]University of Miami, Department of Public Health Sciences, Leonard M. Miller School of Medicine, Miami, United States, [6]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [7]Brown University, School of Public Health, Providence, United States, [8]Columbia University, Department of Sociomedical Sciences, Mailman School of Public Health, New York City, United States, [9]Harvard T.H. Chan School of Public Health, Department of Health Policy and Management, Boston, United States, [10]University of California, School of Medicine, La Jolla, United States

BACKGROUND: People who inject drugs (PWID) are at a disproportionately high risk of HIV infection in the United States. We aimed to determine HIV incidence reduction among PWID in six US cities resulting from highest-valued combination implementation strategies of expanded access to evidence-based prevention and care interventions for PWID.

METHODS: Using a dynamic HIV transmission model calibrated for Atlanta, Baltimore, Los Angeles, Miami, New York City and Seattle, we assessed the value of implementing combinations of evidence-based interventions at optimistic (drawn from best available evidence) or ideal (90% coverage) scale-up. We estimated reduction in HIV incidence among PWID, quality-adjusted life-years (QALYs) and incremental cost-effectiveness ratios (ICERs) for each city (10-year implementation; 20-year horizon; 2018$US). We also examined the impact on HIV incidence of the changing opioid epidemic (40% increase in injection prevalence; increased mortality risk from fentanyl) and further provision of free PrEP.

RESULTS: The reduction in HIV incidence among PWID from 2020 to 2030 varied from 8.1% (95% CI: 2.8%, 13.2%) in Seattle to 54.4% (37.6%, 73.9%) in Miami (Figure) with highest-valued combinations implemented at optimistic levels containing between six (Atlanta and Seattle) and twelve (Miami) interventions. ICER values ranged from $94,069/QALY in Los Angeles to $146,256/QALY in Miami.



[Figure. Projected reductions in HIV incidence among people who inject drugs (PWID)]

Incidence reduction reached 16.1% (Baltimore) to 75.5% (Miami) at ideal scale-up. The changing opioid epidemic had a profound impact on mortality among PWID living with HIV and resulted in more modest incidence reductions, ranging from 8.7% (Baltimore) to 31.6% (Miami). Incidence reduction reached 33.4% (New York City) to 52.2% (Los Angeles) with the provision of free PrEP—with Miami unchanged at 54.4%.

CONCLUSIONS: Evidence-based interventions targeted to PWID can deliver considerable value; however, ending the HIV epidemic among PWID will require innovative implementation strategies and supporting programs to reduce social and structural barriers to care.

PEE1369

COST-EFFECTIVENESS OF HIV SELF-TESTING VS. FACILITY-BASED HIV RAPID-DIAGNOSTIC TESTING SUPPORTED BY COMMUNITY-BASED ORGANIZATIONS AMONG MEN WHO HAVE SEX WITH MEN IN CHINA

S. Huang[1,1], J. Ong[2,2], W. Dai[1,1], Y. Zhou[1,1], X. Li[1,1], W. Tang[3,4]
[1]Zhuhai Municipan Center for Diseases Prevention and Control, Zhuhai, China, [2]Monash University, Melbourne, Australia, [3]Dermatology Hospital, Southern Medical University, Guangzhou, China, [4]UNC Project-China, Guangzhou, China

BACKGROUND: HIV self-testing (HIVST) has been adopted and widely used. Knowing the cost-effectiveness of HIVST is critical for planning and scaling-up HIVST in different settings, especially in resource limited countries. This study aimed to evaluate the cost-effectiveness of an HIVST model implemented in China.

METHODS: A cost-effectiveness analysis (CEA) was conducted by comparing HIVST models and a CBO-led facility-based HIV rapid diagnostics testing (HIV-RDT). The full economic cost, including fixed and variable cost, from a health provider perspective using a micro-costing approach was estimated. By using the information collected from the two testing models, a decision-tree model using TreeAge Pro 2019 was built to explore the cost-effectiveness of these two HIV testing models delivered to a population of 10,000 people. We report costs using US dollars (2018).

RESULTS: From January 2017 to December 2018, a total of 4,633 men tested in the HIVST model, and 1,780 men tested in the HIV-RDT model. The HIV test positivity was 3.3% (95% confidence interval (CI): 2.8-3.9) and 7.1% (95% CI: 5.9-8.4) for the two models, respectively. The mean cost for testing an individual using HIVST was $7.21 and using HIV-RDT was $30.70. HIVST dominates HIV-RDT in both HIV testing and the number of men diagnosed with HIV ($9.19 vs. $36.59 per person tested, and $274.82 vs. $516.88 per person diagnosed) and diagnosed more men with HIV (155 vs. 126).

CONCLUSIONS: This study confirms that compared to facility-based HIV-RDT, a community-based organization led HIVST program is a cost-saving approach to testing and diagnosing MSM living with HIV in China.

PEE1370

SOCIAL CONTRACTING WITH CIVIL SOCIETY ORGANIZATIONS (CSO): AN EFFECTIVE APPROACH FOR SUSTAINABLE HIV/AIDS RESPONSE

H. Nguyen Thi Mai[1], M. Hoang Van[2], D. Nguyen Thuy[2], H. Pham Thai[1], T. Nguyen Mai[1]
[1]Center for Community Health Research and Development, Hanoi, Vietnam, [2]Hanoi University of Public Health, Hanoi, Vietnam

BACKGROUND: In Vietnam, community-based organizations (CBO) have made significant contributions to the achievements of the national HIV/AIDS program. However, the financial sustainability of community-based HIV service deliveries is now one of the greatest challenges for the national HIV prevention efforts. In 2018, the Government of Vietnam just initiated a process to develop new policies for integration of community-based service deliveries into the national program and budget. The study was conducted in response to the request of the Ministry of Health to provide more accurate information about the actual costing and cost-effectiveness of the services provided by the community-based organizations for such policy development.

METHODS: The activity-based costing ingredient approach was employed to calculate the average cost of community-based HIV/AIDS service deliveries provided by local CSO/CBO under an USAID funded project in four provinces of Vietnam during 2015-2018. A static model was adopted from Holtgrave DR. et al. to estimate the potential health impacts of the CBO-based services in comparison with the facility-based. Key indicators selected for assessment included HIV transmission avoided and DALY averted. Empirical data on HIV diagnosed and referred for treatment by both the community-based and facility-based HIV/AIDS services was used as the main input.

RESULTS: The potential health impacts of the CBO-based services were significantly higher than those of health facilities in terms of HIV transmission prevention (237.6 cases vs. 124.4 cases) and number of DALY averted (1,077.9 DALYs vs. 577.4 DALYs). The average cost for the community-based service for finding one new HIV positive case is about US$ 498 and US$ 547 for both finding and linking a new HIV positive case to treatment. This cost ranged from US$ 221 in urban areas to US$ 1,100 in mountainous areas.

CONCLUSIONS: Study results showed that the CBO-based model was cost-effective in reducing HIV transmission and had good impacts on burden of health and healthcare cost outputs. Further analysis of the social and political context should be pooled out for effective implementation in the actual setting.

PEE1371

HEALTH IMPACT AND COST-EFFECTIVENESS OF HIV TESTING, LINKAGE, AND EARLY ART IN THE BOTSWANA COMBINATION PREVENTION PROJECT

S. Resch[1], J. Foote[2], K. Wirth[1], A. Lasry[3], J. Scott[2], J. Moore[3], F. Shebl[2], T. Gaolathe[4], R. Lebelonyane[5], M. Mmalane[4], P. Bachanas[3], L. Yu[2], J. Makhema[4], M. Pretorius Holme[1], M. Essex[1], M.G. Alwano[6], S. Lockman[1], K. Freedberg[2]
[1]Harvard T.H. Chan School of Public Health, Boston, United States, [2]Massachusetts General Hospital, Medical Practice Evaluation Center, Department of Medicine, Boston, United States, [3]Centers for Disease Control and Prevention, Atlanta, United States, [4]Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana, [5]Botswana Ministry of Health and Wellness, Gaborone, Botswana, [6]Centers for Disease Control and Prevention, Gaborone, Botswana

BACKGROUND: The Botswana Combination Prevention Project (BCPP) tested the impact of universal test and treat (UTT) on HIV incidence. Through HIV testing campaigns, improved linkage, and expanded ART eligibility, UTT increased ART coverage and decreased HIV incidence. Our objective was to project the long-term clinical impact and cost-effectiveness of UTT.

METHODS: Based on BCPP results, we estimated the additional cost of universal testing and linkage (US $1.79M) and the number of people with HIV (PWH) started on ART with the intervention compared to control (n=1,284). To project the impact of early HIV detection and ART initiation seen in the intervention, we compared two strategies using the Cost-Effectiveness of Preventing AIDS Complications (CEPAC) model: (1) *UTT*: PWH were tested, in care and on first-line ART at model start, and (2) standard of care (*SOC*): counterfactual in which the same PWH were unlinked to care at model start, with a probability of HIV detection (3%/ month) and linkage (86%) thereafter. Key model inputs were from BCPP data; outcomes included quality-adjusted life years (QALYs), lifetime costs, and per-person first-order transmissions over 10 years. We calculated incremental cost-effectiveness ratios (ICERs, $/QALY) from discounted (3%/year) QALYs and costs, defining cost-effective as an ICER <$4,150/QALY (0.5x Botswana *per capita* GDP). In sensitivity analysis, we varied the additional number of PWH started on ART and UTT cost.

RESULTS: For each additional person started on ART in *UTT*, life expectancy increased by 0.86 QALYs, costs increased by $2,300, and 0.12 first-order transmissions over 10 years were averted compared to *SOC* (Table). Including the impact to those for whom infection was averted, *UTT* increased life expectancy by 1.26 QALYs and costs by $1,300 per additional PWH started on ART; the ICER for *UTT* was $1,000/QALY. In sensitivity analyses, *UTT* was cost-effective over plausible parameter ranges.

	Excluding the impact on HIV transmissions		Including the impact on HIV transmissions (first-order, over 10 years)				
	QALY [a]	Cost [a], US $	Per-person transmissions	QALY [a]	Cost [a], US $	$/ averted transmission [a]	ICER [a], $/ QALY
SOC	15.74	10,200	0.20	15.09	11,900	-	-
UTT	16.60	12,500	0.18	16.35	13,200	11,000	1,000
Difference	0.86	2,300	-0.12 [b]	1.26	1,300	-	-

SOC, standard of care; ***UTT***, universal test and treat; **QALY**, quality-adjusted life year; **ICER**, incremental cost-effectiveness ratio.
[a] Discounted at 3%/ year.
[b] When scaled to the 1,284 people with HIV started on ART, 146 transmissions were averted due to *UTT*.

[Table. Clinical and economic outcomes of the UTT intervention compared to SOC per additional person started on ART (n=1,284)]

CONCLUSIONS: Enhanced HIV testing, linkage, and early ART initiation will improve life expectancy, reduce HIV transmission, and be cost-effective in settings like Botswana.

PEE1372

POINT OF CARE TESTING FOR HIV CARE IS COST-EFFECTIVE IN SOUTH AFRICA

M. Sharma[1], E. Mudimu[2], K. Simeon[3], A. Bershteyn[4], J. Dorward[5], L. Violette[1], K. Thomas[1], D. Donnell[1], S. Abdool Karim[6], C. Celum[1,3], N. Garrett[7], P. Drain[1,3]
[1]University of Washington, Department of Global Health, Seattle, United States, [2]University of South Africa, Pretoria, South Africa, [3]University of Washington, Department of Medicine, Seattle, United States, [4]NYU, New York, United States, [5]University of Oxford, Oxford, United Kingdom, [6]Columbia Mailman School of Public Health, Epidemiology, New York, United States, [7]CAPRISA, Durban, South Africa

BACKGROUND: The scale-up of "HIV test and treat" has rapidly increased the number of persons on antiretroviral therapy (ART) requiring treatment monitoring in low-resource settings. Decentralized point-of-care (POC) testing for ART initiation and monitoring can alleviate burden on laboratories and improve clinical outcomes; however its cost-effectiveness is not well-evaluated.

METHODS: We used primary cost data and effectiveness from the STREAM trial in South Africa, which assessed the effect of POC testing for CD4 count, viral load, and creatinine, with task-shifting from professional to lower-cadre registered nurses compared to standard-of-care lab-based testing without task-shifting. We parameterized an agent-based network model, EMOD-HIV, to project the impact of implementing this intervention in South Africa. In our base analysis, we assumed POC monitoring increased viral suppression by 9%, enrollment into community-based ART delivery by 25%, and switching to second-line ART by 1%, as found in the STREAM trial. We assumed POC testing scale-up in moderately sized clinics (initiating 30 patients on ART/month) but varied this assumption in sensitivity analyses. We use a 20-year time horizon, a cost-effectiveness threshold of $500 per disability-adjusted life year (DALY) averted, and report the mean of 250 model simulations.

RESULTS: Implementing the POC testing at 70% coverage of ART patients was projected to reduce HIV infections by 4.5% and HIV-related deaths by 3.9%. In clinics with an average of 30 ART initiations/month, the intervention was associated with an incremental cost-effectiveness ratio (ICER) of $197/DALY averted. Results remained cost-effective when varying background viral suppression, ART dropout, intervention effectiveness within the 95% confidence bound of the trial. Assuming POC testing did not increase enrollment into community ART delivery produced an ICER of $1,149, exceeding the threshold. At higher clinic volumes of 40 or more ART initiations/month, POC testing was cost-saving compared to standard of care. At lower clinic volumes (20 patients initiated on ART/month) ICERs exceeded the threshold at $734 per DALY averted.

CONCLUSIONS: POC testing with task-shifting is a promising strategy to monitor the growing number of ART patients and reach ambitious 95-95-95 targets in Africa. We found this intervention to be cost-effective in moderately-sized clinics and cost-saving in larger clinics in South Africa

PEE1373

COST-EFFECTIVENESS OF NATIONAL NEEDLE AND SYRINGE PROGRAM AND OPIOID SUBSTITUTION THERAPY TO CONTROL HIV OUTBREAK AMONG PEOPLE WHO INJECT DRUGS IN TAIWAN, 2005-2018

Y.-H. Li[1], W.-H. Mo[1], F.-Y. Chu[1], C.-T. Fang[1]
[1]Institute of Epidemiology and Prevention Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan, Province of China

BACKGROUND: Data on effect and cost-effectiveness of needle-syringe programs (NSPs) and opioid substitution therapy (OST) to control HIV outbreak are sparse. Taiwan launched a national NSPs and OST in 2005 to control a nationwide injecting-drug-use-transmitted (IDUT) HIV outbreak. We aimed to assess its effect and cost-effectiveness.

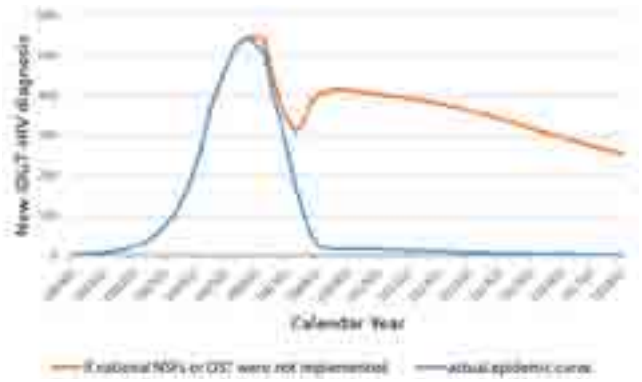
METHODS: We conducted a modelling study to compare the counterfactual scenario (in which national NSPs and OST were never implemented) with the actual epidemic curve from 2005 to 2018. We assessed the cost-effectiveness of natural NSPs and OST during the 14-year time period (2005-2018), using the actual government expenditure data from a payer's perspective. Taiwan National Health Insurance (NHI) provides universal access to antiretroviral therapy and medical care for citizens.

We estimate the lifetime medical cost per new IDUT-HIV case using actual NHI expenditure data with extrapolation of survival curve and the associated medical cost to 50 years after diagnosis, taking a 3% annual discount rate.

RESULTS: National NSPs and OST averted 10,930 IDUT-HIV cases in Taiwan during 2005-2018 (Figure), with a total gain of 146,983 QALYs. National NSPs and OST cost 2.9 million US dollars annually, but averted HIV-associated medical cost up to a total of 1.35 billion US dollars, and therefore are highly cost-effective with a cost-saving ratio of 38.9 per dollar invested (range: 19.4 to 77.8, by sensitivity analysis, see Table).

	Annual cost of NSPs and OST (thousand US dollar)	Total lifetime medical cost (million US dollar)	Averted cases	Total QALYs gained (thousand QALYs)	ICER	Cost-saving ratio
Best estimate	2,987	1,352	10,930	146.9	Dominated	38.9
One-way sensitivity analysis						
Cost of NSPs and OST (50%-200%)	1,449-5,794	1,352	10,930	146.9	Dominated	19.4-77.8
Lifetime medical cost (50%-200%)	2,897	676-2,704	10,930	146.9	Dominated	19.4-77.8
Number of averted cases (±5,000)	2,897	1,352	5,930-15,930	146.9	Dominated	21.0-56.7
QALYs gained/ averted cases (2.3-26.4)	2,897	1,352	10,930	25.6-289.0	Dominated	38.9

[Table. Estimates for incremental cost-effectiveness ratio (ICER) and Sensitivity analysis]



[Figure. Effect of NSPs and OST]

CONCLUSIONS: NSPs and OST, when scaled up to national level, could be highly effective in controlling IDUT-HIV outbreak and highly cost-saving in term of public expenditure.

PEE1374

COST-EFFECTIVENESS OF THE HEALTH RESOURCES AND SERVICES ADMINISTRATION'S RYAN WHITE HIV/AIDS PROGRAM AND THE PROJECTED IMPACT OF THE UNITED STATES' ENDING THE HIV EPIDEMIC INITIATIVE

R. Goyal[1], M. O'Brien-Strain[2], P. Klein[3], D. Luca[1], A. Jones[2], E. Morris[1], W. Addison[2], P. Mandsager[3], S. Cohen[3], C. Hu[1], J. Hotchkiss[1], J. Gao[1], L. Cheever[3], B. Gilman[1]
[1]Mathematica, Cambridge, United States, [2]Mission Analytics Group, San Francisco, United States, [3]Health Resources and Services Administration, HIV/AIDS Bureau, Rockville, United States

BACKGROUND: With an annual budget of $2.3 billion, the Health Resources and Services Administration's Ryan White HIV/AIDS Program (RWHAP) is the third largest source of public funding for HIV care and treatment in the United States. The RWHAP is a key player in the Administration's Ending the HIV Epidemic in the U.S. (EHE) initiative.
Given the complexity of the RWHAP comprehensive system of care, there is little economic modeling to estimate the cost-effectiveness of the current RWHAP or the projected impact of the expanded role of the RWHAP with the EHE Initiative.
METHODS: Using an agent-based, stochastic model, we estimated projected health care costs and health outcomes (a) in the presence of the RWHAP relative to a scenario where the RWHAP was not available over a 50-year time horizon, and (b) under the EHE Initiative with increased diagnosis, linkage to care, re-engagement, and viral suppression compared with the current RWHAP over a 10-year time horizon.
RESULTS: Over a 50-year time horizon, the RWHAP is associated with a 25 percentage point increase in viral suppression, an 18% decrease in new HIV infections, and a 31% decrease in the number of deaths. Compared to the non-RWHAP scenario, the number of quality-adjusted life years (QALYs) would be 2.7% higher, and cumulative health care costs would be 25% higher, yielding an incremental cost-effectiveness ratio of $29,573/QALY. Under the 10-year period of the EHE Initiative, over 700,000 people with HIV are projected to be served by the RWHAP, approximately 200,000 more than the current RWHAP. Decreases in new HIV infections and deaths and increases in viral suppression are primarily driven by activities to re-engage people with HIV who were previously lost to care.
CONCLUSIONS: This agent-based, stochastic model of HIV care in the United States can serve as a template for the use of large-scale and diverse datasets to model complex, national systems of HIV care. The RWHAP plays a critical and cost-effective role in the United States' public health response to the HIV epidemic. This cost-effective model of a comprehensive system of HIV care and treatment can be applied to other global contexts.

PEE1375

THE COST OF COMMUNITY-BASED ART INITIATION AND RESUPPLY IN SOUTH AFRICA AND UGANDA: EVIDENCE FROM THE DO ART STUDY

A. Roberts[1], S. Asiimwe[2], H. Van Rooyen[3], K. Sausi[3], N. Sithole[4], A. Van Heerden[3], P. Joseph[3], T. Schaafsma[1], M. Krows[1], M. Shahmanesh[4], J. Baeten[1], C. Celum[1], R. Barnabas[1], DO ART Study Team
[1]University of Washington, Seattle, United States, [2]Integrated Community Based Initiatives, Kabwohe, Uganda, [3]Human Sciences Research Council, Sweetwaters, South Africa, [4]Africa Health Research Institute, Somkhele, South Africa

BACKGROUND: Community-based HIV programs increase ART uptake and retention by simplifying access to HIV care. However, programs that deliver ART closer to clients may incur additional costs compared to clinic-based programs.
METHODS: We conducted a microcosting study at one site in Uganda (UGA) and two sites in South Africa (SA-SW and SA-NE) participating in the Delivery Optimization for Antiretroviral Therapy (DO ART) Study. Participants initiated ART at a community location and received refills at one month and then quarterly for 12 months. ART was delivered by nurses, who received standardized Ministry of Health (MOH) training. We estimated the annual per-client ART cost from the MOH perspective. We categorized costs as either fixed (personnel, start-up, equipment, vehicles, and overheads) or variable (drugs, lab tests, fuel, and consumables). To project costs under routine program administration, we used public sector salaries for personnel. In the "steady-state" scenario, we calculated costs assuming the steady state volume achieved during the study was maintained for 12 months. Last, in the "efficient" scenario, we used time-motion studies to estimate the increase in the number of clients that could be seen per day by field teams. All costs are reported in 2018 USD.
RESULTS: At steady-state using public sector prices, the annual per-client ART cost was $555 (UGA), $523 (SA-SW), and $446 (SA-NE). Costs were driven by personnel (32-50%), drugs (20-26%), and lab tests (6-13%). From time-motion studies, we estimated field teams could conduct a maximum of 7 (UGA), 13 (SA-SW), and 11 (SA-NE) client visits per day, due to site-specific differences in travel times and encounter lengths. Under this "efficient" scenario, the annual per-client ART cost was $217 (UGA), $312 (SA-SW), and $308 (SA-NE), with drugs (38-50%) constituting the majority of costs.
CONCLUSIONS: Community ART delivery was feasible but incurred higher costs with low client volumes compared to estimated costs from facility-based programs in Uganda ($270) and South Africa ($249). Increasing client volumes, lengthening the prescription interval and task shifting for refill visits would reduce per-client costs of community ART delivery. The cost-effectiveness of community ART will depend on both economies of scale and health outcomes compared to facility-based care.

WHAT WILL IT TAKE TO 'END THE HIV EPIDEMIC' IN THE US? AN ECONOMIC MODELING STUDY IN 6 CITIES

B. Nosyk[1,2], X. Zang[2,1], E. Krebs[2], B. Enns[2], J. Min[2], C. Behrends[3], C. Del Rio[4], J. Dombrowski[5], D. Feaster[6], M. Golden[5], B. Marshall[7], S. Mehta[8], L. Rosen-Metsch[9], A. Pandya[10], B. Schackman[3], S. Shoptaw[11], S. Strathdee[11], Localized Economic Modeling Study Group

[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Weill Cornell Medical College, Healthcare Policy and Research, New York, United States, [4]Emory University School of Medicine, Rollins School of Public Health, Atlanta, United States, [5]University of Washington, Department of Medicine, Division of Allergy and Infectious Disease, Seattle, United States, [6]University of Miami, Department of Public Health Sciences, Leonard M. Miller School of Medicine, Miami, United States, [7]Brown University, School of Public Health, Providence, United States, [8]Johns Hopkins University, Department of Sociomedical Sciences, Mailman School of Public Health, Baltimore, United States, [9]Columbia University, Department of Sociomedical Sciences, Mailman School of Public Health, New York, United States, [10]Harvard T.H. Chan School of Public Health, Department of Health Policy and Management, Boston, United States, [11]University of California, School of Medicine, Los Angeles, United States

BACKGROUND: The HIV epidemic in the US is a collection of diverse microepidemics. New targets have been proposed to 'End the HIV Epidemic' and reduce HIV incidence by 90% within 10 years. We aimed to identify the highest-valued combinations of evidence-based interventions to reach these targets in six US cities.

METHODS: Using a dynamic HIV transmission model calibrated on epidemiological and structural conditions for Atlanta, Baltimore, Los Angeles (LA), Miami, New York City (NYC) and Seattle, we assessed 16 evidence based interventions (HIV prevention, testing, ART engagement and re-engagement) to identify strategies providing the greatest health benefit while remaining cost-effective (23,040 total combinations). Outcomes included averted HIV infections, quality-adjusted life-years (QALYs), total costs and incremental cost-effectiveness ratios (ICERs) (healthcare perspective; 3% annual discount rate; 2018$US). We evaluated combinations of interventions for each city, delivered at previously-documented (drawn from best available evidence) and ideal implementation (90% target population coverage) from 2020 to 2030, compared to the status quo (access to care held constant at 2015 levels) with outcomes evaluated until 2040.

RESULTS: Optimal strategies implemented at previously-documented scale-up included between nine (Seattle) and thirteen (Miami) interventions, and resulted in incidence reductions of 30.7%(95%CI: 19.1%-43.7%) (Seattle) to 50.1%(41.5%-58.0%) (NYC) by 2030, at ICERs ranging from cost-saving in Atlanta, Baltimore, and Miami to $95,416/QALY in Seattle. Implementing the optimal strategies at previously-documented scale-up would entail present-valued savings of $474M[$214M-$895M] in Miami to incremental expenditures of $1.06B[$0.56B-$1.51B] in NYC over the 20-year time horizon, peaking in 2023-25 (an additional $15M annually in Seattle to $179M in NYC).

The costliest strategy on the health production function was not optimal for any city and, in Miami, the absolute costliest strategy produced only 30.1% of the health benefits of the optimal strategy, at an incremental cost of $0.99B.

Under ideal implementation, Atlanta, Baltimore and Miami approached incidence reduction targets (74.4%[67.0%-80.7%], 83.6%[70.8%-87.0%] and 78.3%[51.5%-86.9%] respectively) with LA, NYC and Seattle reaching 41.5%[30.5%-56.1%], 58.1%[48.1%-66.9%] and 39.5%[26.3%-53.8%] incidence reductions, respectively (weighted average of 63.5% across cities).

CONCLUSIONS: Evidence-based interventions can provide good value; however, addressing social and structural barriers to HIV care will be necessary to reach new targets.

PEE1377

A COST CONSEQUENCE ANALYSIS OF THE INCORPORATION OF DOLUTEGRAVIR/ RILPIVIRINE INTO THE CURRENT HIV TREATMENT ENVIRONMENT IN CHINA

S. Zelt[1], D. Xuan[2], J. Xuan[2]

[1]Johnson & Johnson, Global Public Health, New Brunswick, United States, [2]Sun Yat-Shen University, Health Economic Research Institute, Guangzhou, China

BACKGROUND: While still not curable, progress in antiretroviral treatment (ART) has transformed HIV infection to a chronic condition. Dolutegravir/rilpivirine (JULUCA®) is the first NRTI-sparing dual antiretroviral regimen approved for the maintenance therapy of HIV-1 infection in adults who are virologically suppressed on a stable antiretroviral regimen for at least 6 months and with no history of virologic failure. Its adoption into a resource limited setting such as China has the potential to fill an unmet need by mitigating the effects of long-term toxicity and further improving compliance in HIV-infected patients. By addressing these toxicity concerns, the Chinese healthcare system stands to gain from decreased number of healthcare visits and overall costs.

The objective of the current model is to evaluate the cost consequence of introducing dolutegravir/rilpivirine into the current standard of care (SOC) for HIV infection treatment in China, where resources for HIV treatment are limited.

METHODS: The cost-consequence of switch to dolutegravir/rilpivirine in the Chinese treatment environment over the course of a 100-week period was evaluated. Model parameters such as HIV prevalence and ART/dolutegravir/rilpivirine efficacy were taken from clinical trials and literature. Other inputs such as costs, market distribution, and treatment/diagnosis inputs were obtained from a multi-hospital network survey conducted in China and an HIV burden of illness study within Shanghai.

RESULTS: The cost-consequence analysis showed that dolutegravir/rilpivirine had an overall beneficial cost-consequence on the Chinese healthcare system when it was introduced into the HIV treatment environment. Over the course of 100 weeks, the dolutegravir/rilpivirine scenario with a market share of 14% had an overall cost of approximately ¥66,800,000 while the standard of care scenario without dolutegravir/rilpivirine had an overall cost of approximately ¥69,400,000. This change in cost (¥2,600,000 or 3.74%) was primarily driven by a reduction in drug, AE, complication, and clinical monitoring costs.

CONCLUSIONS: The introduction of dolutegravir/rilpivirine represents a cost-effective alternative for HIV therapy. While our cost-consequence model is populated in the context of the Chinese market, the model is built to characterize the cost drivers for consideration in other resource limited settings as well.

PEE1378

ANCILLARY BENEFITS OF CONTINUING EMERGENCY DEPARTMENT OPT-OUT HIV TESTING

M. Buitron[1], C. Hathaway[1], S. Glass[1], T. Cantrell-Warren[2]
[1]Dignity Health St Mary Medical Center, CARE Center, Long Beach, United States, [2]Long Beach Dept of Health and Human Services, Community Health Bureau, Long Beach, United States

BACKGROUND: Persons who access an emergency department (ED) for health services are disproportionately affected by HIV. This includes active drug users, homeless, persons with STDs, and untreated mental illness. While limited start-up funding was available for HIV testing, a case can be made from both an economic and public health standpoint for continued HIV testing and for nominal costs to be absorbed by the hospital.

DESCRIPTION: Near the conclusion of a Gilead-funded ED HIV testing program, the benefits of continued opt-out HIV testing were assessed. Two percent of the 4th generation tests performed were reactive, consistent with HIV prevalence in the community; <0.4% incident cases were identified, which is also consistent with estimates of undiagnosed HIV in the community, of 16-24%. More frequently, staff are available to reengage HIV-positive persons out of care, and connect them to housing, mental health, and other social services that support consistent engagement in care and reduce non-reimbursable emergency room visits. In addition, persons requesting post-exposure prophylaxis (PEP) can be referred to outpatient PEP/PrEP services for follow-up and ongoing care. Also, opt-out testing identifies HIV-positive individuals with limited or no current risk factors.

LESSONS LEARNED: Data on costs for laboratory testing and provider time reduces "frequent flyer" visits to the ED to a comparable cost point. From a public health perspective, this type of non-targeted tested helps to identify incident cases of HIV, including six acute infections over the course of four years. Low opt-out rates (<1%) and automated ordering contribute to a 1400% increase in the number of tests performed, year over year. Once automated testing is in place, providers and administration are more likely to support ongoing testing as a community benefit and an aid in medical decision making.

CONCLUSIONS/NEXT STEPS: Automated HIV testing was implemented as part of the rollout of new electronic medical record software, the algorithms were beta-tested in the rollout site and will later be available to over thirty hospitals in the network. In addition, the State of California was able to use lessons learned from this opt-out testing program to inform recommendations to the legislature for the expansion of opt-out testing throughout the state.

OUT-OF-POCKET HEALTH SPENDING WAS NOT ASSOCIATED WITH MISSED APPOINTMENTS FOR ADULTS ON ANTIRETROVIRAL THERAPY IN CÔTE D'IVOIRE

M. Msukwa[1], R. Stelmach[2], M. Rabkin[3], K. Abo[4], I. Ahoba[4], M. Gildas Anago[5], R. Boccanera[6], H. Brou[5], R. Flueckiger[2], K. Hartsough[3], J. Zech[3], R. Nugent[2]
[1]ICAP at Columbia University, Pretoria, South Africa, [2]RTI International, North Carolina, United States, [3]ICAP at Columbia University, New York, United States, [4]Programme National de Lutte contre le SIDA (PNLS), Abudja, Cote D'Ivoire, [5]ICAP at Columbia University, Abidjan, Cote D'Ivoire, [6]Health Resources and Services Administration (HRSA), Bethesda, United States

BACKGROUND: HIV epidemic control in West Africa has been suboptimal. Although this challenge is multifactorial, the region has some of the world's highest out-of-pocket (OOP) health expenditures, and user fees are common in the public sector. In Côte d'Ivoire (CI), the government provides free antiretroviral therapy (ART) but charged user fees for HIV treatment until early 2019.

METHODS: From March-May 2019, we used an interviewer-administered survey to evaluate OOP spending in a convenience sample of 400 adults receiving HIV treatment at 10 public health facilities in urban and rural CI. Eligibility criteria included being on ART for ≥ 1 year and missing ≥ 1 appointment in the past year. Data were analyzed using descriptive statistics, simple linear regressions, and bootstrapped confidence intervals.

RESULTS: 365/400 participants (91%) reported HIV-related OOP expenditures. 136 (34%) reported direct costs (median $2 USD/year [IQR: 1-41]), such as payments for medication, tests, hospitalization and/or supplies. No participants reported paying user fees. 349 (87%) reported indirect costs (median $17 USD/year [IQR 7-41]), primarily payment for transportation and lost wages. Excluding hospitalization costs, the median total cost (direct + indirect) was $14 USD (IQR: 5-43) per year. 15% of participants reported that they spent > 10% of their household income on HIV services.

Participants reported a median of two missed appointments in the past year (IQR: 2-3). Total OOP expenditure was not associated with the number of missed HIV appointments in a simple linear regression (95% CI -0.0004 to 0.0043). The most commonly reported reasons for missing appointments were that participants were travelling or away from home (35%); unable to leave work, school or home (26%); forgot their appointment (21%); or had transportation issues (13%). Only 7% cited OOP expenditures as a reason for missed appointments and only 5% cited costs as their primary reason for missing an appointment.

CONCLUSIONS: Almost all respondents reported OOP spending for HIV services and most of these costs were indirect; transportation was the most common expense. Although OOP spending has been associated with loss to follow up in other studies, it was not associated with missed appointments in this sample of adults retained in ART care.

PEE1380

REACHING PARTNERS THROUGH SECONDARY DISTRIBUTION OF HIV SELF-TESTING IN MALAWI: A COST ANALYSIS OF A PRAGMATIC CLUSTER-RANDOMIZED TRIAL

L.A. Sande[1,2], A.T. Choko[1], G. Nyirenda[1], R. Chilongosi[3], S. Mphande[1], R. Nyirenda[4], C. Johnson[5], K. Hatzold[6], K. Fielding[7], E.L. Corbett[8], F. Terris-Prestholt[2]
[1]Malawi-Liverpool-Wellcome Trust, HIV/TB, Blantyre, Malawi, [2]London School of Hygiene and Tropical Medicine, Global Health & Development, London, United Kingdom, [3]Population Services International, HIV, Blantyre, Malawi, [4]Ministry of Health, Lilongwe, Malawi, [5]World Health Organisation, HIV, Hepatitis & STIs, Geneva, Switzerland, [6]Population Services International, Johannesburg, South Africa, [7]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [8]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom

BACKGROUND: As countries achieve 90-90-90 targets, identifying the remaining undiagnosed people living with HIV (PLHIV) requires innovative and affordable approaches. Here we assess costs of secondary HIV self-test (HIVST) kit distribution through antenatal clinic (ANC) attendees, including "Index" (newly diagnosed) HIV patients, as part of randomized controlled trial in Malawi.

METHODS: Full and incremental (only direct) costs of a three-arm pragmatic trial randomizing 27 government primary clinics were estimated using ingredients-based costing. Standard of care (SoC) invited partners to attend HIV testing services. In HIVST arms, ANC/Index clients received HIVST kits. HIVST+incentive offered partners US$10 to confirm their HIVST result at the clinic regardless of the HIVST result. HIVST interventions were integrated and delivered by un-incentivized government staff. Unit cost per kit/invitation letter distributed and per partner-tested were estimated for each arm.

RESULTS: Uptake of partner-testing increased substantially across arms: from 38.6% SoC to 77.1% and 62.9% in the HIVST-only and HIVST+Incentive arms, respectively. Costs were higher in the HIVST arms (Table 1) but with reach to substantially more partners. To test one partner required distribution of 2.6 letters in SoC, and 1.3 and 1.6 kits, respectively, in HIVST-only and HIVST+Incentive arms. Incremental unit costs per letter/kit distributed were: US$1.79 SoC, US$5.16 HIVST-only and US$5.06 HIVST+Incentive arm. While incremental unit costs per reported partner testing were: US$5.62 SoC, US$6.57 HIVST-only and US$19.08 HIVST+Incentive (linkage) arm (Table).

Cost Item	Numbers and Full Unit Costs (US$) per ANC/Index partner tested*			Numbers and Incremental Unit Costs (US$) per ANC/Index partner tested		
	SoC	HIVST-Only	HIVST+ Incentives	SoC	HIVST-Only	HIVST+ Incentives
Number Kits/Letters distributed	1,550	1,609	1,829	1,550	1,609	1,829
Number (%) Partners HIV-testing	599 (38.6%)	1,241 (77.1%)	1,151 (62.9%)	599 (38.6%)	1,241 (77.1%)	1,151 (62.9%)
Annualized Training (US$)	$2.51	$1.33	$1.85	$2.51	$1.33	$1.85
Personnel & Per Diems (US$)	$3.89	$10.92	$11.00	$0.43	$0.36	$0.44
Test Kits (US$)	$1.00	$3.32	$4.07	$1.00	$3.20	$4.07
Other (US$)	$1.30	$3.16	$3.18	$1.68	$1.68	$1.68
Uptake incentives (US$)**	-	-	$11.04	-	-	$11.04
Total (US$)	US$8.70	US$18.73	US$31.14	US$5.62	US$6.57	US$19.08

[Table. Scenario Analysis: full and incremental costs of HIV Self-Test Integration]

* 3 years annualization of capital costs

** includes incentive administration

CONCLUSIONS: Reaching the remaining undiagnosed PLHIV requires innovative strategies and investment. HIVST secondary distribution can increase partner-testing substantially when fully integrated into existing government services. A linkage intervention (incentivized partner return) increased costs considerably.

SUPPORTING EFFECTIVE LINKAGES BETWEEN MATERNAL AND HIV SERVICES

PEE1381

ELIMINATION OF MOTHER TO CHILD TRANSMISSION OF HIV AND SYPHILIS IN MALDIVES: A SMALL ISLAND NATION EXPERIENCE

A. Hameed[1], M. Suzana[2], F.N. Rafeeq[1], I.N. Ahmed[1]
[1]Health Protection Agency, TB-HIV, Male, Maldives, [2]Maldives National University, Faculty of Health Education, Male, Maldives

BACKGROUND: Maldives an Island nation with low prevalence of both HIV and Syphilis, high level of ANC coverage and institutional deliveries attended by a skilled birth attendant, was validated as a country eliminated mother to child transmission of HIV and Syphilis in 12 June 2019, this paper highlights the process and findings from the data audit, strengths in the existing system and challenges in maintaining the elimination status.

DESCRIPTION: Maldives has eliminated communicable diseases such as malaria (2015), Measles (2017) and filaria (2016). The tiered health system has preventive services integrated. Universal access to antenatal care and screening for syphilis and HIV is ensured through an extensive network of public sector clinics and hospitals, maintains a high coverage of HIV and Syphilis testing among ANC attendees. A national validation committee lead the process of validation, to verify the data a national level data audit of the program, laboratory services, program data was conducted. A mixed method strategy; primary and secondary sources, quantitative and qualitative methods were used for data collection.

LESSONS LEARNED: Annual rate of new HIV infections has ranged from 0-2 cases per 100,000 population and new cases of syphilis have fluctuated from 0-9 per 100,000 population. No cases of MTCT of either HIV or syphilis were detected in the last many years. The audit confirmed the confidence level on universal ANC attendance in years 2016/ 2017 and 100% screening for both HIV and syphilis. The findings established that the impact and process indicators for validation meet and well surpassed the minimum criteria set by the WHO. No case for either vertical infection reported during the last two years and one case of maternal HIV was detected (acquired through blood transfusion in 2014).

CONCLUSIONS/NEXT STEPS: To maintain the elimination status an integrated computerized individual patient ANC record keeping system such as DHIS2 is proposed to strengthen the verification of status sustainability. A post elimination plan with a multi-stakeholder consultative approach is essential, and country wide access to ANC testing for both local and expatriate migrants, through an affordable universal health care system is essential to maintain the high levels of ANC and testing coverage.

PEE1382

ASK-BOOST-CONNECT-DISCUSS (ABCD): FEASIBILITY AND ACCEPTABILITY OF A PEER-DELIVERED M-HEALTH TOOL TO IMPROVE MENTAL HEALTH AMONG PREGNANT AND POSTPARTUM ADOLESCENT GIRLS AND YOUNG WOMEN LIVING WITH HIV

G. Makota[1], L. Phillips[1], C. Laurenzi[2], D. Mark[1], E. Toska[3], C. Wittesaele[4,5], A. Ronan[1], T. Burdock[1], L. Hatane[1], A. Whiting[1], L. Cluver[4,6]
[1]Paediatric - Adolescent Treatment Africa, Cape Town, South Africa, [2]Stellenbosch University, Institute for Life Course Health Research, Department of Global Health, Cape Town, South Africa, [3]University of Cape Town, Centre for Social Science Research, Cape Town, South Africa, [4]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [5]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology, Faculty of Epidemiology and Population Health, London, United Kingdom, [6]University of Cape Town, Child and Adolescent Psychiatry, Cape Town, South Africa

BACKGROUND: Programmatic data from sub-Saharan Africa documents worse health outcomes among pregnant and postpartum adolescent girls and young women living with HIV compared to adults. Qualitative research has highlighted the psycho-social and mental health needs of this highly vulnerable population.

METHODS: Ask-Boost-Connect-Discuss (ABCD) was designed to build capacity among young peer supporters living with HIV to provide psycho-social support for pregnant and postpartum peers in low resource settings. A m-Health application for smart phones was developed as a platform for delivery of care to screen ("Ask"), support ("Boost") and refer ("Connect") young mothers, with embedded supervision ("Discuss"). ABCD was driven by young peer supporters who were engaged across from programme design to evaluation. The Boost component was adapted from the World Health Organization's evidence-based Thinking Healthy Program, a cognitive behavioural therapy intervention for non-specialist delivery in resource-limited contexts. From May 2018 to October 2019, 20 trained peer supporters implemented ABCD for 18-24-year-old young mothers in 15 health facilities across Malawi, Tanzania, Uganda and Zambia., supported by four technical assistants and health workers.

RESULTS: Data included real-time quantitative data via the app (young mothers' attendance and session ratings), as well as five post-hoc qualitative focus groups (n=15 peer supporters) and in-depth interviews (n=16 supervisors and health workers). Attendance rates of the young mothers (n=147) varied from 75% to 88% across sites. Eighty-three percent of young mothers attended at least two-thirds of sessions.

Peer supporters reported that ABCD increased maternal mental health awareness among young mothers, effectively linked them to necessary services and demonstrated the scale of unmet mental health needs to health facility staff. Implementation challenges related to stigma, logistics and recruiting of younger adolescent participants.

CONCLUSIONS: Compared with similar programming for vulnerable adolescent mothers, attendance was high, and ABCD was reported to be feasible, acceptable and responsive to young mothers' needs. The promising findings indicate that mobile technology can equip peer supporters to deliver psycho-social services for young mothers. Outcomes also highlighted the value of partnering with young people to produce feasible and engaging interventions for young populations.

PEE1383

IMPROVING RETENTION AND VIRAL SUPPRESSION AMONG HIV POSITIVE PREGNANT WOMEN IN NAMPULA, MOZAMBIQUE: RESULTS FROM A QUALITY IMPROVEMENT COLLABORATIVE

I. Rondinelli[1], R. Boccanera[2], M. Bonou[3], H. Caliche[4], G. Dougherty[5], S. Franscisco[6], E. Pimentel De Gusmão[4], H. Macul[3], C. Manjate[4], L. Matavel[4], O. Mungambe[3], I. Pereira[7], E. Simbine[4], R. Sutton[1], F. Tsiouris[1], E. Ussene[8], M. Urso[7], M. Vitale[4], L. Walker[1], M. Rabkin[1]
[1]Columbia University, ICAP, New York, United States, [2]Health Resources and Service Administration, HAB/OTCD/Global, Rockville, United States, [3]Ministry of Health, National HIV/AIDS and STI Control Program, Maputo, Mozambique, [4]Columbia University, ICAP, Nampula, Mozambique, [5]University of Columbia, ICAP, New York, United States, [6]FHI360, Nampula, Mozambique, [7]U.S. Centers for Disease Control and Prevention (CDC), Maputo, Mozambique, [8]Ministry of Health, Nampula Province Department of Health, Nampula, Mozambique

BACKGROUND: Although Mozambique has reduced mother-to-child transmission (MTCT) of HIV by achieving high testing and antiretroviral therapy (ART) coverage among pregnant and breastfeeding women (PBF), its MTCT rate remains amongst the world's highest. Approximately 15% of infants born to HIV-positive mothers acquire HIV by the end of breastfeeding largely due to suboptimal retention in care and failure to achieve viral load suppression (VLS) <1,000 copies/mL.We describe results of a quality improvement collaborative (QIC) designed to improve retention and VLS in this population.

DESCRIPTION: In collaboration with Mozambique's Ministry of Health, the U.S. Centers for Disease Control & Prevention, and the Health Resources & Services Administration, ICAP at Columbia University designed and implemented a QIC at 30 health facilities (HF) in Nampula Province. Over a 10-month period (October 2018-July 2019), participating HF aimed to improve 3-month retention and VLS from baseline to 90% among PBF enrolled in antenatal care (ANC). Teams at each HF used the same targets and indicators, conducted root cause analyses, designed and prioritized change ideas, used QI methods and tools to conduct rapid, iterative tests of change, received monthly supportive supervision (SS) visits, and convened quarterly to share results and best practices.

LESSONS LEARNED: QI teams at the 30 HF tested 44 change ideas and received 327 SS visits. Three-month retention rates among all PBF improved from 55% to 74% and VLS improved from 55% to 70%. Among PBF newly diagnosed with HIV, 3-month retention rates improved from 51% to 72% and VLS rose from 55% to 68%. Among the PBF on ART at ANC enrollment, 3-month retention improved from 61% to 76% and VLS improved from 55% to 72%. Five HF (17%) achieved both aims. Successful interventions included linking PBF with nearby mentor mothers, modification of VL results management systems, and in-service training on adherence counseling skills.

CONCLUSIONS/NEXT STEPS: The QIC led to robust improvement in 3-month retention and VLS amongst PBF, although only five HF achieved the aims of 90% retention and VLS. Focused support, empowerment of teams to develop and test local solutions and use of QIC methodology to accelerate the diffusion of innovations were critical to success.

PEE1384

EFFECTIVENESS OF A SIMPLE POST TEST ASSESSMENT TOOL (SPAT) ON HIV TESTING SERVICES IN NAIROBI, KENYA: A LONGITUDINAL STUDY

J. Okal[1], D. Lango[1], J. Matheka[1], D. Mwanga[1], C. Ngunu-Gituathi[2], M. Mugambi[3], M. Owino[2], A. Sarna[4]
[1]Population Council, Nairobi, Kenya, [2]Nairobi County, Nairobi, Kenya, [3]Nascop, Nairobi, Kenya, [4]Population Council, New Delhi, India

BACKGROUND: We evaluated the effectiveness of a simple post test assessment tool (SPAT), in efficiently identifying pre- test and post-test services to facilitate linkage to treatment, care and other support services for newly diagnosed HIV positive individuals compared to standard care in Nairobi, Kenya.

METHODS: 222 newly diagnosed HIV positive clients (both men and women) were recruited into the longitudinal study from 10 health facilities. Participants in the intervention (n=108) and comparison arm (n=114) were followed prospectively for 2 months. In-depth interviews (n=16) were conducted with providers in the intervention sites where SPAT was implemented.

The intervention comprised the use of the SPAT checklist in following key steps addressed at every stage of HTS from when the HIV test is done to referral, and linkage to HIV care services (including pre-test and post-test counselling and support).

RESULTS: Pre-test counselling information on sharing HIV results (I: 96.3% vs. C: 88.6, p=0.003), modes of HIV transmission (I: 93.5% vs. C: 74.6, p=0.000) and window period for HIV infection (I: 78.7% vs. C: 63.2, p=0.000) was higher in the intervention arm. Elements of post-test counselling such as couple testing, prevention of HIV transmission of HIV and condom use increased significantly in the intervention group (p<0.05). Confirmatory HIV testing was higher in the intervention arm (I: 85% vs. C: 25%; p=<0.001). There were no differences between the two groups on referral, linkage, privacy and confidentiality. However, the mean score of ART knowledge significantly increased in the intervention (1.59 to 4.01; p<0.001) than in the comparison arm (from 1.43 to 1.62; p=0.120). Discussion on risk factors for loss to follow up (i.e. alcohol and substance abuse, disclosure, sexual relationships, gender-based violence, sexually transmitted infections, and support groups, P<0.001) was higher in the intervention arm. Providers narratives showed that the SPAT ensured quick action was taken on potential challenges in HTS and the continuum of HIV care.

CONCLUSIONS: The SPAT checklist was effective in enhancing pre-test and post- test counselling, confirmatory testing, knowledge of ART and discussion on risk factors for loss to follow up. The SPAT offers a practical tool to enhance HTS across the continuum of care.

PEE1385

STRENGTHENING COMMODITIES/SUPPLIES MANAGEMENT SYSTEMS AT LOWER LEVEL GOVERNMENT HEALTH CENTERS (HC IIS) POSITIVELY IMPACTS PERFORMANCE OF PMTCT INDICATORS

B. Nsangi[1], P. Niwagaba[1], R. Iriso[1], E. Kayongo[1], K. Baleeta[1], A. Muhwezi[1], N. Tumwesigye[1]
[1]University Research Co., LLC, Jinja, Uganda

BACKGROUND: Despite national progress towards elimination of mother to child transmission of HIV, PMTCT indicators specifically HIV testing at ANC1 and ART initiation among HIV positive pregnant women in the East Central (EC) region remained low by end of 2017 at 87.1% and 72% respectively. Program data review for 11 EC districts showed gaps at HC IIs with HIV testing at ANC1 at 54.6% and ART initiation at 44% vs >95% and >75% respectively at higher-level facilities. Over 66% of health facilities in the region are HC IIs with 33% of the HC IIs accredited to provide PMTCT services. Non-accredited HC IIs do not routinely receive HIV testing kits and ARVs as per the national Essential Medicines List. On average, 35% of women receive ANC services at HC IIs and over 20% of positive pregnant women are identified at HCIIs. To improve PMTCT performance, we strengthened commodities/supplies management systems at HCIIs.

DESCRIPTION: With District leadership support, HCIIs providing ANC were twinned with higher level ART sites that became the distribution points for testing kits and ARV starter packs. Monthly reporting tools were designed to enable reporting by HCIIs. The monthly reports were submitted by the HCIIs to the higher-level ART sites to facilitate accurate ordering and reporting. We analyzed program data at the end of 2019 to assess the impact of strengthening commodities/supplies management systems at HCIIs on regional PMTCT indicators specifically HIV testing and ART initiation.

LESSONS LEARNED: HIV testing at HC IIs improved from 47.5% to 54.6% to 64.4% to 87% in 2016, 2017, 2018 and 2019 respectively leading to a regional improvement from 82.4% in 2016 to 95.3% in 2019. ART initiation improved from 72% in 2017 to 84% in 2019 with ART initiation at HCIIs improving from 44% to 59%. ART initiation at higher-level facilities was >90%. Gaps in provision of testing kits and ARV starter packs at the HC IIs affected performance.

CONCLUSIONS/NEXT STEPS: Provision of PMTCT services at HC IIs is key in achieving the last mile in PMTCT. Strengthening commodities/supplies management systems at these facilities positively impacts PMTCT and their Supply chain management systems should be supported.

APPROACHES TO EFFECTIVE HIV/SRH INTEGRATION

THE BURDEN OF HIV/HCV IN CANADA: MAPPING THE PROGRESS IN SASKATCHEWAN INDIGENOUS COMMUNITIES (2010-2018)

I.M. Khan[1], S. Skinner[2], D. Wardman[3], D. Kupchanko[3], C. Cyr[3], D. Garner[3], J. Mirasty[3], L.A. Smith[3], N. Reed[4], B. Dow[5], L. Jagoe[3], S. Konrad[3], G. Bukassa Kazadi[3], M. Andkhoie[3], G. Akinjobi[6], D. Bryant[7], L. Ahenakew[8], G. Cote[9], N. Ndubuka[10], T. Wong[11]
[1]Government of Canada, Indigenous Services Canada, Regina, Canada, [2]Regina Infectious Disease Clinic, University of Saskatchewan, Department of Medicine, Regina, Canada, [3]First Nations Inuit Health Branch-Sask Region, Indigenous Services Canada, Government of Canada, Regina, Canada, [4]Ahtahkakoop Cree Nation, Nurse Manager, Ahtahkakoop Cree Nation, Canada, [5]First Nations Inuit Health Branch-Sask Region, Indigenous Services Canada, Government of Canada, F, Saskatoon, Canada, [6]Northern Inter Tribal Health Authority, Prince Albert, Canada, [7]Cote First Nations, Cote First Nations, Canada, [8]AhtahKakoop Cree Nations, AhtahKakoop Cree Nations, Canada, [9]Cote First Nations, Cote First Nations, Cote First Nations, Canada, [10]Northern Inter Tribal Health Authority, Northern Inter Tribal Health Authority, Prince Albert, Canada, [11]First Nations Inuit Health Branch, Indigenous Services Canada, Government of Canada, First Nations Inuit Health Branch, Indigenous Services Canada, Government of Canada, Ottawa, Canada

BACKGROUND: To address alarming rates of HIV/HCV in Saskatchewan (SK) indigenous communities on reserves (IC) have undertaken numerous culturally grounded and destigmatizing measures as part of a multidisciplinary robust response, including community driven integrated STBBIs programs termed "Know Your Status" (KYS). Partnership with IC, have received international recognition for the effective outcomes in Canada.

METHODS: To assess SK's progress since 2010, an environmental scan was conducted in 9 areas like investments, community-driven, patient focused KYS programs, health outcomes, epidemiology, treatment outcomes, and use of technology.

RESULTS: The reported new diagnosis rates of HIV (year 2018: 32.1 per 100,000) and HCV (year 2018: 198 cases per 100,000) have remained disproportionately high in SK IC. Access to testing has improved significantly from only 2 rural communities in 2010 to 72 in 2018 (a 53% increase in HIV testing volume since 2014). With a 4 times increase in STBBI funding in 2018/19, SK IC have 27% fully* and 67% partially** implemented KYS programs.

In 2018, SK (909090) specific estimates were 77% for the 2nd 90 and 75% for 3rd 90 respectively. From 2014 to 2018, linkage to HIV care improved from 56% to 100% respectively, the majority being linked to care within one month. Between 2009/10-2018/19, about 1,600 and 1,200 people living with HIV and HCV respectively had received medication coverage. 19 Targeted KYS on site-HIV clinics decreased the HIV rate by 49%. The use of portable technology and telehealth has made a difference in timely starts of ARVs.

HIV-HCV co-infection rates in 2018 remains high (52% of new HIV diagnoses) with injection drug use as the major risk factor (70% of the HIV-HCV co infections). Currently, there are 38 harm reduction sites in 2019 across IC that serves 67% of the population, a significant increase from 2 sites in 2010. There are HCV micro elimination projects underway in two communities. Partner communities receive regular local epidemiological trends and HIV public health case reviews.

CONCLUSIONS: Canada attributes the progress made in SK to Indigenous partnership, multidisciplinary and community lead approaches. The outcomes of KYS have inspired many IC to launch similar response that aims towards healthy outcomes and zero transmission.

PEE1387

RETENTION OF PREGNANT WOMEN LIVING WITH HIV IN PREVENTION OF MOTHER-TO-CHILD TRANSMISSION SERVICES BEFORE AND AFTER PATIENT FEEDBACK SURVEYS IN ESWATINI

C.A. Teasdale[1], A. Geller[2], S. Shongwe[3], A. Mafukidze[4], M. Choy[3], E. Pimental De Gusmao[3], C. Ryan[5], T. Ao[5], T. Callahan[2], S. Modi[2], E.J. Abrams[3]
[1]City University of New York (CUNY), Epidemiology & Biostatistics, New York, United States, [2]US Centers for Disease Control and Prevention (CDC), Atlanta, United States, [3]ICAP-Columbia University, New York, United States, [4]ICAP-Columbia University, Mbabane, Eswatini, [5]US Centers for Disease Control and Prevention (CDC), Mbabane, Eswatini

BACKGROUND: Negative interactions with healthcare providers may impact retention in prevention of mother-to-child transmission (PMTCT) services. We conducted an intervention to improve retention using anonymous patient feedback surveys to assess satisfaction with providers completed by pregnant women attending antenatal care (ANC) at two health facilities in Manzini, Eswatini. Survey data were incorporated into feedback sessions with facility staff to identify rapid quality improvement approaches and improve PMTCT retention.

METHODS: We retrospectively analyzed electronic medical records to compare retention among two cohorts of women living with HIV (WLHIV) newly enrolled in PMTCT during two periods before and after survey implementation (January–February 2017: period 1; January–February 2018: period 2). We compared demographic information, HIV status at the first ANC visit, gestational age, and 3-month and 6-month retention after the first ANC visit (within a 1-month window before/after the anticipated 3-month or 6-month visit). Proportions of women retained at 3 and 6 months were compared using chi-square tests.

RESULTS: In the period 1 cohort (n=102), 60 (58.8%) knew their HIV-positive status at first ANC visit, 42 (41.2%) had a new HIV diagnosis, and 90 (88.2%) had an antiretroviral therapy (ART) start date. In the period 2 cohort (n=124), 77 (62.1%) knew their HIV-positive status, 47 (37.9%) had a new diagnosis, and 109 (87.9%) had an ART start date. Median age was 30 years in both periods; median gestational age at PMTCT entry was 20 weeks in period 1 and 19 weeks in period 2. In period 1, 80.4% of participants were retained at 3 months and 69.6% were retained at 6 months, compared to 83.1% (p=0.60) and 72.6% (p=0.62), respectively, in period 2. Among newly diagnosed women, 85.1% and 76.6% were retained at 3 and 6 months, respectively, compared to 81.8% (p=0.64) and 70.1% (p=0.43) among women with known HIV status.

CONCLUSIONS: We observed high retention rates among pregnant women newly diagnosed with HIV and non-significant differences of PMTCT retention following implementation of patient surveys and healthcare worker feedback sessions. In the Eswatini setting, baseline retention was already high; the intervention may be more successful in countries with lower baseline retention.

PEE1388

IMPACT OF AN INTEGRATED MODEL OF COMBINATION HIV PREVENTION, CARE AND RESEARCH: EXPERIENCE OF THE GOOD HEALTH FOR WOMEN PROJECT IN KAMPALA, UGANDA, 2013-2019

Y. Mayanja[1], A. Ssali[2], D. Bagiire[3], W. Ssenyonga[4], P. Mayaud[1,5], D. Kabatesi[6], R. King[7], J. Seeley[2,5]

[1]MRC/UVRI & LSHTM Uganda Research Unit, HIV Interventions, Entebbe, Uganda, [2]MRC/UVRI & LSHTM Uganda Research Unit, Social Aspects of Health, Entebbe, Uganda, [3]MRC/UVRI & LSHTM Uganda Research Unit, Statistics, Entebbe, Uganda, [4]MRC/UVRI & LSHTM Uganda Research Unit, Central Diagnostic Laboratory Services, Entebbe, Uganda, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Centers for Disease Control and Prevention, Division of Global HIV and TB, Kampala, Uganda, [7]University of California, San Francisco, United States

BACKGROUND: Integrated models combining HIV, Sexual and Reproductive Health (SRH) and other health care services are an effective tool for promoting cost-effective and acceptable HIV interventions for key populations. We report the experience and impact of the Good Health for Women Project (GHWP), which has been providing integrated HIV/SRH services to female sex workers (FSWs) in Kampala, Uganda.

DESCRIPTION: The GHWP was set up as a closed (2008-12) then open (2013-19) cohort of women at high-risk of HIV-infection in Kampala. The clinic enrolled approximately 800 women per year, who were provided with comprehensive HIV/SRH check at enrolment and at quarterly visits, including: HIV counselling and testing, condom distribution, sexually transmitted infections (STI) screening, hepatitis B testing and vaccination, family planning, elimination of mother to child transmission (EMTCT) services, intimate partner violence (IPV) and harmful alcohol consumption prevention. Women were encouraged to bring sexual partners for HIV/STI testing and care.

LESSONS LEARNED: Overall, 6664 women were recruited over 10 years, and 5637 women from the open cohort (2013-19). HIV incidence was 6.0/100 person years in 2008, 4.5/100 in 2009 and 3.0/100 in 2010. In the open cohort, incidence reduced from 4/100 person-years in 2013-14 to 2.7/100 in 2016-17.

In its first year, 355 (26.5%) of 1338 currently enrolled HIV-negative women have initiated pre-exposure prophylaxis (PrEP), with zero incident HIV, 270 male sexual partners (including 36% HIV-positive) have also been followed-up at the clinic. Overall, 100% of participants have accepted HIV testing; 1734 (36%) tested positive, of whom 1233 (71%) have initiated anti-retroviral therapy (ART); and among those with at least 12-months follow-up, viral load suppression was 97%. Condom use increased from 52% to 71% after 12 months in the project while reports of intimate partner violence reduced from 45% to 9%. Baseline STI prevalence (chlamydia, gonorrhoea, active syphilis) among women <25yr is 27%; all received same day STI treatment. Overall, 23% (842/3664) were tested for Hepatitis B infection; of 514 eligible for vaccination, 93% started the vaccination regimen.

CONCLUSIONS/NEXT STEPS: The programme has demonstrated the scalability, uptake and effectiveness of HIV prevention and care services for this population when integrated with SRH and other health care services.

PEE1389

AN INITIATIVE TO INCREASE UPTAKE OF CERVICAL CANCER SCREENING SERVICES AMONG WOMEN LIVING WITH HIV AND BUILD THE CAPACITY OF PROVIDERS IN CERVICAL CANCER SCREENING

E. Msukwa[1], G. Kang'oma[2], S. Ahmed[3]

[1]Baylor College of Medicine Childrens Foundation, Clinical, Lilongwe, Malawi, [2]Baylor College of Medicine Childrens Foundation, Adolescents, Lilongwe, Malawi, [3]Baylor College of Medicine Childrens Foundation, Medical, Lilongwe, Malawi

BACKGROUND: Women with HIV have a four times higher risk of developing cervical cancer if HPV infected compared with women who do not have HIV when infected with HPV. Although screening using visual inspection with acetic acid (VIA) and treatment of pre cancer lesions can help with secondary prevention of cervical cancer, the service is not widely available in Malawi more so among women living with HIV. A major challenge preventing the availability of VIA services at a national scale is that the service is provider-dependent and demands continued mentorship to ensure service quality. And hence a cervical cancer screening week was introduced.

DESCRIPTION: The screening week was conducted from March to May 2019 at high-volume facilities in Mangochi, Salima and Phalombe districts. Community sensitization was conducted prior to and during the screening week. Health talks at the antiretroviral therapy (ART) clinic were given and women linked to the screening services. Any identified pre cancer lesions were treated immediately with thermal coagulation. HIV testing services were provided to women with unknown HIV status. A library of cervical images was used to assess knowledge and skill levels before and after the screening week.

LESSONS LEARNED: A total of 2,016 women were screened with VIA (Mangochi 496, Salima 514, Phalombe 1006). Sixty-six (3.3%) were VIA positive. Among those who were VIA positive, 57 (86.3%) were treated with thermal coagulation on the same day or the day after while 9 (13.6%) were referred for Loop Electrosurgical Excision Procedure. The VIA positivity rate was 5.3% in women with HIV compared to 2.4% in those without HIV. Six (0.3%) women had lesions suspicious of cervical cancer. HIV testing was offered to 952 women and 23 (2.4%) tested HIV positive. The mean pre- and post-intervention scores were 66.2% (range 47.5% - 89.0%) and 76.8% (range 65% to 90%), respectively.

CONCLUSIONS/NEXT STEPS: The initiative strengthened the linkage between ART/VIA clinics and HIV testing services and increased the service demand . Importantly, the initiative demonstrates that it's possible to create demand for cervical cancer screening services and that making such services available at national scale through provider capacity building should be a policy priority.

APPROACHES TO EFFECTIVE HIV/TB SERVICE DELIVERY

PEE1390

PREDICTORS OF INITIAL LOSS TO FOLLOW UP AMONG HOSPITAL-DIAGNOSED HIV-INFECTED TUBERCULOSIS PATIENTS IN CAPE TOWN, SOUTH AFRICA

S.-A. Meehan[1], A.C. Hesseling[1], A. Boulle[2,3], A. von Delft[2,3], P. Hendricks[1], M. Smith[2], A. Heekes[4], M. Osman[1]
[1]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [2]Western Cape Government (Health), Health Impact Assessment Directorate, Cape Town, South Africa, [3]University of Cape Town, School of Public Health and Family Medicine, Faculty of Health Sciences, Cape Town, South Africa, [4]Western Cape Government (Health), Health Impact assessment Directorate, Cape Town, South Africa

BACKGROUND: In South Africa, tuberculosis (TB) remains the most common opportunistic infection for 7,5 million people living with HIV (PLHIV). Estimated TB incidence among PLHIV was 177,000 in 2018. In South Africa, hospital-diagnosed TB patients are referred to primary health care (PHC) facilities for continued clinical care and registration. TB patients not registered are defined as "initial loss to follow up" (ILTFU). We aimed to determine predictors of ILTFU among hospital-diagnosed HIV-infected TB patients in Cape Town, South Africa.

METHODS: Utilizing the Provincial Health Data Centre (PHDC), we identified all patients routinely diagnosed with TB in 2 sub districts, in the Western Cape Province (WCP) during October 2018- June 2019. The PHDC integrates multiple sources of routine health data resulting in single patient records. We stratified TB patients by place of TB diagnosis (PHC vs. hospital), with analysis restricted to HIV-infected TB patients diagnosed at hospital level. A multivariable logistic regression model identified factors associated with ILTFU.

RESULTS: Overall, 942/3561 (26%) patients diagnosed with TB in hospital were HIV-infected; 536/942 (57%) started TB treatment in hospital. 73/942 (8%) died within 14 days of their TB diagnosis. Of 869/942 (92%) eligible for PHC TB registration, 280/869 (32%) were ILTFU (Table 1). Factors associated with ILTFU included starting TB treatment in hospital vs. no TB treatment in hospital (aOR 6.12 95% CI: 4.06-9.24) and not being on ART (aOR 2.28 95% CI:1.44-3.60).

		Diagnosed with TB in Hospital (n=869)	Started TB Treatment in hospital (n=498)	% started TB Treatment in hospital (57%)	Not registered at a PHC facility (ILTFU) (n=280)	% not registered at a PHC facility (ILTFU) (32%)
Sex	female	495	268	54%	151	31%
	male	374	230	61%	129	34%
Age	<15 years	51	28	55%	14	27%
	≥15 years	818	470	57%	266	33%
ART Status	HIV+ no ART	135	84	62%	66	49%
	HIV+ on ART	734	414	56%	214	29%
Site of Disease	Extra-pulmonary TB	386	228	59%	112	29%
	Pulmonary TB	214	74	35%	6	3%

[Table]

CONCLUSIONS: In the WCP, South Africa, ILTFU among HIV-infected patients diagnosed with TB in hospital is high. Patients who start TB treatment in hospital were at significant risk of ILTFU. This requires further investigation, but may be due to severity of disease. Patients on ART were less likely to be ILTFU, possibly indicative of prior and ongoing attendance at PHC services. Improved registration of hospital-diagnosed TB/HIV patients is critical.

PEE1391

IMPROVING UPTAKE OF ISONIAZID PREVENTIVE THERAPY AMONG PLHIV IN COMMUNITIES SERVED BY MILITARY HEALTH FACILITIES IN UGANDA

H. Musinguzi[1], A. Tumusiime[1], E. Lugada[1], D. Bwayo[1], B. Kikaire[2], N. Kak[3], A. Hala[3], J. Akao[4], C. Wamundu[5], A. Musinguzi[5], T. Rwegyema[1], G. Seruwagi[6], S. Lawoko[7]
[1]University Research Co., LLC - Department of Defense HIV/AIDS Prevention Program (DHAPP), Kampala, Uganda, [2]Makerere University/University Research Institute, Kampala, Uganda, [3]University Research Co., LLC, Washington DC, United States, [4]U.S. Department of Defense (DoD), Kampala, Uganda, [5]Directorate of HIV/AIDS, Uganda Peoples Defence Forces (UPDF), Kampala, Uganda, [6]Makerere University, Kampala, Uganda, [7]Gulu University, Gulu, Uganda

BACKGROUND: Globally, TB remains the leading cause of death among People Living with HIV (PLHIV). In Uganda, approximately 40% of TB patients are HIV co-infected, representing a TB incidence of 80/100,000. Although Isoniazid preventive therapy (IPT) is effective in preventing active TB in PLHIV, its uptake remains low. URC-Department of Defense HIV/AIDS Prevention Program implements interventions to improve IPT uptake in Uganda's military setting. We describe strategies and processes used to improve INH uptake in a military setting.

DESCRIPTION: We implemented interventions that included training, onsite mentorship of health workers, provided job aids, strengthened stock management, obtained daily and weekly reporting of INH initiation, supervised all 28 supported military health facilities and implemented differentiated INH service delivery. Data on INH initiation from IPT registers in 28 military health facilities between October 2018 to August 2019 was analyzed.

LESSONS LEARNED: In less than a year we registered 86.5% increase in the numbers of clients initiating INH from 178 in October 2019 to 7,068 in August 2019. IPT uptake improvement requires; dedicated personnel responsible for tracking patients initiated, not started, and those completed treatment. In addition, monitoring stock availability, setting facility level targets, data utilization to improve quality of services and kitting available INH into 6 months courses enhances quality of services offered. The main barrier to INH uptake was commodity stock out.

CONCLUSIONS/NEXT STEPS: This multi-pronged strategy demonstrated an exponential increase in uptake of INH in a military setting. Differentiating IPT delivery is essential in improving uptake among deployed troops. Interventions to address INH supply chain are vital for sustained IPT coverage.

PEE1392

LEVERAGING ZIMBABWE'S COMMUNITY ANTIRETROVIRAL GROUPS (CARGS) TO DELIVER TB PREVENTIVE TREATMENT IS FEASIBLE AND ACCEPTABLE: FINDINGS FROM A MIXED METHODS STUDY

M. Msukwa[1], T. Apollo[2], M. Mapingure[3], R. Boccanera[4], I. Chingombe[3], C. Gwanzura[2], A. Howard[5], J. Mantell[6], T. Masvawure[7], G. Musuka[3], J. Zech[5], M. Rabkin[5]
[1]ICAP at Columbia University, Pretoria, South Africa, [2]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe, [3]ICAP at Columbia University, Harare, Zimbabwe, [4]Health Resources and Services Administration (HRSA), Bethesda, United States, [5]ICAP at Columbia University, New York, United States, [6]Columbia University, Department of Psychiatry, New York, United States, [7]College of the Holy Cross, Department of Sociology and Anthropology, Worcester, United States

BACKGROUND: TB preventive treatment (TPT) coverage for HIV-positive Zimbabweans is suboptimal. As stable patients on antiretroviral therapy (ART) are shifted into less-intensive differentiated service delivery models (DSDM), opportunities to expand TPT coverage and completion may emerge. ICAP and the Zimbabwe Ministry of Health and Child Care (MoHCC) assessed the feasibility and acceptability of integrating TPT into community antiretroviral refill groups (CARGs).

METHODS: We conducted 25 "central-level" key informant interviews (KII) with MoHCC staff, implementers, and clinicians; 20 KII with CARG leaders; 16 focus group discussions (FGD) with 136 CARG members (half of whom had received TPT); and 8 field-based observations of CARG meetings. CARG leader KIIs, FGDs, and CARG observations were conducted at 4 urban and 3 rural health facilities. KIIs and FGDs were transcribed and analyzed using DedooseÔ software with thematic coding and content analysis. Closed-ended questions from KIIs and FGDs and the field-based observations were analyzed using STATA.

RESULTS: 96% of central-level informants and 85% of CARG leaders described providing TPT via CARGs as a "good" or "very good" idea. When presented with hypothetical models for TPT delivery, all cadres strongly preferred approaches that included multi-month TPT dispensing, fewer clinic visits, and monitoring for side effects and incident TB symptoms by both CARG leaders and clinicians rather than the current standard of monthly clinic visits at which one months' worth of TPT is dispensed. Perceived advantages of this model included convenience and access to the ongoing adherence and psychosocial support provided by CARGs. Participants also noted that this approach would require additional training and supervision of CARG leaders. During field-based observations, 2/8 CARG leaders (25%) asked every CARG member if s/he had TB symptoms despite 17/20 (85%) mentioning TB screening as one of their main roles in interviews. 7/16 (44%) had received additional training since becoming CARG leaders in the last 2-3 years.

CONCLUSIONS: Stakeholders agreed that provision of TPT via CARGs would be a feasible and acceptable approach to increasing TPT coverage and completion in Zimbabwe. The perceived need for additional training and supervision of CARG leaders was reinforced by the observation that only 25% screened CARG members for TB symptoms.

PEE1393

TB HIV JOINT RESPONSE IN HUMANITARIAN EMERGENCIES: BRAC EXPERIENCE

F. Khatun[1], A. Islam[1], Q. Al Mamun Siddiqui[1], I. Azmery Rifat[1], S. Islam[2]
[1]BRAC, Communicable Disease, Dhaka, Bangladesh, [2]NTP, TB, Dhaka, Bangladesh

BACKGROUND: Access to health care is more important than ever in humanitarian emergencies such as refugee crisis. There is an influx of Mynmar nationals in Bangladesh from September, 2017. As part emergency response to FDMN (Forcibly displaced Mynmar nationals), BRAC with the support of National Tuberculosis Control Programme (NTP) and National AIDS and STD Programme (ASP) started TB control activities and HIV screening for TB patients for FDMN. People living with HIV are at increased risk of developing TB disease and TB remains the leading cause of death among people living with HIV despite the existence of effective prevention and treatment interventions.

DESCRIPTION: BRAC established 15 laboratories for both TB and HIV services in FDMN. Services include quality microscopy and HIV screening. Health workers from BRAC and other NGOs visit households and screen TB presumptive. Microscopy was done at the laboratories. Gene Xpert & X-ray are referred to government facilities if needed. TB patients are registered at Government centres. DOT is done by community leaders (Majhi) and family members. HIV screening is done for all TB patients and other high risk group. If anybody found positive, referred to Government centre for confirmation followed by registration and ART. Investigation and nutritional support including transportation cost were offered to patients.

LESSONS LEARNED: From September, 2017 to December, 2019, total 6,521 TB patients are diagnosed among FDMN. Among them, 6,090(93%) are bacteriologically confirmed, 188(3%) clinically diagnosed, 116(2%) extra pulmonary and 127(2%) relapses. Also 146 child TB and 5 DR TB is diagnosed among them. HIV screening is done for 5,511 TB patients and 412 high risk group. Total 28 patients found positive among TB patients and 16 became positive among high risk group.

CONCLUSIONS/NEXT STEPS: As TB is the world's leading killer among infectious disease, quality controlled TB diagnosis and free treatment facilities should be provided to emergency situation. In such humanitarian crisis TB and HIV programme should be closely coordinated. Establish and strengthen mechanism for delivering TB HIV collaborative activity should be implemented which will reduce the dual burden of TB and HIV in emergency crisis management.

PEE1394

UPTAKE, YIELD AND LINKAGE TO CARE AFTER HOME-BASED HIV COUNSELLING AND TESTING AMONG HOUSEHOLD CONTACTS OF TUBERCULOSIS PATIENTS IN UGANDA

P.M. Amuge[1], A. Rukyalekere Kekitiinwa[2], R. Tuwayenga[3], B. Kunihira[4], S. Kalyegira[5], G. Taasi[6], D. Lukoye[7], J. Kalamya[7], M. Adler[7], R.M. Odeke[8], M. Patel[9], H. Kirking[10]
[1]Baylor College of Medicine Children's Foundation, Research, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Executive Director, Kampala, Uganda, [3]Elizabeth Glazier Paediatric AIDS Foundation (EGPAF), Medical and Psychosocial, Kampala, Uganda, [4]Baylor College of Medicine Children's Foundation, Strategic Development, Monitoring and Evaluation, Kampala, Uganda, [5]Ministry of Health, Kyenjojo General District Hospital, Kyenjojo, Uganda, [6]Ministry of Health, STIs and AIDS Control Program, Kampala, Uganda, [7]US Centers for Disease Control and Prevention - (CDC Uganda), DGHT, Kampala, Uganda, [8]Baylor College of Medicine Children's Foundation, Medical and Psychosocial, Kampala, Uganda, [9]US Centers for Disease Control and Prevention-Atlanta (CDC Atlanta), DGHT-Maternal and Child Health Branch, Atlanta, United States, [10]US Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: In Uganda, 81% of people living with HIV (PLHIV) know their HIV status, and 40% of TB patients are co-infected with HIV. Few studies document yield of HIV testing from integrated community-based HIV-TB activities. With support from PEPFAR, we evaluated uptake, yield of home-based HIV counselling and testing (HBHCT), and linkage to antiretroviral therapy (ART) among household members of TB patients in a rural Ugandan district.
METHODS: We prospectively enrolled index TB patients from 1st October-2017 to 30th September-2018 and conducted home visits. Household members were screened for TB and HIV following national guidelines. Those at risk for HIV were offered HBHCT and tested by routine counselling and testing volunteers (RCTs) using rapid HIV tests. HIV-exposed infants (HEIs) not enrolled in early infant diagnosis (EID) program were referred for HIV-DNA-PCR testing. Newly diagnosed PLHIV were referred for confirmatory HIV testing and ART initiation. We analysed data to describe the HBHCT cascade (eligibility, uptake and yield, linkage and ART initiation) among household members.
RESULTS: We identified 459 index TB patients of whom 38.5% (165/429 with HIV status available) were co-infected with HIV. We identified 1692 household members (57.8% female, median age 19years) of whom; 33.6% (569/1692) were children of index clients, 21.9% (371/1692) siblings, 9% (153/1692) partners, (102/1692)6% parents, 21.6% (365/1692) other relations and 7.8% (132/1692) unknown relations. Over half (56.0%, 883/1578) self-reported being HIV negative, 5.5% (87/1578) HIV positive and receiving ART, and 39% (608/1578) unknown HIV status. Five hundred thirty five household members with unknown HIV status were eligible for and offered HBHCT, of whom 93.3% (499/535) accepted testing. Of those tested, 2% (10/499) tested HIV positive; 100% (10/10) of identified positives initiated ART. Two members (0.4%) had indeterminate HIV results, one retested negative but one declined retesting. All the identified HEIs (9/9) tested negative by HIV DNA PCR.
CONCLUSIONS: Uptake of HBHCT is high among household members of TB patients. Though HIV positivity yield was low, HBHCT should be designed to optimise testing high-risk household members as an opportunity for successful linkage of PLHIV and HEIs into care.

PEE1395

INTEGRATING TB SERVICES IN HIV/AIDS PROGRAM TARGETING FEMALE SEX WORKERS (FSWS). EXPERIENCE OF GLOBAL FUND PROGRAM IN MALAWI

A. Ngosi[1], D. Kuphanga[1], I. Malomo[1], K. Mshali[1], D. Kambauwa[2], J. Kachingwe[3]
[1]Actionaid Malawi, Global Fund Program, Lilongwe, Malawi, [2]Familly Planning Association of Malawi, Programs, Lilongwe, Malawi, [3]Ministry of Health, HIV/AIDS Department, Lilongwe, Malawi

BACKGROUND: In Malawi it is estimated that 60 percent of FSWs are estimated to be HIV positive. The TB prevalence study has shown that there are 1041 TB cases per 100 000 people and 50 percent of cases remain undetected. HIV/AIDS is fueling a continued increase in TB cases among FSWs. From 2019 the Joint HIV/TB Global fund program is targeting female sex workers with prevention, diagnosis and referral HIV/AIDS and TB services in 11 districts.
DESCRIPTION: To improve TB/HIV integration among FSWs the program established 150 hotspots in the target districts. A total of 200 peer educators and 80 Peer Navigators were trained in TB prevention, screening and referral and were deployed to the hotspots. The PEs and PNs were tasked to offer TB information, screening and referral services. The Peer Navigators offered services to HIV positive FSWs only. FSWs with suspected TB were referred for diagnosis and treatment at a nearest health facility. TB data was tracked monthly using standardized data tools.
LESSONS LEARNED: A total of 5402 FSWs were screened for TB against a target of 4994 representing 108 percent. 301 (5.6%) had signs and symptoms of active TB and only 289 (68 %) were referred for diagnosis. A total of 28 FSWs (8.7 %) were diagnosed with TB. Among HIV positive FSWs, 822 received TB prevention information representing 107%. A total of 786 FSWs were screened for TB, 84 were suspected to have TB representing 10.9 percent. A total of 13 (15.4%) FSWs were diagnosed.
CONCLUSIONS/NEXT STEPS: The integration of TB screening in HIV/AIDS program targeting FSWs has proved to effective with the with Peer educator/navigator model. TB positivity rate was also noted to be higher among HIV positive female sex worker. Although promising results were observed, there is need to ensure that quality of service delivery is observed at service delivery points in all districts. There is also a need to strengthen coordination especially at district and community levels for proper integration of services.

PEE1396

REGULAR TUBERCULOSIS SCREENING OUTREACHES IMPROVE CASE NOTIFICATION RATE IN A REFUGEE CAMP: AN EXPERIENCE AT KYANGWALI REFUGEE SETTLEMENT IN UGANDA

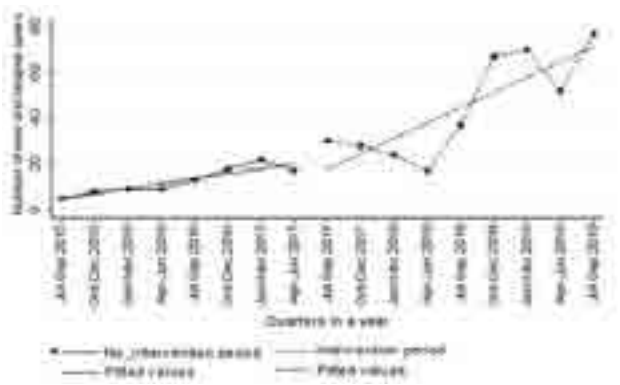
A. Kiyimba[1], I. Senteza[1], H. Baluku[1], J. Timbigamba[2], D. Lukoye[3], D. Bogere[3], M.S. Nabaggala[1], G. Anguzu[1], N. Kalema[1], A.M. Muganzi[1]
[1]Infectious Diseases Institute - Makerere University, Kampala, Uganda, [2]Kikuube district local government, Health, Tuberculosis and Leprosy Supervision Unit, Hoima, Uganda, [3]Centres for Disease Control and Prevention, Kampala, Uganda

BACKGROUND: Reports have shown that Tuberculosis (TB) prevalence among refugee communities is relatively higher than the general population. However, facility-level aggregated program data at Kyangwali HCIII which serves 132,000 refugees in Uganda, indicate a TB notification rate comparable to the national average of 128 per

100,000 populations. We set out to determine the incremental value of, PEPFAR supported, targeted screening outreaches on TB case notification rates (CNR) documented for this settlement

DESCRIPTION: We abstracted data from DHIS2 on TB CNR for the period July 2015-September 2019 for Kyangwali HCIII. We reviewed PEPFAR supported facility TB program reports to establish the baseline TB CNR for the period July 2015-June 2017. We used patient addresses in the TB register, to map TB hotspots and trained health workers on key TB screening processes, data capture, sample collection and handling procedures. Additionally, we engaged other key stakeholders, and mobilised community members for quarterly TB screening using community-based peers for the period July 2017 to September 2019. Health workers identified presumed TB patients in the community, collected and transported sputum samples to the facility for GeneXpert testing. Facility teams delivered results to persons diagnosed with TB with support of community-based peers. We used a modified Poisson model with robust standard errors to compare the mean difference of TB case notification in the pre and post intervention periods.

LESSONS LEARNED: The TB case notification in the post intervention period was associated with a 3.54 higher mean ratio compared to the pre intervention period (mean ratio = 3.54; CI= 2.84 - 4.40) (see trend figure below).



[Figure. Trends of new TB cases post and pre-intervention for the period July 2015 to September 2019 - Kyangwali HCIII]

CONCLUSIONS/NEXT STEPS: Regular targeted TB screening in refugee hot spots improved TB CNR. We recommend that besides the TB screening done at entry into the refugee camps, regular targeted TB screening in hot spots be strengthened and supported to control spread of TB in this population.

PEE1397

LESSONS LEARNED FROM TRANSGENDER WOMEN PEERS OFFERING HIV-SELF TESTING AND ASSISTED PARTNER NOTIFICATION SERVICES IN MALINDI, KENYA

M. Shally[1], M. Dijkstra[2], N. Mukuria[1], F. Ibrahim[3], A. Wesonga[1], W. Kazungu[1], O. Chirro[1], E.J. Sanders[1], E.M. van der Elst[1]
[1]Kenya Medical Research Institute-Wellcome Trust Research Programme, HIV/AIDS Key Populations, Kilifi, Kenya, [2]Public Health Service of Amsterdam, HIV/AIDS, Amsterdam, Netherlands, [3]Kilifi County Department of Health, National AIDS and STI Control Programme, Kilifi, Kenya

BACKGROUND: Transgender women (TGW) are a newly emerging key population in Kenya, with a high burden of undiagnosed HIV, often not engaged in the HIV prevention and care response. We assessed whether HIV self-testing (HIVST) and assisted partner notification services (APNS) (the first 90), facilitated by TGW peer educators from LGBTQ Community-Based Organizations (CBOs), would enable testing LGBTQ members, and link newly HIV infected peers into care.

DESCRIPTION: In April-August 2019, 10 TGW peer educators, trained on confidentially, referring and linking their peers into care, extended HIVST kits (Ora-quick) to LGBTQ members in Malindi. After HIV status confirmation of mobilised participants at the research clinic, indexes' sexual partners were contacted by the TGW peer educators and HIV testing discussed. TGW used their knowledge of LGBTQ sexual networks (i.e. bars, private meeting places, and time of day that peers gather) as entry points to contact sexual partners. Partners were referred to the clinic for HIV testing, and offered immediate ART when infected.

LESSONS LEARNED: Out of 379 HIVST distributed, 290 LGBTQ members reported for confirmatory testing with median age 27 years (interquartile range (IQR): 23-33). Twelve participants (4.1%) were newly diagnosed, of whom 11 immediately initiated ART after a median of 1 (IQR 0-14) days. Sixteen participants, including 4 sexual partners became index participants for APNS. A total of 65 sexual partners (20 females; 36 males; 9 TGW) were identified. For 20 partners (30.5%) no lead or contact details were available, hence they could not be traced. Of the remaining 45 traced partners, 18 (15 males and 3 females) were known HIV positive, and 2 females were newly diagnosed. A total of 14 (7 males and 7 female) tested HIV negative, while 3 TGW were known HIV positive and 6 TGW tested HIV negative. One male and 1 female refused HIV testing.

CONCLUSIONS/NEXT STEPS: Within an interconnected community, TGW peer-led HIVST followed by APNS identified undiagnosed HIV-infection. TGW's understanding of sexual network characteristics of the LGBTQ community, and efforts reaching out to peers helped to inform, fine-tune, and amplify the potential effectiveness of HIVST and is a promising strategy to further optimize APNS.

PEE1398

CONFRONTING TB/HIV COLLABORATIVE CHALLENGES IN HARD-TO-REACH CONFLICT AREAS IN MYANMAR

M. Kay Khine[1], A. Yu Naing[1], K. Wut Yee Kyaw[1], N. Shwe Yee[1]
[1]Asian Harm Reduction Network, Medical, Yangon, Myanmar

BACKGROUND: Northern Myanmar is facing prolonged internal armed-conflicts, poverty, widespread drug use and a high HIV and TB burden. HIV prevalence among people who inject drugs (PWID) is as high as 61% and during 2017 up to 16% of TB deaths in Myanmar were among people living with TB and HIV co-infection. In the remote hard-to-reach areas, people live without knowing their HIV and TB status and have limited access to services provided at public health settings.

DESCRIPTION: AHRN operate nine clinics/drop-in-centers (DICs) and one TB active case finding (ACF) team in Kachin State. Since 2017 AHRN harm reduction cascade integrate innovative TB/HIV point-of-care (PoC) services. The ACF team, equipped with a portable digital X-ray machine, sputum microscopy and HIV testing service (HTS) is covering remote shooting galleries and other hard-to-reach areas, to find missing TB cases. Once TB diagnosed, HTS is offered and TB DOTS providers are assigned for each patient, making monthly home visits and provide accompanied referral to ART centers. They give emotional support, educate and counsel on the importance of ART and anti-TB treatment.

LESSONS LEARNED: TB/HIV collaborative activities have significantly improved after the introduction of this innovation. Patients trust, awareness of the importance of treatment and adherence significantly increased. From 2015 to 2018 1,578 TB patients were diagnosed and among them 512 (32.4%) were TB/HIV co-infected. Annual data shows TB patients with HIV results has increased from 68.4%, 81.9%, to 92.4%, 95.8% with the HIV positivity rate of 35.2%, 25.1%, 39.5% and 46.1% respectively. The percentage of TB patients living with HIV receiving co-trimoxazole preventive therapy has increased from 76.7%, 86.8% to 96.5%, 94.8% and ART from 28.9%, 39.7% to 56.3%, 70.1%.
CONCLUSIONS/NEXT STEPS: Integration of point-of-care HTS into clinics/DICs and ACF substantially increases testing uptake and referral linkages to treatment and care. Community-based DOTS provider plays a critical role in ensuring adherence to anti-TB treatment and uptake of ART improved significantly. The outcomes suggest to expand this strategy to other hard-to-reach areas and scale up ART coverage among TB-HIV co-infected cases.

PEE1399

MOBILIZING LOCAL ORGANIZATIONS TO MAKE A GREATER CONTRIBUTION TO ACHIEVING EPIDEMIC CONTROL: AN EXPERIENCE OF DEVELOPMENT AID FROM PEOPLE TO PEOPLE ON A CDC-FUNDED HIV/AIDS PROJECT IN ZAMBIA

J. Kanyanda[1], DAPP TCE Study group
[1]*Development Aid People to People, Total Control of the Epidemic, Lusaka, Zambia*

BACKGROUND: The local Zambian NGO Development Aid from People to People (DAPP) and the Provincial Health Office (PHO) of the Zambian Ministry of Health (MoH) are jointly implementing a four-year (2019-23) project to reach HIV epidemic control in seven districts of Eastern Zambia through implementation of optimal community HIV services. The project is implemented by DAPP and the PHO with funding and technical assistance from the U.S. Centers for Disease Control and Prevention (CDC) and strategic leadership from the Government of the Republic of Zambia (GRZ). Programmatically, the project aims to increase uptake of targeted HIV testing in Eastern Zambia. Strategically, the project aims to demonstrate how international donors (such as CDC), governments (such as GRZ), and local organizations (such as DAPP) can cooperate to assist a country to reach its 95-95-95 targets and achieve epidemic control in a country-led and cost-effective way and as a model for replication.
DESCRIPTION: On the intervention, local Health Center staff link already-identified people living with HIV – known as "index clients" – with DAPP's community-based Field Officers (FOs). The FOs elicit from index cases lists of sexual contacts. FOs locate the sexual contacts and offer HIV screening and testing, facilitating immediate ART initiation for those testing positive. The project aims to elicit at least 3 contacts per index client, test a minimum of 70% of eligible contacts, achieve a positivity rate of 30%, and successfully link to treatment at least 95% of people testing positive.
LESSONS LEARNED: From March to September 2019, 7,962 index clients provided contact information for 19,110 sexual partners (2.4/client). 17,390 partners (91%) were successfully traced, of whom 15,079 (87%) did not know their HIV status and agreed to be tested. 3,670 were diagnosed HIV+, constituting a 24% yield rate. High participation among index clients and partners is a result of the project's non-judgmental communications. High HIV yield is explained by frequency of unprotected sex with multiple, concurrent partners.
CONCLUSIONS/NEXT STEPS: The project's strong performance demonstrates the capacity of local organizations – with modest funding, targeted technical assistance, and government leadership – to make a significant contribution to epidemic control in the most HIV-burdened countries.

SUPPORTING RESILIENT HEALTH SYSTEMS

PEE1400

EFFECTIVE HIV COMMUNITY PLAN. THE ROLE OF COMMUNITY ORGANIZATIONS IN BUILDING RESILIENT HEALTH SYSTEMS TO DELIVER AND LINK HIV AND HARM REDUCTION SERVICES TO PEOPLE WHO INJECT DRUGS IN UGANDA

M. EDWARD[1,1]
[1]*Uganda Christian University, Mbale, Uganda*

BACKGROUND: PWIDs (People Who Inject Drugs) have a probability of HIV transmission through injection use which is estimated at 0.0100 compared to 0.0009 through heterosexual sex. (Baggaley et. al., 2004) In Uganda HIV prevalence among PWIDs is estimated at 16.7% compared to 6.2% in general population and with 6% of 42,000 new HIV infections in 2018.(UNAIDS 2018) PWIDs are a hidden and hard to reach key population due to punitive laws, stigma, discrimination and violence in their communities. Scaling up HIV and harm reduction services to this key population is possible when community organizations support public health systems to build resilience by filling critical gaps through providing supportive services that buttress clinic-based care or extend the reach of services to PWIDs. For example the implementation of the HHRCI (HIV and Harm Reduction Community Initiative) which supported PWIDs on HIV treatment, care, retention and education.
DESCRIPTION: Project: HIV/TB (UGA-C-TASO) and Health Systems Strengthening-HSS (UGA-S-TASO) 2017-2018.
Under this project community organizations built advocacy capacities for PWIDs and their access to quality health services was promoted including within policy design, legal frame work review and their participation in national and regional policy debates to fight against stigma, discrimination and other human rights violations. Implementation of community-based service delivery system which designed peer outreach programs for example condom distribution,voluntary HIV testing and counselling and implementation of the HHRCI in which PWIDs leaving with were given treatment, support and care.Carried out community sensitization meetings with PWIDs about the dangers of sharing injecting needles in relation to the spread of HIV and other blood borne diseases.
LESSONS LEARNED: This project reached 112PWIDs with 38 being females which developed a good practice guide for health system for PWIDs. The HHRCI increased the number of PWIDs on HIV treatment from 42 to 94 with 33% being females .It also increased the visibility PWIDs' issues and improved the quality of their health care at various health centers.
CONCLUSIONS/NEXT STEPS: Transformation of how community-based HIV services are linked and work with health systems through improved linkages and synergies. Emphasize on other resilient HIV prevention methods like behavioral change communication and addiction treatment.

PEE1401

IMPROVING TURNAROUND TIME OF VIRAL LOAD RESULTS AT SELECTED HIGH VOLUME SITES IN NINE DISTRICTS OF NORTHERN UGANDA: A QUALITY IMPROVEMENT PROJECT

J. Mulindwa[1], J. Tusiime[1], D. Kitwe[1], B. Picho[1], T. Mahaba[1], M.S. Nabaggala[1], R. Wadri[1], S. Ninsiima[1], A. Kiyimba[1], M. Ssuuna[1], B. Kalebbo[1], J. Kigozi[1], A. Muganzi[1]
[1]Infectious Diseases Institute, Makerere University, Outreach, Kampala, Uganda

BACKGROUND: Turnaround time (TAT) is a critical indicator for monitoring the quality of laboratory services. Viral load (VL) testing in Uganda is majorly centralized at one national reference laboratory. In June 2019, data from 30- PEP-FAR - supported facilities in northern - western Uganda showed an increase in TAT ranging from 30 to 54 days versus a national recommendation of 14 days. A quality improvement project was initiated to establish the root causes of delayed TAT and develop interventions to correct the anomalies.
METHODS: A retrospective cross sectional study was conducted to determine causes of long TAT at the study sites between June and September 2019. A continuous quality improvement package with real time monitoring and appropriate action on identified gaps was implemented. The key stakeholders (Laboratory personnel at facility CPHL and clinical team) were engaged.
Baseline TAT data was collected to inform setting realistic targets for each step in the testing cascade. Thereafter, TAT data was collected daily, analysed weekly using Microsoft excel and feedback provided to key stakeholders to take respective corrective actions.
The testing cascade included specimen collection, transportation (district reference (hub) and national molecular testing laboratory); posting results at the national viral load dash board, printing of results and transmittance to requesting facilities.
RESULTS:

[Figure. Trend analysis of turn around time along the viral testing cascade across the selected high volume facilities in West Nile region, July - Sept 2019]

The overall regional TAT from test requisition to receipt of results improved from an average of 29 - 19 days. Transportation of specimens from requesting to testing laboratory consumed 34% of the total TAT; processing to release of results 60% and transmittance of results to requesting sites, 6% of the total TAT.
CONCLUSIONS: Routine monitoring of turnaround time at each phase of the testing process and collaboration with key stakeholders involved in the testing cascade is critical to identifying root causes of long TAT and effecting appropriate respective corrective actions to inform prompt clinical decision.

PEE1402

FACTORS RELATED TO CARE SEEKING BEHAVIOR FOR HYPERTENSION FOR INDIVIDUALS WHO ARE ON ANTIRETROVIRAL THERAPY

K. Phiri[1], J. Phuka[2], R.M. Hoffman[3], C. Moucheraud[3]
[1]Partners in Hope, Lilongwe, Malawi, [2]College of Medicine, School of Public Health and Family Medicine, Blantyre, Malawi, [3]David Geffen School of Medicine at University of California, Los Angeles, United States

BACKGROUND: Hypertension is highly prevalent in Malawi; the majority being undiagnosed and hence untreated. Poor health seeking behavior, unhealthy lifestyles and poor access to health care remain key challenges to the prevention, control and management of hypertension. We sought to identify factors related to care seeking behavior for hypertension among adults on antiretroviral therapy (ART).
METHODS: Between January and April 2019, in-depth interviews (IDIs) were conducted with individuals ≥18 years, on ART and hypertension treatment. We recruited from 3 hospitals in central Malawi that deliver ART and hypertension care as non-integrated outpatient services. Interview questions focused on barriers and enabling factors to care seeking and individuals' perceived risks and benefits to health care utilization for hypertension. Andersen's behavior model for health services utilization was used as an organizing framework. Data were analyzed through constant comparison methods, using Atlas.ti 8, applying both deductive and inductive techniques using a modified grounded theory approach.
RESULTS: We performed 30 IDIs (21 females): mean age 57.5 (IQR: 52-63); median years on ART 8 (IQR:4-11); median years on antihypertensives 4 (IQR:2-9). Three the respondents had severe hypertension on their most recent clinic visit. Fifteen respondents were taking first-line hypertension therapy (hydrochlorothiazide). The most common barriers for care seeking included financial challenges (transport money, money for antihypertensives, lost wages from time away from work), managing multiple medical problems, poor health and medication side effects. At the health system level, participants reported that lack of integrated care, lack of available hypertension medications, long waiting times, and poor quality of care were major challenges to care seeking. Respondents understood the risks of untreated hypertension and benefits of treatment, and this motivated individuals to properly manage their hypertension, despite barriers to care.
CONCLUSIONS: Among our participants on ART with hypertension there was a high level of knowledge about the risks of hypertension and high motivation for treatment, but individuals faced significant challenges to care seeking. Patient barriers could be reduced through integration of hypertension treatment within ART clinics, free or low cost access to antihypertensives, improvements in the supply chain for hypertension medication, and support services (counseling or other) for patients with multi-morbidity.

PEE1403

ROADMAP TO LABORATORY ISO 15189 ACCREDITATION UNDER THE SOUTH AFRICAN NATIONAL ACCREDITATION SYSTEM (SANAS): A CASE STUDY FROM ENTEBBE REGIONAL REFERRAL HOSPITAL IN UGANDA

L. Kobusingye[1], M. Nassali[1], S. Mwebaze[1], E. Omony[1], J.B. Baluku[2], P. Busingye[3], C. Senyimba[3]
[1]Mildmay Uganda, Laboratory, Kampala, Uganda, [2]Mildmay Uganda, Research, Kampala, Uganda, [3]Mildmay Uganda, HSS-Programs, Kampala, Uganda

BACKGROUND: Globally, countries rely on accreditation of laboratories to determine their competences. In Africa, fewer than 60% of clinical decisions are based on laboratory results. Uganda had only 5 accredited laboratories as of November 2016. The Uganda Ministry of Health (MOH) recommended 16 laboratories to fast-track for international accreditation to ISO 15189 standard under SANAS, of which Entebbe Regional Referral Hospital Laboratory was among. Here we present the experience and lessons learnt in the process of acquiring the SANAS accreditation for Entebbe Regional Referral Hospital Laboratory, a PEPFAR supported Public Hospital in semi-urban Uganda.
DESCRIPTION: After launching the 16 laboratories to accreditation journey in 2016, targeted facility based mentorships and trainings were organized by MOH to ensure Entebbe Regional Referral Hospital Laboratory staff are competent and comply to ISO 15189 requirements. In the year 2017-2019, Mildmay Uganda and A Global Healthcare Public Foundation resident mentors supported the facility staff in implementation of the ISO 15189 Standard. Eight laboratory and top management staff underwent training. The laboratory staffing level was increased from 3 in 2016 to 10 staff in 2019. This was done to support the implementation activities and laboratory structural improvements (sample accessioning and reception area) made to ensure compliance to the international standard.
LESSONS LEARNED: Entebbe Regional Referral Hospital Laboratory was recommended for accreditation for Malaria, CD4, Full Haemogram, Hepatitis B, Human Chorionic Gonadotropin, Cryptococcal Antigen, Tuberculosis GeneXpert, Syphilis, HIV, ABO Blood grouping tests. There was an improvement from 82 Nonconformities at baseline audit to 62 nonconformities in mock audit and finally to 7 nonconformities in the final assessment leading to accreditation.
CONCLUSIONS/NEXT STEPS: With trainings, mentorships, staffing and hospital management involvement in public laboratories foster improvement in Quality management systems and this enables them to meet the requirements for accreditation.

PEE1404

AN INTEGRATION APPROACH TO INVENTORY STOCK VISIBILITY: MEDICAL ACCESS UGANDA LIMITED INTEGRATED FACILITY DATA MANAGEMENT SYSTEM

O. Micheal[1], P. Otage[1], B. Lubega Muhamed[1], R. Settaala[1], S. Ninsiima[1], E. Sebyatika[1], S. Sendagala[2], S. Malamba[3], S. Muyingo[1]
[1]Medical Access Uganda Limited, Kampala, Uganda, [2]U.S. Centers for Disease Control and Prevention, Kampala, Uganda, [3]U.S. Centers for Disease Control and Prevention, Kigali, Rwanda

BACKGROUND: Real-time data visibility within the health supply chain is needed to inform public health responses in Uganda. The introduction of RxSolution into Uganda's Health Systems has greatly improved data management, quality and reporting of logistics data. However, RxSolution implementations have remained siloed, limiting insights into supply chain performance. In 2018, Medical Access Uganda Limited (MAUL), with support from the CDC and PEPFAR, developed and adopted an integrated early warning system and dashboard, called the Integrated Facility Data Management System (iFDMS), and a lightweight electronic Logistics Management Information System (eLMIS)-based integrator, called the Facility Data Integrator (FDI). The main objectives of this intervention was to create real-time visibility, provide early warning mechanisms to avert stock-outs and expiry of health commodities and support targeted technical assistance.
DESCRIPTION: iFDMS was piloted at five health facilities across Uganda before rollout in >115 health facilities by December 2018. As part of the roll-out process, MAUL strengthened the national rollout of RxSolution, the Ministry of Health-approved eLMIS, in 157 health facilities and trained 180 health facility staff through targeted regional workshops conducted across the country. FDI was deployed at 130 health facilities to track and transmit, in real-time, stock status changes and stock levels at the health facility level to the central warehouse.
LESSONS LEARNED: RxSolution adoption improved by over 90%. Stock status visibility and traceability was greatly improved, with reductions in reported expired drugs (14.94%) and stock-outs (16%), partially due to using real-time early warning mechanisms (SMS and e-mail alerts) and stock top-up/lend-out reports that advise supply chain technical support teams on inter-facility commodity transfers, based on stock levels, expiration analysis, and min-max levels. Completeness and accuracy of RxSolution data increased from 84% in 2018 to 93% in 2019 across all linked health facilities. Implementation challenges included limited access to the internet (21%) and limited work force at health facilities (45%).
CONCLUSIONS/NEXT STEPS: Implementing iFDMS increased data visibility and improved efficient service delivery in health facilities and central warehouses. Continued onsite supervision and mentorship and additional system/infrastructure enhancements, including internet connectivity, could further enhance iFDMS performance.

PEE1405

HEALTH SYSTEM RESPONSIVENESS: LESSONS FROM THE SOLTHIS-EMPOWER PROJECT END LINE SURVEY OF EXPERIENCES OF PATIENTS RECEIVING CARE IN SIERRA LEONE

K.B.G. Ngwatu[1], F.H. Konteh[2]
[1]Clinton Health Access Initiative, Clinical Sciences Team, Kampala, Uganda, [2]Conflict Management and Development Associates, Freetown, Sierra Leone

BACKGROUND: Health system responsiveness, its ability to respond to the needs and expectations of patients, should be considered as an intrinsic goal of health service delivery. It is measured across eight domains themed on aspects of health systems related to the rights of patients as human beings.
This study aimed to investigate the end-project responsiveness at 12 facilities supported by the three-year EMPOWER project in Sierra Leone which pursued a human rights based approach towards a) empowering people living with HIV (PLHIV) to demand for and receive quality health services, and b) capacity building of health workers at the facilities.
DESCRIPTION: The cross-sectional and explanatory study investigated 2080 outpatients (1048 PLHIV and 1032 non-PLHIV) selected using convenience sampling method. Respondents were randomly

selected for both patient groups. Standard responsiveness questionnaire applied at baseline was used for data collection. Data analysis was done applying descriptive statistics, Pearson Chi-square tests, and SPSS 16 at significance level of 0.05 to compare baseline and endline results.

LESSONS LEARNED: Favorability across most domains at endline was higher for PLHIV (Table 1). Composite indices showed generally improved favorability at endline from those at baseline. Significantly, at end line, communication was reported as "the most important domain" by both patient groups (26.9% of PLHIV v 24.2% for non-PLHIV).

Domain	Indicator	PLHIV [n=1048] (%)	Non-PLHIV [n=1032] (%)	Pearson Chi-square Tests
Autonomy	Opinion asked when making decisions	80.7	69.5	P=.00
	Permission asked before tests	80.7	67.5	P=.00
	General experience on autonomy	89.3	79.6	P=.00
Choice	Choice of healthcare provider	65.5	69.7	P=.04
	Skills of healthcare provider	98.1	97.4	P=.23
	Ability to change healthcare provider	28.5	37.9	P=.00
	General experience of choice	90.6	95.8	P=.00
Communication	Clarity of explanations	98.8	97.0	P=.05
	Time to ask questions	89.9	84.2	P=.00
	Patients being listened to	97.8	97.3	P=.45
	General experience of communication	98.7	97.9	P=.16
Confidentiality	Privacy of consultations	97.3	94.1	P=.00
	Personal records being kept secret	95.4	92.0	P=.00
	General experience of confidentiality	97.8	94.4	P=.00
Dignity	Respect of intimacy	99.0	96.6	P=.00
	Being shown respect	99.2	97.1	P=.00
	Whether or not treated badly	98.8	98.3	P=.34
	General experience of dignity	98.6	97.1	P=.02
Prompt attention	Waiting time at the clinic	87.3	74.0	P=.00
	Operating hours of the clinic	94.3	86.0	P=.00
	Waiting time for test results	76.4	77.7	P=.70
	Get care as soon as wanted	90.1	80.2	P=.00
	General experience of prompt attention	92.2	81.9	P=.00
Environment	Adequacy of medical equipment	97.7	92.8	P=.00
	Availability of drugs	94.3	75.6	P=.00
	Cleanliness of the facility excluding toilets	96.7	95.7	P=.27
	Space in the waiting and examination rooms	94.6	91.4	P=.00
	General experience of environment	97.3	95.0	P=.00
Social support	Spoken to by provider about social support	26.1	8.1	P=.00
	Social support clearly explained	31.2	9.5	P=.00
	General experience of social support	30.8	9.4	P=.00

[Table 1.]

CONCLUSIONS/NEXT STEPS: The EMPOWER project improved the responsiveness for PLHIV and non-PLHIV patients at the facilities. We recommend sustained resource allocation to capacity building of health workers in the non-clinical aspects of care of both PLHIV and non-PLHIV for desired uptake of health services.

PEE1406

IMPLEMENTATION OF LABORATORY INFORMATION MANAGEMENT SYSTEM (LIMS) FOR EARLY INFANT DIAGNOSIS AND VIRAL LOAD IN MALAWI

J. Mtaula[1], C. Banda[2]
[1]Clinton Health Access Initiative, ICT, Lilongwe, Malawi, [2]Clinton Health Access Initiative, Infectious Diseases, Lilongwe, Malawi

BACKGROUND: Malawi started to advance in Early Infant Diagnosis (EID) activities for HIV exposed infants in 2010. At that time, the country did not have any formal system to manage the data and information for blood samples, testing process, and test results. This lack of proper system to manage EID testing process also made it impossible for the Ministry of Health and Population (MoHP) and stakeholders to have access to the information for decision making as well as to the overall visibility of the initiative.

DESCRIPTION: The project began in 2011 in 2 laboratories with the plan to setup and improve data management system for Early Infant Diagnosis (EID) and Viral Load (VL) in all molecular laboratories in the country. The activities completed during the project include system development, implementation, trainings and continuous user support.

The system has expanded and is currently running in 10 Molecular laboratories. It has also been integrated to other systems and interfaced with diagnostic machines in the laboratories.

LESSONS LEARNED: Throughout the project, we used periodic system reviews to unearth areas of improvement and ensure the system would be user-friendly. Support from MoHP leadership was crucial for the sustainability of the system since the intent is to transition the system to the MoHP, but there is often a lack of resources to absorb all the work needed to design, develop and implement computer systems. Consistent stakeholder engagement and collaboration provided new challenges in timely system implementation due to differences in working styles, cultures and work priorities.

CONCLUSIONS/NEXT STEPS: The finding sets out new approach to computer system development for health service delivery. Implementation should revolve around understanding the needs of the MoHP and being flexible to accommodate new requirements as testing protocols in laboratories change in response to program changes. The MoHP to take control and leadership of the development process, having continuous system reviews with users in order to improve the system and continuously make it user friendly and having a dedicated technical team in order to provide timely technical support to users.

MAKING HEALTH SYSTEMS WORK FOR ADOLESCENTS

PEE1407

GROUP ANTENATAL CARE FOR IMPROVING RETENTION OF ADOLESCENT AND YOUNG PREGNANT WOMEN LIVING WITH HIV IN KENYA

C.A. Teasdale[1,2], J. Odondi[2], C. Kidiga[2], M. Choy[2], B. Ngeno[3], B. Ochanda[4], S. Modi[3], D. Odera[2], E.J. Abrams[2]
[1]City University of New York (CUNY), Epidemiology & Biostatistics, New York, United States, [2]ICAP-Columbia University, New York, United States, [3]US Centers for Disease Control and Prevention (CDC), Atlanta, United States, [4]CDC, Nairobi, Kenya

BACKGROUND: Pregnant and breastfeeding adolescents and young women with HIV (AYWLH) have lower retention in prevention of mother-to-child transmission (PMTCT) services compared to older women yet PMTCT services are not usually adolescent-friendly.

METHODS: We implemented group care, as a differentiated service model for AYWLH at seven health facilities in western Kenya from December 2017 to March 2019. All pregnant AYWLH <25 years receiving antenatal care (ANC) attended group ANC visits which included health education, self-care (measuring own weight, blood pressure, etc.) and mentor-led group counseling sessions.

Monthly group visits were conducted by health facility nurses following Kenya's national standards of care. ART register data were used to compare six-month ART retention among newly enrolled pregnant AYWLH in two periods, the pre-intervention period (January-December 2016) and the intervention period (December 2017-January 2019). Time on ART was calculated using first ANC date and last

month of ART pick-up. Kaplan-Meier estimators and log-rank test were used to estimate retention; women with documented transfer, death, or stopped ART were censored at last ART pick-up.

RESULTS: In the pre-intervention period, 353 AYWLH enrolled in ANC and 223 (63.2%) had an ART start date. Of those missing ART start data, 54(41.5%) were indicated as on ART at other facility, 20(15.4%) documented as declined ART and 56(43.1%) lacked information. In the intervention period, among 388 AYWLH enrolled in ANC, 260 (67.0%) had an ART initiation date. Of those missing data, 100 (78.1%) were indicated as on ART at another facility, 5 (3.9%) were documented as declining ART and 23(18.0%) lacked information. The median age in both periods was 22 years (interquartile range 20-23); in the pre-period 21.1% were <20 years and median gestation at first ANC was 22 weeks(IQR:16-26), in the post-period 13.5% were <20 and median gestation was 19 weeks(IQR:12-26). Six months after first ANC among AYWLH starting ART, 87.6%(95%CI:83.5,91.7) were retained in care in the post-period compared to 84.0%(95%CI:79.2,88.9) in the pre-period(p=0.21).

CONCLUSIONS: Six-month retention among pregnant AYWLH who started ART was higher in the post-intervention, however the difference was not statistically significant. High proportions of pregnant AYWLH were not documented as starting ART which requires enhanced attention.

PEE1408

ACADEMIC-PUBLIC HEALTH PARTNERSHIPS FOR DATA DRIVEN IMPLEMENTATION SCIENCE RECRUITMENT OF YOUTH LIVING WITH HIV IN FLORIDA

M. Pooler-Burgess[1], S. Butame[1], S. Naar[1]
[1]Florida State University, Center for Translational Behavioral Science, Tallahassee, United States

BACKGROUND: Youth living with HIV are at high risk for drop off at each point of the cascade. Thus, traditional recruitment in academic health centers in the US is not sufficient for real-world implementation trials as the highest risk youth are missed. Florida is suffering from an unusually severe HIV epidemic with only two clinics in the state actively involved in our current youth research network. The purpose of this project was to develop academic-public health partnerships to utilize available data to identify where youth living with HIV are served in Florida and develop appropriate recruitment strategies to support a youth-focused state-wide research network for significant public health impact across the state.

DESCRIPTION: Florida Youth SHINE (Sexual Health Implementation Network for Equity) is a newly developed community-based research network. The first step was to analyze public health records and data from the OneFlorida Clinical Research Consortium, a statewide medical records database, to determine where youth with HIV have received services in the previous year. The second step was to develop a Youth Advisory Board with members from each target area. The third step was to develop formal collaborations with county health departments, medical providers, and social service agencies in the target areas.

LESSONS LEARNED: Public health and clinical research records can be leveraged to develop a targeted research network, and we will present data maps to demonstrate this approach. Support at the highest levels within the public health sector is necessary to fully engage county health departments and the organizations they fund. Community-engagement is critical with multiple stakeholder involvement including youth, public health officials, providers, and researchers, and findings from a collaborative agenda setting process will be presented.

CONCLUSIONS/NEXT STEPS: The next steps are to develop new implementation science studies with community engagement at all levels of the research process and to create developmentally tailored recruitment materials. We will continue to utilize these big data initiatives as pragmatic outcomes in our implementation trials. Florida Youth SHINE will integrate with the Adolescent Trials Network for HIV/AIDS to increase access to implementation science studies for all youth with HIV to end the epidemic in Florida.

PEE1409

IMPROVING HIV VIRAL SUPPRESSION AMONG ADOLESCENTS 10-19 YEARS USING SELF-SELECTED TREATMENT BUDDIES; LESSONS FROM EAST-CENTRAL UGANDA

R. Nyinoburyo[1], D. Kamya[1], G. Ndikabona[1], M. Mutonyi[1], A. Muhwezi[2]
[1]University Research Co., LLC, TB/HIV, Jinja, Uganda, [2]University Research Co., LLC, Health System Strengthening, Jinja, Uganda

BACKGROUND: In 2018, HIV suppression among adolescents (10-19 years) was only 67.8% compared to 88.3% among adults ≥20 years. This has been attributed to; poor adherence due to stigma and poor psychosocial support that is not tailored to adolescent needs. To improve treatment adherence among adolescents in order to achieve the UNAIDS "third 95" target on viral suppression, the USAID funded Regional Health Integration to Enhance Services project in East-Central Uganda supported health facilities to improve viral suppression rates among adolescents by assigning self-selected treatment buddies.

DESCRIPTION: Working with district and health facility teams, file audits were done to identify adolescents with unsuppressed viral load at four high-volume sites in the region. These had remained unsuppressed viral load for over a year despite consecutive intensive adherence counselling (IAC) sessions. These were allowed to select treatment buddies of their choice; any trusted friend, relative or school mate, a shift from the routine practice of the adolescents' parent/guardian being the default treatment supporter. The selected buddies were trained and given weekly reminders to support the adolescents to adhere to their medicines. This was implemented in addition to routine monthly IAC at the health facilities. Program data was collected and analyzed for the cohort of adolescents with unsuppressed viral load and overall suppression rates at the three sites after 10 months of implementation.

LESSONS LEARNED: At the start of January 2019, there were 106 adolescents with unsuppressed viral load, 63% were females. After continuous support from their self-selected buddies in addition to IAC sessions, a total of 75 (71%) adolescents had achieved viral suppression after re-testing by October 2019. This led to an overall improvement of viral suppression rates from 85% to 91.2% at the three implementation facilities.

CONCLUSIONS/NEXT STEPS: In order to meet the UNAIDS "third 95" target for viral suppression, treatment adherence among HIV infected adolescent can be achieved through allowing self-selected treatment buddies in addition to other psycho-social interventions like intensive adherence counselling. The next steps for the project will be to cascade the implementation self-selected treatment buddies, not only for adolescents with unsuppressed viral load but all adolescents at other supported sites.

COMMUNITY PARTICIPATION IN SYSTEMS FOR HEALTH

PEE1410

APPLYING THE RE-AIM FRAMEWORK TO EVALUATE A DRIED BLOOD SPOT TESTING PILOT WITHIN AN INDIGENOUS COMMUNITY CONTEXT

D. Atkinson[1], R. St. Denys[2], K. Ogilvie[2], C. Lund[3], R. Masching[3], R. Landy[1], C. Worthington[1], DRUM & SASH Team
[1]University of Victoria, School of Public Health and Social Policy, Victoria, Canada, [2]Shining Mountains Living Community Services, Red Deer, Canada, [3]Canadian Aboriginal AIDS Network, Edmonton, Canada

BACKGROUND: As one of three constitutionally recognized Indigenous groups in Canada, Métis communities experience higher rates of HIV and STBBI compared to non-Indigenous Canadians. Métis service providers in Alberta (AB), Canada identified dried blood spot testing (DBST) as an approach to potentially increase access to testing for sexually transmitted and blood borne infections (STBBI) for Métis people. In September 2019, the Métis Nation of Alberta through Shining Mountains Living Community Services launched the first provincial pilot of DBST for HIV, HCV, HBV and syphilis.

METHODS: Drawing upon community-based and Indigenous methodologies, survey, gathering circle and interview instruments were developed in partnership with the Métis community. Surveys were administered to self-identifying Métis recipients of DBST at two Métis community events in AB. Four gathering circles with DBST recipients were held, and three semi-structured interviews were conducted with individuals who provided DBST at the events to obtain testing providers' perspectives. Supplemental data including minutes and researcher notes from meetings with stakeholders and policy decision makers was collected. Gathering circles and interviews were audio recorded and transcribed. Data was thematically analyzed. The RE-AIM framework (Reach, Effectiveness, Adoption, Implementation, Maintenance) was applied to facilitate evaluation.

RESULTS: 30 Métis individuals received testing at Métis community events; of those 26 completed surveys and 19 participated in a gathering circle. 73% of survey participants self-identified as female. 96% of survey participants indicated they agreed or strongly agreed their testing experience was positive. Key emergent themes from the application of the RE-AIM framework include: the need to reach men with testing services (Reach), comparable sensitivity/specificity to venous blood tests (Effectiveness), ability to be led by community (adoption), and pilot support from decision makers (implementation/maintenance).

CONCLUSIONS: Results suggest that DBST was an acceptable form of testing among Métis community members who participated in DBST within community event settings. Participants were supportive of DBST being offered at future events, particularly in rural/remote Métis communities, to increase access to STBBI testing. Application of the RE-AIM framework identified barriers and facilitators to the implementation and adoption of DBST in Indigenous communities which will be useful for future implementation efforts.

PEE1411

A COMMUNITY ART MODEL AND CLIENT-CENTRED ART SERVICES FACILITATE HIGH ART ADHERENCE AND CLIENT RETENTION IN ZAMBIA

E. Mwila[1], K. Mwanda[1], L. Cicciò[1], C. Madevu-Matson[2], A. Fullem[2], M. Chikuba-McLeod[1]
[1]JSI Research & Training Institute, Inc., Lusaka, Zambia, [2]John Snow, Inc., Boston, United States

BACKGROUND: A key mandate of the USAID DISCOVER-Health Project (DISCOVER) is to improve access to and utilization of quality and integrated HIV, FP/RH, and MNCH services in under-served communities in Zambia. With approximately 1.2 Million PLHIV, the Zambian health system faces severe challenges coping with an increasing HIV care and treatment burden, with most clients: traveling long distances to ART facilities with high transport costs; experiencing long wait-times (3-6 hours) at health facilities due to congestion; and bearing high opportunity costs. Funded in 2015, DISCOVER responded by designing and implementing a community ART model, in collaboration the MOH, which expanded the range of services (adding ART/other services) provided in Health Posts (lowest-level community-based facilities ordinarily offering basic first-aid), and establishing non-conventional community-based health service delivery sites, in partnership with churches.

DESCRIPTION: In 2019, DISCOVER provided ART services in 242 health posts and non-conventional facilities, and in two mine hospitals. DISCOVER ensured that ART and other services met quality standards, which bred confidence among PLHIV to access care/ART from the sites and sustain use. The ART program grew by 97%, almost doubling from 29,002 in Sep-18 to 57,014 in Sep-19. With 26,570 newly-initiated and 1,734 transfer-outs, overall addition of 28,012 ART clients signifies high transferring-in from other facilities and sustained care/ART.

LESSONS LEARNED: 1. PLHIV will access and utilize quality and client-centred community ART programs and sustain ART use.

2. Where higher-level health facilities' ART programs are congested, quality community ART programs serve as decongestion-points, providing faster ART point-of-care with clients spending less time (< 1hour) at facility.

3. Client-centred community ART programs reduce the burden of accessing ART on clients, reducing travel distance, transport costs and opportunity costs.

CONCLUSIONS/NEXT STEPS: Decentralizing ART services to the community can respond to the needs of the health system and under-served communities, but must be of good quality for clients to access them and sustain use. DISCOVER ART sites: are increasingly the point-of-care of choice for catchment-area clients, mitigating transport and opportunity costs in a challenging economy; decongest higher-level facilities with health system-wide benefits; enable client continuity care and retention on ART, helping to maintain momentum towards HIV epidemic control.

PEE1412

HOW TO ENGAGE PRIORITY POPULATIONS THROUGH A REPRESENTATIVE WORKFORCE

J. Zondlo[1], J. O'Neal[1]
[1]*San Francisco AIDS Foundation, Strut Health Center, San Francisco, United States*

BACKGROUND: A known barrier for priority populations in San Francisco (e.g. Latinx and African American MSM and Trans People of Color) accessing HIV and STI treatment and prevention services is a shortage of providers representative of those communities. People are more likely to access services, especially HIV/STI testing and treatment, when their providers look and sound like them and have shared backgrounds and experiences.

A lack of compensated opportunities designed to train and educate individuals from priority communities in sexual health service provision results in a workforce that is often exclusively comprised of people who maintain the highest levels of privilege (such as the ability to work without pay). This can cause people from marginalized communities to not access services which ultimately leads to higher rates of HIV and STI acquisition within these communities.

DESCRIPTION: San Francisco AIDS Foundation (SFAF) created a Clinical Assistantship Program at the health center Strut that utilizes community connections, often created through social event programming, to recruit exclusively from priority populations. This paid program mentors new leaders by providing hands-on, comprehensive training on how to deliver sexual health and social support services.

Since the fall of 2017, SFAF has recruited and trained 12 Clinical Assistants from Trans and Non-binary, Black, Latinx, API, Youth, and First Nation communities. By rotating through a variety of departments, participants emerge from the program ready to enter the workforce with skills in HIV testing and counseling, mobile testing, syringe access services, community-centered event production, and program administration operations and logistics.

LESSONS LEARNED: More than half of the people who participated as Clinical Assistants are currently working full time in programs that promote wellness efforts in their communities. Creating tailored, on-the-job training opportunities and removing the monetary barrier of unpaid internships/volunteering increases the possibility of marginalized communities to become health care professionals.

CONCLUSIONS/NEXT STEPS: Entry level positions into prevention organizations should be more widely available with specific support, including compensation, for the highest priority populations. Career paths for Queer and Trans People of Color in management and executive level leadership in HIV and AIDS organizations need to be created.

PEE1413

BEYOND ENGAGEMENT AND PARTICIPATION: COMMUNITY-LED MONITORING TO BRIDGE GAPS IN HIV CARE CONTINUUM SERVICES AMONG PEOPLE WHO INJECT DRUGS (PWID) IN INDIA

H. Khosa[1], R. Prasad[1]
[1]*India HIV/AIDS Alliance, New Delhi, India*

BACKGROUND: Nirantar programme, under (PEPFAR) – (CDC), in India considered community monitoring imperative to broaden HIV service reach, engage KPs to facilitate better health, improve access to healthcare and overcome stigma, discrimination; community scorecard is a systematic and sustained approach to strengthen community led responses. Through the score card, Nirantar established community-monitoring system for providing feedback, helping to reorient and improving quality of health services. Real-time monitoring of health services makes them need-based with better utilization.

METHODS: Participatory action research was conducted in India. Community scoring was done in 72 focus group discussion with 447 PWID community members and 446 health care providers (HCP), for quality of services, availability and accessibility of commodities, access to services, forms of stigma and discrimination and attitudes of staff towards PWID. Structured questionnaire was used to score for both baseline and endline (after 3 months) for three quarters. Findings of baseline were shared with HCP.

RESULTS: Increased quality of services of HIV prevention programme (from mean score 6.3 at baseline to 8.1 at endline), reduction in stigma and discrimination (2.8 to 0.4), reduction in bad attitude of HCPs (2.1 to 0.6) were observed significantly ($p<0.05$). Stigma and discrimination reduction among HCPs showed improvement (2.8 to 2.1) significantly ($p<0.05$). Availabiliy and access to services also increased, with hospital services showing improvement in reduction of the stigma and discrimination (2.8 to 2.1) ($p<0.05$).

CONCLUSIONS: HCP are the frontline to service delivery to PWID, however are yet not prepared socially and have internal moral conflicts to serves drug users. Considering that community monitoring is imperative to broaden HIV service reach, engaging KPs to facilitate better health, improve access to health care and overcome stigma, discrimination; community scorecard is a systematic and sustained approach to strengthen community led responses.

PEE1414

EFFECTS OF TRANSITIONING FROM DONOR SUPPORT TO CENTRAL SUPPORT ON COMMUNITY HIV SERVICES AT SUB-NATIONAL LEVEL IN UGANDA

E. Ssegujja[1], M. Mukuru[1], H. Zakumumpa[1], F. Ssengooba[1]
[1]*Makerere University School of Public Health, Health Policy Planning and Management, Kampala, Uganda*

BACKGROUND: Globally, declining funding for HIV/AIDS response and subsequent transition of support from donor to country ownership has necessitated a critical review of measures to stabilize service provision amidst these changes. Moreover uncertainties persist in light of the country's ability to fully embrace the financial resources to meet the cost of these changes and systems response in order to sustain the successes as well as increase on the dividends already realized. At the time when the HIV response is moving towards biomedical ART-based prevention, strengthening the community component to actively maintain clients in care is critical if the intended clinical outcomes are to be realized. This paper analyses the practitioner's understanding of transition from donor support to national ownership and how this shapes the services that they deliver.

METHODS: A longitudinal case study was conducted in Uganda with qualitative interviews conducted among health workers, facility managers, district health managers, implementing partners and focus group discussions with the beneficiaries receiving HIV services at the time of the transition. Data was collected using audio recorders , transcribed and analyzed using Atlas.ti where emerging themes informed the results.

RESULTS: Overall results reflect discontent on rationale and process for transition characterized by minimal preparation of sub national level implementer was expressed by respondents. Different approaches were adopted to cope with the spectrum of community HIV services offered. Although structures remained, innovative community approaches and services for active engagement of clients were recalled to the facilities such as mentor mothers' structures, ART linkage facilitators and RCT volunteers who offered psycho social support. Specialized services were instead integrated into routine HIV care. For sensitization and other HIV awareness activities were co-opted into general community outreaches while the intensity of client tracing for those lost to follow-up were reduced to the minimum.

CONCLUSIONS: Complexities in system response required adequate planning and preparation for innovative approaches to transition service provision. Where no immediate resources would be leveraged upon services were terminated, integrated into ongoing activities or recalled to be offered from the facility reflecting the need to configure service requirements to existing resources.

PEE1415

INCREASE IN HIV SERVICE UPTAKE AMONGST CHILDREN, ADOLESCENT AND YOUNG WOMEN THROUGH INVOLVEMENT OF FAITH LEADERS: THE MIYA NGIMA PROJECT

A. Kariuki[1]
[1]*World Vision Kenya, Faith and Development, Nairobi, Kenya*

BACKGROUND: Homa Bay County in Kenya has a HIV prevalence of 20.7%, 4.5 times higher than the national average, with the highest number of children under 14 years living with HIV, and contributed 10.5% of new HIV infections in youth (15-24 years) in 2017 (Kenya HIV Estimates, 2018). Recognizing religious leaders have profound influence within communities, World Vision Kenya partnered with Gwassi Association of Pastors (GAPA) to implement "Miya Ngima" a 3-year project funded by Positive Action for Children Fund (PACF) targeting Children, Adolescent and Young Women (CAYW) in Suba sub county from 2017-2020.

DESCRIPTION: The project aimed to increase uptake of HIV interventions among CAYW through strengthening faith communities collaboration with community structures on HIV prevention and response, increasing knowledge, promoting HIV testing and counseling (HTC)

A total of 51 faith communities, 20 schools and 9 support groups, were engaged in organizational capacity building, catalyzing workshops, formation of congregational hope action teams (CHAT), training on HIV, stigma, target groups and resilience strategies such as savings schemes and entrepreneurship.

LESSONS LEARNED: 40 faith leaders were trained on World Vision's Channels of Hope HIV model[1], which then facilitated training for 240 (120 female, 120 male) CHAT members. CHAT members reached 5239 people (610 children and adolescents girls, 302 children and adolescents boys, 2371 young women, and 1956 men) through community outreach with standardized HIV prevention interventions. CHAT-led efforts on advocacy increased access to HIV Testing and Counseling from 76% to 90% among adolescents & young women with more emphasis on elimination of mother to child transmission. 1140 mothers received HTC at antenatal care, of which 167 HIV positive women were enrolled on ARVs. ARV treatment among pregnant women increased from 312 in 2017 to 517 in 2018 (DHIS 2017/18). Total direct and indirect project beneficiaries were 15534, 31,176 respectively.

[1] http://www.wvi.org/church-and-interfaith-engagement/channels-hope-hiv

CONCLUSIONS/NEXT STEPS: Community members who belong to faith congregations trust their faith leaders. They are responsive to HIV messages and prevention strategies when shared to them by their faith leaders. To achieve notable success in HIV programming, faith leaders must be involved.

PEE1416

SAFE ACCESS FELLOWSHIP: LEVERAGING COMMUNITY PARTNERSHIP MODEL TO IMPROVE ACCESS TO NON-DISCRIMINATORY AND STIGMA-FREE HEALTHCARE SERVICES FOR LGBTQ+ COMMUNITIES ACROSS INDIA

S. Choudhary[1]
[1]*Qequal Foundation, Delhi, India*

BACKGROUND: In India, the LGBTQ+ communities have been historically marginalized via section 377, which criminalized homosexuality till September 2018. In our survey, 53% of respondents were fearful of approaching healthcare providers for sexual health because of prior negative experiences of homophobia and abuse. 82% of respondents could not think of healthcare providers they could trust to disclose gender identity or sexual orientation, which could lead to misdiagnoses, delays in healthcare and negative health outcomes. The medical fraternity, especially in tier-2 and tier-3 cities are not equipped to understand the needs and challenges of the community.

DESCRIPTION: Safe Access Fellowship helps local community members, organizers, and activists to become LGBTQ+ health champions. We recruited 20 local queer activists and allies from 16 cities of 12 states across the gender and sexuality spectrum. The fellows received in-depth training on LGBTQ+ health disparities and challenges. As part of the fellowship, they identified and sensitized healthcare providers and on-boarded them at our website where community members can locate healthcare providers, and rate and review their experiences for shared trust.

LESSONS LEARNED: Sensitization and on-boarding of local healthcare providers worked best when the local community members were empowered through training due to cultural and language affinity. In-person sharing of lived experiences played an important role in making healthcare providers into our allies. A robust mix of online and on-ground outreach worked as the communities in tier-2 and tier-3 cities are still learning how to navigate the internet. Trust in Safe Access web platform was established since the on-boarding of health service providers was done by a local community member.

CONCLUSIONS/NEXT STEPS: The fellows are now known as LGBTQ+ health champions in local communities, and a bridge between the community and sensitized healthcare providers have been built. Our network of 75+ sensitized healthcare providers spread across 16 cities have taken a pledge to provide non-discriminatory and stigma-free services to the LGBTQ+ communities. To meet the demand for in-depth LGBTQ+ healthcare training, we plan to launch detailed online modules that our network of healthcare providers could access to increase their capacity to become an LGBTQ+ affirmative provider.

PEE1417

THE ROLE OF NGOS IN THE CONTROL OF THE HIV EPIDEMIC IN MEXICO THROUGH THE DEVELOPMENT OF COMMUNITY HIV DETECTION CENTERS (2016-2018)

R. Leyva[1], C. Infante[1], T. Gonzalez[1]
[1]*National Institute of Public Health, Health Systems, Cuernavaca, Mexico*

BACKGROUND: During 2016 to 2018, the Mexican Government financed the development of strategies for the timely detection of HIV in which NGOs participate with the creation of community diagnostic centers (CCDs) that referred cases to specialized AIDS care centers (CAPASITS). This work aims to analyze the characteristics of CCD participation as part of public policy for HIV/AIDS prevention in key populations such as men that nave sex with men, sex workers and transgender persons.

METHODS: A Qualitative transversal study (2016-2018) was carried out in 20 states of Mexico. There were 63 interviews with CCD key actors and 25 interviews with directors of CAPASITS. We explored the characteristics of CCD, relationship with health care services and prevention activities and their linkage to health services. Information on the views of CCDs was also obtained from the perspective of local health service providers.

RESULTS: The NGOS that participated in the CCD strategy had experience and adequate infrastructure to develop HIV prevention, diagnosis and linkages to care services. CCD staff had a profile that facilitated the development of outreach strategies with populations and it also contributed to generate spaces free of stigma and discrimination. These strategies include outreach activities, promoting their activities and applying rapid tests on points and meeting times of key populations. Collaboration between CCDs and CAPASITS strengthened local health care systems and services and allowed for faster linkages to services in order to initiate with treatment. The strategy to implement CCDs achieved several goals and represented important changes in diagnosis and linkage to treatment, especially in relation with key populations. This becomes more relevant because the HIV epidemic in Mexico is concentrated precisely in key populations.

CONCLUSIONS: This strategy helped to improve collaboration between CAPASITS and CSOs by recognizing their complementarity, different areas of action and the benefits of coordinated work. I also recognize that NGOs are a valid and fundamental partner, and play a key role in the control of the AIDS epidemic. It is important that the current government in Mexico recognizes and accepts the importance of cross-sectoral collaboration with civil society in the definition and development of HIV combined preventive strategies.

PEE1418

ASSESSMENT ON THE EFFECTIVENESS OF COMMUNITY ENGAGEMENT IN HIV PLANNING IN THE ERA OF 'ENDING THE EPIDEMIC'

M. Tonelli[1], B. Belo[1], B. Hujdich[1]
[1]*HealthHIV, Capacity Building, Washington, United States*

BACKGROUND: Effective, inclusive, and efficient HIV prevention and care planning is essential to advance local Ending the HIV Epidemic initiatives. However, many planning bodies are not positioned to assess the effectiveness of their existing HIV planning bylaws, policies, and procedures. Jurisdictions are being charged to leverage existing planning bodies and community engagement activities for Ending the HIV Epidemic planning, thus, having structured, effective HIV planning processes is more important than ever.

DESCRIPTION: In 2019, HealthHIV developed and fielded a first-of-its-kind HIV planning body assessment. The mixed-method assessment involved analysis of quantitative data (anonymous online survey) and qualitative data (key informant interviews, documents review). HealthHIV piloted the assessment tool with four state and local HIV planning bodies to determine the applicability and impact of the assessment tool for a diverse group of HIV planning bodies. Then, presented a report of aggregate data, implications, and key recommendations to the HIV planning body for discussion. The findings and implications from each assessment, when presented in an engaging format, provided the opportunity for members to develop specific, actionable strategies and solutions to the identified challenges.

LESSONS LEARNED: HealthHIV sought to develop a process through which HIV planning bodies could better understand how their effectiveness is defined, measured and tracked. Some areas for improvement identified were: membership recruitment; unconscious bias; monitoring and evaluation; goal setting and follow through; and, meeting facilitation.

CONCLUSIONS/NEXT STEPS: Providing the external, third-party assessment accelerated improvement of processes impacts on the local HIV epidemic. This session will review components of the assessment and application for planning bodies.

DELIVERING PAEDIATRIC HIV SERVICES

PEE1419

IMPROVING HIV CARE FOR HIV-EXPOSED CHILDREN THROUGH THE PREVENTION MOTHER-TO-CHILD TRANSMISSION (PMTCT) CASCADE FOR TIMELY PMTCT-FINAL OUTCOME AT SELECTED USAID-FUNDED SITES IN HAITI: CHALLENGES, MITIGATION AND LESSONS LEARNED

M.L. Excellent[1], E. Emmanuel[1], M. Leonard[1], S.T. Omero[1], F. Jean Louis[1], D. Lauture[1], J.W. Domercant[1]
[1]*Institut pour la Sante, la Population et le Developpement (ISPD), Petion-Ville, Haiti*

BACKGROUND: In Haiti, paediatric HIV-prevention/care remains a challenge despite the work put into prevention mother-to-child transmission of HIV/AIDS(PMTCT). Particularly, regarding follow-up for HIV-exposed children aged 0-24 months, there is a misunderstanding of the HIV-final-outcome indicator(PMTCT-FO) by providers and data officers. Additionally, ordering the required blood tests according to the National HIV-paediatric-guidelines is often delayed. And the high lost-to-follow-up rate hinders timely results leading to unknown PMTCT-FO. We will present the interventions that helped improve PMTCT-FO for HIV-exposed-children.

DESCRIPTION: HIV-exposed-children register was overlooked by providers, which delayed follow-up particularly for required HIV-blood tests(PCR/HIV-rapid tests). Data validation showed no reporting of HIV-exposed-children as contacts of index-patients(ICT). In collaboration with Haiti National AIDS Control Program(PNLS), we conducted trainings on paediatric HIV-prevention/care for 61 physicians/nurs-

es. We collaborated with National Public Health Laboratory(LNSP) to ensure timely delivery of PCR-results via user-friendly unique electronic-portal. During technical assistance (TA) visits, we clarified the meaning/reporting of PMTCT-FO for the staff who learned to timely order PCR/HIV-rapid tests and monitor results in HIV-exposed-children-register. To better capture the HIV-exposed-children as contacts, PNLS recommended using HIV-Testing-register with the code PEE (Pédiatrie Enfants Exposés), which was implemented at 27 sites to document HIV-rapid tests performed on those children and to report them as contacts tested for HIV. Moreover, appointments' dates were discussed with parents/caregivers and tracking through phone calls/home visits conducted for missed appointments/lost-to-follow-up. We reviewed HIV-exposed-children register to ensure that children aged 18-24 months had a known PMTCT-FO.

LESSONS LEARNED: HIV-exposed-children aged up-to 24-months with unknown PMTCT-FO has significantly decreased from 304 (FY18) to 192 (FY19). Consequently, the proportion of HIV-exposed-children with known HIV-negative status as PMTCT-FO improved from 209 (FY18) to 292 in FY19. Furthermore, HIV-exposed-children under 5-years-old reported as contacts tested significantly improved from 23 (FY18Q4=July-September2018) to 135 (FY19Q4= July-September 2019). The training and ongoing coaching, helped strengthen providers' skills and confidence in their ability to ensure standardized follow-up of HIV-exposed-children for effective PMTCT.

CONCLUSIONS/NEXT STEPS: Our interventions led to an improvement from 53% in FY18 (N=566 HIV exposed-children) to 36% in FY19 (N=531 HIV exposed-children) regarding HIV-exposed-children with unknown HIV-final status (PMTCT-FO). Data managers should always consult registers for accurate reporting on HIV-exposed-children. Monitoring and coaching are instrumental for sustainable improvements of PMTCT-FO.

PEE1420

RAPID ANTIRETROVIRAL THERAPY INITIATION AND THE RISK OF MORTALITY AND LOSS TO FOLLOW-UP IN CHILDREN WITH HIV IN EAST AND SOUTHERN AFRICA: A RETROSPECTIVE COHORT STUDY

P.J. Elyanu[1,2], R. Li[1], L.-Y. Hwang[1], C. Markham[1], S. Wanless[3], M. Matshaba[4], M. Hlatshwayo[5], L.K. Thahane[6], P. Kazembe[7], L. Mwita[8], A. Kekitiinwa-Rukyalekere[2], M.E. Paul[9,3]

[1]University of Texas Health Science Center at Houston, School of Public health, Houston, United States, [2]Baylor College of Medicine Children Foundation, Kampala, Uganda, [3]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [4]Baylor Children's Foundation, Gaborone, Botswana, [5]Baylor College of Medicine Children's Foundation, Mbabane, Eswatini, [6]Baylor College of Medicine Children's Foundation, Maseru, Lesotho, [7]Baylor College of Medicine Children's Foundation, Lilongwe, Malawi, [8]Baylor College of Medicine Children Foundation, Mwanza, Tanzania, United Republic of, [9]Baylor College of Medicine, Retrovirology, Houston, United States

BACKGROUND: In 2017, WHO recommended rapid antiretroviral therapy(ART) initiation in people living with HIV following demonstration of retention, viral suppression and survival benefits in adults. However, data on these benefits in Children living with HIV (CLHIV) are scarce. We determined the association between rapid ART initiation in CLHIV and 24-month all-cause mortality and loss to follow-up (LTFU).

METHODS: We pooled data of a cohort of CLHIV (0-14 years) who initiated ART between 2014-2017 at seven Baylor clinics in Botswana, Eswatini, Lesotho, Malawi, Tanzania(2 clinics) and Uganda. Rapid ART initiation was defined as initiating ART on the same day or within 2-7 days of entry into care. Those who initiated within 8-90 days were the comparison group. The outcomes were all-cause mortality and LTFU(≥90 days late for the last clinic appointment). Follow-up time accrued from ART initiation date to the earliest of LTFU, death, transfer-out, 24-months follow-up or database closure date(31-December-2017). Considering death and LTFU as competing events, we determined the association between rapid ART initiation, and mortality or LTFU using sub-distribution hazard regression, adjusting for known risk-factors of mortality and LTFU.

RESULTS: Of the 3,299 participants (50% girls; 40% aged <2 years), 46% initiated ART within 8-90 days, 20% within 2-7 days and 24% on the same-day. Over 57,153 person-months, 254 (7.7%) died, 306 (9.3%) children were LTFU, 315 (9.6%) transferred care and 2424 (73.5%) remained in care. The adjusted sub-distributional hazard ratio (asHR) of mortality was similar between the study arms(table 1). However, the asHR of LTFU was 1.86 times higher in children who initiated ART on the same day and 1.83 times higher in those who initiated within 2-7 days, compared to those who initiated within 8-9 days (table 1).

Timing of ART	Mortality				Loss to follow-up			
	Events (n/N)	CIF (%) 95%CI	Unadjusted sHR (95%CI)	Adjusted§ sHR (95% CI)	Events (n/N)	CIF (%) 95%CI	Unadjusted sHR (95%CI)	Adjusted§ sHR (95% CI)
8-90 days	110/1516	7.85 (6.50, 9.35)	1	1	88/1516	6.83 (5.52, 8.31)	1	1
2-7 days	79/1004	8.32 (6.67, 10.20)	1.09 (0.81, 1.45)	1.05 (0.77, 1.43)	117/1004	13.29 (11.12, 15.66)	2.05 (1.56, 2.71)	1.83 (1.38, 2.43)
same-day	65/779	9.91 (7.67, 12.49)	1.21 (0.89, 1.65)	1.10 (0.79, 1.54)	101/779	16.32 (13.43, 19.47)	2.60 (1.95, 3.45)	1.86 (1.39, 2.49)

§ Adjusted for age, immune suppression, Hemoglobin level, period of ART initiation and country income level. WHO clinical stage was adjusted for in mortality analysis only; CIF- cumulative incidence function

[Table 1: Unadjusted and Adjusted all-cause mortality and loss to follow-up sub-distributional hazard ratios for the first two years of antiretroviral therapy, by the timing of ART.]

CONCLUSIONS: Our findings suggest no survival benefit of rapid ART initiation in CLHIV but higher risk of LTFU. Strategies to reduce LTFU are required when implementing Rapid ART initiation in children.

PEE1421

TIME TO ART INITIATION AMONG NEWLY-BORN HIV POSITIVE INFANTS IN 10 HEALTH FACILITIES IN THE INNER CITY OF JOHANNESBURG, SOUTH AFRICA: RESULTS FROM A RETROSPECTIVE ANALYSIS OF ROUTINE DATA

L. Farlane[1], L. Fairlie[1]

[1]University of the Witwatersrand, Wits Reproductive Health & HIV Institute, Johannesburg, South Africa

BACKGROUND: Worldwide, 1.4 million new HIV infections among children (<15 years) have been averted since 2010, however in 2017 only half of HIV-positive children were on antiretroviral treatment (ART) as such, linkage and retention on ART still lag behind. In July 2015, the Pediatric and Adolescent Scale-up Plan (PASP) targeted HIV exposed children in the inner City of Johannesburg in ten health facilities with strategies such as Kids-Alive training and tracing previously diagnosed children, however there is no information on PASP's effect in improving time to ART.

METHODS: We analysed routine infant data from Tier.Net (ART client management system) at pre (January - June 2015) and post (July 2015 - March 2019) PASP implementation irrespective of age at HIV diagnosis. We calculated time to ART using date of birth and ART start date, and used Chi-squared test to assess associations between ART initiation and PASP. Logistic regression models were built for the outcome variable (ART initiation) and odds ratios reported at 95% CI with p-values significant at ≤ 0.05.

RESULTS: 444 ART initiated infants were included in the analysis. Table 1 shows an overall improvement in time to ART at post-implementation. Infants who were less likely to be initiated late (>90 days) were those born at 18 (OR 0.24, CI=0.073 – 0.75), 24 (OR 0.16, CI=0.04 – 0.54), 36 (OR 0.30, CI=0.09 – 1.0), and 45 (OR 0.24, 0.08 – 0.97) months post implementation.

Time to ART (Days)	Pre-implementation	6 months post-implementation	12 months post-implementation	18 months post-implementation	24 months post-implementation	30 months post-implementation	36 months post-implementation	42 months post-implementation	45 months post-implementation	Total
≤ 90	12	30	22	22	15	26	23	39	15	204
> 90	5	24	27	39	38	23	31	31	22	240
Total	17	54	49	61	53	49	54	70	37	444
% of ART clients	3.83 %	12.16 %	11.04 %	13.74 %	11.94 %	11.04 %	12.16 %	15.77 %	8.33 %	100%

[Table1: Time to ART initiation for HIV-positive infants]

Sixty-three infants diagnosed in the post-implementation phase were not initiated on ART at these facilities and 79% of them were diagnosed in two hospitals. Twenty-nine (46%) of these infants were transferred to other facilities, 28 (44.4%) lost to follow-up, 2(3.1%) died and 4 (6.3%) had undocumented outcomes.

CONCLUSIONS: Time to ART initiation improved significantly post-implementation of PASP, but hospitals had more infants not linked to ART. Immunization services provide a critical opportunity to initiate children who were missed from hospitals, and should be considered as one of the pediatric ART strategies.

PEE1422

LONG-TERM SURVIVAL OF HIV-INFECTED CHILDREN TREATED WITH ANTIRETROVIRAL THERAPY IN EASTERN AND SOUTHERN AFRICA: 2006-2017

P.J. Elyanu[1,2], L.-Y. Hwang[1], R. Li[1], C. Markham[1], S. Wanless[3], M. Matshaba[4], M. Hlatshwayo[5], L.K. Thahane[6], P. Kazembe[7], L. Mwita[8], A. Kekitiinwa-Rukyalekere[2], M.E. Paul[9,3]
[1]University of Texas Health Science Center at Houston, School of Public health, Houston, United States, [2]Baylor College of Medicine Children Foundation, Kampala, Uganda, [3]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [4]Baylor Children's Foundation, Gaborone, Botswana, [5]Baylor College of Medicine Children's Foundation, Mbabane, Eswatini, [6]Baylor College of Medicine Children's Foundation, Maseru, Lesotho, [7]Baylor College of Medicine Children's Foundation, Lilongwe, Malawi, [8]Baylor College of Medicine Children Foundation, Mwanza, Tanzania, United Republic of, [9]Baylor College of Medicine, Retrovirology, Houston, United States

BACKGROUND: Despite providing antiretroviral therapy (ART) for >10 years, data on long-term survival of children living with HIV (CLHIV) receiving ART in resource-limited settings are limited. We describe 10-year survival and risk factors for early mortality (2 years) among CLHIV receiving ART.

METHODS: We conducted a retrospective cohort study of CLHIV (0-14 years) who initiated ART between 2006-2017 at seven Baylor centers of excellence in Botswana, Eswatini, Lesotho, Malawi, Tanzania(2 clinics), and Uganda. Time to death was measured from ART initiation date, and right-censored at the earliest of either loss to follow-up (≥90 days late for last clinic appointment), transfer out, 10-years follow-up or database closure date (Dec 31, 2017). Kaplan-Meier analysis was used to compute 10-year survival and Cox proportional hazard regression to identify independent risk factors for mortality.

RESULTS: Data from 18,010 CLHIV (50% girls; median age, 4.5 years) contributed over 85,140 person-years (PY) of follow-up. Median follow-up was 4.34(IQR: 1.69-7.47) years. Half of the deaths occurred within 6-months of ART. At 10-years, survival (95%CI) was 83.7%(82.5%-84.8%) in children aged <2 years; 91.9%(90.7%-93.0%) in 2-4 years, 92.6%(91.5%-93.6%) in 5-9 years and 88.8%(87.2%-90.2%) in 10-14 years(p<0.01). 10-year survival was 91.7%(89.1%-93.7%) in Botswana,90.7%(89.6%-91.6%) in Uganda,89.8%(88.1%-91.2%) in Eswatini,86.9%(85.2%-88.4%) in Lesotho, 86.5%(84.9%-88.0%) in Malawi, and 5-year survival in Tanzania(COEs started in 2012) was 89.5%(88.0%-90.9%) (p<0.01). Age<2 years[adjusted Hazard Ratio(aHR) 95%CI:1.41:95% CI:1.11,1.79], WHO stage 3(aHR: 1.36: 95%CI: 1.06-1.73) or stage 4(aHR 2.95:95%CI 2.33,3.73) , moderate immune-suppression(aHR: 2.64:95%CI 1.90,3.66), severe immune-suppression(aHR 6.71:95%CI 5.29,8.52), and severe underweight(-3sd WAZ) (aHR 1.84:95%CI:1.48,2.29) were independently associated with a higher risk mortality in the 1st 6 months, and after 6 months of therapy. Factors associated with lower risk of mortality were: Initiating ART with PI regimen(aHR 0.67:95%CI: 0.49,0.91), Initiating ART in 2014-2017 compared to 2006-2009 (aHR: 0.77:95%CI 0.62,0.96).

CONCLUSIONS: Long-term survival among CLHIV receiving ART is good; however, mortality is highest in the first 6-months of therapy and the risk of death is higher in younger children and those with advanced disease at ART start. Our findings re-emphasize the need for early infant diagnosis and treatment and close monitoring at therapy start as measures to reduce mortality in CLHIV receiving ART.

PEE1423

WHERE ARE THE CHILDREN? A GEO-SPATIAL LOOK AT CHILDREN LIVING WITH HIV AND ON TREATMENT IN NIGERIA

B. Onifade[1], D. Adeyinka[2], D. Adeyinka[1], G. Eluwa[3], C. Nzelu[1], A. Davies[4], F. Oluwasina[5], D. Odoh[1], B. Jibrin[1], O. Ilesanmi[6], R. Mpazanje[6]
[1]National HIV/AIDS Control Program, Federal Ministry of Health, Public Health, Abuja, Nigeria, [2]University of Saskatchewan, Department of Community Health and Epidemiology, College of Medicine, Saskatchewan, Canada, [3]Population Council, Research, Abuja, Nigeria, [4]The United Nations Children's Fund, HIV, Abuja, Nigeria, [5]AIDS Healthcare Foundation, Abuja, Nigeria, [6]World Health Organization, Abuja, Nigeria

BACKGROUND: About 1.7 million children were estimated to be living with HIV globally in 2018. In West and Central Africa, there were 58,000 new infections of which Nigeria accounted for about 41%. As at December 2018, Nigeria has an estimated 140,000 Children Living with HIV (CLHIV) with about 36% identified and were on ART. We describe the spatial pattern of HIV burden and ART coverage among children aged 0 -14 years in all the states in Nigeria.

METHODS: The 2019 Spectrum-generated estimates for the 36 states plus FCT in Nigeria were triangulated with the 2018 National HIV routine programme data and the projected population of children from the 2006 census were used to map the burden of CLHIV and ART coverage sub-nationally. Dorling cartogram was developed using the children population, CLHIV and ART coverage as a percent to show a comprehensive view of paediatric populations by state. With a spatial weight of 407Km, local indicator spatial autocorrelation analyses were performed to identify hot and cold-spots.

RESULTS: The median paediatric population living with HIV was 2,703 (IQR: 1,747-5,037) and paediatric ART coverage was 32.1% (IQR: 20.6%-52.4%). There was significant clustering of paediatric ART (PART) coverage in Nigeria (Moran's I index=0.1, p-value=0.023). The hot-spots (clusters of states with significantly higher paediatric ART coverage, compared to their adjacent states) comprised of four states, located in North-Central region (FCT and Nasarawa state), and North-East region (Bauchi and Taraba states). Lagos and Bayelsa states formed cold-spot clusters for PART. However, there was no significant spatial autocorrelation for burden of paediatric HIV children (Moran's I index=0.05, p-value=0.087). The multivariate Dorling cartogram shows that ART coverage of CLHIV is not determined by the population size or the burden of CLHIV.

CONCLUSIONS: Paediatric ART coverage is still sub-optimal in Nigeria. This study offers evidence for a wide geographic variations in paediatric ART coverage in the country, therefore, there is an urgent need for a programming shift, focusing on the geographical inequity and putting in place geographically sensitive programmatic actions on to prevent, find cases, initiate treatment and ensure retention in order to reach 95-95-95 UNAIDS target for CLHIV by 2030.

PEE1424

EXPERIENCES OF CAREGIVERS ADMINISTERING LOPINAVIR/RITONAVIR PELLETS AS PART OF FIRST LINE ANTI-RETROVIRAL THERAPY FOR HIV INFECTED CHILDREN BELOW THREE YEARS OF AGE IN UGANDA

C. Katureebe Mboijana[1], S. Kalra[2], P. Nawaggi[2], V. Nabitaka[2], E. Magongo[1], G. Kirungi[1], A. Musoke[2], J. Conroy[2], C. Amulen[2], H. Busobozi[2], E. Twinomujuni[2]

[1]Ministry of Health, STD/AIDS Control Program, Kampala, Uganda, [2]Clinton Health Access Initiative, Kampala, Uganda

BACKGROUND: Lopinavir/ritonavir (LPV/r) pellets were included as the preferred LPV/r formulation for the 0-<3-year-old patient population in the 2016 National HIV Guidelines and were rolled out country-wide in 2017. This study was conducted to explore the perspectives of caregivers administering LPV/r pellets to children with the aim of identifying any existing barriers to their uptake.

DESCRIPTION: The study was conducted from July-August 2019 in 30 health facilities across 16 districts in Uganda. Facilities with a high number of eligible children (<3 years of age) and those that had a regular supply of LPV/r pellets over the June-December 2018 period were purposefully selected.

Responses from 133 caregivers of children ≥3 months to <3 years were collected either through one-on-one interviews or focus group discussions depending on the number of interviewees available. Responses were analyzed thematically.

LESSONS LEARNED: 86% of caregivers reported correct methods of administration, mostly adding the pellets to milk, porridge or water and immediately administering to the child. However, 14% of mothers reported incorrect administration methods including crushing, grinding, attempting to dissolve pellets and administering unopened capsules.

Care givers who reported incorrect administration techniques mostly reported negative experiences such as unpalatability of the medicine and side effects such as vomiting after administration. Changing caregivers and frequent switches between LPV/r tablets and pellets due to drug stock outs contributed to these incorrect administration practices. Overall, there was high acceptability of LPV/r pellets amongst caregivers with 93% of them answering in the affirmative when asked if they would recommend LPV/r pellets for another child who is HIV positive.

CONCLUSIONS/NEXT STEPS: Although a majority of caregivers are administering pellets well, there is still a significant percentage of caregivers (14%) who deployed poor administration practices and mostly negative experiences with the medicine. To address this gap, the national program is going to develop, translate and disseminate caregiver literacy materials including videos, posters and brochures. In addition to this, the program is emphasizing the need for cross checking pellets administration at every clinic visit and demonstration of pellets administration in cases of a new caregiver or of one reporting incorrect practices.

PEE1425

PREFERENCES FOR TUBERCULOSIS PREVENTIVE TREATMENT (TPT) AMONG CHILDREN WITH HIV IN ESWATINI: A DISCRETE CHOICE EXPERIMENT

Y. Hirsch-Moverman[1], M. Strauss[2], J.E. Mantell[3], G. George[2], W. El-Sadr[1], A. Mafukidze[4], S. Dube[5], A.A. Howard[1]

[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [2]University of KwaZulu Natal, Health Economics and HIV/AIDS Research Division (HEARD), Durban, South Africa, [3]New York State Psychiatric Institute and Columbia University Irving Medical Center, HIV Center for Clinical & Behavioral Studies, Division of Gender, Sexuality and Health, New York, United States, [4]ICAP in Eswatini, Mbabane, Eswatini, [5]Eswatini Ministry of Health, National TB Control Program, Mbabane, Eswatini

BACKGROUND: Tuberculosis (TB) prevention in children with HIV is a priority for protecting their health and well-being but isoniazid preventive therapy initiation and completion rates are suboptimal. Shorter TB preventive treatment (TPT) regimens have demonstrated safety and efficacy but are not widely used in high TB/HIV-burden countries. Children's preferences regarding TPT regimens' characteristics and service delivery models are key to developing services aimed at improving TPT uptake and completion.

METHODS: We conducted a discrete choice experiment from August through December 2019 to examine TPT preferences among children with HIV attending clinics monthly to collect antiretroviral therapy in Eswatini. We enrolled children aged 10-14 years from 12 healthcare facilities in the Manzini Region. Drug regimen and service delivery characteristics included pill size and formulation; dosing frequency; medication taste; duration of treatment and visit frequency; cost; clinic wait time; and clinic operating hours. An unlabeled, binary choice design was used; data were analyzed using a fixed effects logistic regression model to estimate main effects parameters.

RESULTS: Among 150 children, median age was 12 years (interquartile range 11-13), 49% were female. Children were willing to make trade-offs, with medication taste, cost, and wait time statistically significant characteristics driving preferences. The most important preferred characteristic was medication taste, with children being more than twice as likely to choose a regimen if the taste was palatable compared to medication that was bitter (OR=2.2; p<0.001). Free services were preferred to services costing $0.70 (OR=1.5; p=0.001), while a service fee of $5.60 decreased preferences compared to a fee of $0.70 (OR=0.5; p<0.001). A wait time of 15 minutes compared to 45 minutes was preferred (OR=1.3; p=0.022), while a wait time of 3 hours decreased preferences compared to wait time of 45 minutes (OR=0.8; p=0.045). Other attributes had no significant influence on preferences.

CONCLUSIONS: Participants' preferences in this study indicate that medication palatability, low cost and reduced wait time are more significant drivers of choice than decreased duration or dosing frequency of TPT regimens. These characteristics are important to consider in the design of TPT services for children aimed at improving uptake and adherence.

APPROACHES TO MINIMIZING LOSS IN THE PREVENTION/TREATMENT CASCADE

PEE1426

A QUALITY-IMPROVEMENT COLLABORATIVE APPROACH FOR INCREASING PEOPLE WITH HIV CURRENTLY ON TREATMENT BY TARGETING HIGH-VOLUME HEALTH FACILITIES, WESTERN PROVINCE, ZAMBIA – 2019

H. Mushisha[1], N. Msiska[2], L. Chingumbe[2], C. Mumbwe[3]
[1]WPHO COAG-CDC, Mongu, Zambia, [2]ICAP, Mongu, Zambia, [3]WPHO COAG, Mongu, Zambia

BACKGROUND: It is estimated that Zambia has 1,200,000 people living with HIV (PLHIV) of whom 87% are diagnosed, and, of the 78% were currently on treatment (CoT). The Western Province has low rates of diagnosis and poor retention for Current on Treatment. We sought to increase the proportion of all PLHIV aged >15 years that are CoT in the western province from 60% to 81% using Quality Improvement (QI) collaboration in the first nine months of 2019.

DESCRIPTION: We focused on the 10 high-volume treatment sites that were supported by PEPFAR through the U.S. CDC, which was 10% of these sites and represented 45% of the provincial total CoT, defined as having had at least one HIV treatment visit in the last six months. QI collaboration was implemented in facility-based teams that examined drivers of barriers and potential solutions, with analyses conducted on a weekly basis, both case identification and retention were emphasized. Interventions included after-hours services for men, index challenge mop up this included obtaining a list of clients found positive in the last three months not indexed and initiate a daily follow up of clients, moonlighting and intensified appoint register this included provision of a phone and airtime at facility, daily appointment register generation, and call-in of patients prior to clinical or pharmacy appointment, implementation of DSD (Differentiated Service Deliver models such as MMS (Multi-month Scripting).

LESSONS LEARNED: To aid data collection for accurate reporting, we used a dual system with both Smartcare, an electronic health record system, and hard copy registers. The number of PLHIV who were CoT in the Western Province increased from 62,308 in January 2019 to 73,533 in September 2019, which was 63% and 81% of all PLHIV, respectively. The most effective interventions were focusing on the high-volume facilities, improving daily appointment registers, and calling in patients who missed appointments.

CONCLUSIONS/NEXT STEPS: Our use of QI collaboration contributed to the increase of ART coverage in Western Province, Zambia, in nine months from 63% to 81% through enhancing case finding and addressing key drivers of attrition. Immediate call back of patients after a missed appointment was a critical intervention, along MMS.

TREATMENT OUTCOMES OF PATIENTS ENROLLED ON ANTI-RETROVIRAL THERAPY: A COMPARISON AT TERTIARY AND PRIMARY LEVELS OF THE HEALTH CARE SYSTEM IN BOTSWANA

B. Moali[1], B. Nkomo[2], M. Otieno[3], N. Sirili[4], M. Nsoh[5], A. Mgasa[6], A. Busi[7], T. Lebapotswe[8], K. Taylor[9], N. Majingo[10], E. Seloilwe[11], Y. Mashalla[12]
[1]Ministry of Health and Wellness, Okavango District Health Management Team, Gumare, Botswana, [2]Ministry of Health and Wellness, HIV/AIDS Prevention,Treatment and Care, Gaborone, Botswana, [3]Ministry of Health, National AIDS and Sexually Transmitted Infections Control Program (NASCOP), Nairobi, Kenya, [4]Muhimbili University of Health and Allied Sciences, Development Studies, Dar es Salaam, Tanzania, United Republic of, [5]School of Health Sciences, Catholic University of Central Africa, Public Health, Yaounde, Cameroon, [6]Ministry of Health, Community Development, Gender, Elderly and Children: National Blood Transfusion Service, Dar es Salaam, Tanzania, United Republic of, [7]Cameroon Baptist Convention Health Services, Women Health Program, Mbingo Baptist Hospital, Yaounde, Cameroon, [8]Ministry of Health and Wellness, Child Health Division,Under-Five Mortality, Gaborone, Botswana, [9]Ministry of Health and Wellness, Ngamiland District Health Management Team, Maun, Botswana, [10]Ministry of Health and Wellness, Disease Control, Gaborone, Botswana, [11]University of Botswana, School of Nursing, Gaborone, Botswana, [12]University of Botswana, Faculty of Medicine, Gaborone, Botswana

BACKGROUND: HIV/AIDS remains a significant public health problem in Botswana with a prevalence of 18.5%. Anti-Retroviral therapy (ART) has led to a significant reduction in morbidity and mortality associated with HIV/AIDS. Currently, about 370 000 persons living with HIV (PLWHIV) in Botswana are receiving ART and decentralization of ART has improved access to treatment. The objective of this study was to compare treatment outcomes of patients enrolled on ART at tertiary and primary levels of health care.

METHODS: This was a cross-sectional study. We conducted a retrospective analysis of secondary data obtained from the Ministry of Health and Wellness data warehouse for patients who were enrolled on ART in the selected health facilities from January 2017 to December 2018 at tertiary and primary levels of care. Variables included were demographic profile, date of diagnosis, date of ART initiation and viral load at 12 months. The capacity of the facilities to offer HIV/AIDS testing and treatment services was also assessed. Data analysis was done using Statistical Analysis Software (SAS).

RESULTS: Nine hundred and sixty(960) patient's records were included in analysis. More than half (63%) of patients were enrolled at primary care level while 37% were at tertiary level. Sixty one percent (n=587) were females while 39 % (n=373) were males. The median age was 38 years old. There was no statistically significant differences in viral load suppression after 12 months of treatment between patients enrolled at tertiary and primary levels of care, $\chi 2$ =0.75, p value = 0.56. Time to initiation was longer at tertiary (median = 126 days) compared to primary care level (median = 18 days) and the difference was statistically significant, p<0.001. The facilities under study demonstrated a satisfactory capacity to provide comprehensive ART services.

CONCLUSIONS: Treatment outcomes for patients on ART were the same at both tertiary and primary levels of care. However, decentralization of ART services to lower levels of health care reduces significantly the time taken to initiate ART thereby increases number of patients initiated on treatment.

PEE1428

FEASIBILITY AND EFFECTIVENESS OF THE SOCIAL NETWORKING STRATEGY IN IDENTIFYING NEW HIV POSITIVES IN RURAL UGANDA

B. Kalebbo[1], H. Katende[1], F. Namimbi[1], A. Kiyimba[1], A. Muganzi[1]
[1]Infectious Diseases Institute, Makerere University, College of Health Sciences, Kampala, Uganda

BACKGROUND: UNAIDS aims to end the AIDS epidemic by 2030 through the 95-95-95 strategy. By 2018 Uganda had identified 84% Persons Living with HIV(PLHIV), 87% were on treatment and 88% were virally suppressing (UNAIDS 2019). With HIV prevalence of 5.7%(UNAIDS 2019), Uganda needs effective and efficient HIV testing innovations to identify the remaining cases.

With funding from PEPFAR/CDC Infectious Diseases Institute implemented a social networking strategy(SNS), in which HIV positive clients and high-risk HIV negative individuals (KPs/PPs) identify those within their social networks at risk of HIV infection and recommend them for HIV testing. We assessed the feasibility and effectiveness of SNS for identifying new PLHIV in rural Uganda.

DESCRIPTION: We sensitized and engaged leaderships in eight rural districts in Midwestern(MW) Uganda about SNS; and co-developed Standard Operating Procedures, data collection and reporting tools in alignment to national policies and guidelines.

Between October 2018 and September 2019, we implemented SNS at 40 purposively selected facilities. At facility level Health workers formed SNS teams which were trained to offer counseling and support, elicit social contacts and their information, and use SNS customized data tools. SNS teams explained and offered SNS to index PLHIV and at-risk HIV negative persons. They elicited social contacts and their information from individuals who accepted SNS, and invited contacts for HIV testing. Testing was done at facility or home depending on willingness and convenience of contacts.

LESSONS LEARNED: 13,232 contacts were elicited from 3,619 informants: 3,438(95%) informants were index PLHIV and 181(5%) at-risk HIV negative contacts. 97%(12,876/13,232) disclosed contacts were notified and 98%(12,626/12,876) notified contacts tested. Out of 12,626 contacts tested, 1,470(11.6%) were newly identified PLHIV. A positivity rate of 11.6%(1,396/11,995) was realized from contacts of index clients; and 11.7%(74/631) from contacts of at risk HIV negatives. The positivity rate of 11.6% was higher than 3.2% reported by MW region in October 2018 to September 2019 (DHIS2). 1,334(91%) PLHIV identified were linked to care.

CONCLUSIONS/NEXT STEPS: SNS is a feasible and effective strategy for identifying new PLHIV and linking them to care. Its critical to integrate SNS into existing HIV programs as the pool of unidentified PLHIV dwindles.

PEE1429

INCREASING ART TREATMENT OUTCOMES IN HIV PATIENTS USING COMMUNITY BASED PEER NAVIGATORS IN MALAWI DEFENCE FORCE HIV SETTINGS

A.V. Nanchito[1], H. Ben Azouz[2], A. Rurangwa[3]
[1]Malawi Defence Force, HIV Program/Epidemiology, Zomba, Malawi, [2]International Senior Consultant, HIV AIDS, Johannesburg, South Africa, [3]Project Concern International, Senior Technical Advisor HIV/AIDS & Health, Washington D.C, United States

BACKGROUND: For its HIV program Malawi Defence Force (MDF) adapted recently UNAIDS 90 90 90 recommendations of HIV viral load testing (6 months initially then 12 months.However). Despite notable achievements in the first 90 through index testing scale up and improved linkage rates, the second and third 90 indicators such as retention in care, routine VL testing and VL suppression rates have been recently suboptimal with significant performance gaps in MDF health settings.

DESCRIPTION: We sought to adopt the IHI QI framework to devise a targeted approach to bring LTFU clients back into care to increase Tx Current from 71.6% to 95% and improve routine VL monitoring that could increase VL coverage from 69.9% to 95% in a period of 3 months through use of community based peer navigators.

LESSONS LEARNED: The change idea consisted of usingpeer navigators/expert clients to track LTFU clients and those due for VL collection through the Back To Care program and patients that had a high VL result to access IAC sessions and unsuppressed ARTclients with a follow up VL to second line regimen switch as appropriate.

In Back to Care QI initiative, out of 1,716 defaulters, 1165 (67.9%) were brought back to care, 257(14.9%) were confirmed to have died, 178(10.3%) had self-transferred themselves to other health facilities while 116 were untraceable (6.7%). The Tx Current rate increased by 36.5% through back to care and by 12.4% through new initiations. Out of 823 clients due for VL flagged on patient cards, 600 (72.9%) had their blood samples taken. Out of 61 clients with high VL, 52 were successfully switched to second line regimen during QI implementation.

CONCLUSIONS/NEXT STEPS: Use of peer navigators/expert clients within a QI approach to track clients who defaulted on ART and those due for VL blood sample collection through the BTC initiative needs to be enhanced. Identifying patients that have a high VL result to access IAC sessions and ART clients with a high F/U VL to alternate ART regimens needs to be strengthened using a similar QI approach to reduce the 90 90 performance gaps. Further cost-analysis needs to be conducted to assert cost-efficiency of such approaches.

PEE1430

CLINIC STAFF MEMBERS' PERCEPTIONS OF BARRIERS TO HIV CARE IN THE RURAL SOUTHERN UNITED STATES

M. Moore[1], C. Golin[2], H. Swygard[1], M. Floris Moore[1], S. Watson[2], T. Vu[2], C. Sellers[1]
[1]University of North Carolina, Medicine, Division of Infectious Diseases, Chapel Hill, United States, [2]University of North Carolina, Health Behavior, Chapel Hill, United States

BACKGROUND: A majority of new cases of HIV in the United States are now diagnosed in the South, including a substantial number in rural areas. Many rural areas of the South lag behind other regions in proportions of persons living with HIV (PLWH) who are retained in care and achieve viral suppression, despite extensive, multifaceted

efforts to reach out-of-care PLWH in the region. Improved understanding of the problem and new strategies to foster reengagement and retention are needed. As formative research for Project Reengagement and Adherence Mobile Program (RAMP), a study pilot-testing a field-based HIV care delivery intervention for persistently out of care PLHW, we conducted interviews with clinic providers and staff to tailor patient interview and intervention design.

METHODS: All clinic staff members from a publicly-funded HIV clinic serving a large, predominantly rural catchment area in North Carolina were invited to participate in individual in-depth interviews regarding barriers and facilitators to re-engaging patients in HIV care. Interviews were conducted in person at the clinic and ranged in length from 21 to 47 minutes. All data were coded independently by two experienced coders in Dedoose and thematically analyzed.

RESULTS: Ten clinic staff members (50% male, 50% female) with roles of nurse, nursing assistant, physician, social worker, bridge counselor and peer educator were interviewed. The following themes emerged as barriers to care: the critical need for transportation resources, lack of mental health services, financial and insurance challenges, and issues with medication adherence. Identified facilitators included creating a more welcoming environment, offering telehealth services or home visits, offering financial incentives or assistance, providing more flexible clinic hours, increasing patient education on the importance of HIV treatment, offering mental health resources, and providing transportation assistance.

CONCLUSIONS: The large number and diverse types of barriers to HIV care, and the need for multipronged approaches to facilitate reengagement were common refrains from the interviews. Staff members with different roles in the clinic tended to focus on different needs, highlighting the importance of involving a diversity of stakeholders in intervention design and policy change. Interviewees emphasized the significant unmet needs of out of care PLWH in the rural South.

PEE1431

"RIGHT UNDER OUR NOSE": A SIMPLE SCREENING TOOL TO IDENTIFY HIV-POSITIVE CHILDREN OUTSIDE OF THE PMTCT PROGRAM AT OUTPATIENT DEPARTMENTS IN MALAWI

A. Tallmadge[1], C. Stillson[1], G. Nyirenda[1], N. Nyambi[1], C. Banda[1], A. Gunda[1], M. Muyaso[2], K. Namachapa[2], M. Eliya[2]
[1]Clinton Health Access Initiative, Lilongwe, Malawi, [2]Ministry of Health, Department of HIV/AIDS, Lilongwe, Malawi

BACKGROUND: In Malawi, only 67% of HIV-infected children have been linked to treatment. Linkage of known infected children is high but there is a persistent challenge of identifying children who have dropped out of the PMTCT cascade or were infected postnatally. These children likely account for a large proportion of the remaining gap in pediatric treatment coverage. There are insufficient resources to conduct universal testing in high-volume entry points like facility outpatient departments (OPDs) and a lack of guidance for screening. Therefore, these children often remain undiagnosed until they have progressed to advanced disease, despite having frequent contact with the health facility. With systematic screening at the health facility, there is a unique opportunity to identify these "missed" children earlier and link them to life-saving care.

METHODS: Through a national taskforce, a screening tool was developed for use in facility OPDs. The tool was formatted as a simple checklist and screened children 2-12 years old, focusing on their mother's testing history instead of risk factors. Mothers without a documented HIV negative result at the end of breastfeeding were referred for HIV testing and, if positive, their children were also referred for testing. If the mother was not available, the child was screened in directly. The tool was piloted at 32 health facilities in Malawi from July-September 2019 and implemented by existing lay cadres.

RESULTS: 8811 screening slips were collected during the pilot period. The median age of children screened was 5.3 years (IQR: 3—7). 22.0% of available mothers were referred for testing (1827/8288) based on screening. Of those tested, 1.9% tested newly positive (28/1474). Overall, 8.3% of children were screened in for testing (658/7897). Of those who accepted testing, 3.9% tested newly positive (17/437). Screening was found to be feasible in OPDs through task-shifting to lay cadres.

CONCLUSIONS: Systematic screening of mothers and children leads to earlier identification of HIV infected children and more efficient testing within resource constraints, allowing for earlier linkage to care which is proven to improve children's health outcomes and chances of survival. These results will inform revisions to the screening tool for national adoption.

PEE1432

OFFERING STARTER PACKS OF ANTIRETROVIRAL DRUGS IMPROVES TREATMENT OUTCOMES AMONG HIV-INFECTED FEMALE SEX WORKERS IN NAIROBI, KENYA

N. Njuguna[1], J. Gacheru[2], S. Mwangi[2], H. Wanyungu[1], C. Akolo[3]
[1]FHI 360/EpiC, Nairobi, Kenya, [2]Bar Hostess Empowerment and Support Program (BHESP), Nairobi, Kenya, [3]FHI 360/LINKAGES, Washington DC, United States

BACKGROUND: Female sex workers (FSWs) in Kenya remain disproportionately affected by HIV, yet have lower access to, uptake of, and retention on treatment than the general population. Their highly mobile nature and irregular hours are contributing factors. The PEPFAR/USAID-funded LINKAGES project led by FHI 360, working with Bar Hostess Empowerment and Support program (BHESP), sought to improve linkage to treatment for HIV-positive FSWs in Nairobi by offering starter packs during outreaches.

DESCRIPTION: BHESP provides comprehensive HIV services, including HIV testing, to FSWs at their drop-in center (DIC) or through outreaches to hot spots where FSWs congregate. All newly identified HIV-positive FSWs are referred for treatment at the DIC or other facility of their choice. As part of same-day antiretroviral treatment initiation, in May 2019, BHESP clinicians began offering five–14-day ART starter packs to those diagnosed during outreaches. The number of tablets offered corresponded to the number of days until the first appointment at the DIC or link facility. The FSWs were then followed up by peer navigators to ensure completion of linkage to treatment. Outcomes were analyzed using descriptive statistics.

LESSONS LEARNED: During five months, a total of 109 FSWs were newly identified as HIV positive. Their median age was 34 (IQR 29–41). Of these, 79 FSWs (73%) were diagnosed during outreaches, and all received starter packs with an average of 12 pills. Of women receiving starter packs, 86% attended their initial clinic visit as scheduled, with the majority (95%) accessing services at the BHESP DIC. Overall linkage to treatment improved from 76% (35/46 FSWs testing positive during seven months before intervention) to 100% (109/109 FSWs testing positive during intervention).

Of those eligible for viral load testing who had the test done and received a starter pack, 96% were virally suppressed at their six-month visit compared to 47% of all FSWs newly identified as HIV positive in the preceding year.

CONCLUSIONS/NEXT STEPS: Offering ART starter packs to FSWs diagnosed at outreaches provides an opportunity for same-day ART initiation, leading to improved treatment outcomes. The program will build on the success of this intervention by expanding it to all outreach activities.

PEE1433

POINT-OF-CARE (POC) DATA DRIVEN REVIEWS FOR IMPROVED RETENTION IN CARE: A CASE OF USAID RHITES N-LANGO PROJECT, NORTHERN UGANDA

G. Aguze[1,2], P. Donggo[3], J. Ictho[4], D. Ogwal[5], P. Lochoro[4], H.R. Atim[5], J. Okello[6], M. Obizo[7], J.B. Orech[8], L. Akello[5], G. Sangadi[9]

[1]John Snow Inc., USAID Regional Health Integration to Enhance Services (RHITES N Lango Project), Community, Kampala, Uganda, [2]Doctors with Africa CUAMM USAID Regional Health Integration to Enhances Services (RHITES N Lango), Community, Kampala, Uganda, [3]John Snow Inc., USAID Regional Health Integration to Enhance Services (RHITES N Lango Project), Technical, Kampala, Uganda, [4]Doctors with Africa CUAMM, Technical, Kampala, Uganda, [5]USAID RHITES N Lango Project, Community, Kampala, Uganda, [6]USAID RHITES N Lango Project, Monitoring and Evaluation, Kampala, Uganda, [7]Doctors with Africa CUAMM, Monitoring and Evaluation, Kampala, Uganda, [8]USAID RHITES N Lango, Community, Kampala, Uganda, [9]USAID RHITES N Lango, Technical, Kampala, Uganda

BACKGROUND: The Lango sub-region in northern Uganda has 2.4 million people, 80% are rural communities, 50% are below 15 years of age, HIV prevalence at 7.2%, above national average of 6.2%. The expected annual number of clients on antiretroviral therapy (ART) by the end of September 2019 was 87,278. By March 2019, only 62% and 69% of clients previously started on ART were still in care at 6 and 12 months respectively. The USAID supported RHITES-N, Lango project is committed to improving client access to and retention on lifelong ART.

DESCRIPTION: We conducted (POC) data-driven reviews and real-time client follow up in 44 facilities that provide ART. Data was retrieved from the national data system (DHIS2), reviewed, and used to select sites with poor retention, focusing on the six months' cohorts. Health workers and community volunteers (linkage facilitators) updated appointment registers, line listed the lost clients, developed a search list, and drew a client tracking plan. Client follow up was conducted by community volunteers and the tracking outcome was documented in the client registers at the facility. To reduce the increasing number of lost clients from care, daily tracking of missed appointments through phone calls and use of pre-appointment reminder messages were then instituted at all ART sites.

[Figure 1. Retention in care and lost to follow up among clients on ART in Lango subregion in Uganda]

LESSONS LEARNED: Findings indicate that six-month retention increased from 62% (October-September 2018) to 70% (July-September 2019) whereas number of lost clients decreased from 30% to 16%. Hence the total number of clients on ART increased from 73,595 (December 2018) to 81,776 in September 2019

CONCLUSIONS/NEXT STEPS: Point of Care data driven reviews and real time follow up significantly improved retention of HIV clients in care. Routine technical support to health facility teams ensure client tracking and follow up efforts are done in real time, an approach that is effective and can be adopted by similar HIV treatment programs.

PEE1434

IMPACT OF RAPID HIV ENGAGEMENT PROGRAM IN A SOUTHERN UNITED STATES CLINIC

S. Weissman[1], P. Patel[2], C. Ruggiero[2], A. Milgrom[1], C. Derrick[1]

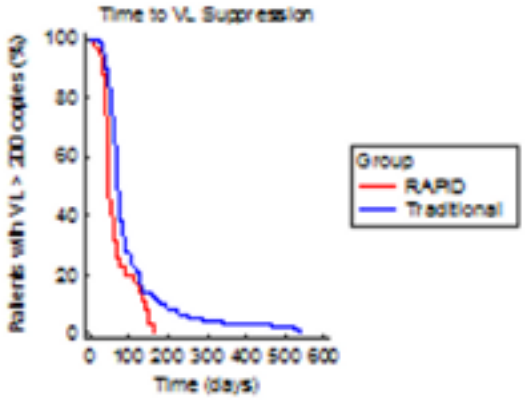
[1]University of South Carolina, Medicine, Division of Infectious Diseases, Columbia, United States, [2]University of South Carolina, School of Medicine, Columbia, United States

BACKGROUND: Recent data suggest that rapid initiation of antiretroviral therapy (ART) is associated with improved short-term adherence and virological suppression. Early HIV diagnosis and rapid initiation of ART are pillars of the end the HIV epidemic campaign. The purpose of this study is to evaluate the effectiveness of a Rapid Engagement program in a high prevalence, southern U.S. HIV clinic.

METHODS: In 10/2018 a Rapid Engagement program was initiated with the goal to start ART within 48 hours of diagnosis or return to care (off ART for >6 months). A retrospective analysis was performed comparing Rapid group of individuals entering care from 10/1/2018 to present and Traditional group of individuals entering care from 10/1/2017-9/30/2018. Data was extracted from the electronic health records. These results represent an interim analysis.

	Traditional (N= 107)	RAPID (N = 47)	P-value
Gender, n (%) M F MTF	 77 (72%) 27 (25%) 3 (3%)	 34 (72%) 13 (28%) 0	NS
Mean Age, year	34.9	38.2	NS
Race, n (%) Black White Other	 86 (80%) 12(12%) 8 (8%)	 38 (81%) 7 (15%) 2 (4%)	NS
Mean baseline CD4, cells/μL	267	301	NS
Risk Group, n (%) MSM Hetero Other	 45 (42%) 46 (43%) 17 (15%)	 19 (40%) 14 (30%) 14 (30%)	NS
Time to intake, days Mean Median Range	 13 7 0 – 174	 7 2 0 – 45	 0.0434 0.00859
Time to provider visit, days Mean Median Range	 35 27 0 – 344	 12 4 0 – 97	 0.0006 0.000002
Time to ART start, days Mean Median Range	 54 35 0 – 518	 19 8 0 – 111	 0.0021 < 0.000001
Time to VL suppression, days Mean Median Range	 102 72 26 – 542	 66 49 10 – 165	 0.0286 0.001156

[Table: Comparison of Traditional versus Rapid Groups]



[Figure]

RESULTS: 154 patients were included in this analysis, 47 in the Rapid group and 107 in the Traditional group. Comparison of the Traditional and Rapid groups are shown in the table. There was no difference in baseline characteristics. Rapid group had a shorter time to initial intake, provider visit, ART initiation and viral load (VL) suppression (viral load < 200 copies/ml). VL suppression occurred a mean of 102 days in Traditional group versus 66 days in the Rapid (Table, Figure).
CONCLUSIONS: Rapid engagement program is effective in decreasing the time from patient referral to first provider visit, ART initiation, and VL suppression. Impact on long-term outcomes, particularly retention in care and sustained viral suppression, will be assessed.

PEE1435

PREPARING A FINANCIAL INCENTIVE PROGRAM TO IMPROVE ADHERENCE TO ART FOR SCALE: USING AN IMPLEMENTATION SCIENCE FRAMEWORK TO EVALUATE AN MHEALTH SYSTEM IN TANZANIA

L. Packel[1], C. Fahey[1], A. Kalinjila[2], A. Mnyippembe[2], P. Njau[2,3], S. McCoy[1]
[1]University of California, School of Public Health, Berkeley, United States, [2]Health for a Prosperous Nation, Dar es Salaam, Tanzania, United Republic of, [3]Ministry of Health, Community Development, Gender, Elderly, and Children, National AIDS Control Programme;, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Viral suppression is key to ending the epidemic, yet only 58% of people living with HIV (PLHIV) in sub-Saharan Africa are suppressed. Cash transfers are an effective strategy to improve adherence, but little is known about optimization of implementation; for example, designing effective programs that integrate into existing clinic workflows. We report on an implementation science study of an mHealth system within an effectiveness trial of cash transfers for adherence.
METHODS: We conducted an "effectiveness-implementation science" randomized controlled trial evaluating cash transfers conditional on visit attendance among Tanzanian PLHIV initiating ART. An mHealth system using fingerprint identification was used in pharmacies to automatically disburse mobile money to eligible PLHIV. With the goal of creating a program for future scale, we used Proctor's framework, defining implementation constructs for the mHealth system at multiple levels: PLHIV, provider, and organization. To assess these constructs, we conducted: surveys (n=100; Health Information Technology Usability Evaluation Scale (HITUES) and in-depth interviews (IDIs; n=25) with PLHIV; IDIs with clinic and pharmacy staff (n=10) and study research assistants (RAs; n=5); and structured observations in clinics (n=2348 visits).
RESULTS: PLHIV reported high scores (above 4.0/5.0) across HITUES domains (impact, usefulness, ease of use, user control) for fingerprinting and automated money. Pharmacists praised the efficiency of the system, but concerns about duplicative record-keeping arose. Clinic management staff voiced excitement for the system's potential to bring the cash program to patients and simplify workflows; yet concerns about multiple systems, staffing shortages, and intermittent connectivity tempered enthusiasm, highlighting structural issues beyond the program. Management emphasized the importance of training all staff on new systems. RAs were key in ensuring fidelity of use; also in lightening staff burden by helping with routine tasks when understaffed. Structured observations showed a steep learning curve; repeat fingerprint scans and manual entry declined precipitously over time
CONCLUSIONS: Despite praise by PLHIV, staff and clinic-level factors - staff shortages, access to resources and training - are crucial considerations for scale-up and sustainability. Understanding implementation science constructs at multiple stakeholder levels is essential in bridging the know-do gap and bringing effective programs to scale.

PEE1436

BELIEFS AND LACK OF KNOWLEDGE ABOUT METHADONE AMONG PWID LIVING WITH HIV PRESENT BARRIERS FOR SERVICE UTILIZATION IN KAZAKHSTAN

M. Darisheva[1], T. McCrimmon[2], A. Terlikbayeva[1], S. Primbetova[1], P. Gulyaev[1], Y. Rozental[1], D. Bekishev[1], A. Kuskulov[1], T. Hunt[2], E. Wu[2], L. Gilbert[2], N. El-Bassel[2]
[1]Global Health Research Center of Central Asia, Almaty, Kazakhstan, [2]Columbia University, School of Social Work, New-York, United States

BACKGROUND: Opioid Substitution Therapy (OST) has been introduced in Kazakhstan since 2008, offering methadone to people who inject opioid drugs (PWID), with people living with HIV (PLWH) in priority. However, while the estimated number PWID/LWH in the country is 7,473 (KSCDID, 2018), only 85 (1%) received methadone in 2019. More information is needed about attitudes toward OST and barriers to utilizing this treatment.
METHODS: Baseline assessments were conducted among 618 PWID/LWH recruited from 4 cities in Kazakhstan who participated in a longitudinal panel of an implementation science study focusing on improving HIV care cascade and recruited from the four cities in Kazakhstan in 2017 - 2019. Participants were asked about general knowledge and attitudes toward OST, including how they perceived its connection to criminal activities, risk of HIV transmission, adherence to antiretroviral treatment (ART), and illicit opioids consumption, and barriers to accessing OST.
RESULTS: The baseline survey results showed that only 23 (3.7 %) of PWID/LWH were currently on methadone and 41 (7.2 %) had ever received methadone. One third (34 %) of the respondents held the misperception that OST blocked the effects of heroin. Almost half (46 %) of the respondents believed that OST was just substituting one addiction for another. Less than a half agreed that OST reduced criminal activities and risk of HIV acquiring or transmitting. Most respondents did not know how OST changed adherence to ART (61 %) and HIV risk taking behavior (51 %). About half of the respondents did not know if OST reduced consumption of illicit opioids (49 %). In terms of reported barriers to participation in an OST program, the respondents reported the beliefs that dependence on methadone was greater than on some other drugs, concerns about the side effects of

medication, uncertainty if methadone would remain available. Only one third of participants would like to participate in an OST program if it's offered.

CONCLUSIONS: The lack of knowledge among PWID/LWH and their negative attitudes toward OST may be major barriers to expanding engagement into OST in Kazakhstan. More information about OST should be distributed among PWID communities.

PEE1437

EXPERIENCES IN LINKAGE AND RETENTION SERVICES AMONG PEOPLE LIVING WITH HIV USING EXPERT CLIENTS IN MALAWI

V. Singano[1], M. Nkosi[1], T. Mayani[1], C. Chilangwa[1], E. Scheepers[2], K. Schitmz[2], M. Mbule[2]
[1]mothers2mothers, Lilongwe, Malawi, [2]mothers2mothers, Cape Town, South Africa

BACKGROUND: There is a growing demand for proven, high impact interventions to achieve the 90-90-90 UNAIDS targets. Task shifting using lay health workers as a peer support model has been implemented to enhance linkage and retention to HIV services. There is limited evidence on the impact of lay health workers in HIV services.

DESCRIPTION: Expert Clients (ECs) model was introduced by mother2mothers (m2m) in 98 facilities in Malawi in April 2018. ECs were employed as facility based lay health workers who are open about their HIV positive status and show exemplary life style on adherence to HIV services. They were deployed in the general outpatient departments (OPD), maternal and child health departments and ART clinics. They create demand for HIV Testing Services (HTS); physically escort newly tested HIV positives to ART initiation and provide pre ART counselling; and physically trace clients who miss ART appointments. Data is captured on paper based registers and then exported into DHIS2. Data for clients accessing HIV services in 98 m2m supported facilities in Malawi from April to December 2019, was used to explore the role of ECs in linkage to ART and management of clients who miss ART appointments.

LESSONS LEARNED: In the OPD, ECs referred 262,087 clients to HTS of whom 9% (20729) tested HIV positive, 97% were initiated on ART, 42% of those not initiated on ART were traced, 11% were initiated on ART after tracing. 49579 HIV positive clients missed their ART appointments after 14 days, 82% (40747) were traced, 68% brought back to care, 25% lost to follow up, 5% transferred out, 1% died and 1% stopped.

Newly tested HIV positive clients refused ART due to religious beliefs, fear of disclosure to partner and HIV retesting whilst already on ART. Clients from long distances were not traced and some traced clients did not honor their promise to go back to ART care.

CONCLUSIONS/NEXT STEPS: While the EC model achieved optimal linkage to ART, return to care among lost patients need to be improved by routinely assessing risk of attrition from care and provide client tailored follow up.

PEE1438

COMMUNITY HEALTH VOLUNTEERS CONTRIBUTE TO REDUCED MISSED OPPORTUNITIES IN PMTCT THROUGH PROACTIVE IDENTIFICATION AND REFERRALS: TEMBELEA PROJECT IN TRANS NZOIA AND TURKANA COUNTIES, KENYA

D. Kiptalam Kimosop[1], S. Siamba[1], R. Otieno Masaba[1], J. Laktabai[2], P. Semo[3], E. Maiyo[4], J. Epakan[5], E. Mwangi[1], A. Yemane Berhan[6]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Programs, Nairobi, Kenya, [2]Ministry of Health-Trans Nzoia County, HIV, Kitale, Kenya, [3]Ministry of Health-Trans Nzoia County, Community, Kitale, Kenya, [4]Ministry of Health, Turkana County, Community, Lodwar, Kenya, [5]Ministry of Health, Turkana County, Nursing, Lodwar, Kenya, [6]Elizabeth Glaser Pediatric AIDS Foundation, Programs, Washington, DC, United States

BACKGROUND: Kenya is currently off-track to achieve elimination of HIV mother-to-child transmission (MTCT); MTCT was 11.5% in 2017. Antenatal care (ANC) attendance remains low, leading to poor identification of HIV-positive mothers and linkage to treatment. EGPAF, with active engagement of Community Health Volunteers (CHVs), implemented and assessed the Tembelea project in two counties to increase access and utilization of ANC, identify and link HIV-positive pregnant and breastfeeding women (PBFW), and their infants, to PMTCT services

DESCRIPTION: Existing CHVs were recruited in November 2018 within each county, trained and began conducted household visits between December 2018 and March 2019. They identified, visited and referred pregnant women for ANC and skilled delivery services. Postnatally, women, infants, and children (age <2 years) were referred for family planning, immunization and early infant HIV diagnosis services. Clients received HIV testing, and HIV-positive women offered treatment. CHVs visited corresponding health facilities weekly to confirm linkage with subsequent home visits for unlinked clients. Enrolled HIV-positive PBFW were proactively visited to promote adherence; defaulters were returned to care. HIV-positive PBFW successfully referred were evaluated for utilization of services at linked facilities.

LESSONS LEARNED: First ANC attendance in Keiyo and Nakalale increased from 71 and 14 clients, respectively, in October 2018, to 161 and 64 in March 2019 (see Figure).

[Figure. 1st ANC. Know status (All) and HIV+ (All) by month and county]

During the study, 13 of 679 PBFW tested HIV-positive in linked facilities; of these, 7/13(53%) were newly diagnosed following CHV referrals; two newly diagnosed women had tested negative at initial ANC visit and seroconverted by delivery. CHVs also identified two known HIV-positive clients who had defaulted and were returned to care. All nine HIV-positive clients identified by CHV accessed treatment.

CONCLUSIONS/NEXT STEPS: CHVs contributed to identifying new PMTCT clients and defaulters. Integrating CHVs into mainstream PMTCT programs has the potential to contribute to reduced missed opportunities and ultimate reduction in MTCT rates.

PEE1439

REASONS FOR LOST TO FOLLOW-UP ON ANTIRETROVIRAL THERAPY AND TRACING OUTCOMES IN ETHIOPIA

L.A. Mekuria[1], E. Seid[2], N. Mohammednur[2], M. Kalayu[2], T. Kenyon[3], D. Abraham[4]
[1]Project HOPE, Monitoring, Evaluation, Research, Learning & Quality - CHCT, Addis Ababa, Ethiopia, [2]Project HOPE, M&E - CHCT, Addis Ababa, Ethiopia, [3]Project HOPE, MPH - Chief Health Officer, Virginia, United States, [4]Project HOPE, Chief of Party - CHCT, Addis Ababa, Ethiopia

BACKGROUND: Anti-retroviral therapy (ART) scale-up in Ethiopia has increased access to care and reduced mortality but, could be improved if we understood reasons for lost to follow-up (LTFU) and linked patients back to care.

DESCRIPTION: In a community-based HIV care and treatment program, we partnered with eight local civic society organizations (CSOs) and received line lists and contact addresses of LTFU patients from health facilities on weekly basis. LTFU was defined as not being seen at the ART clinic for at least one month following patients' most recent planned clinic visit. Community Engagement Facilitators (CEFs) and Community Response Persons (CRPs) from CSOs traced them via house-to-house and by phone. Patients traced alive were asked about reasons for LTFU, and were re-engaged back to care if agreed. A mobile phone-based platform called CommCare was used for data management.

LESSONS LEARNED: 3,101 LTFU patients were identified between October 2018 and December 24, 2019. The majority (2,314, 74.6%) were from Addis Ababa, aged ≥30 years (2,021, 65.1%), and female (1,800, 58%). Current status of 1,856 (59.8%) LTFU patients was ascertained, no information was found for 512 (16.5%), and tracing is ongoing for 733 (23.6%). Of those successfully traced, 1,551 (83.6%) were linked to clinical care, 94 (5%) had self-transferred to another facility, 42 (2.3%) were on ART, 23 (1.2%) reportedly died, and 57 (3.1%) mentioned other reasons. Of the 1,551 linked to ART, 737 (47.5%) gave reasons for LTFU, including forgetfulness 281 (38%), being away from home 210 (28.5%), lack of family support 46 (6.2%), misunderstanding medical instructions 14 (1.9%), wanted to stop ART 14 (1.9%), and alcohol intake 8 (1.1%). Socio-economic reasons included lack of money for transportation 203 (27.5%), lack of food 103 (14%), resorting to traditional medicines 29 (3.9%), and inconvenient clinic appointment dates 20 (2.7%). Health systems-related reasons included long waiting times 72 (9.8%), insufficient counseling 14 (1.9%), and bad attitude of health-care providers 10 (1.4%).

CONCLUSIONS/NEXT STEPS: A variety of patient-, socioeconomic-, and health system-related factors are the most common reasons for patient LTFU. Innovative community-based LTFU tracing mechanisms are needed to improve retention in care and patient health outcomes.

PEE1440

THE LAST MILE OF PMTCT: A SIMPLE SCREENING TOOL FOR TARGETED RE-TESTING OF POSTNATAL MOTHERS AT OUTPATIENT DEPARTMENTS IN MALAWI

A. Tallmadge[1], C. Stillson[1], G. Nyirenda[1], N. Nyambi[1], C. Banda[1], A. Gunda[1], M. Muyaso[2], K. Namachapa[2], M. Eliya[2]
[1]Clinton Health Access Initiative, Lilongwe, Malawi, [2]Ministry of Health, Department of HIV/AIDS, Lilongwe, Malawi

BACKGROUND: Mother to child transmission (MTCT) of HIV is the primary means of infection among infants in Malawi. Currently, the national strategy focuses on identifying HIV-positive women at ANC and enrolling them and their exposed infants into follow-up through the end of breastfeeding. However, there is no systematic guidance for identifying mothers who are infected between ANC and the end of breastfeeding or mothers who drop out of the PMTCT cascade. As such, postnatal infection is the primary driver of MTCT, accounting for over 70% of new childhood infections in Malawi.

In lieu of costly universal postnatal maternal retesting, systematic screening could more efficiently identify mothers for targeted re-testing.

METHODS: Through a national taskforce, a tool was developed to screen breastfeeding mothers at outpatient departments. The tool was formatted as a simple checklist. All mothers who had not been HIV tested at delivery, had not been tested within the last 6 months, or had defaulted from the PMTCT program were referred for HIV testing. Infants of HIV-positive mothers were also screened for adherence to EID testing milestones. The tool was piloted at 32 health facilities in Malawi from July-September 2019.

RESULTS: Of the 10515 mothers screened using the tool, 44% (4584/10515) were referred for testing, 81% tested (3720/4584) and 0.7% tested newly positive (26/3720). Of the 95 infants screened in, 24% (23/95) were newly identified as exposed, 47% (45/95) were previously known as exposed but had missed a testing milestone and 27% (26/95) had unknown exposure but were screened in because the mother was deceased or had an inconclusive HIV result. 11.8% (2/17) of the exposed infants have been confirmed infected via DNA-PCR.

CONCLUSIONS: The tool effectively identified mothers who had defaulted from PMTCT, missed a testing milestone or seroconverted during breastfeeding, and linked them and their exposed infants into care. While a 44% referral rate may seem high, it is significantly more efficient than universal retesting.

If this posed a strain on testing volumes, the retesting interval could be extended (e.g. test every 12 months, rather than every 6). Further, saturating delivery ward testing could reduce the referral rate by upwards of 45%.

PEE1441

IMPLEMENTING A TRACKING SYSTEM TO IMPROVE LINKAGE IN CARE FOR PEOPLE DIAGNOSED WITH HIV IN SURINAME

D. Stijnberg[1,2,3], M. Mckee[3], W. Schrooten[1], M.R. Adhin[4]
[1]Hasselt University, Patient Safety, Hasselt, Belgium, [2]Anton de Kom Universiteit, Public Health, Paramaribo, Suriname, [3]Ministry of Health, National AIDS Program, Paramaribo, Suriname, [4]Anton de Kom Universiteit, Biochemistry, Paramaribo, Suriname

BACKGROUND: Suriname created a de-duplicated case-based registry system from HIV surveillance source data in 2013, which has enabled the creation of the HIV treatment cascade. Of the 3,136 HIV positive cases found from 2010 to 2015, 78% were found linked into care. To identify the issues behind this and to reduce the numbers not entering into care, the National AIDS Program implemented the tracking system.

DESCRIPTION: From the national HIV test database, all individuals that were tested positive in 2015 and 2016 and didn't have a CD4, Viral load test or a treatment pick-up on file, were classified not linked to care. Tracking consisted of the coordinator contacting the listed physician. The clinic personnel were asked to contact the person if found in their records. The tracking coordinator kept in touch with the clinic to obtain further information. All information obtained was entered in a database.

LESSONS LEARNED: From the 271 records shown as not linked in care, 219 (80.1%) were evaluated by the tracking coordinator. Removing duplicates, identified through code correction from the clinics, 217 persons are in this group. Of these 178 (82.0%) were untraceable due to lack of information and 26 (12.0%) were found to be linked in care. For 11 out of these 26 (42.3%), a coding error was found to be the reason for not being registered as linked in care. Also completing the process of speaking to the clinics took on average 2 years (0.8 – 3.5) while subsequent analysis shows that the mean time linking in care for individuals in this group is 1.4 years.

CONCLUSIONS/NEXT STEPS: The high percentage of not linked into care requires a routine system of following up with people diagnosed with HIV. Better registration of patient data would improve the result of data linkage. For people not linked, this type of retrospective tracking does not work. This highlights the need for a more proactive tracking system from the point of diagnosis.

PEE1442

EFFECTIVENESS OF A COMBINATION APPROACH AMONG HIV-POSITIVE INDIVIDUALS IN ESWATINI ON CONSISTENCY OF ENGAGEMENT IN CARE AND VIRAL LOAD SUPPRESSION

I. Mushamiri[1], M.R. Lamb[1,2], V. Madau[3], J. Justman[1,2], W.M. El-Sadr[1,2]
[1]Columbia University, Mailman School of Public Health, Epidemiology, New York, United States, [2]ICAP at Columbia, Mailman School of Public Health, Columbia University, New York, United States, [3]ICAP in Eswatini, Mbabane, Eswatini

BACKGROUND: Consistent engagement in HIV care is essential for achieving favorable outcomes among HIV-positive patients. The additional value of clinic visits beyond antiretroviral therapy (ART) pick-up for stable HIV patients and the subsequent effect on viral load suppression is unclear. We assessed the effectiveness of a combination intervention targeting the HIV care continuum on consistency of engagement in care and subsequent viral load suppression in Eswatini.

METHODS: Link4Health was a cluster-randomized controlled trial conducted in 10 clusters of HIV clinics in Eswatini, evaluating the effectiveness of a combination intervention strategy (CIS) compared to standard of care (SOC) on linkage and retention outcomes. The CIS package included point-of-care CD4+ testing at the time of HIV testing, accelerated ART initiation for eligible patients, mobile phone appointment reminders, care and prevention educational materials, and mobile airtime financial incentives. Adults at least 18 years newly testing HIV positive were eligible, and enrolled participants were followed for 12 months. Consistent engagement in care was defined as completing all scheduled visits within 5 days of the appointment, including a final clinic visit within 90 days of end of study. Viral load suppression was defined as a recorded HIV RNA < 1000 copies/mL at the 12-month visit. Multivariable random-intercept models employed in multi-level log-Poisson models with robust standard errors were used for all analyses.

RESULTS: Between August 2013 and November 2014, 2,197 adults enrolled. Of these, 1,321 initiated ART during follow-up, and 1,120 (592 CIS vs. 528 SOC arm) were on ART for at least 4 months. In the intent-to-treat analysis, CIS intervention had no effect on consistency of engagement in care (relative risk [RR] 1.22, 95% CI [0.74-2.03]) among participants on ART for at least 4 months. Consistency of engagement in care had no effect on viral load suppression even after adjusting for the intervention arm (adjusted RR = 1.15, 95% CI [0.94-1.39]).

CONCLUSIONS: Among a population of newly ART initiating individuals, consistent visit engagement beyond ART pick-ups is not related to viral load suppression. In the era of differentiated care services, the utility of frequent clinic visits among patients who may otherwise be adherent to ART should be reexamined.

PEE1443

PATIENT MOBILITY AND RETENTION AMONG ART USERS IN ZAMBIA: FINDINGS FROM A MULTISTAGE SAMPLING-BASED SURVEY

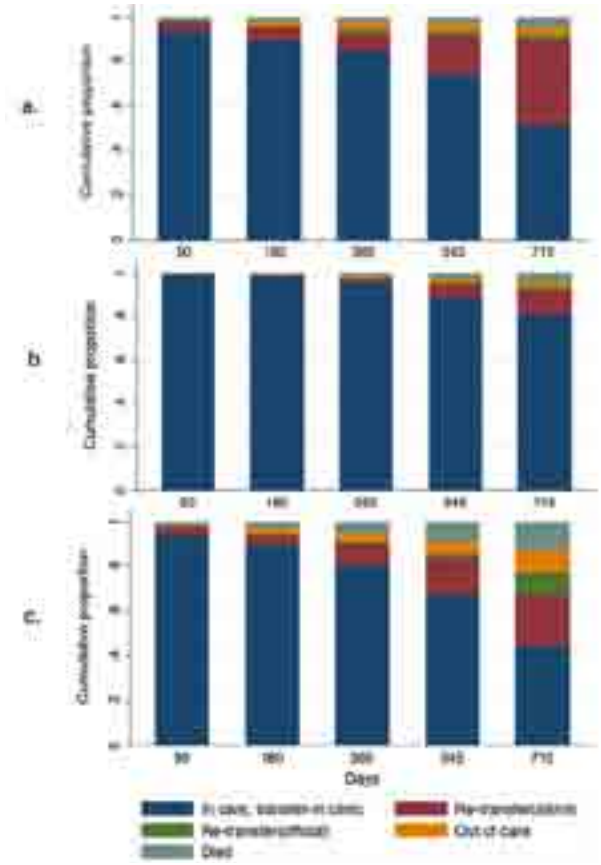
I. Eshun-Wilson[1], A. Mody[1], K. Sikombe[2], J. Pry[2], I. Sikazwe[2], C. Bolton-Moore[2], E. Geng[1]
[1]Washington University in St Louis, Infectious Diseases, St Louis, United States, [2]Center for Infectious Diseases Research, Lusaka, Zambia

BACKGROUND: Although mobility is a recognized feature of life in many low and middle-income countries, it remains unclear how this mobility impacts on ART care and treatment outcomes. We explored the treatment experience and outcomes of patients who transferred between ART facilities in Zambia.

METHODS: We identified HIV positive adults who transferred into ART care at 64 facilities across four provinces during a two-year period (1 August 2013 to 31 July 2015). We traced a representative sample and established updated care states and reasons for re-transfer. We applied inverse probability sampling weights to competing risks analysis to generate revised retention estimates, and compared transfers to non-transfers who were: a) already established on ART or b) newly initiating ART at the facility. We additionally calculated medication possession ratios (MPR) up till 1 January 2018.

RESULTS: We identified 3,682 ART users as transferred into care during the two-year period. Median age was 36yrs (IQR: 30-43), 66% were female, median CD4 at transfer was 372 cells/ml (IQR: 228-547). ART was re-initiated at first visit for 59%, within 30 days for 81%, and all were re-initiated within four years. The median MPR was 100% (IQR: 81-100) in the first year after transferring into care and this was maintained for the following four years. At two years, 95% of transfers

(95%CI: 90-99%) were retained, this was comparable to non-transfers established on ART (94%; 95%CI: 93-95)) and greater than new ART initiates (79%; 95%CI: 73-84%). Transfers were however more likely to re-transfer (Figure 1) and cited structural reasons related to transport (27%), travel (36%) and work obligations (29%) as the primary reasons for re-transfer.



[Figure 1. Updated care states at two years among: (a) patients who transferred into care on ART, (b) patients already established on ART and (c) patients newly initiating ART during the study period]

CONCLUSIONS: Patient who transfer between ART facilities are highly likely to transfer again. Strategies that facilitate rapid ART re-initiation and support future re-transfer are needed for programs to effectively accommodate mobile populations and minimize treatment gaps.

GETTING POLICIES INTO PRACTICE

PEE1444

A CAPACITY BUILDING APPROACH FOR EARLY DETECTION AND MANAGEMENT OF CRYPTOCOCCAL MENINGITIS AMONG PEOPLE LIVING WITH HUMAN IMMUNE-DEFICIENCY VIRUS IN WESTERN UGANDA

I. Namuleme Ddumba[1]
[1]*Baylor College of Medicine Children's Foundation, Capacity Building, Fort Portal, Uganda*

BACKGROUND: Cryptococcal meningitis (CCM) accounts for 30% of the deaths among HIV positive persons in Uganda. To improve the outcomes of patients with Cryptococcal meningitis, Uganda adapted the WHO 2016 guidelines recommending CD4 screening for all new patients and a serum cryptococcal antigen screening test (crAG) for all with CD4 less than 200. A review of the uptake indicated sub-optimal CD4 coverage at 23.2%.To increase early identification and management of patients at risk of developing CCM, a capacity building project was started to train and mentors health workers in the screening and management protocols for CCM.

DESCRIPTION: Health workers (nurses and clinical officers) from selected high volume health facilities were identified and trained in the screening and management of cryptococcal meningitis. Health workers were provided with mentorship, coaching skills and assigned health facilities to train, mentor and follow up other nurses and clinical officers attached to the HIV clinic and laboratory. Health facilities were trained for two days and followed up with one day mentorships, quarterly for nine months. The CD4 coverage and the serum crAg screening was tracked quarterly for 9 months. Clients that had a positive serum CrAG were followed up for treatment completion with fluconazole.

LESSONS LEARNED: The CD4 coverage increased from 23,2% to 58%, the clients screened for serum CrAg increased from 65% to 79% and the clients with a positive serum crAg completing treatment with fluconazole increased from 54.2% to 87.50%. The health workers gained knowledge and skill in the screening and management of patients with Cryptococcal meningitis. There was a reduction in the number of patients dying from CCM after initiation of treatment with fluconazole.

CONCLUSIONS/NEXT STEPS: Health workers that received the mentorship were able to identify patients at risk of CCM and follow up with the serum CrAg test. Follow up of patients with positive serum crAG tests on treatment improved with higher completion rates. Mentorship of health workers after training is critical in the translation of theory and policy in to practice. A capacity building approach can be used to improve all quality of care indictors for patients in HIV chronic care.

PEE1445

REVITALIZING PRIMARY HIV PREVENTION IN NIGERIA: A SURE PATH FOR ENDING AIDS BY 2030

I. Ezirim[1], F. Oki[2], K. Essomeonu[2], T. Ajiboye[2], L. Ajaja[2], E. Okey-Uchendu[2]
[1]*National Agency for the Control of AIDS, Research, Monitoring and Evaluation, Abuja, Nigeria,* [2]*National Agency for the Control of AIDS, Community Prevention, Abuja, Nigeria*

BACKGROUND: Delivering prevention at scale is essential to achieving fewer than 500 000 annual new infections by 2020, and ending AIDS by 2030. Global HIV Coalition (GPC) was established to strengthen political commitment for primary prevention. The coalition maintains accountability in member countries through country scorecard and poster for assessing progress in 4 primary prevention pillars (i.e. combination prevention for Adolescent Girls and Young Women (AGYW), Key Population (KP), condoms and PrEP). Nigeria used GPC HIV prevention score card and poster to review progress.

DESCRIPTION: Prevention Technical Working Group updated the scorecard and poster with data on Global AIDS Monitoring (GAM) indicators, surveys (DHS, NAIIS, MICS, IBBSS, population size estimates) and 2019 program data. Next, 2-days validation meeting was held to review score card and poster. 74 participants attended the validation meeting representing KPs, AGYW, CSOs, donors, private sector, policymakers including People Living with HIV (PLHIV). Participants were divided according to four pillars to discuss challenges

and recommendations. The groups identified enablers and systems to attain targets for each pillar and reported back in plenary session, inputs were made and next steps agreed on.

LESSONS LEARNED: Score card and poster showed state of Nigeria HIV prevention in 2019 and key messages. New HIV infections among adults rose by 8% from 2010-2018. Condom use among adolescents is poor (females 38%, males 62%). Also, programmes integrating HIV with Sexual and Reproductive Health among AGYW are insufficient. Sex workers (98%) use condoms with clients while condom use among MSM is low (51%). Condom use in general population with non-regular partner is low, but higher among males (65%) than females (36%). Only 41% PWIDs adopt safe injection practices. PrEP wasn't implemented in 2019, however, PrEP will be provided to KPs in 2020.

CONCLUSIONS/NEXT STEPS: In Nigeria, 1 million of 1.9 million PLHIV are on treatment, yet new infections is rising. To end AIDS, Nigeria must strengthen primary prevention (including PMTCT) in high burden and incidence locations and populations. Prevention programmes should be reviewed against prevention targets to measure progress and hold policy makers accountable. Fund allocation for prevention, needs to increase in line with globally recommended 'quarter for prevention.

PEE1446

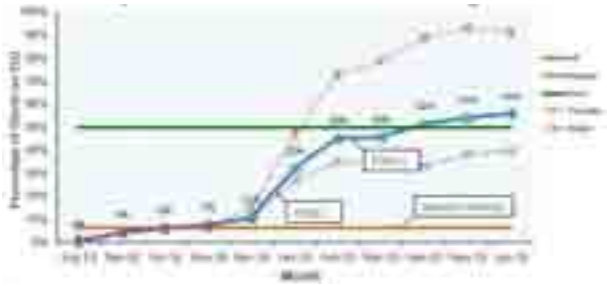
OPTIMIZING TRANSITIONING TO TENOFOVIR/LAMIVUDINE/DOLUTEGRAVIR COMBINATION AS THE PREFERRED REGIMEN FOR HIV TREATMENT IN NIGERIA

S. Balogun[1], I. Orogbemi[2], Z. Rufai[2], V. Popoola[2], E. Nwabueze[2], E. Ijezie[2]
[1]AIDS Healthcare Foundation, Programing, Lokoja, Nigeria, [2]AIDS Healthcare Foundation, Lokoja, Nigeria

BACKGROUND: Tenofovir/Lamivudine/Dolutegravir (TLD) combination was adopted by Nigeria as the preferred first-line drug for HIV treatment in 2018. Because of the Initial fear of the use of Dolutegravir-based combinations in pregnancy, it was not recommended for use in women who could become pregnant. The nation planned to have at least 50% of its adult clients on first-line medications transitioned to TLD by mid-2019 starting from August 2018. By end of December 2018, only 11% of clients had been transitioned across 8 treatment sites in the state. The project aimed to ensure these sites achieve the national target by June 2019.

METHODS: A multi-disciplinary team conducted root-cause analysis using 5 whys, fish-bone diagram and Pareto Chart. These revealed that lack of facility commitment, low family planning uptake, and fear of commodity stock-out were the most important factors for slow transitioning. Interventions addressing the identified root-causes were implemented in two Plan -> Do -> Study -> Act cycles starting January 2019. First cycle included raising facility champions and demand creation for family planning uptake while the second cycle ensured commodity security and client tracking for transitioning.

RESULTS: During intervention, 1097 adult clients on first-line regimen were seen. Of these clients, 66% were females (n = 724) while 34% were males (n = 373). Of the women, post-menopausal women accounted for 15% (n = 109) while those on family planning were 16% (n = 116). A sharp rise in TLD transitioning following the first PDSA cycle up to 73% and 35% was seen among males and females respectively. This was followed by steady sustenance of improvement reaching a peak of 93% in males and 40% in females.



[Figure. TLD optimization percent in clients attending clinics]

CONCLUSIONS: Implementation of 2 PDSA cycles successfully led to TLD transitioning target achievement. This approach should be considered for future similar plans to bridge the gap between performance and targets.

PEE1447

IMPLEMENTING AN OPTIMAL ADVANCED HIV DISEASE (AHD) PACKAGE OF CARE: LESSONS LEARNT FROM NATIONAL SERVICE DELIVERY PLANNING IN MALAWI

D. Telela[1,2], Y. Gumulira[2], E. Matupa[2], S. Macgovern[3], P. Nyasulu[4], B.W. Matola[4], R. Nyirenda[4], C. Banda[2], A. Gunda[2]
[1]Clinton Health Access Initiative, Health, Lilongwe, Malawi, [2]CHAI, Lilongwe, Malawi, [3]CHAI, Pretoria, South Africa, [4]Ministry of Health, Lilongwe, Malawi

BACKGROUND: Since 2010, Malawi has tripled the number of people living with HIV (PLHIV) accessing antiretroviral therapy (ART) from ~250,000 to over 800,000 by 2019. Despite significant gains in ART coverage, HIV still claim 15,000 lives every year. A major driver of this mortality: patients still present to care with AHD and are more susceptible to deadly opportunistic infections like TB and cryptococcal meningitis (CM). With an aim to curb deaths, the Malawi Ministry of Health and Population (MoHP), with support from national partners, developed new set of AHD policy recommendations in line with World Health Organization guidance. These policies laid a strong foundation for potential AHD service delivery but required a well-coordinated and holistic implementation approach to ensure a sustainable national transition to the new package of AHD care.

DESCRIPTION: In 2018, Malawi MoHP included AHD management in the revised HIV treatment guidelines. To facilitate decision-making around implementation, a national taskforce was established and responsible for coordinating and leading a number of activities, including, but not limited to: quantifying commodity need, mapping and placing CD4 machines, leading consultative meetings with districts, defining AHD service-delivery and implementation approach, and developing AHD SOPs and training curriculum.

LESSONS LEARNED: Establishing a taskforce with HIV experts and partners was critical for ensuring a coordinated AHD implementation strategy. Phased implementation was identified as the best approach to ensure smooth introduction and allow for continuous improvement and sharing of lessons for onward rollout. A hub-and-spoke model was adopted to make AHD implementation feasible given the limited capacity of periphery sites. The adoption of the global AHD toolkit was an efficient way to adopt and tailor existing job aides, training curriculum, and SOPs to Malawi's needs. Ultimately, 108 health facilities out of 751 were selected for the first phase of implementation with more than 300 service providers trained to provide AHD services. Quantification, procurement, and distribution of focal AHD commodities were completed.

CONCLUSIONS/NEXT STEPS: Strategic preparation and coordinated stakeholder engagement has led to successful AHD rollout and Malawi will continue to monitor implementation. Countries that have yet to adopt and implement AHD management can learn from Malawi's implementation model.

PEE1448

COMPLIANCE WITH INFECTION CONTROL PROCEDURES IN MILITARY HIV/AIDS CLINICS IN UGANDA

A. Asiimwe Kamugisha[1,2], T. Rwigyema[3], S. Lawoko[4], E. Lugada[3], K. Neeraj[5], J. Akao[6], G. Akao[7], D. Bwayo[3], c. Wamundu[2], D. Rwangoga[2], A. Musinguzi[2], B. Kikaire[7]
[1]University Research Co., LLC - Department of Defense HIV/AIDS Prevention Program (DHAPP), Monitoring and Evaluation, Kampala, Uganda, [2]Directorate of HIV/AIDS, Uganda Peoples Defense Forces (UPDF), Kampala, Uganda, [3]University Research Co., LLC - Department of Defense HIV/AIDS Prevention Program (DHAPP), Kampala, Uganda, [4]Gulu University, Kampala, Uganda, [5]University Research Co., LLC, Washington DC, American Samoa, [6]U.S. Department of Defense (DoD), Kampala, Uganda, [7]Makerere University, Kampala, Uganda

BACKGROUND: Compliance with infection control (IC) measures is a critical component of HIV care. In general, evidence on levels of compliance by health workers to IC standards is lacking in the Ugandan military health facilities. The URC-Department of Defense HIV/AID Prevention Program implements and provides technical assistance and material support for IC in military health facilities in Uganda. We assessed compliance to IC standards at 28 military ART sites in Uganda.

METHODS: A validated structured questionnaire and observational checklist were used to assess availability of IC items and compliance with IC measures. Key informant interviews were used to provide context. Descriptive statistics, chi-square test and logistic regression were used to analyze quantitative data. Qualitative data were analyzed using template and thematic analysis.

RESULTS: A total of 84 laboratory staff (7% female) were observed and interviewed. Slightly more than half (53%) of the respondents had a certificate of Medical laboratory technology, 35% had a diploma and only 12% had a bachelor's degree. 52% of the study participants exhibited good knowledge on infection control standard precautions. While 70% of infection control items were available at the health facilities, only 45% of interviewed staff were compliant with recommended IC measures. Factors significantly associated with compliance to infection control procedures were; higher level of education (AOR =3.22, 95%CI= 1.31-2.24), years of experience (AOR= 2, 95%CI=2.92-4.63), high military rank (AOR= 4, 95%CI= 1.15-3.10) and good knowledge (AOR=3.30, 95%CI=3.22-4.21).

Barriers to adherence to standard IC procedure were; lack of regular bio-safety training, lack of equipment and infrastructure, low commander involvement; inadequate prioritization of IC and human resource gaps.

CONCLUSIONS: Modifiable challenges to infection control within the military ART sites were identified. Interventions such as close supervision and targeted stakeholder engagement particularly the commanders, on importance of IC in public health and specifically in HIV care. Targeted training on IC procedures for lower cadres is needed to achieve universal IC standards.

PEE1449

SUCCESSFUL TRANSITION FROM EFAVIRENZ TO DOLUTEGRAVIR-BASED FIRST-LINE ART IN LIBERIA: STRENGTH OF A COLLABORATIVE APPROACH BETWEEN NATIONAL AIDS AND STI CONTROL PROGRAM AND IMPLEMENTING PARTNERS

J.T. Garbo[1], S.C. Caldwell[1], R. Chesson[2], A. Passawe[1], D. Nyanplu[1], M. Odo[1], W. Fassah[1], M.J. Jones[1], I. Ibegbunam[2], G. Kamanga[3], N.F. Clement[3], B. Kanyemba[4]
[1]National AIDS and STI Control Program, Ministry of Health, Monrovia, Liberia, [2]Global Health Supply Chain Program-Procurement and Supply Management, Monrovia, Liberia, [3]FHI 360, Global Health Population and Nutrition, Monrovia, Liberia, [4]USAID Liberia, Monrovia, Liberia

BACKGROUND: Liberia has approximately 40,000 people living with HIV (PLHIV). about 15,000 of whom are on antiretroviral therapy, including 73% on tenofovir, lamivudine, and efavirenz-600 (TLE-600). In June 2019, the country revised the national treatment guidelines to allow transition to tenofovir, lamivudine, and dolutegravir (TLD), as recommended by the World Health Organization. We present our experience with TLD transition through a collaborative effort between the country's health leadership and collaborating partners.

DESCRIPTION: The Ministry of Health's National AIDS and STI Control Program (NACP) led the technical working group to spearhead the transition to TLD, together with the USAID-/PEPFAR-funded and FHI 360-led LINKAGES/EpiC project, and Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM). The process included:

(1) developing and pretesting TLD literacy material for PLHIV, the general population, and clinical staff;

(2) conducting a facility preparedness assessment;

(3) implementing pharmaco-vigilance surveillance; and

(4) trainings of staff in high burden facilities and removal of nevirapine from service delivery points.

The transition started in September 2019 and should be completed by December 2020.

LESSONS LEARNED: During pilot testing of materials and preliminary staff training, PLHIV and some clinical staff were anxious to transition immediately rather than follow the phased strategy. Clear and motivational communication tailored to both audiences was critical to reduce their concerns and ensure compliance with the transition plan. Total number of PLHIV estimated to be transitioned to DTG by December 2020 is 13,971. So far by 31 December 2019, a total of 1,356 PLHIV were transitioned according to the following priority groups; 192 key population groups, PLHIVs on NVP-Based Regimen 691, newly PLHIV initiated 367, pregnant women 29, and other 77.

CONCLUSIONS/NEXT STEPS:

- Migration of both treatment-experienced and treatment-naïve patients to TLD on a national scale requires considerable planning and collaborative processes.
- National HIV programs should consider country-specific scenarios such as investing in public and health care worker awareness to minimize the risk of large-scale treatment failure among possibly stable patients who may otherwise be inclined to leave the previous regimen of TLE and rush for TLD.

PEE1450

INNOVATIVE NATIONAL STRATEGIES TO IMPROVE NATIONAL GENOTYPING NETWORK IN BRAZIL

A.F. Kolling[1,2], A.A. Cunha Mendes Ferreira[1], T. Cherem Morelli[1], R. Vianna Brizolara[1], M. Araújo de Freitas[1], A. Sposito Tresse[1], A.I. Costa de Menezes[1], M. Camelo Madeira de Moura[1], P. Adamy[1], G.F. Mendes Pereira[1]
[1]Ministry of Health of Brazil, Department of Cronic Disease and Sexually Transmited Infectious, Brasília, Brazil, [2]University of Brasilia, Public Health, Brasilia, Brazil

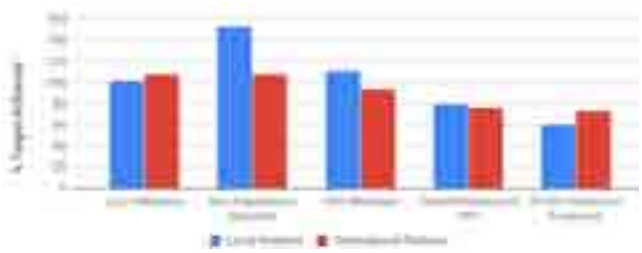
BACKGROUND: In 2015, the Ministry of Health of Brazil (MOH) started providing HIV genotyping exams countrywide and established a network of Genotyping Reference Doctors (GRD) to support prescribers in interpreting results. In addition, MOH implemented the National Genotyping System (SISGENO), an electronic system with genotyping results and reports with the feedback from GRD to support switch to adequate ART regimen based on these results. However, over the years use of SISGENO has been inconsistent and turnaround time between issuance of results and the feedback from GRD was high. The aim of this study was to describe strategies tackle those issues.
DESCRIPTION: In 2017, Brazilian Ministry of Health (MoH) reorganized the national genotyping network. Some of them were assigned to analyze specifically genotyping results from children. Paper-based systems were extinguished and only GDR who effectively used the electronic system were maintained as a reference doctor. In addition, GDR were periodically evaluated, a network of tutors were established to supervise new RDG, a network pediatric GDR was settled, and national and regional workshops for case discussions for RDG were conducted by MOH.
LESSONS LEARNED: From 2015 to 2019, there was an increase of 17% (7,916 to 9,264) in genotyping exams performed. However, a substantial decrease in the average amount of days between ART switch request and issuance of final decision by GRD of 97% was observed, from 681 to 20 days.
CONCLUSIONS/NEXT STEPS: Innovative national strategies to manage the National Genotyping Network in Brazil contributed to increase the request of genotyping tests and to drastically improve support to prescribers on a timely manner over the years. The next steps is maintain these strategies and reduce more the average time for issuance of genotyping reports.

PEE1451

USAID'S HIV LOCAL PARTNER TRANSITION: THE JOURNEY TO SELF RELIANCE IN THE ERA OF THE SUSTAINABLE HIV RESPONSE

C. Raulfs-Wang[1], D. Kaliel[1], J. Porter[1], L. Bonanno[1], C. Wahle-Knight[1]
[1]USAID, Office of HIV/AIDS, Washington, United States

BACKGROUND: To advance HIV sustained epidemic control, in April 2018, Ambassador Deborah Birx announced that 70 percent of PEPFAR funds must go to local organizations as prime recipients of funding by the end of Fiscal Year (FY) 2020. For USAID, these efforts also support USAID Administrator Mark Green's vision of advancing partner countries on their Journey to Self-Reliance.
DESCRIPTION: In November 2018, 23 USAID PEPFAR field programs developed strategies to advance the local partner transition. At baseline and one year into the transition, USAID analyzed the funding trends, percentage of targets, quality of service delivery, and performance across key indicators of local partners compared to international partners. Data were pulled from PEPFAR reporting systems.
LESSONS LEARNED: In September 2018, USAID PEPFAR funding to local partners was 34 percent and by October 2019, 46 percent of PEPFAR funding was planned for local partners. Analyses of targets, quality, and performance data demonstrate that local partner performance is on par with international partners across all key PEPFAR indicators. Funding and targets have increased to local partners across critical technical areas. Performance data, as measured by percentage of achievement of key PEPFAR targets, are better for local partners in programs designed for key populations and OVC, and are close to the achievement of international partners in clinical cascade targets, such as testing and treatment. FY 2019 data will be presented at IAS.



[Figure 1. Comparison of USAID local partners vs international partners on key PEPFAR indicators (FY 2018)]

CONCLUSIONS/NEXT STEPS: In FY 2020, a further shift of resources to local organizations and governments is required to reach the PEPFAR 70 percent funding goal. There is a need to support program monitoring, ensuring the transition does not jeopardize performance and quality. This can be accomplished by careful monitoring and enhanced organizational capacity support. The aims of the transition will support the sustainability of the HIV national response beyond PEPFAR, especially pertinent as countries achieve epidemic control.

PEE1452

CLOSING THE GAP IN TENOFOVIR/LAMIVUDINE/DOLUTEGRAVIR (TLD) TRANSITIONING: AN EXPERIENCE OF MENTORSHIP AND COACHING IN NINE DISTRICTS IN RWENZORI REGION, MID-WESTERN UGANDA

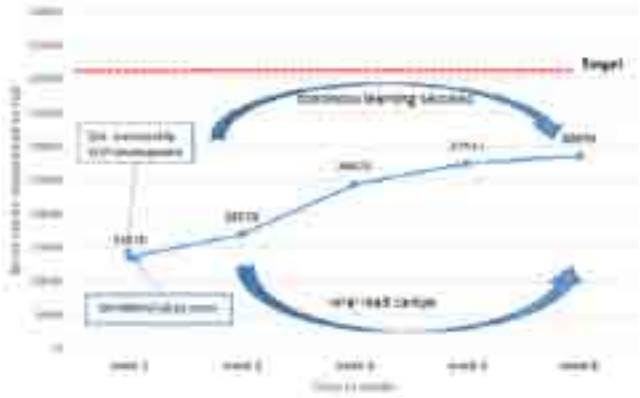
I. Namuleme Ddumba[1], L. Namale[2], G.P. Kisitu[3], C. Epidu[4]
[1]Baylor College of Medicine Children's Foundation, Fort Portal, Uganda, [2]Baylor College of Medicine Children's Foundation, Health Systems Strengthening, Fort Portal, Uganda, [3]Baylor College of Medicine Children's Foundation, Research, Fort Portal, Uganda, [4]Baylor College of Medicine Children's Foundation, Care and treatment, Fort Portal, Uganda

BACKGROUND: To achieve epidemic control and fast track progress towards the 95.95.95 UNAIDS goal, Uganda revised and rolled out new HIV care and treatment guidelines in 2018, recommending Tenofovir/Lamivudine/Dolutegravir (TLD), a potent regimen for viral suppression as the first line. All eligible clients were to be transitioned to TLD. A review of the uptake of TLD ten months after ART guideline roll out showed a regional TLD uptake of only 33% in mid-western Uganda. We set out to improve regional TLD uptake to 80% within an eight week period in mid-western Uganda.
DESCRIPTION: Trained regional and district mentors on TLD transition reached out and interviewed 55 health workers to elicit for barriers to TLD uptake using a standardized questionnaire across the 70 facilities in the region. Mentors were assigned specific health facilities and clinicians for follow up. Follow up schedules were deter-

mined by the mentor-mentee pairs biweekly. Identified barriers to TLD uptake included; missing standard operating procedures (SOPs) on TLD transition, low access to viral load services, knowledge gaps on the transition process and failure to track and identify newly eligible client on community Differentiated Service Delivery Models. (DSDM) We addressed the TLD transition barriers through; onsite mentorship and site based continuous learning sessions for health workers, development and display of SOPs on TLD transition in clinic rooms, conduct of viral load camps to increase access to viral load tests, use of stickers to identify in-eligible files and prompt assessment at every client visit. TLD uptake was assessed weekly using a standard dash board.

LESSONS LEARNED: 41,821 clients were eligible for TLD transition in the region by 30/10/2018. TLD uptake increased from 33% (13,610) to 69% (28,654) between 9/08/2019 and 16/09/2019.

CONCLUSIONS/NEXT STEPS:



[Figure 1. TLD uptake trend in Rwenzori region]

TLD uptake improved with concerted intervention initiatives. Site specific interventions need to be developed to overcome any barriers to uptake of TLD.

PEE1453

ACCELERATING RAPID ART IN JAKARTA, INDONESIA: FAST-TRACKING NATIONAL POLICY TO SYSTEMATIC PRACTICE

K. Baraq[1], M. Kurniasari[1], M. Luciana Laibaho[2], L. Ferradini[1], C. Francis[1]
[1]FHI 360/LINKAGES Project, Jakarta, Indonesia, [2]Provincial Health Office, Communicable Diseases, Jakarta, Indonesia

BACKGROUND: In July 2018, the Indonesia Ministry of Health (MOH) issued updated national policy guidance that formalized the practice of Test and Treat All and introduced provisions for rapid antiretroviral therapy (ART) (same day – up to seven days). The Jakarta Provincial Health Office (PHO) immediately operationalized a rapid ART saturation strategy and, within a one-year implementation period, demonstrated the application of rapid ART services at all subdistrict health facilities across the capital city.

DESCRIPTION: Jakarta's rapid ART acceleration plan consists of intensive socialization of the benefits of rapid ART to health providers and people living with HIV (PLHIV); implementation of technical guidance, including standard operating procedures; facility-based mentoring and peer-to-peer sharing; and comprehensive monitoring of facility performance. Together with technical assistance provider USAID- and PEPFAR-funded LINKAGES, the PHO and five District Health Offices rolled out rapid ART in a stepwise fashion, intensifying service provision in two districts before expanding coverage in the remaining three areas. Coordination-and-review-stakeholder consultations took place quarterly to review performance and identify areas where additional support was necessary.

LESSONS LEARNED: Between July 2018 and September 2019, 67% of 3,120 newly diagnosed and enrolled PLHIV were provided with rapid ART, with 47% receiving same day ART at 42 subdistrict facilities and two private clinics. Rapid ART coverage rose in each quarter of implementation, from 61% rapid ART provision July–September 2018 to 80% July–September 2019. Retention rates for new PLHIV at six months of ART have similarly improved, reaching 85.6% for those initiating ART January–June 2019 compared to 81.4% for the PLHIV cohort initiating ART January–June 2018 (p =.00449).

CONCLUSIONS/NEXT STEPS: Rapid scalability of impactful interventions is achievable when enabling government policy is in place, district-level leadership is activated, technical assistance capitalizes on the resources of diverse implementers, and data is used for evidence-based planning, implementation, and oversight.

PEE1454

DO INTERNATIONAL HIV CONFERENCES REFLECT AN INCREASED COMMITMENT TO HETEROSEXUAL MEN?

K. Dovel[1], I. Robson[2], S.S. Dworkin[3], S. Gupta[2,1], M. Cornell[4]
[1]University of California, David Geffen School of Medicine, Division of Infectious Diseases, Department of Medicine, Westwood, United States, [2]Partners in Hope, Science Deptartment, Lilongwe, Malawi, [3]University of Washington, School of Nursing and Health Studies, Bothell, United States, [4]University of Cape Town, School of Public Health & Family Medicine, Capte Town, South Africa

BACKGROUND: Men account for half of HIV infections but the majority of HIV-related morbidity and mortality. Heterosexual men have been largely absent from international HIV conferences. Men are increasingly recognized as key to curbing HIV epidemics – "engaging men" has rapidly become a key strategy within the HIV community. However, it is unclear if this increased attention has translated into increased representation of men in international conferences, and subsequent guidelines and funding priorities.

METHODS: We examined men's representation in oral presentations at the International AIDS Society (IAS) conferences from 2016-2019. We focused on oral presentations since they represent the highest-priority research areas. IAS abstract books from 2016-2019 were imported into Atlas.ti. Abstracts were coded with results disaggregated by sex. We included those with an exclusive focus on either men or women. Sub-codes were used to identify the specific sub-population focused on within each abstract (i.e., key populations, PMTCT, youth).

We assessed changes over time in the proportion of oral presentations focused on men and women, and the sub-populations within each sex. A count and proportion method was used.

RESULTS: 744 IAS oral abstracts were published between 2016-2019. Heterosexual men represented 0% and 0.4% of oral presentations in 2016 and 2017, and 4% and 3% of oral presentations in 2018 and 2019. MSM represented ~7% of oral presentations across 2016-2019 The proportion of oral abstracts exclusively focused on either general women or PMTCT remained fairly consistent (~8%) across all four years. Nearly none of the conference oral presentations included a focus on young heterosexual men who were absent whereas ~3% of oral presentations across all years focused on young women.

[Table. Men's representation in IAS conference oral abstracts: 2016-2019]

CONCLUSIONS: Men represent the majority of HIV-related morbidity and mortality, yet have remained largely absent from IAS conferences. HIV policies and programs would significantly benefit from including men in current and future research agendas.

PEE1455

SPATIAL DISTRIBUTION OF HEALTH INFRASTRUCTURE AND DISTANCE-TO-CARE IN UGANDA

K.H. Tram[1]

[1]*Washington University in St. Louis School of Medicine, Internal Medicine, Saint Louis, United States*

BACKGROUND: The availability of health facilities has a direct impact on access to healthcare, an essential component of HIV prevention, treatment, and care. Geographic information systems (GIS) offer powerful tools for measuring and understanding geospatial factors that may influence health equity. In Uganda, one of the objectives of the Health Sector Strategic & Investment Plan is to provide a network of functional health facilities within walking distance (5 km) of every community. This study employs geospatial analysis to measure and characterize the distribution of healthcare infrastructure in Uganda.
METHODS: Using QGIS 2.18.0, single-point representative household clusters from the Demographic and Health Survey (DHS) for Uganda 2011 were plotted alongside geo-located health facilities. Healthcare facilities in Uganda are categorized by level, with the lowest level of formal healthcare delivery being Health Centre II (HCII) and progressing to HCIII, HCIV, and Hospital. Distance-to-care was calculated as the straight-line distance to the nearest health facility. For each DHS cluster, we also calculated the number and type of facilities available within a certain radius.

[Figure 1.]

RESULTS: Of the 400 DHS clusters in this analysis, 239 (60%) were within 5 km of the nearest HCII, HCIII, or Hospital. Over ninety percent of urban DHS clusters (n=119) met this target in contrast to 46% of rural DHS clusters (n=281). Distances ranged from 0.02 km to a maximum of 54 km. For all DHS cluster, the mean distance was 6.6 km [IQR 1.5-7.8]. For urban DHS clusters, the mean distance was 2.7 km [IQR 0.4-2.5], and for rural DHS clusters, it was 8.2 km [IQR 3.1-9.8]. Thirty-five percent of DHS clusters were located more than 25 km from the nearest Hospital, and 11% were over 50 km.
CONCLUSIONS: Geospatial analysis and mapping can be used to identify underserved communities and guide planning of healthcare infrastructure and HIV service provision.

PEE1456

OVERCOMING BARRIERS TO RAPID ART IN REAL-WORLD COMMUNITY HEALTH CENTER AND PUBLIC HOSPITAL SETTINGS

S.S. Wong[1,2], M. Crowley[1], L. Smith[3], X. Ortiz Soto[3], HIV ACCESS network

[1]*Alameda Health Consortium, HIV ACCESS, San Leandro, United States,* [2]*East Bay Getting to Zero, Oakland, United States,* [3]*Alameda Health System, Adult Immunology Clinic, Oakland, United States*

BACKGROUND: Timely access to HIV antiretroviral therapy (ART) remains a challenge worldwide, with 74% people living with HIV (PLWH) who are newly diagnosed linked to care within 30 days in the US, and globally 53% PLWH achieving viral load suppression.
In 2019 HIV care teams from four community health centers and the county public hospital serving low-income populations in the HIV ACCESS network of Alameda County, California, USA implemented standardized metrics and collected data on barriers to rapid ART as a quality improvement project.
DESCRIPTION: Rapid, same-day access to ART was initially implemented at the four community health centers in 2017. Early inconsistencies in how rapid ART was defined and how data was collected led to network-wide collaborative protocols, a shared definition, and a shared data collection spreadsheet in 2018. These tools were implemented at the community health centers and the public hospital in 2019. The data was collected and analyzed for quarterly network-wide quality improvement reports.
LESSONS LEARNED: The HIV ACCESS network defined rapid ART as ART prescribed within 1 day of the first in-person visit with the HIV team. From October 2018 through September 2019, 76% PLWH (54 of 71) who were newly diagnosed and referred to the HIV ACCESS teams received rapid ART.
Of the PLWH who did not receive rapid ART, 47% were due to a provider decision to delay ART and 35% were due to difficulty contacting the client at the public hospital. 18% were due to delays in HIV provider availability at a community health center facing high staff turnover. There were no cases in which the client declined rapid ART. The majority of barriers to rapid ART in this setting were due to provider-related delays. Support and uptake of rapid ART was strong among non-provider staff and PLWH.
CONCLUSIONS/NEXT STEPS: These findings highlight the need to invest in provider education, reliable client contacts, staff retention and task-shifting. The next steps are to review clinical indications for ART delay, improve client contact information, implement interventions to increase staff retention, and train non-HIV provider staff on the provision of streamlined, people-centered linkages and rapid ART.

PEE1457

EXPANSION OF HIV CARE BEYOND ANTI-RETROVIRAL THERAPY FOR VULNERABLE POPULATIONS IN RURAL NIGERIAN COMMUNITIES: LEAVING NO ONE BEHIND

O.B. Onokala[1], E. Nwabueze[1], E. Ijezie[1], L. Buzaalirwa[2], P. Iutung[2]
[1]AIDS Healthcare Foundation Nigeria, Treatment, Abuja, Nigeria, [2]AIDS Healthcare Foundation Uganda, Treatment, Kampala, Uganda

BACKGROUND: Many HIV treatment programmes are designed to basically provide anti-retroviral therapy (ART) for persons living with HIV (PLWH). In rural communities, PLWH are often left behind in the treatment of HIV co-morbidities and HIV-associated infections. They are usually referred to other healthcare facilities in urban areas. Subsequently, sub-optimal treatment outcomes, increased cost of care and decreased client retention ensue. The expanded HIV treatment programme (EHTP) was established to provide vulnerable PLWH with free access to ART, treatment of HIV co-morbidities and HIV-associated infections within their rural communities in Nigeria.

DESCRIPTION: The 5-year EHTP was implemented in 45 randomly-selected HIV clinics located within rural Nigerian communities. EHTP was prioritized for PLWH who were dependent, with meagre income or internally-displaced by communal conflicts. Free drugs were obtained through multiple public-private collaborations. Healthcare workers were trained on comprehensive HIV care, and integrated drug-inventory management. Clinic workflows were re-designed to facilitate efficiency in implementation of EHTP with emphasis on maintaining quality healthcare and preserving confidentiality of PLWH. Clinic appointments were harmonized for family members and treatment partners. Data obtained from medical records were utilized for pre- and post-intervention assessments of EHTP, in October 2014 and October 2019 respectively.

LESSONS LEARNED: Overall, ART was provided for 13, 043 females (aged 2-72 years) and 9,125 males (aged 2-69 years). Among them were those treated for co-morbidities (malaria (n=3,590), cardiovascular diseases (n=458), diabetes (n=86) and HIV-associated infections (candidiasis (n=5,170), herpes zoster (n=349) and uncomplicated bacterial infections (n=12, 216). Treatment outcomes improved from 32% (pre-intervention) to 88% (post-intervention). This was attributed to increased access to drugs, and seamless HIV care continuum. The cost of patient care reduced through EHTP due to elimination of of user fees and additional transportation costs to urban areas. Client retention rates increased from 41% (pre-intervention) to 90% (post-intervention). This was attributed to improved healthcare efficiency due to optimization of existing human and infrastructural resources within the clinics.

CONCLUSIONS/NEXT STEPS: EHTP was effective in provision of ART, treatment of HIV co-morbidities and HIV-associated infections for vulnerable PLWH in rural Nigerian communities. The next step includes: EHTP-expansion to other rural communities in Nigeria.

PEE1458

CREATING A SAFE SPACE FOR KEY POPULATIONS WITHIN HEALTH FACILITIES: EXPERIENCE FROM MONTSERRADO COUNTY, LIBERIA

G. Kamanga[1], P.K. Thakur[2], M. Odo[3], T. Hallie[1], C. Kerbay[1], B. Zinnah[1], M. Miller[1], L. Harris[1], D.D. de Mora[2], N.F. Clement[1], C. Akolo[2]
[1]FHI 360, Global Health Population and Nutrition, Monrovia, Liberia, [2]FHI 360, Global Health Population and Nutrition, Washington DC, United States, [3]National AIDS and STI Control Program, Ministry of Health, Monrovia, Liberia

BACKGROUND: Liberia's HIV prevalence is 2.1% but heavily skewed toward key populations (KPs), with 9.8% prevalence among female sex workers and 19.8% among men who have sex with men. KPs are the least likely to access HIV testing and lifesaving antiretroviral treatment due to pervasive stigma; therefore, inclusive approaches for KPs to freely access HIV services are needed. While designated community-based safe spaces or drop-in centers have been successful in other countries, they are deemed not viable in Liberia due to stigma and safety concerns. The USAID/PEPFAR-funded LINKAGES project led by FHI 360 presents a unique experience of creating "safe spaces" within existing health facilities.

DESCRIPTION: LINKAGES uses an integrated, coordinated community and health facility model in Liberia. Nine civil society organizations were competitively selected to spearhead peer outreach and HIV testing, to partner with 11 high-burden health facilities in Montserrado County to ensure linkage to treatment for those who are HIV positive. Facility staff were trained and mentored to provide non-stigmatizing, KP-friendly HIV services, and linkage retention coordinators were hired for each facility to help KP individuals navigate HIV services including linkage to treatment.

LESSONS LEARNED: From May to September 2019, 6,946 KP individuals were reached with comprehensive HIV services in Montserrado County. For the first time a total of 2,364 KP individuals were recorded as openly accessing services in the 11 health facilities. Peer outreach workers collaborated with health facility staff to mobilize people for HIV testing and return to treatment those who had stopped. In the community and facilities, 4,250 KP individuals (76%) were tested for HIV, of whom 249 (6%) were diagnosed HIV positive and 242 (97%) initiated treatment. With the help of linkage retention coordinators and peer navigators, 793 PLHIV who had stopped treatment were successfully brought back to treatment.

CONCLUSIONS/NEXT STEPS:

- Partnerships between civil society organizations and health facility staff can lead to quick gains in getting all PLHIV on treatment and contribute to epidemic control.
- Adequate sensitization and mentorship of health facility staff to be receptive to KPs has created health facilities that are "safe spaces" for KPs.

PEE1459

A MULTI-COMPONENT STRATEGY IMPROVES HIV VIRAL LOAD SUPPRESSION AMONG PERSONS LIVING WITH HIV (PLWHIV) EXPERIENCING HOMELESSNESS IN SAN FRANCISCO

A. Sombredero[1], T. Nguyen[2], R. Arnold[3], F. Escobar[4]
[1]San Francisco Community Health Center, Wellness Clinic, San Francisco, United States, [2]San Francisco Community Health Center, Clinical Data and Panel Management, San Francisco, United States, [3]San Francisco Community Health Center, HHOME, San Francisco, United States, [4]San Francisco Community Health Center, TACE, San Francisco, United States

BACKGROUND: Homelessness is a growing problem nationwide and in San Francisco (SF). The 2019 SF Homeless Point-in-Time Count enumerated 8,035 homeless persons-- a 17% increase from 2017. Emerging research suggests housing instability is associated with poorer HIV outcomes--the overall viral suppression (VS) rate in SF among PLWHIV is 74%, while those experiencing homelessness is 30%. The SF Community Health Center (SFCHC) is a federally qualified health center dedicated to serving vulnerable communities living with and at risk for HIV. The agency is committed to implementing innovative strategies to address the local HIV epidemic and needs of persons experiencing homelessness.

DESCRIPTION: Given a SFCHC VS rate of 23% among our patients living with HIV experiencing homelessness in 2014 (VS defined as <40 copies/ml), we implemented a multi-component strategy called the HIV Homeless Health Outreach Mobile Engagement program (HHOME) that sought to address the complex needs of this population. We also established a new primary care clinic and on-boarded medical and behavioral health staff who offered scheduled and drop-in urgent and primary care services. All staff were cross-trained in prevention, counseling, and harm reduction strategies (e.g., needle exchange). We also added street health services through a mobile clinic that integrated mental health and substance use services along with intensive case management, peer navigation, and directly observed therapy (DOT). In addition, we prioritized housing stabilization and legal aid and offered food and transportation vouchers.

LESSONS LEARNED: Overall, 375 PLWHIV with at least two viral load measurements were seen from 2015-2019; 115 (30%) identified as homeless. For these patients, 19% were transgender, 66% were male, and 45% were over the age of 50. This population was racially and ethnically diverse: 15% Hispanic/Latinx, 27% Black/African American, 12% Asian or Pacific Islander, 0.8% Native American, and 42% Caucasian. Over 5 years, we observed dramatic improvements in VS rates among PLWHIV experiencing homelessness (23% VS in 2014; 54% VS in 2016 and 70% in 2019).

CONCLUSIONS/NEXT STEPS: SFCHC's interdisciplinary team successfully integrated multiple care and support services that addressed the needs of PLWHIV experiencing homelessness. This strategy was associated with improved VS rates equivalent to those with stable housing.

PEE1460

IMPLEMENTATION OF A COLLABORATIVE, MULTI-STAKEHOLDER PROGRAM TO STANDARDIZE AND SCALE HIV SERVICES FOR KEY POPULATIONS IN PUBLIC SECTOR HEALTH FACILITIES IN ZIMBABWE

C. Johnson[1], H. Ndondo[1], R. Dhlamini[1], S. Leuschner[1], N. Madidi[1], B. Mutede[1], O. Mugurungi[2], G. Ncube[2], T. Bhatasara[2], R. Yekeye[3], A. Mpofu[3], T. Mbengeranwa[3], M. Sibindi[4], C. Samba[5], N. Chabata[6], N. Taruberekera[1]
[1]Population Services International, Harare, Zimbabwe, [2]Ministry of Health and Child Care, Harare, Zimbabwe, [3]National AIDS Council, Harare, Zimbabwe, [4]Sexual Rights Centre, Bulawayo, Zimbabwe, [5]Gays and Lesbians of Zimbabwe, Harare, Zimbabwe, [6]Hands of Hope, Harare, Zimbabwe

BACKGROUND: Key populations (KP) in Zimbabwe, including female sex workers (FSW) and men who have sex with men (MSM), experience low HIV service uptake in public health facilities due to stigma, discrimination, and criminalization. To achieve and sustain epidemic control, the Ministry of Health and Child Care (MoHCC) implemented a collaborative, multi-stakeholder program to institutionalize delivery of KP-competent public sector HIV services. Objectives were to develop policy and program guidance documents and to strengthen staff KP clinical competency and sensitivity.

DESCRIPTION: MoHCC convened a working group inclusive of National AIDS Council, KP communities and implementing partners (IPs) to develop a clinical manual, handbook, job aid, and training curriculum based on WHO guidance, best practices, and equitable healthcare access. These materials established a minimum service package and addressed stigma and discrimination. Concurrently IPs, including Population Services International (PSI), improved or drafted standard operating procedures (SOPs) and worked closely with public facilities and KP communities to refer and transition clients to facilities recognized as KP-competent. The working group selected facilities in the districts of Bulawayo, Gweru, Masvingo and Mutare for initial training and support, including staff sensitizations and KP membership on quality assurance (QA) committees.

LESSONS LEARNED: Between October 2018 and September 2019, MoHCC activated 18 public sector facilities as KP-competent, with 515 staff sensitized, 101 healthcare workers trained on KP clinical service delivery, and 10 KP QA committees established. 1,341 FSW and 41 MSM stable on antiretroviral treatment (ART) were successfully transitioned from PSI New Start Centre clinics to public sector facilities; 608 FSW and 44 MSM newly diagnosed with HIV were directly linked to public sector facilities and commenced on ART. Through government technical leadership and meaningful engagement of KP communities throughout the process, these results demonstrate that it is possible to provide KP services within historically restrictive environments.

CONCLUSIONS/NEXT STEPS: Implementing KP-competent HIV services within a national healthcare system requires a comprehensive approach led by the Ministry of Health and inclusive of KP communities, IPs, and local public facility leadership. Next steps include sustained coordination, access and retention across partners; implementation of standardized assessments by which facilities are determined to be KP-competent; and national scale-up.

PEE1461

THE HEALTHY LIVING PLATFORM: LEVERAGING TECHNOLOGY TO PROVIDE DIFFERENTIATED HIV SERVICE DELIVERY TO KEY POPULATIONS IN GHANA

D. Komlagah[1], D. Kwablah[1], Y.A. Abdul Rahman[1], E. Bruce[1], S. Maher[2], E. Alve-Gavor[1], S. Thompson[1], H. Nagai[1]
[1]JSI Research and Training Institute, Inc., Accra, Ghana, [2]JSI Research and Training Institute, Inc., Boston, United States

BACKGROUND: Key populations (KP) in Ghana often prefer anonymity to avoid stigma and discrimination from healthcare providers, resulting in social exclusion and low utilization of health care services, and hindering their reaching HIV services. There is the urgent need to identify strategies tailored to unique KP needs. This abstract presents evidence of a successful innovative approach in reaching KPs with HIV services in poor resource settings, such as Ghana.

DESCRIPTION: The USAID Strengthening the Care Continuum Project, implemented by JSI Research & Training Institute, Inc. (JSI), designed and developed the Healthy Living Platform (HLP), a two-way interactive system developed to transmit short message services (SMS) and interactive voice response (IVR). HLP is integrated with another JSI-led approach, helpline counselling (HLC) trained nurses who provide private, confidential phone counselling to KPs as an entry point to the HIV care continuum, and connects them via a three-digit short code (212). KPs who subscribe for text and voice messages also have access to professional counsellors who provide HIV, STI and ART counselling and referrals for follow-up services. The platform contains three campaigns (It's My Life, It's My Turn, I'm Someone's Hope) in four local languages (Twi, Ewe, Ga and Hausa) and in English.

LESSONS LEARNED: Between August 2018 when the platform was launched to September 2019, 23,510 KPs aged 15-75 years subscribed and accessed various HIV prevention and treatment literacy messages. There were 164,923 interactions of which 45,361 were from IVR; 115,845 were Unstructured Supplementary Service Data (USSD); and 3,717 were interactions with counselors. The platform has also sent out 1,123,316 messages to KPs who subscribed to the campaigns over the period. Reaching HLCs is easier for KPs than directly dialing 10-digit personal numbers and allows for reaching discrete KPs missed out by peer education including transgender.

CONCLUSIONS/NEXT STEPS: The HLP effectively meets the HIV related needs of high risk KPs. This system of reaching KPs has the potential to eliminate both structural and individual level barriers including stigma and discrimination and fear of breach of confidentiality. The client feedback mechanism helped to improve the HLC content and the unmet needs of KP sub-groups.

PEE1462

CULTURAL COMPETENCY AND PATIENT NAVIGATION TO REINFORCE CARE FOR MSM AND TRANSGENDER WOMEN LIVING WITH HIV IN A HOSPITAL IN LIMA, PERU -PROYECTO ORGULLO+

A. Silva-Santisteban[1], A. Maiorana[2], G. Calvo[1], K. Konda[3,1], C. Caceres[1], S. Kegeles[2]
[1]Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Studies in HIV, AIDS and Society, Lima, Peru, [2]UCSF, San Francisco, United States, [3]UCLA, Los Angeles, United States

BACKGROUND: The 90-90-90 targets set a challenge to public health systems in Latin America, where overcrowded systems, compounded with HIV stigma, decrease linkage and retention in care, especially for MSM and transgender women (TW). As part of an ongoing multi-component HIV prevention intervention, we implemented a program to improve the quality of care for MSM and TW in the HIV service of a hospital in southern Lima. The intervention focused on MSM/TW cultural competency for providers and the implementation of peer-led patient navigation.

DESCRIPTION: The 90-90-90 targets set a challenge to public health systems in Latin America, where overcrowded systems, compounded with HIV stigma, decrease linkage and retention in care, especially for MSM and transgender women (TW). As part of an ongoing multicomponent HIV prevention intervention, we implemented a program to improve the quality of care for MSM and TW in the HIV service of a hospital in southern Lima that has around 2500 people receiving antiretroviral treatment. The intervention focused on cultural competence for providers and peer-led patient navigation.

LESSONS LEARNED: The delivery of trainings and dissemination of materials was feasible, low resource demanding as well as welcomed by providers. The commitment of the clinical team director, who championed the intervention, was key to foster its implementation among other medical providers. Time constraint was a barrier among physicians to deliver some of the planned messages to patients. The incorporation of PN tools by counselors, allowed them to develop trustful relationships with 174 clients that initiated/reengaged in treatment. The acquisition and application of these tools also strengthen their role within the health team: physicians started relying on counselors to address patients that showed signs of social or individual vulnerability that could interfere with their retention in care, as part of their newly PN activities.

CONCLUSIONS/NEXT STEPS: While the completion of the intervention will allow us to better assess its impact, the process of implementation has shown us that addressing MSM and TW cultural competency with medical providers and reinforcing the role of peer-counselors, is a feasible, acceptable and low resource demanding intervention to implement in hospitals in Peru and potentially in Latin America.

SERVICE GAPS FOR PEOPLE WITH INTENSIVE MEDICAL AND PSYCHIATRIC NEEDS: WHEN WILL HEALTHCARE SYSTEMS MEET THE NEEDS OF PEOPLE WITH SERIOUS MENTAL ILLNESS?

K. McKinnon[1], F. Cournos[2], J.-M. Alves-Bradford[1], F. Jafaar[2]
[1]Columbia University, Psychiatry, New York, United States, [2]Columbia University, Mailman School of Public Health, New York, United States

BACKGROUND: Worldwide, people with serious mental illness have higher HIV infection rates than the general population: In the US, general population prevalence is 0.4%, whereas among people with serious mental illness the estimated rate is 6%. With increased investment to end the HIV epidemic, access to HIV services in outpatient mental health programs would enhance efforts to improve HIV prevention and care outcomes in this population. Barriers to integrating services include the complexity of treatments for both HIV and serious mental illness, which, overwhelmingly, are only available in separate systems of care.

METHODS: We surveyed directors of licensed outpatient mental health care programs throughout New York State to examine: (1) HIV-related services being delivered; (2) service setting characteristics supporting greater integration of HIV and mental health care; (3) training needs of service providers; and (4) current practices compared to those that were in place earlier in the. New York is both a major US epicenter of HIV infection and a state in which innovative programs to address the HIV epidemic have been carried out. Data were compared to prior surveys conducted in 1997 and 2004 to examine differences in services between geographic regions and time periods.

RESULTS: Outpatient mental health programs have improved in the volume and range of HIV services they offer, but their provision of pre-exposure prophylaxis, condoms, HIV testing, and HIV antiretroviral treatment monitoring are lagging; fully half (50%) of programs were unable to estimate how many of their HIV clients were taking ART.

CONCLUSIONS: New York's initiative to end the HIV epidemic is not optimized for people with serious mental illness in settings designed for their care. Integrated care models do not appear to fit patients with intensive medical and psychiatric needs, who may be unable to access a single setting that can meet those needs.

PEE1464

SCALING UP HIV TREATMENT AND CARE IN RURAL POST-EBOLA LIBERIA: LESSONS LEARNED FROM OPENING A NEW HIV CLINIC IN A HIGH-VOLUME PRIMARY HEALTH CENTER

A. Bayiah[1], A. Cooper[2], J. Lusaka[1], G. Sayor[2], K. Socree[2], F. Baadio[3], L. Jabateh[1], J. Beauchamp[1], R. Cook[1,4]
[1]Partners In Health, Monrovia, Liberia, [2]Ministry of Health, Harper, Liberia, [3]National AIDS Control Programme, Monrovia, Liberia, [4]Harvard Medical School, Boston, United States

BACKGROUND: Partners In Health (PIH) is committed to a preferential option for the poor. PIH launched work in Liberia in 2014 at the height of the Ebola epidemic by invitation of the Liberian Ministry of Health (MOH) and has continued to work in one of the most geographically isolated and impoverished regions. During the epidemic, many PLHIV were lost to follow-up, in response, PIH worked with the MOH launched a community health worker (CHW) program in 2015. In 2017 a new ART clinic site was established in the highest volume health center. The strategic objectives of our HIV program in Liberia are to:

1. Improve HIV detection through community engagement and active case-finding
2. Offer high quality HIV treatment and care
3. Improve clinical outcomes with CHW and socioeconomic support

DESCRIPTION: In 2017, recognizing an unmet need for HIV care, PIH-Liberia collaborated with the MOH and the National AIDS Control Program to open a new ART clinic in the largest primary health center in the county with population of 135,938 with 1.8% HIV prevalence. The clinic is run by one MOH nurse supported by a PIH physician assistant. CHWs make home visits to ensure medication adherence and the socioeconomic assistance program provides transportation reimbursement to all patients and additional social support for the most vulnerable patients.

LESSONS LEARNED: Since initiation of the HIV program in 2015, the number of PLHIV enrolled in care has nearly tripled; 44% of these new enrollments were from the new ART clinic. Initiation of ART has increased five-fold. Despite these gains, less than half of the estimated total population living with HIV in the county are enrolled in care and treatment and loss to follow-up (LTFU) continues to be a challenge with 16% of patients LTFU.

CONCLUSIONS/NEXT STEPS: The PIH model of accompanying the public sector with the "five S's": Staff, Stuff, Space, Systems, and Social Support has led to significant improvements in HIV testing and treatment. Innovative approaches are needed to further reduce LTFU and expand the reach of HIV testing to hard-to-reach populations including targeted strategies to reduce stigma and discrimination.

HIV SERVICES IN HEALTHCARE AND/OR COMMUNITY SETTINGS

PEE1465

COMMUNITIES CULTIVATE HOPES OF CHILDREN LIVING WITH HIV: STUDY FINDINGS OF 'TOWARDS AN AIDS FREE GENERATION IN UGANDA' (TAFU2) PAEDIATRIC HIV PROJECT

D. Bitira[1], E. Vrolings[2,2], M. Musinguzi[3,3], J. Rujumba[4,4]
[1]Community Health Alliance Uganda, Programs, Kampala, Uganda, [2]Aidsfonds, Amsterdam, Netherlands, [3]Aidsfonds, Kampala, Uganda, [4]Makerere University, Kampala, Uganda

BACKGROUND: 37% of children 0-14 years living with HIV in Uganda miss life-saving HIV-related services. 30% of children living with HIV (CLHIV) are lost to follow up (LTFU). Viral suppression is lower among children (39.3%) than adults (59.6%). Paediatric HIV related services mainly health facility-based.

TAFU project aimed at enrollment and retention of more CLHIV in care. Its community-led model and multi-sectoral approach with health facility (HF) collaboration addressed children's barriers to uptake, adherence and retention in HIV services. Facilitated community health workers (CHW) educated families on paediatric HIV and care; accompanied exposed children for HIV testing; linked HIV positive children to Anti-Retro-Viral (ARV) treatment at HF; visited families of CLHIV on treatment; tracked and returned lost to follow up (LTFU)

into care. Established children peer support groups (PSG) facilitated CLHIV's clinic appointments and ARV re-fills. Supported Village Saving and Loans Associations (VSLA) promoted caretakers' income generation, food security and resilience; resultantly CLHIV's appointments for ARV refills; meals to take pills; and cope with stigma. Studies were conducted to assess project impact.

METHODS: TAFU-Makerere University team conducted baseline (2017) and end-line (2019) surveys in three project districts. Employed community-based cross-sectional applied research; purposive and systematic sampling; quantitative and qualitative data collection methods.

26 Focus Group Discussions, five in-depth interviews, 35 Key Informant Interviews collected qualitative data from CLHIV, caregivers, CHW, health workers (HW); community leaders. Quantitative data obtained from Ministry of Health data base, 12 health facilities, HIV services registers. Quantitative data analyzed using Epidata software. Content thematic approach analyzed qualitative data.

RESULTS: 120 CHW, 27 VSLA, 13 PSG operationalized. More (3,958) children reached; tested for HIV (3,700); CLHIV enrolled onto ARV 377 (96 %); LTFU, missed appointments retuned (350); retained in care 362 (96%); virally suppressed 327 (87%) within two years. 'CHW visited me, guided me on time child to take medicine and treatment adherence. My son is back to life.'

CONCLUSIONS: Empowered communities significantly maintain more CLHIV along HIV treatment cascade greatly complementing facilities. Organizations to integrate innovative community-driven paediatric HIV interventions into district social service programs to sustainably bridge hurdles; find, enroll and retain more CLHIV in care.

PEE1466

UNDERSTANDING DE-IMPLEMENTATION AND PERSISTENCE OF LOW VALUE HIV PREVENTION INTERVENTIONS IN THE UNITED STATES: A MIXED-METHOD STUDY

V. Mckay[1], T. Combs[1], M. Reid[1], L. Ingaiza[1], E. Tetteh[1], S. Chithenga[1]
[1]Washington University in St. Louis, Brown School, St Louis, United States

BACKGROUND: As more effective or efficient interventions emerge to address HIV prevention, it may be appropriate to de-implement low-value interventions, or interventions that are less effective or efficient. Factors that contribute to appropriate de-implementation are not well identified. We examined continuation or de-implementation of low-value interventions among public health organizations providing HIV services and factors contributing to continuing or de-implementing interventions.

METHODS: We conducted a sequential mixed-methods study. Stage one was an online cross-sectional survey with organizations (N=188) providing HIV prevention. Organizations were recruited between 2017-2019 from the Center for Disease Control and Prevention's (CDC) website gettested.org from the 20 metropolitan statistical areas with the highest HIV incidence. An organization was eligible if at least one of the HIV prevention interventions identified as inefficient by the CDC in the last ten years had been implemented and one HIV prevention programming administrator responded. The second stage consisted of interviews with providers (N=29) from a mix of organizations (N=10) that reported either continuing or de-implementing interventions based on the survey. Survey responses were analyzed to identify organizational and intervention characteristics associated with de-implementation using logistic regression. Surveys and interviews were analyzed further to describe and thematically elaborate on reasons for continuing or de-implementing interventions.

RESULTS: Organizations reported 359 low-value interventions were implemented. Of interventions implemented, 46% had since been de-implemented. We examined a number of factors theoretically associated with de-implementation, but organization size was the only factor statistically associated with de-implementation, with larger organizations being 3.1 times more likely to de-implement than smaller organizations (95% CI: 1.3-7.5). Forty-seven percent of participants responded that funding was the primary reason for de-implementing. Qualitative results further elaborated that decisions to continue or de-implement interventions were multi-factorial and interconnected with funding, perceptions of intervention effectiveness and relevance of the intervention to the target population.

CONCLUSIONS: Our work is one of the first in HIV prevention to demonstrate that while low-value interventions are frequently de-implemented among HIV prevention organizations, many persist, which may represent inefficiency. However, from a provider perspective, the decision to continue or end interventions is influenced by a number of factors beyond funding and cost.

PEE1467

ABSENCE OF ANTIRETROVIRAL DRUGS IN BLOOD SAMPLES OF ADULTS SELF-REPORTING ANTIRETROVIRAL THERAPY (ART) USE IN ESWATINI IS ASSOCIATED WITH YOUTH, NOT COST OF TRAVEL

C. Ngcamphalala[1,2], N. Gwebu[2], M. Ndlangamandla[2], R. Sahabo[2], M.C. Shongwe[3,4], Z. Mnisi[5], T.T. Ao[6], Y. Wu[7], H. Nuwagaba-Biribonwoha[2]
[1]Health Research Training Program (HRTP) Fellow, ICAP in Eswatini, Mbabane, Eswatini, [2]ICAP at Columbia University, Mailman School of Public Health, Mailman School of Public Health, Mbabane, Eswatini, [3]Health Research Training Program (HRTP) Mentor, ICAP in Eswatini, Mbabane, Eswatini, [4]University of Eswatini, Department of Midwifery Science, Faculty of Health Sciences, Mbabane, Eswatini, [5]Ministry of Health, Mbabane, Eswatini, [6]U.S. Centers for Disease Control and Prevention/U.S. President's Emergency Fund for AIDS Relief (PEPFAR), Mbabane, Eswatini, [7]Columbia University, Department of Epidemiology, Mailman School of Public Health, Department of Epidemiology, Mailman School of Public Health, New York, United States

BACKGROUND: The Eswatini government provides free HIV/AIDS treatment services, but there are limited data on correlates of antiretroviral therapy (ART) uptake substantiated by presence or absence of antiretroviral (ARVs) in blood samples. With approximately 60% of the population living under the $1.25 poverty line, we hypothesized that that cost of travel to access HIV services could be a significant factor in ART uptake.

METHODS: Secondary data analysis of the Swaziland/Eswatini HIV Incidence Measurement Survey (SHIMS2 2016) was conducted. We utilized questionnaire data on cost of travel at the last HIV service visit and sociodemographic characteristics; and accessed biomarker data for HIV status and ARVs commonly used in the Eswatini HIV treatment guidelines (Efavirenz, Nevirapine and Lopinavir). We included adults ≥15 years who self-reported ART use and had ARVs tested from dried blood spot samples (DBS). Self-reported cost of travel was collected as one-way cost ($1.0=SZL13) and doubled to reflect total cost. We used logistic regression to examine the relationship between cost of travel and other sociodemographic characteristics and absence of ARVs.

RESULTS: There were 2,088 adults self-reporting ART use, median age 38 years (IQR 32-48), 69%(n=1458) female. Most (96%, n=2014) had detectable ARVs in DBS samples, and 4%(n=74) did not. Median cost

of travel per visit was $1.2(IQR $0.9-2.3), with no significant variation by region or residence. Just over one-third 38%(n=776) were on ART 0-2 years, 29%(n=600) for 3-5 years and 33%(n=712) for 6+years. In adjusted analyses, there was no association between cost of travel and absence of ARVs (AOR 1.2, 95% CI 0.7-2.1). Absence of ARVs in DBS samples was associated with youth 15-24 years (AOR 4.8, 95% CI 2.2-10.5) and adults 25-34 years (AOR 2.2, 95% CI 1.1-4.5); reference: adults 35 years and older; but not associated with sex, region, urban/rural residence, education, HIV status disclosure, or alcohol consumption

CONCLUSIONS: Nearly all adults self-reporting ART use had detectable ARVs in DBS samples. The $1.2 median cost of travel was equal to the international poverty line but had no impact on current ARV use. Resource allocation to support treatment uptake should focus on youth and younger adults.

PEE1468

PRIMARY CARE FOR HIV POSITIVE PATIENTS IN MOZAMBIQUE: FINDINGS FROM A NATION-WIDE TIME AND MOTION STUDY

F. Moi[1], F. Fabozzi[1], M. Romanelli[1], J. Cabral[1]
[1]ThinkWell, Maputo, Mozambique

BACKGROUND: With an estimated 2.2 million people living with HIV and a health professional to population ratio well below international standards, understanding how primary health care (PHC) professionals in Mozambique spend their time is essential to identify efficiency gains and improve HIV care in the country. This study investigates health workers' use of time at the health facility and the duration of consultations in Mozambique to assess differences in attending to HIV+ and HIV- patients and uncover potential opportunities for improvement within this scarce resource setting.

METHODS: In 2017, a time and motion study was conducted in a nationally representative sample of 29 PHC facilities across Mozambique. The study observed 192 days of work undertaken by the main cadres of PHC professionals involved in HIV care provision (physicians, nurses, maternal and child health (MCH) nurses, clinical officers), for a total of 8342 patient-provider interactions. Data was recorded directly on tablets using a locally designed software, and analyzed on STATA to estimate means and 95% confidence intervals.

RESULTS: The average duration of outpatient consultations for HIV+ patients was found to range from 8.67 [8.14-9.19] to 10.90 minutes [9.22-12.59], when performed by clinical officers or nurses respectively. Maternal health consultations for HIV+ patients ranged between 8.05 minutes [5.23-10.88] for postnatal consults and 14.34 minutes [12.32-16.35] for antenatal consults, both performed by MCH nurses. While these consultations are short, our analysis shows that they are 2 to 3 times longer than when performed for HIV- patients. Additionally, our study showed that health professionals spend on average 1.5 to 2 hours on personal matters or waiting for patients during their time at the facility. This suggests it would be possible to increase the duration of consultations without increasing the number of health workers.

CONCLUSIONS: Our findings indicate that there are opportunities to improve the efficiency in the use of health workers' time at PHC facility in Mozambique and improve the duration of consults for HIV positive patients without increasing the number of human resources. Furthermore, the short durations of consultations raise questions about the quality of care and indicate the need to further investigate this topic.

PEE1469

SCALE UP OF GENDER AFFIRMING HORMONE TREATMENT IN COMMUNITY-LED HEALTH CENTERS INCREASING ACCESS TO HIV AND PREP SERVICES AMONG TRANSGENDER WOMEN IN THAILAND

P. Getwongsa[1], R. Janamnuaysook[1], P. Patpeerapong[2], N. Manojai[2], A. Kaewburee[2], S. Janyam[3], C. Phanengnongyang[3], N. Rittiwong[3], D. Linjongrat[4], P. Panpet[4], S. Saiwaew[4], S. Sittikarn[5], J. Peelay[1], O. Nampisarn[1], A. Arunmanakul[6], S. Umasa[6], M. Avery[6], S. Mills[6], R. Vannakint[7], P. Phanuphak[1], R. Ramautarsing[1], N. Phanuphak[1]
[1]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]MPLUS Foundation, Chiangmai, Thailand, [3]Service Worker in Group Foundation, Bangkok, Thailand, [4]Rainbow Sky Association of Thailand, Bangkok, Thailand, [5]CAREMAT, Chiangmai, Thailand, [6]FHI 360 and LINKAGES, Bangkok, Thailand, [7]Office of Public Health, USAID Regional Development Mission Asia, Bangkok, Thailand

BACKGROUND: Transgender women (TGW) are disproportionally affected by HIV and are key to the response. TGW have specific health needs, especially gender-affirming hormone treatment (GAHT), and often don't prioritize HIV services despite the increased risk. Tangerine Community Health Clinic has successfully increased the service uptake by integrating GAHT into HIV services. This abstract will explore how scaling up this model to community-led health center could increase HIV service uptake among TGW across the country since 2018.

METHODS: The integrated GAHT-HIV services model, was scaled up to seven community-led health centers in Bangkok, Chiangmai, Pattaya and Songkhla. Between January 2018 and November 2019, we analyzed demographic and self-reported risk characteristics of TGW who accessed to GAHT and services to see if GAHT was able to reach TGW who were vulnerable to HIV.

RESULTS: Of 2,464 TGW who received overall services at seven community-led health centers, 62.1% expressed GAHT was their primary purpose of the clinic visit, 28.0% said HIV testing was their primary purpose, 2.2% came for PrEP and 7.7% preferred other services. 43.5% (n=1,072) TGW were tested for HIV. Median (IQR) age was 24 (21-29) years. Median (IQR) monthly income was USD 400 (0-667) and 61.5% had lower than bachelor's degree level education. 15.6% engaged in sex work.

Among TGW tested for HIV, 43.5% were first-time testers. HIV prevalence was 5.7%, highest in Pattaya (8.2%) followed by Chiangmai (7.7%), Chiangrai (6.4%), Bangkok (5.4%) and no HIV identified in Songkhla. Antiretroviral treatment was 100% initiated among HIV-positive clients. Among 1,011 TGW tested HIV-negative, 11.0% received PrEP. HIV incidence was 8.8 per 1000 person years, with no seroconversion among PrEP users. We found 1.1% in substance use, 1.4% participated in group sex and 10.2% with multiple sex partners among PrEP user.

CONCLUSIONS: We demonstrated the feasibility of scaling up the integrated GAHT-HIV services to generate health demand and access among TGW in Thailand. The model was effective in bringing in TGW with vulnerability and providing them with HIV prevention and care. GAHT should be offered as part of the essential HIV service package for TGW and be scaled-up to other priority provinces.

PEE1470

ART DECENTRALISATION AND QUALITY OF HIV TREATMENT SERVICES IN EASTERN ZIMBABWE: A MULTILEVEL ANALYSIS IN THE TREAT-ALL ERA

M. Tlhajoane[1], F. Dzamatira[2], N. Kadzura[2], C. Nyamukapa[1,2], J.W. Eaton[1], S. Gregson[1,2], L. Moorhouse[1]
[1]Imperial College London, Department for Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe

BACKGROUND: Decentralising HIV services to primary care facilities has been a key implementation strategy within high-burden countries in sub-Saharan Africa. The effects of decentralisation on the quality of care has rarely been evaluated. Here we analysed the impact of this strategy on ART uptake and quality of care in east Zimbabwe following the introduction of treat-all.

METHODS: We conducted a retrospective medical record review of adult patients enrolled in HIV care at health facilities in Manicaland, Zimbabwe, in the year following introduction of treat-all (July 2016 to June 2017), and a parallel cross-sectional health facility survey (August to October 2017). Using multilevel logistic regression models, we compared: (i) timely ART initiation - within 14 days of HIV diagnosis; (ii) availability of a CD4 count at baseline; and (iii) provision of isoniazid preventative therapy (IPT), at six first-referral level hospitals, six large health centres (LHCs), and six small clinics (SCs).

RESULTS: Compared to hospitals (68.3%), the proportion of patients initiating ART within 14 days was higher at LHCs (83.4%; odds ratio [OR]=2.31; p=0.01) and intermediate at SCs (76.7%; OR=2.06; p=0.09). Compared to those at hospitals, patients at LHCs and SCs had approximately 80% lower odds of having a CD4 count at baseline (p=0.011 and p=0.034, respectively); and fewer patients at LHCs received IPT (OR=0.33; p=0.026). Men (aOR=0.65; p=0.016) and patients at early stages of infection (stages I versus stages III/IV: aOR=0.53; p=0.006) were less likely to have CD4 count at baseline in multivariable analysis. Patients attending facilities where ART services were provided free of charge (aOR=0.40; 95%CI 0.18-0.91; p=0.029) or facilities with low staff-to-patient ratios, and patients at early stages of infection (stages I versus stages III/IV: aOR=0.41; p=0.001) were less likely to receive IPT.

CONCLUSIONS: In this cohort of patients in east Zimbabwe, decentralised HIV service delivery contributed to accelerated ART initiation. This strategy may, however, have reduced the overall quality of services. Investments may be required to improve access to clinical monitoring and other ancillary services for patients attending for treatment at primary healthcare facilities.

PEE1471

THINKING OUTSIDE THE "HEALTH FACILITY" BOX: FEASIBILITY OF OFFERING HIV TESTING AND TREATMENT SERVICES AT AN ALTERNATIVE MEDICINE CENTER (AMC) IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

C. Tendo[1], S. Muyano[1], J. Mubenga[2], L. Tshisumpa[2], C. Tshibambe[3], D. Canagasabey[4], P. Kibwa[1], J.-C. Kiluba[1]
[1]PATH, Lubumbashi, Congo, Democratic Republic of the, [2]Rosalie Health Center, Kasumbalesa, Congo, Democratic Republic of the, [3]Centre Americaine, Kasumbalesa, Congo, Democratic Republic of the, [4]PATH, Washington DC, United States

BACKGROUND: Data from 2018 indicates only 63% of estimated PLHIV (people living with HIV) in the DRC are aware of their status with 53% accessing antiretroviral therapy (ART), highlighting a need for new strategies to expand HIV testing and ART coverage. PATH, through the USAID-funded Integrated HIV/AIDS Project, piloted provision of HIV testing and treatment services outside of a traditional health facility setting at an AMC.

DESCRIPTION: From April 2019, Rosalie Health Center collaborated with an AMC in Kasumbalesa, a large mining/transit hub in Haut Katanga, to offer HIV testing services to clients with chronic illness not responding to alternative treatments. AMC providers were trained to screen clients using an HIV risk assessment tool, test those likely to be infected, and initiate PLHIV on treatment. The AMC provides all treatment and care services to identified PLHIV, and refers patients to Rosalie for viral load and tuberculosis preventive therapy.

LESSONS LEARNED: From April through October 2019, 217 clients with chronic illness attending the AMC were tested for HIV, among whom 51 were newly identified PLHIV and 11 were known positives (PLHIV lost to follow up at neighboring facilities), yielding a 28% seropositivity compared to 9% (736/7,878) at project-supported facilities in Kasumbalesa. All PLHIV were identified at WHO clinical stage 1 or 2. Forty-eight PLHIV (94%) were newly initiated on ART and all known positives accepted ART re-enrollment at the AMC.

The high testing yield and ART enrollment/re-enrollment rates observed demonstrate the feasibility of using AMC providers to efficiently reach, test, and enroll into treatment clients who opt for health services outside of a traditional facility setting. Providing testing services at an AMC enabled earlier enrollment of PLHIV on ART. The recent popularity of AMCs and trust in these providers also facilitated re-enrollment of PLHIV who dropped out of care at health facilities.

CONCLUSIONS/NEXT STEPS: This pilot highlights collaboration with AMCs as an effective strategy to efficiently reach and test PLHIV who seek healthcare services outside of a traditional setting and encourage re-enrollment of known PLHIV in ART. The project plans to collaborate with additional AMCs in Haut Katanga to support the DRC achieve epidemic control.

PEE1472

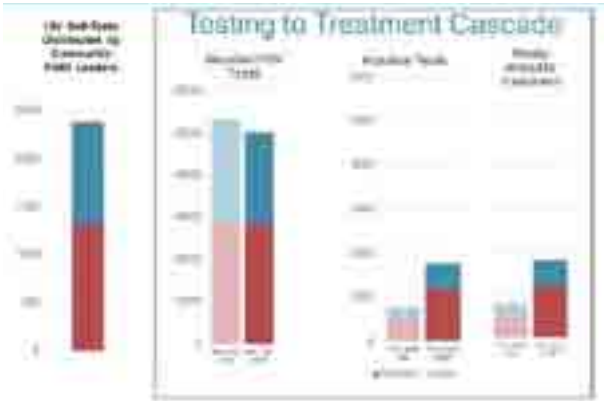
ENGAGEMENT OF FAITH LEADERS IN TARGETED HIV SELF-TESTING INCREASED CASE IDENTIFICATION AND NEW LINKAGES TO TREATMENT IN NAIROBI, KENYA

R. Bauer[1], C. Simbiri[1], J. Motoku[1], A. Njoroge[1], H. Weyenga[2], J. Mwangi[2], S. Anangwe[3], V. Ojiambo[4], J. Barker[2], M. Maxwell[5], A. Katana[2], S. Hillis[6]
[1]Eastern Deanery AIDS Relief Program, Nairobi, Kenya, [2]CDC, Nairobi, Kenya, [3]DOD/HJF, Nairobi, Kenya, [4]USAID, Nairobi, Kenya, [5]PEPFAR Coordination Office, Nairobi, Kenya, [6]U.S. Office of Global AIDS Coordinator, Washington, DC, United States

BACKGROUND: Gaps in HIV testing uptake and antiretroviral coverage, particularly for men, are evidence of significant barriers to health services. To increase HIV case-finding and linkage into care for persons living with HIV (PLHIV), particularly men, the faith based Eastern Deanery AIDS Relief Program (EDARP) engaged faith leaders in both community and clinical settings to introduce HIV self-testing (HIVST) in Nairobi Kenya.

DESCRIPTION: EDARP, a Faith-Based Organization providing holistic care for 26,000 PLHIV, links clinical and community care in 14 sites in Nairobi slums. In collaboration with the Ministry of Health, 1332 staff and Community Health Workers (CHWs) who were leaders from local faith communities, were trained in use of HIVSTs. In May 2019, EDARP implemented targeted dissemination of HIVSTs at home or in facilities, with patient-centered partner notification services.

LESSONS LEARNED: From November 2018–April 2019 to May 2019–October 2019, new HIV diagnoses increased 117% and 134% for men and women, respectively, with similar increases in numbers newly linked into treatment. Testing yield for men increased from 1.2% (294/22,429) to 2.8% (604/21,703, p,<00001), and for women, from 1.7% (491/28/952) to 4.1% (1169/28,321, p,<00001), with fewer diagnostic tests (Figure).



[Figure. Increase in HIV-positive tests and new linkages to treatment (disaggregated by sex) before and after the distribution of HIV self-tests by faith leaders in Nairobi, Kenya (November 2018 - October 2019)]

Successful practices included seamless clinical-community integration, training for CHW/staff addressing:-skills-building for improved partner elicitation, for clients with new diagnoses or detectable viral loads welcoming environments for all (especially for key populations), responsibility of all staff to advance case-finding and linkage, emotional and spiritual support for staff, 24-hour hotline for HIVST-users, weekly data reviews to identify successes and challenges and celebration of top performing staff and sites.

CONCLUSIONS/NEXT STEPS: Distribution of HIVSTs by faith leaders can substantially increase case-finding and linkage to care for both men and women. Expanding this model in and beyond Kenya may help advance epidemic control.

PEE1473

CURRENT STATE OF HIV PARTNER NOTIFICATION SERVICES IN CHINA: STAKEHOLDER PERSPECTIVES

C.X. Shi[1], S. Meng[1], T. Tang[1], S. Zhang[2], Z. Wu[3], S.H. Vermund[1]
[1]Yale School of Public Health, New Haven, United States, [2]Kunming Medical University, Kunming, China, [3]Chinese Center for Disease Control and Prevention, National Center for AIDS/STD Control and Prevention, Beijing, China

BACKGROUND: As China's HIV epidemic becomes increasingly driven by heterosexual transmission, rethinking approaches for HIV testing is needed to improve coverage among hard-to-access groups. Provider-assisted partner notification (PN) may be particularly beneficial in low prevalence settings in identifying undiagnosed people living with HIV (PLHIV). The national PN policy relies on passive referral by patients, but some provinces have established additional policies that authorize providers to notify partners. We sought to explore stakeholder perspectives on the implementation, challenges, and future directions for PN in China.

METHODS: We interviewed 31 healthcare professionals who have a role in designing, implementing, or researching PN services about their experiences and opinions on best practices: 12 staff members from 11 Centers for Disease Control (CDC), 7 clinicians, 3 community health workers, 4 community-based organization (CBO) representatives, and 4 researchers. We also interviewed 39 recently-diagnosed PLHIV on their PN experiences. Transcripts were analyzed using inductive thematic analysis.

RESULTS: Key findings include:

1. In areas with limited national or provincial policy guidance, implementation varied greatly between clinic/hospitals. Yunnan Province stood out for providing PN training and certification for healthcare staff.
2. While CDC data report that spousal PN is consistently >90%, some health providers indicated much lower estimates for their institution/region, as low as 30-50%. There was a strong consensus that PN of non-spousal partners, especially partners of men who have sex with men, was very low.
3. Stakeholders were divided on compulsory PN: some participants voiced ethical concerns about patient privacy and decreased willingness to test while other participants felt that the public health benefits outweighed potential harms, particularly in China's cultural context.
4. The success of a clinic/hospital's PN services was often credited to 1-2 individuals who were exceptionally trusted and motivated, e.g., doing home visits in off-hours.
5. CBOs and peer support groups can be highly effective in increasing HIV disclosure.

CONCLUSIONS: The uneven implementation of high-quality PN and testing in China is likely contributing to missed public health opportunities. Research is urgently needed on PN for non-spousal partners. Future strategies can include scaling up PN training for providers, expanding CBO involvement, and creating forums to discuss culturally-specific ethical concerns.

PEE1474

THE VALUE OF PARTNERSHIP WITH HEALTH CENTRES IN IMPROVING ART ADHERENCE FOR ADOLESCENTS LIVING WITH HIV IN THE TRIPLE R PROJECT

O. Hlungwani[1], H. Mkhatshwa[2]
[1]University of the Witwatersrand, Wits School of Governance, Johannesburg, South Africa, [2]none, Mbabane, Eswatini

BACKGROUND: World Vision Eswatini is one of the Pact partners implementing the USAID/ PEPFAR funded Ready Resourceful and Risk Aware (Triple R) project. The goal is to prevent new HIV infections, reduce vulnerability and increase socio-economic resilience among OVC, adolescent girls and young women. Implementation is in six constituencies in south of the country.

DESCRIPTION: The project is addressing the needs of AYLHIV through a number of interventions that include both prevention interventions and effective treatment interventions for adolescents living with HIV. For the interventions to reach the target groups, the project works in partnership with Ministry of Health through Health centres.

To ensure that adolescents living with HIV/AIDS are retained in care, adhere to treatment and have a low viral load the health centres are the centres for treatment and house and coordinate Teen Clubs, which meet regularly. The Teens club members get to refill tablets, receive, psychosocial support and viral load measurement.

The health centres also brings professionals like Nutritionists and Social workers to provide support to AYLHIV and caregivers.

LESSONS LEARNED: The partnership with the Health Centres provides platform for a plethora of services to AYLHIV and their caregivers. This reduced frequency of absenteeism among AYLHIV because they do their refills on weekend. Adherence to treatment has increased since AYLHIV and caregivers get support and information from different service providers. There are early signs of sustainability of the program, since the health centres are taking ownership and a coordination of teen clubs.

CONCLUSIONS/NEXT STEPS:

- The project partnership with health centres has improved ART adherence among target groups, which are ordinarily difficult to reach. Empowering caregivers has also increased ART adherence among AYLHIV.
- The project will continue to advocate for more resources to be allocated to health centres to specifically, fund all activities associated with ART, adherence support for AYLHIV and the teen club program. This will ensure sustainability of the program, way beyond the funding current funding.

PEE1475

ENROLMENT OF NEWLY DIAGNOSED AND ANTIRETROVIRAL THERAPY EXPERIENCED HIV POSITIVE CLIENTS INTO AN ADVANCED HIV CARE CLINIC IN MALAWI

J. Luke[1], B. Longwe[1], T. Maphosa[1], N. Buono[2], A. Auld[2], E. Kim[2], A. Maida[2]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Lilongwe, Malawi, [2]Centers for Disease Control and Prevention, Lilongwe, Malawi

BACKGROUND: There are limited data on the characteristics of patients with advanced HIV disease (AHD) in Malawi, who require prioritization for targeted interventions to reduce morbidity and mortality. We describe here the characteristics of patients enrolled in four AHD clinics in high-HIV burden districts of Thyolo, Blantyre and Dedza in Malawi.

DESCRIPTION: In Malawi, clients eligible for AHD clinics include those with CD4 <200 cell/mm3, WHO stage 3 or 4, or children <5 years regardless of CD4 or clinical staging. In our clinics, we also included ART-experienced clients with viral load (VL)>1000 copies/mL with CD4 <200. Enrolled clients received a clinical evaluation; screening for cryptococcal meningitis (CM) using serum cryptococcal antigen (CrAg), and if positive, cerebrospinal fluid (CSF) CrAg; and screening for tuberculosis (TB) using Xpert MTB/RIF, TB lipoarabinomannan (LAM) or chest x-ray. TB prophylaxis and treatment were provided, as appropriate. Demographic and clinical data of clients enrolled in AHD clinics between October 2018 and September 2019 were abstracted from patient records and AHD registers. Descriptive analyses of AHD screening were conducted.

LESSONS LEARNED: Of the 401 clients enrolled into AHD clinics, 228 (57%) were ART-experienced with high VL and CD4 <200, while 173 were newly diagnosed HIV-positive clients with CD4 <200. Most of the AHD clinic clients were male (53%) and median age (interquartile range [IQR]) was 34.5 (25.8-44.4) years. All the clients seen were evaluated for TB using TB LAM, GeneXpert or chest x-ray, resulting in 36 confirmed TB cases (27 were diagnosed by TB LAM, 6 by GeneXpert and 3 by chest x-ray) and all were linked to treatment. Almost all (n=382, 95%) clients were screened for CM by blood; 15 (4%) screened positive and of these, 8 had a positive CSF CrAg and were initiated on treatment with Amphotericin B, while 6 were started on fluconazole prophylaxis.

CONCLUSIONS/NEXT STEPS: A larger proportion of enrollees into Malawi AHD clinics were ART-experienced with high VL. Our findings also demonstrated late presentation of newly diagnosed HIV-positive patients. AHD clinics provided an opportunity to diagnose and manage TB/HIV coinfected clients.

PEE1476

FACTORS ASSOCIATED WITH NEWLY DIAGNOSED HIV INFECTION AMONG FSW

O. Zekiros[1], F. Kedir[2], I. Lemma[3], A. Anteneh[4], E. Bahru[5]
[1]Population Service International (PSI-Ethiopia), Monitoring and Evaluation, Addis Ababa, Ethiopia, [2]Population Service Internatuonal, Clinical, Addis Ababa, Ethiopia, [3]Populatin Service International, Clinical, Addis Ababa, Ethiopia, [4]Population Service International, Research, Addis Ababa, Ethiopia, [5]Population Services International, M&E, Addis Ababa, Ethiopia

BACKGROUND: The USAID MULU Key Populations Activity has been implementing a HIV prevention project targeting female sex workers (FSWs) through Drop-in Centers (DICs) and outreach services since 2018. FSWs in Ethiopia are disproportionately impacted by HIV, with

a prevalence of 23% compared to a national prevalence of 0.9%. To reach the remaining FSWs with undiagnosed infections, we used index case testing (ICT) for sexual partner and respondent driven testing (RDT) for social networks of HIV+ to offer HIV testing service The objective of this analysis was to identify factors associated with newly diagnosed HIV infection among FSWs in the community.

METHODS: We used program data from all implementation sites in the Amhara region and Addis Ababa City from October 2018-December 2019. We assessed new HIV positivity outcomes (number of new positives, and yield [proportion of all those tested who were new positives]) by testing approach (ICT vs RDT), age, HIV testing history, and region. Multiple logistic regression analysis was used to identify variables associated with identifying undiagnosed FSW living with HIV.

RESULTS: A total of 23,600 FSW were tested during the reporting period. Of these, 1,582 (6.7%) were tested through ICT, and 411 (26% yield) were diagnosed with HIV. In comparison 22,018 (93.3%) were tested through RDT, and 793 (3.6% yield) were diagnosed with HIV. A total of 1,204 cases (5.1% yield) were newly diagnosed with HIV. The odds of testing positive among FSWs was 9 times higher among FSWs tested through ICT compared to RDT (AOR=9; 95%CI=8.1-10.5). The odds of testing positive among FSWs who tested for the first time was 1.4 times higher compared to those with prior testing (AOR=1.4; 95%CI=1.2-1.6). There was no statistically significant relationship between age and region with HIV diagnosis. Linkage to HIV care and treatment within 90 days was 93%, but lower among FSW tested at outreach (90%) compared with those tested at DIC (95%).

CONCLUSIONS: ICT is an effective case finding approach and the volume of tests should be expanded to result in better case finding. The program should focus on FSWs who have never tested for HIV.

PEE1477

A QUALITATIVE ANALYSIS OF COUNSELLING SESSION CONTENT AND DELIVERY IN A ROUTINE HIV PROGRAMME IN SOUTH AFRICA

T. Mabuto[1,2], N. Mshweshwe-Pakela[3], N. Mqedlana[1], M. Hlongwane[1], S. Charalambous[1,2], D. Kerrigan[4], V. Wong[5], C.J. Hoffmann[6,1]
[1]The Aurum Institute, Implementation Research, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [3]The Aurum Institute, Johannesburg, South Africa, [4]American University, Department of Sociology, Washington DC, United States, [5]United States Agency for International Development, Global Health Bureau, Office of HIV/AIDS, Prevention Care and Treatment DivisionDepartment of Health, Behavior, and Society, Washington, United States, [6]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States

BACKGROUND: Early identification of people living with HIV and subsequent engagement into HIV treatment is the key to reducing HIV-related illness, HIV-related deaths, and HIV transmission. With the scale-up of antiretroviral therapy (ART) programmes, counselling provided after HIV (post-test counselling) is aimed at leading to linkage to care and ART initiation. We sought to assess whether the delivery of post-test counselling sessions in a routine HIV programme was consistent with person-centred counselling and whether the health messages were aligned with the goals of universal test and treat as articulated by the World Health Organisation and local HIV testing service guidelines.

METHODS: We analysed transcripts of 40 post-test counselling sessions performed by 34 counsellors for clients who tested positive in ten public sector health facilities in a single urban district of South Africa. We used thematic analysis to identify key aspects of counselling technique and content provided to the patient.

RESULTS: Overall, the counselling sessions were highly didactic. Health communication mostly focused on healthy "lifestyle" messages regarding food and exercise, and on "safe" sex and condom use. When ART was mentioned it was described mostly in terms of costs of ART, ranging from required schedule and behaviour changes to risks of severe adverse reactions.

Further, use of ART was nearly always described as secondary to condom use. Overall, we identified five key themes of counselling messages which were often premised on incorrect information:

(1) behaviour changes that are required to maintain or improve health when living with HIV,

(2) the benefits of ART,

(3) misinformation supplanting the health benefits of ART,

(4) behaviour changes required for ART to be effective, and

(5) a need for caution with ART due to a wide range of severe side effects.

CONCLUSIONS: Based on our observations, counselling does not meet current recommendations and may even undermine efforts for universal ART initiation. A substantial re-adjustment is needed to deliver best practice counselling. This may include a combination of digital media-based counselling, counselling scripts, and truly person-centred counselling for a sub-set of individuals who are at risk of not linking to care, or not initiated ART within a specified time period.

PEE1478

INCREASED HIV CASE FINDING AND EFFICIENCY THROUGH FAITH-ENGAGED COMMUNITY POSTS: CATHOLIC RELIEF SERVICES CIRCLE OF HOPE, ZAMBIA (MARCH 2018–SEPTEMBER 2019)

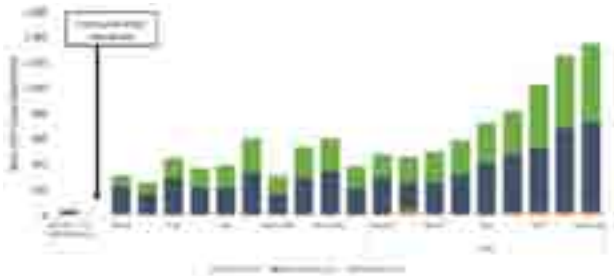
M. Shah[1], G. Makangila[2], A. Mwango[3], O. Adedeji[3], S. Hillis[4], N. Kancheya[5], K. Nkwemu[5], I. Essiet-Gibson[1], L. Erickson Mamane[1], I. Zulu[1], A. Medley[1], K.J.-C. Mwayabo[3], S. Agolory[5]
[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]Circle of Hope, Lusaka, Zambia, [3]Catholic Relief Services, Lusaka, Zambia, [4]Office of the Global AIDS Coordinator, Washington DC, United States, [5]Centers for Disease Control and Prevention, Lusaka, Zambia

BACKGROUND: Catholic Relief Services-Circle of Hope expanded HIV services to four decentralized faith-engaged community posts (CPs) in Lusaka, Zambia, to reach men who are often missed by conventional healthcare services. CPs, staffed by multidisciplinary teams from local faith communities, provide confidential, comprehensive HIV services in areas of high commercial activity, such as marketplaces, that are frequented by men. Testing strategies include risk-based testing and the testing of sexual contacts and biological children. We evaluated the effect of CPs on HIV case finding, especially among men and children.

METHODS: HIV test results reported to PEPFAR were analyzed for the 17 months before CP introduction (October 2016–February 2018) and the 19 months following introduction (March 2018–September 2019). Testing yield (number of HIV-positive results/number of HIV tests) was compared using chi-squared tests, and results were disaggregated by age and sex and compared using Wilcoxon rank-sum tests, with p-values <0.05 considered statistically significant.

RESULTS: Significantly more people living with HIV (PLHIV) were newly identified after CP introduction (11,457; yield, 26%) than before CP introduction (866; yield, 22%; p<0.0001). Overall, the monthly median of PLHIV identified increased from 46 (interquartile range [IQR], 40–62) to 500 (IQR, 385–723; p<0.0001), increased among men from

16 (IQR, 11–21) to 239 (IQR, 160–310; p<0.0001), and increased among children from 0 (IQR, 0–2) to 10 (IQR, 7–27; p<0.0001). The proportion of HIV-positive men of all positive results increased from 34% to 43% (p<0.0001).



[Figure. People living with HIV newly identified by CRS Circle of Hope before and after the introduction of faith-community engaged health posts (March 2018)]

CONCLUSIONS: HIV services in faith-engaged CPs increased HIV case finding and testing efficiency. CPs were especially effective in identifying HIV-positive men and children. Involving community and faith organizations in the HIV response may help close the gaps in HIV case finding.

PEE1479

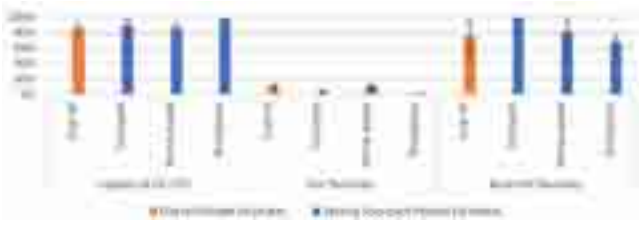
COMMUNITY-BASED HIV TESTING SERVICES ARE EFFECTIVE IN REACHING AND DIAGNOSING MEN: A SYSTEMATIC REVIEW

A.K. Groves[1], P. Stankard[2], S. Bowler[3], M.S. Jamil[4], S. Shaw[2], L.T. Gebrekristos[1], C. Quinn[4], R. Baggaley[4], C. Johnson[4]
[1]Drexel Dornsife School of Public Health, Community Health and Prevention, Philadelphia, United States, [2]Independent Consultant, Washington DC, United States, [3]Drexel Dornsife School of Public Health, Health Management and Policy, Philadelphia, United States, [4]World Health Organization, Global HIV, Hepatitis and STIs Programme, Geneva, Switzerland

BACKGROUND: Men with HIV are less likely to know their status and be on ART than women. Strategies are needed to increase HIV testing among men if we are to reach 95-95-95 targets by 2030. Here we explore the potential of community-based HIV testing services (CB-HTS) among men.

METHODS: We conducted a global systematic review following PRISMA, searching seven electronic databases and published abstracts from CROI and IAS, for studies on CB-HTS published/presented between January 2015 and July 2018. This analysis presents studies reporting disaggregated CB-HTS outcomes among men and women (age 15+) in the general population. We estimated pooled proportions for each outcome using random effects models.

RESULTS: 76/13,218 studies were included in this review; 75% of which were in sub-Saharan Africa. More than half of all people tested through CB-HTS were men (61%; 95% CI: 57-65%). Men's pooled HIV testing uptake was 85% (CI: 75-92%), with highest uptake through workplace testing (97%; CI: 96-98%), followed by outreach (90%;95% CI: 75-98%) and home-based approaches (85%; CI: 74%-93%). Pooled uptake was lowest in TB index testing (33%; CI: 28-38%). Pooled HIV positivity was 5%; (CI: 4%-7%), with higher positivity in home-based (9%, CI: 6%-12%) as compared to workplace (1%, CI: 1%-2%) and outreach approaches (3%, CI: 2%-4%). A majority of diagnoses were new (89%, CI: 61%-100%); workplace testing yielded fewer new diagnoses (67%, CI: 53%-78%) than other approaches. Only 2 studies reported on ART initiation, ranging from 12%- 94%.



[Figure 1. Uptake, HIV positivity and new diagnoses of men via CB HTS]

CONCLUSIONS: CB-HTS continues to be an effective way to reach men, many of whom are first-time testers and with undiagnosed HIV, particularly using workplace and outreach approaches. Understanding men's pathway to HIV prevention, care and ART initiation following CB-HTS remains a key gap for further research. Failure to understand male engagement following CB-HTS will inhibit progress in meeting the 95-95-95 targets.

PEE1480

USING A MODELING-BASED APPROACH TO ASSESS AND OPTIMIZE HIV LINKAGE TO CARE SERVICES

V. Mckay[1], C. Cambey[2], T. Combs[1], L. Pichon[3], S. Andrea[4], L. Ingaiza[1], G. Aditya[4]
[1]Washington University in St. Louis, Brown School, St Louis, United States, [2]Vassar College, Poughkeepsie, United States, [3]University of Memphis, College of Public Health, Memphis, United States, [4]St. Jude Children's Research Hospital, Memphis, United States

BACKGROUND: Timely engagement in care from an initial HIV diagnosis has patient and public health benefits. Identifying the most viable approaches to abbreviate this time is important. We used agent-based modeling, an innovative simulation approach, to explore the potential impact of viable approaches to strengthening HIV testing and linkage to care services (LTC) for timely engagement in care.

METHODS: We developed a prototype model to simulate testing HIV testing and LTC approaches with/without direct referral to an existing, evidence-based LTC referred to as SMILE servicing Memphis, Tennessee for recently diagnosed youth and young adults aged 13-24. From their testing location, patients are referred to SMILE either directly or indirectly via the Health Department. The model was informed by multiple sources including local epidemiological data, SMILE implementation data, and interviews with HIV services providers.

We tested two interventions separately and in combination: expanding testing to pharmacies and improving direct referral to SMILE staff from organizations currently providing testing. The primary outcomes were referral path and days to an initial treatment visit from initial day of diagnosis.

RESULTS: Detailed results are presented in the figure. Overall, the left panels describe the proportion of clients referred directly to SMILE for a typical year including, under Condition 3, where all current testing sites directly refer all clients to SMILE LTC compared to about one third of clients at current baseline. In the right panels, we see direct referrals, including expanding testing to pharmacies shortened days to linkage to care, but expanding testing to pharmacies without direct referrals lengthened days to linkage to care overall.

CONCLUSIONS: We demonstrate how different approaches to improving testing and linkage to care differentially affect timely engagement in care. Simulation methods like agent-based modeling can help to fill the gap through their capacity to test and compare many potential interventions.

[Figure.]

PEE1481

TIMELY DETECTION OF PEOPLE WITH HIV IN MEXICO: EFFECTIVENESS OF COMMUNITY INTERVENTIONS AND HEALTH CARE SERVICES

R. Leyva[1], C. Infante[1], B. Aracena[2]
[1]National Institute of Public Health, Health Systems, Cuernavaca, Mexico, [2]National Institute of Public Health, Nutrition, Cuernavaca, Mexico

BACKGROUND: Globally, one of the most important challenges for controlling the AIDS epidemic is increasing access to HIV testing and initiating treatment immediately. In Mexico in the period 2016-2018, the participation of civil society in timely detection strategies was strengthened and 32 community centers (CCDs) were developed. Objective was to evaluate the effectiveness of community organizations and health care services for the timely detection of people with HIV in Mexico.

METHODS: National trend analysis of the supply and application of HIV rapid tests according to territory and population groups from 2010 to 2017. Effectiveness for detection in health institutions was analyzed compared to CCDs. The measure of effectiveness was the timely detection of people with HIV (CD4 >500 cells/mm3 at the time of diagnosis). A descriptive analysis and conditional logistic regression were performed that included CCDs. The information analyzed was obtained from the official public records of health institutions and CCDs.

RESULTS: HIV testing increased 118% from 1,175,500 to 2,564,629 (2010-2017), which amounted to doubling the number of cases. Effectiveness was significantly higher in CCDs, 2.6 times (IC: 1.4-4.6) more cases detected in a timely manner than hospital and outpatient care units.

CONCLUSIONS: CCDs could contribute to timely diagnosis and rapid linkage to treatment to accelerate response to the epidemic. CCDs correspond to peer-served spaces, which could explain differences in effectiveness in health services.

PEE1482

IMPROVING ACCESS FOR YOUNG WOMEN: AWARENESS AND ATTITUDES AMONG DISPENSERS AND YOUNG WOMEN ABOUT ORAL PRE-EXPOSURE PROPHYLAXIS, THE DAPIVIRINE RING, AND DISTRIBUTION THROUGH PRIVATELY-OWNED DRUG SHOPS IN SHINYANGA, TANZANIA

J. Tubert[1], J.X. Liu[2], P. Njau[3,4], L.A. Hunter[1], L. Packel[1], R. Mfaume[5], S.I. McCoy[1]
[1]University of California, School of Public Health, Berkeley, United States, [2]University of California, Institute for Health and Aging, Bixby Center for Global Reproductive Health, San Francisco, United States, [3]Health for a Prosperous Nation, Dar es Salaam, Tanzania, United Republic of, [4]National AIDS Control Programme, Ministry of Health, Community Development, Gender, Elderly, and Children, Dar es Salaam, Tanzania, United Republic of, [5]Shinyanga Regional Medical Office, Shinyanga, Tanzania, United Republic of

BACKGROUND: Adolescent girls and young women (AGYW, ages 15-24) in sub-Saharan Africa are at higher risk of HIV compared to their male peers. When accessing services at health facilities, many AGYW experience stigma and provider bias, which deter their use of HIV prevention and other sexual and reproductive health (SRH) services. Privately-owned drug shops, ubiquitous in many communities, may be an effective and less stigmatizing channel to deliver SRH products to AGYW, including HIV prevention products such as oral pre-exposure prophylaxis (PrEP) and the forthcoming dapivirine vaginal ring.

METHODS: In July-August 2019, we enrolled 26 drug shops in Shinyanga, Tanzania in an ongoing study to create “girl-friendly” drug shops where AGYW can access HIV self-testing and other SRH products. We interviewed all dispensers at baseline about shop operations and perceptions of SRH products. Dispensers were provided basic information about oral PrEP (approved in Tanzania) and the dapivirine ring (pending regulatory approval) and were asked about their interest in stocking each item. During follow-up, we surveyed AGYW (n=56) exiting shops about their interest in oral PrEP and the ring.

RESULTS: Dispensers were, on average, 43 years of age and 77% were female. Overall, 42% had heard of a medication for HIV prevention. Most dispensers reported interest in stocking oral PrEP (81%) and/or the ring (73%); no significant differences in interest were found by age, gender, or education. Most (85%) reported they would provide oral PrEP to AGYW who requested it. AGYW customers were, on average, 18 years old and 61% were in school. Only 19% of AGYW had heard of a medication to prevent HIV, yet 64% and 43% expressed some interest in using oral PrEP and the ring, respectively, after receiving basic information about the products.

CONCLUSIONS: We found high levels of interest in oral PrEP and the dapivirine ring among shop dispensers and AGYW in Shinyanga. Though hypothetical, these results warrant further exploration to understand to what extent these stated preferences are real. Privately-owned drug shops represent a unique and promising strategy to deliver HIV prevention to AGYW, who experience high rates of HIV and significant barriers to prevention services at health facilities.

PEE1483

MEDICATION SAFETY FOR HIV PROGRAMS IN NIGERIA: A FOCUS ON RESOURCE-CONSTRAINED SETTINGS

O. Onokala[1], F. Lumenze[2], A. Ogih[2], A. Dada[2], P. Unwana[2], T. Orogbemi[2], S. Michael[2,2]
[1]AIDS Healthcare Foundation Nigeria, Treatment Department, Abuja, Nigeria, [2]AIDS Healthcare Foundation Nigeria, Calabar, Nigeria

BACKGROUND: It is essential to ensure appropriate medications are accessible to persons living with HIV (PLWH). However, it is equally important to ensure the medications are appropriately administered to PLWH without causing harm to them. Medication safety is possible but could have several limitations especially in resource-constrained settings where there are no electronic devices for monitoring medication safety. The aim of the study was to evaluate the cost-effective interventions made to ensure medication safety for PLWH within Nigerian HIV programs located in resource-constrained settings.
METHODS: The study was done at 20 HIV treatment facilities located in resource-constrained settings in Nigeria. Medication safety was defined as freedom from preventable harm with medication use. Medication safety interventions included, but were not limited to: training of community healthcare workers through continued medical education programs and clinical mentorship by pharmacists, as well as the provision of information on medication safety to PLWH during medication adherence sessions at the facilities. Interventions were evaluated by adopting the World Health Organization's methods for the calculation of outstanding unintentional medication discrepancies, medication reconciliation, and provision of information on medication safety measures for patients during medication adherence counselling sessions at the facilities. The pre- and post-intervention evaluations were done in December 2017 and December 2019 respectively. Chi-square was applied as inferential statistics; P <0.05 indicated statistical significance.
RESULTS: The percentage of outstanding unintentional medication discrepancies reduced from 4.70% (pre-intervention), to 0.13% (post-intervention). This was attributed to the increase in medication reconciliation from 70.09% (pre-intervention), to 98.20% (post-intervention). Provision of information on medication safety measures increased from 76.00% (pre-intervention), to 99.05% (post-intervention). This subsequently improved adverse drug reporting by patients from 41.00% (pre-intervention), to 98.00% (post-intervention). However, there were few gaps identified in the provision of information required for medication safety during tuberculosis preventive therapy.
CONCLUSIONS: The cost-effective interventions significantly improved medication safety at HIV treatment facilities and are recommended for HIV programs in resource-constrained settings in Nigeria. However, further interventions should be targeted at provision of optimum information for medication safety during tuberculosis preventive therapy.

EVIDENCE ON MAKING TASK SHIFTING WORK

PEE1484

A PHARMACIST-DRIVEN INTERVENTION FOR ROUTINE ANTIRETROVIRAL (ARV) REFILL REQUESTS CAN IMPROVE ARV PRESCRIBING AND OVERALL HIV CARE

D.P. Nguyen[1], T. Phengrasamy[1], C.B. Hare[1]
[1]Kaiser-Permanente, HIV Care and Prevention, San Francisco, United States

BACKGROUND: Kaiser Permanente is an integrated health care delivery system that includes clinical care, pharmacy services and insurance coverage for 2,972 persons living with HIV in San Francisco. 97.7% of these persons are prescribed ARV medications and 96.3% have undetectable serum levels of HIV RNA.
DESCRIPTION: A pharmacist-driven intervention was established to review ARV prescription refill requests. An HIV-specialty pharmacist reviewed all ARV refill requests for appropriateness of regimen, drug-drug interactions, timeliness of refills, presence of updated safety and viral monitoring laboratory tests, appointments with primary HIV providers and issues with prescription drug coverage. In the first 4 months of this program, 693 ARV refill requests were reviewed. 10 ARV modifications were made to simplify or update regimens; 7 clinically significant drug-drug interactions were identified and corrected; 114 patients were contacted to update safety and/or viral monitor laboratory tests; and 46 patients were contacted to address other issues (e.g., drug coverage, overdue primary care appointments).
LESSONS LEARNED: 1) Routine ARV refill requests offer an opportunity to identify and correct ARV prescribing issues. 2) Pharmacists are well-positioned and well-trained to address several issues related to ARV prescribing and HIV monitoring. 3) Use of pharmacists in this capacity offloaded refill requests from primary HIV providers and provided high satisfaction from providers.
CONCLUSIONS/NEXT STEPS: The use of pharmacists to address routine ARV refill requests offers benefits in ARV prescribing as well as the overall quality of HIV care and engagement.

INTEGRATING MENTAL HEALTH AND WELLNESS IN HIV PROGRAMMING

PEE1485

MENTAL HEALTH MATTERS: HIGH PREVALENCE OF DEPRESSION AMONG THAI TRANSGENDER WOMEN IN THAILAND

P. Srimanus[1], R. Janamnuaysook[1], K. Samitpol[1], A. Chancham[1], J. Kongkapan[1], T. Amatsombat[1], J. Rueannak[1], L. Himma[1], P. Getwongsa[1], O. Nampaisan[1], J. Peelay[1], S. Mills[2], R. Vannakit[3], P. Phanuphak[1], R. Ramautarsing[1], N. Phanuphak[1]
[1]PREVENTION, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]FHI 360 and U.S. Agency for International Development LINKAGES Project, Bangkok, Thailand, [3]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

BACKGROUND: Transgender women (TGW) are among the key populations with very high risk of HIV infection. Research data, mainly from Europe and North America, points to a high prevalence of mental health disorders among TGW, especially among those living with HIV. Unfortunately, prevalence of common mental health disorders

among TGW in Thailand, a country with a population size estimation of 313,747 TGW, is unknown. We sought to establish the prevalence of depression among TGW clients seeking healthcare services at Tangerine Community Health Clinic, a transgender-led clinic located in Bangkok, Thailand.

METHODS: In July 2019, mental health screening was integrated into Tangerine Clinic's transgender health and HIV services. A self-administered nine-item Patient Health Questionnaire (PHQ-9) was used to screen for depression. We conducted a cross-sectional evaluation of PHQ-9 scores, demographic characteristics and HIV behavioral risks among TGW clients accessing HIV testing services during July – September 2019.

RESULTS: Of 382 TGW screened, depressive symptoms were detected as mild in 30.9%, moderate in 15.2%, moderately severe in 7.9%, and severe in 1.3%. The remaining 45 % had no depressive symptoms. HIV-positive status was found to be higher in TGW with depressive symptoms than those without (8.7% vs. 3.6%, p=0.043). TGW with depressive symptoms were more likely to be older than 35 years old (81.2% vs. 76.6%, p=0.041) and had monthly income of less than 20,000 THB (76.5% vs. 66.3%, p=0.039). Of 348 (91.1%) who reported sex in the past 12 months, 52.9% had anal sex, 13.4% had neo-vaginal sex and 45.0% had oral sex. No difference was seen between TGW with and without depressive symptoms in terms of engagement in sex work, education level, access to gender-affirming care or sexual routes.

CONCLUSIONS: More than half of Thai TGW had depressive symptoms, highlighting the urgent need to integrate mental health screening, referral and treatment into HIV prevention, care and treatment services. A more thorough understanding of mental health conditions and their relationships to certain socio-demographic, behavioral and gender-affirming care access characteristics is needed to guide tailored interventions for integrated mental health and HIV care for TGW.

PEE1486

ACHIEVING VIRAL LOAD SUPPRESSION AND QUALITY OF LIFE FOR HIV+ ADULTS IN KENYA

M. Heacock[1], L. Korir[1], D. Kimani Kamau[1], C. Onyango Nyaywera[1]
[1]*CARE for AIDS, Nairobi, Kenya*

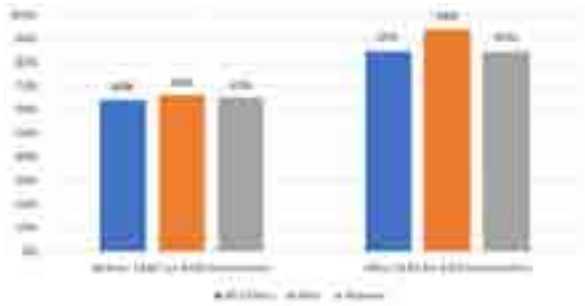
BACKGROUND: CARE for AIDS (CFA) is a faith-based organization that aims to serve HIV+ adults living in urban slums throughout Kenya to move them toward viral load suppression (VLS) and reduction in internalized stigma. We serve the last 5% of virally unsuppressed clients in an effort to contribute to 95, 95, 95, 95 goals, quality of life being the fourth 95.

DESCRIPTION: CFA centers operate within local churches and serve all persons without discrimination. Each center employs two social workers who are trusted leaders in the community motivated by compassion to serve the most vulnerable in their communities. Each center serves 80 HIV+ adults annually - many are non-suppressed and lost to follow up clients referred to CFA through government clinics. All clients in this dataset (n=636) live in urban slums and are experiencing extreme poverty. In an effort to move clients to VLS and to achieve the fourth 95, quality of life (reduction in internalized stigma) we implement the following interventions: one-on-one weekly counseling sessions to help clients achieve and maintain VLS and cultivate strong self-worth, and bi-monthly group therapies to further encourage VLS through peer support and to decrease internalized stigma.

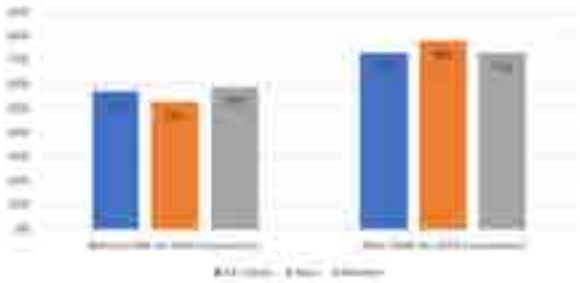
LESSONS LEARNED: After CFA interventions, clients showed significant increase in VLS and increase in public status disclosure, showing an improved quality of life and decreased internalized-stigma (figures).

Lessons learned regarding success include:

- Establishing trusting relationships between clinics and church based centers
- Locating centers in existing community churches
- Targeting the last 5% of unsuppressed clients
- Employing compassion-driven local staff in all CFA centers
- Integrating medical and mental/emotional health interventions



[Figure. Viral load suppression rates pre and post CFA]



[Figure. Client disclosure rates (as measure of decrease in stigma) pre and post CFA]

CONCLUSIONS/NEXT STEPS: Lessons learned regarding serving the last 5%, partnering with both local churches and government clinics, and leveraging local, compassion driven staff can be extended to other settings throughout Sub Saharan Africa to help reach VLS and high quality of life for vulnerable populations.

PEE1487

COLLABORATIVE CARE FOR THE DETECTION AND MANAGEMENT OF DEPRESSION AMONG ADULTS RECEIVING ANTIRETROVIRAL THERAPY IN SOUTH AFRICA: THE COBALT RANDOMISED CONTROLLED TRIAL

B. Zani[1], L. Fairall[2,3], I. Petersen[4], A. Bhana[5,4], C. Lombard[6,7], N. Folb[1], S. Carmona[8,9], O. Selohilwe[4], D. Georgeu-Pepper[1], R. Petrus[4], N. Mntambo[4], T. Kathree[4], J. Hanass-Hancock[10,11], M. Bachmann[12], N. Levitt[3], C. Lund[13,14], G. Thornicroft[14]
[1]University of Cape Town Lung Institute, Knowledge Translation Unit, Cape Town, South Africa, [2]King's College London, King's Global Health Institute, London, United Kingdom, [3]University of Cape Town, Department of Medicine, Cape Town, South Africa, [4]University of KwaZulu-Natal, Centre for Rural Health, Durban, South Africa, [5]South African Medical Research Council, Health Systems Research Unit, Durban, South Africa, [6]South African Medical Research Council, Biostatistics Unit, Cape Town, South Africa, [7]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [8]University of Witwatersrand, Department of Molecular Medicine and Haematology, Johannesburg, South Africa, [9]National Health Laboratory Services, Johannesburg, South Africa, [10]South African Medical Research Council, HIV Prevention Research Unit, Durban, South Africa, [11]University of KwaZulu-Natal, School of Health Sciences, Durban, South Africa, [12]University of East Anglia, Norwich Medical School, Norwich, United Kingdom, [13]University of Cape Town, Alan J Flisher Centre for Public Mental Health, Cape Town, South Africa, [14]King's College London, Centre for Global Mental Health, London, United Kingdom

BACKGROUND: Detection and treatment of comorbid depression is critical to achieve viral suppression. We assessed the effectiveness of a collaborative care intervention for depression in adults on antiretroviral treatment with depressive symptoms, in reducing depressive symptoms and improving viral suppression.

METHODS: CobALT was a pragmatic, cluster-randomized trial in 40 primary care clinics in South Africa conducted from April 2015 to January 2018. Participants were≥18 years, receiving ART and scored≥9 on the Patient Health Questionnaire-9 (PHQ-9). The control comparison included the integrated chronic care programme as usual care while intervention clinics added a collaborative care package. This entailed supplementing primary care 101 training with four additional mental health sessions and nurse-training on clinical communication skills. Lay depression counsellors provided manualised depression counselling with structured supervision. We estimated intervention effects using multiple mixed effects regression models adjusting for trial clustering. All participants were enrolled in their randomized group.

RESULTS: A total of 6623 patients were screened and 2002 enrolled (1008 intervention vs 994 control). Follow-up rates were 88% vs 87% at 6-months and 92% in both arms at 12-month. While PHQ-9 response was common in both treatment groups, the difference between treatment groups was not statistically significant (risk difference=-0.08, 95% CI=-0.19; 0.03, p=0.184). There was no statistically significant difference in viral suppression between groups (RD=0.02, 95% CI= -0.01; 0.04, p=0.125). More than 4000 patients were referred to facility-based counsellors, however, uptake of the counselling service among ART patients enrolled in the data collection component of the trial was low, with 5% of the participants receiving counselling. Forty-six deaths occurred during the trial, 25 in the intervention and 21 in the control arm. The intervention was not significantly associated with death (HR=1.18, 96% CI=0.65; 2.15, p=0.589). One death occurred by suicide.

CONCLUSIONS: The collaborative care intervention for depression among patients receiving ART had no effect on either mental or physical health outcomes and the intervention uptake was low. With the large burden of untreated depression, nurses appear to be referring the most severe depression cases for counselling. Facility-based counselling has a role to play in the treatment of depression.

PEE1488

INTEGRATING BEHAVIORAL HEALTH AND HIV CARE: LESSONS LEARNED FOR PRACTICE TRANSFORMATION AND RESEARCH

K. McKinnon[1], A. Thompson[2], L. DeLorenzo[3], D. Boccher-Lattimore[4], M. Hager[5], F. Cournos[6]
[1]Columbia University, Psychaitry, New York, United States, [2]Jefferson University, Voorhjees, United States, [3]Organizational Ideas, Blacksburg, United States, [4]Columbia University, New York, United States, [5]Hager Health, LLC, New York, United States, [6]Columbia University, Mailman School of Public Health, New York, United States

BACKGROUND: Disabling behavioral health (BH) conditions are more prevalent among people living with HIV. Despite the availability of models for care integration and the tools to achieve it, most HIV programs struggle to offer BH services even though HIV expert clinicians and leaders identify HIV mental health as their most urgent training need. New Jersey's HIV and Behavioral Health Integration Project (BHIP) is a multi-year quality improvement Learning Collaborative designed to (1) integrate BH and HIV care; (2) improve access to BH care; (3) improve patient outcomes, and (4) create system change in BH capacity for the New Jersey HIV care system.

DESCRIPTION: Eighteen HIV care sites engaged in the Learning Collaborative, seven Learning Sessions, Technical Assistance and monthly webinars, Practice Transformation coaching, and Twinning match-ups with mentor sites. BHIP used the Institute for Healthcare Improvement's Breakthrough Learning Series Model with innovations including a partnership with the Northeast/Caribbean AIDS Education and Training Center for capacity-building, the addition of ongoing Practice Facilitation coaching to implement change ideas, and engagement with Twinning sites. BHIP sites reported bimonthly performance data and carried out quality improvement projects to improve BH screening, referral, retention in evidence-based BH care, and improved viral suppression.

LESSONS LEARNED: Over the three-year implementation, gaps in services and processes were identified by sites as points where tests of change could have greatest impact. BH screening increased 2-6%; follow-up planning increased from 58% to 70%; retention in behavioral care increased by 3%; viral suppression among those with BH disorders increased from 73% to 84%; and overall viral suppression increased from 77% to 85%. Lessons learned, particularly for settings in which no additional funding for BH specialty care is possible, include the need for greater task-shifting and referral network development, as well as the need for performance measurement precision. Best practices were shared among Learning Collaborative members, strengthening processes, policies, and procedures for these sites, which is, itself, a best practice.

CONCLUSIONS/NEXT STEPS: BHIP sites enhanced their care continuum outcomes. BHIP's model/processes served as the basis for a NIH-funded planning grant to develop an implementation study to achieve multiple integration goals for HIV care continuum outcomes.

PUBLIC-PRIVATE PARTNERSHIPS

PEE1489

REACHING NAMIBIA'S NATIONAL HIV PREVENTION GOALS THROUGH PUBLIC-PRIVATE PARTNERSHIPS TO EXPAND ACCESS TO VOLUNTARY MALE MEDICAL CIRCUMCISION (VMMC) SERVICES

D.D. Pereko[1], L. Kahindi[1], K. Brouahrd[1], A. Tjaronda[2], M. Aupokolo[2]
[1]Abt Associates, Rockville, United States, [2]Ministry of Health and Social Services, Windhoek, Namibia

BACKGROUND: Namibia's Ministry of Health and Social Services (MoHSS) prioritizes VMMC as a core intervention to avert new HIV infections. To achieve this goal the country has set out to conduct 330,000 circumcisions by 2022(HIV Combination Prevention Guidelines 2018; National Strategic Framework for HIV and AIDS Response in Namibia 2017/18 to 2021/22). However, Namibia's national VMMC scale up plan is challenged by limited access to public-sector services in a country where 70% of physicians work in the private sector. To capitalize on the human resources available in the private sector the AIDSFree project, with support from PEPFAR through USAID, partnered with Khomas regional VMMC team to pilot and introduce free VMMC services for both insured and non-uninsured males accessing services at private health facilities.

DESCRIPTION: Facilities were assessed using a standard checklist developed by AIDSFree and the MOHSS. Designated health workers were trained in VMMC demand creation, counseling and surgical skills. Private facilities were also supported to set up a dedicated quality management team for VMMC. AIDSFree provided training, mentorship, onsite coaching as well as supplies such as disposable surgical kits, data collection tools and emergency kits. All VMMC data were entered into the national DHIS system. A standard fee negotiated with the Namibia Medical Aid Fund is used to reimburse for each verified circumcision performed. Since inception the program has expanded to four regions with a total of 29 participating private facilities.

LESSONS LEARNED: Between October 2016 and November 2019, 61,199 boys and men received safe, high-quality VMMC services through AIDSFree support. Over three years, the private sector contributed 40% to the overall milestone of 150,000 circumcisions, the halfway mark of the Namibia's VMMC target of 330,000.

CONCLUSIONS/NEXT STEPS: Namibia has a well-developed, robust private health sector whose potential to contribute to important public health goals was not fully utilized. AIDSFree's engagement of private sector providers in these regions clearly accelerated the achievement of previously lagging national VMMC targets. By leveraging resources in the private sector and collaboration with the medical fund Namibia could further open windows to resources previously untapped and strengthen its journey to sustainable AIDS response.

PEE1490

INFORMING A SUSTAINABLE FARM WORKERS MODEL FOR PRIMARY HEALTHCARE SERVICES TO LOW INCOME WORKERS IN THE AGRICULTURAL SECTOR IN SOUTH AFRICA

C. du Preez[1], J. Miot[2], S. Girdwood[2], K. Govender[2]
[1]Hoedspruit Training Trust, Health, Hoedspruit, South Africa, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa

BACKGROUND: The Hoedspruit Training Trust (HTT) a private-public partnership operating in the Limpopo area offering primary healthcare (PHC) services focused around HIV prevention and treatment as well as a range of broader health-related services. HTT operations rely on a combination of funding mechanisms including partnerships with the Department of Health (DOH) and local and international funders. Services are currently offered free of charge or at a minimal fee to low-income workers in the agriculture, nature conservation and tourism sectors. Limited resources and funding uncertainty created a need to develop a more sustainable funding model.

DESCRIPTION: A funding model for the delivery of core HTT services was developed using different strategies that ensure cost-recovery. Model inputs included top-down and bottom-up costing as well as patient and employer perspectives to inform different funding scenarios. Model components included ongoing donor funding, a selection of healthcare packages targeted at local farmers for their workforce, as well as options for patients to pay different levels of co-payments per visit. Packages included a varying number of covered visits and volume-based pricing.

The crude average cost per patient visit based on 24,000 annual visits, ranged from R272 to R340 depending on DOH support levels. Per patient visit costs ranged from R42 (minor acute), R51 (chronic), to R206 (HIV). The model predicts that with the continuation of the DOH partnership for the provision of ARVs and laboratory tests and a moderate uptake by farmers of healthcare packages together with expected patient levels of willingness to pay, HTT will still be required to source additional donor funding. Added health services and costing strategies were also identified.

LESSONS LEARNED: A feasible funding model that delivers a cost-neutral solution relies on multiple levers. Clinical and financial data is necessary to ensure the model is relevant to the context. The design of a community-based health funding model should take willingness to contribute by both employer and farm workers and community-based social capital into consideration.

CONCLUSIONS/NEXT STEPS: The design and associated pricing of a healthcare funding model should consider clinic costs, clinic volumes, employer concerns and willingness to contribute, employee ability to pay, and social capital for long-term sustainability.

PEE1491

PUBLIC-PRIVATE-PARTNERSHIP (PPP) FOR COUNTRYWIDE SCALE-UP OF HIV-1 VIRAL LOAD TESTING IN INDIA

N. Goel[1], S. Kamal[1], A. George[2], G. Oruganti[2], V. Yeldandi[2]
[1]Ministry of Health and Family Welfare, National AIDS Control Organization, New Delhi, India, [2]SHARE INDIA Society for Health Allied Research & Education, Secunderabad, India

BACKGROUND: Viral suppression is the goal for People Living with HIV(PLHIV) as well as the metric for HIV epidemic control. In 2018, India launched countrywide Viral Load (VL) testing to reach UNAIDS 90-90-90 targets as part of public health priority.The National AIDS Control Organization is scaling up VL testing from 14000 annually in 2016 to 1,500,000 in 2020- 2021, across a geographically and culturally complex sub-continent,by increasing public sector testing, as well as strategic purchase of services from the private sector.

DESCRIPTION: The purpose of this commentary is to examine the operational challenges and innovative solutions from large-scale implementation of a public-private-partnership (PPP) model for HIV-1 viral load testing and identify key lessons for quality laboratory services in the public health implementation of epidemic control.

LESSONS LEARNED: Framework for a PPP model included making available "Guidelines on Quality Monitoring System for Outsourced Viral Load Tests" and a "National Quality Assurance Committee" to ensure quality for outsourced testing.Private sector partner engagement is based on capacity to handle the testing load, experience in sample collection and safe transport across India with adherence to global standards of quality. Private sector entities are required to train staff on sample collection, sample handling, transportation, sensitivity to PLHIV and proper bio-medical waste management.Supervisory visits and assessments at the collection and testing facilities are part of routine monitoring.

PPP model was initiated in February 2018 with routine viral load testing for HIV-1.Key issues identified and addressed included: efficiency of the sub-contracted partners for collection and transport, avoiding contamination of samples, calibration of centrifuges and continuous site level training through LMS. Evidences for success are:reduction in complaints from providers and beneficiaries as well demonstration of the program level improvement in viral suppression rate from 65% to 80%, with a total 6, 43,000 tests done through the private sector.

CONCLUSIONS/NEXT STEPS: Leveraging the PPP model with responsive innovations for efficient implementation of High Quality laboratory support for the public health response to HIV in India's large geographically and culturally complex subcontinent can guide high quality implementation science.

PEE1492

PUBLIC PRIVATE PARTNERSHIP: PRIVATE SECTOR PLAYS A CRITICAL ROLE IN GOVT. OF INDIA'S GOAL OF EMTCT. EXPERIENCE FROM GLOBAL FUND SUPPORTED AHANA PROJECT IN INDIA

k. Biswas[1], R. KB[1], S. Kanoujia[1], M. Singh[1], D. Nirwal[1], R. Mitra[2]
[1]Plan India, Monitoring & Evaluation, New Delhi, India, [2]Plan India, Programme, New Delhi, India

BACKGROUND: India is aiming for EMTCT by 2020 and saturation of pregnant women with HIV testing is the first step towards achieving EMTCT of HIV. While the country has an elaborate public health system to reach out to the pregnant women coming for the services in the public sector and captures the record, there is an estimated 20-25 percent out of 29 million pregnancies catered by the private sector in the country. Project Ahana funded by The Global Fund aims to engage private sector to ensure HIV testing and recording those for the country EMTCT response.

DESCRIPTION: A mobile application based reporting system was introduced to capture the HIV testing information at the private sector. Altogether, 6982 private facilities catering to estimated 2.4 million pregnancies across 357 districts of 14 intervention states were reached out and provided orientation on HIV testing and reporting. Data for a period of April, 2018 to Sept, 2019 was analysed using Microsoft excel.

LESSONS LEARNED: Ahana adopted a cascaded approach, with A) 6,982 hospital mapped for potential engagement, B) 2,747 hospitals got engaged after a structured assessment with 4,500 private medical practitioners provided with the orientation on PMTCT and reporting, C) 2,732 hospitals were registered in the mobile application database and started reporting in the database regularly. While the mapping and engagement is a continuous process, a total of 1.5 million pregnant women received HIV testing through private facilities and for the first time reported in the national HIV response during the period of April, 18 to Sept, 19 thus reducing the gap in the service access and reporting.

CONCLUSIONS/NEXT STEPS: With 1.5million HIV testing among pregnant women recorded in the 14 intervention states, contributes a clear 10 percentage against the estimated 14 million total pregnancies; which has been recorded and reported for the first time towards country HIV response. While there is a long way to go and a complete saturation of all cases in the private facilities, the intervention suggests, that EMTCT can be possible only through an integrated public and private integrated response.

PEE1493

THE GETTING TO ZERO SAN FRANCISCO (GTZ-SF) CONSORTIUM: A COLLECTIVE IMPACT APPROACH TO ADDRESSING OUR LOCAL EPIDEMIC THAT CAN BE REPLICATED IN OTHER JURISDICTIONS

D. Havlir[1], C. Liebi[1], C.B. Hare[2], J. Hollendoner[3], L. Thoemmes[4], T. Newman[5], J. Moody[6], M. Shriver[7], C. Farley[8], M.-L. Hicks[1], H. Scott[1,9], S. Buchbinder[1,9]
[1]University of California, San Francisco, United States, [2]Kaiser Permanente, San Francisco, Infectious Diseases, San Francisco, United States, [3]San Francisco AIDS Foundation, San Francisco, United States, [4]UCSF Alliance Health Project, San Francisco, United States, [5]St. James Infirmary, San Francisco, United States, [6]San Francisco Community Health Center, San Francisco, United States, [7]San Francisco EMA HIV Community Planning Council, San Francisco, United States, [8]City & County of San Francisco Office of Transgender Initiatives, San Francisco, United States, [9]San Francisco Department of Public Health, Bridge HIV, Population Health Division, San Francisco, United States

BACKGROUND: In 2013, a small group of academic, health department, and community leaders formed the GTZ-SF Consortium, with the goals of getting to zero new HIV infections, HIV-associated deaths, and HIV-stigma.

DESCRIPTION: GTZ-SF operates under collective impact, where multiple sectors of society unite under a common agenda, using shared measurement, mutually reinforcing activities, continuous communication, and supported by a small organizational backbone. We have grown to >300 members, supported by 1 administrator. While headway has been made in decreasing new HIV diagnoses (51% decrease from 2013-2018), and in viral suppression (74% for all San Franciscans),

less progress has been made in reducing HIV-deaths (19% decline), and no or modest declines in stigma. Diagnoses and viral suppression are poorer among African Americans, Latinx, people who inject drugs, and people experiencing homelessness.

LESSONS LEARNED: 1) GTZ strategies require widespread engagement from community, providers, scientists, politicians, and the private sector.

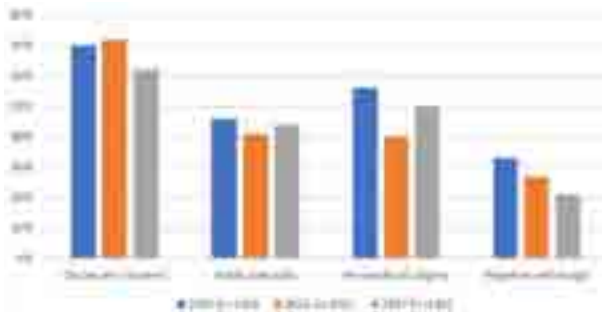
2) A cross-sector approach (e.g., partnering with homelessness advocacy organizations, End Hepatitis C, STI efforts) is an effective way to address cross-cutting issues.

3) Volunteer committees and task forces are an effective way to move targeted agendas forward. We have launched PrEP, same-day-treatment, and retention programs and initiated city-wide calls-to-action regarding homelessness, mental health treatment, and substance use.

4) A small but diverse steering committee provides real-time communication on funding and policies, allowing nimble responses.

CONCLUSIONS/NEXT STEPS: The collective impact approach has mobilized broad teams to address gaps identified through surveillance data. This approach can serve as a model for other jurisdictions planning to launch GTZ efforts.

[Figure 1. HIV diagnoses, deaths and prevalence, 2006-2018, San Francisco]



[Figure 2. Stigma measures from the Medical Monitoring Project]

PEE1494

PUBLIC-PRIVATE PARTNERSHIP MODELS HELPED ACCELERATE SCALE-UP OF EMTCT SERVICES TO 26,000 PRIVATE HEALTH FACILITIES ACROSS 22 STATES OF INDIA

P. Mohanty[1], A.K. Puri[2], L. Ramakrishnan[1], V. Balasubramaniam[1], J. Niranjan[1], A. Bose[1], R. Sindhu[2], M. Balani[3], V. Jori[4], V. Jayaseelan[1], L. Ramakrishnan[1], A.S. Kumar[1], S.S. Raghavan[1]

[1]SAATHII, New Delhi, India, [2]National AIDS Control Organization, New Delhi, India, [3]NCPI+, Chandigarh, India, [4]Prayas, Pune, India

BACKGROUND: India has an estimated 30 million pregnancies annually, and 29% of them deliver in the private health sector. Thus, engagement and saturation of the private sector are essential to achieve the Elimination of Mother to Child Transmission of HIV (EMTCT). Recognizing this, the government of India formulated a policy framework and developed flexible models of public-private partnerships (PPP) for engaging the private health sector. SAATHII-led Svetana program partnered with government to scale-up EMTCT services through PPP in 22 states which account for 64% of 8.7 million estimated private sector deliveries in India.

DESCRIPTION: The Svetana consortium partners (SAATHII, SVYM, Prayas, NCPI+, and GSNP+) with GFATM funding, initiated the scale-up from October 2015 in 14 states and expanded to 22 states in January 2018. Interventions components included advocacy with professional medical associations (PMA), mapping and enrollment of eligible private facilities under one of the PPP models, tailored to their willingness to enter into formal agreements with the government, provide EMTCT services and share data. Enrolled facilities were provided customized technical assistance for the integration of HIV testing and counseling services and establishment of referral systems with public facilities for confirmation of test results, provision of HIV care and treatment for diagnosed positive and infant diagnosis. In addition, simplified technology-based reporting system called HIV Pulse was developed and deployed for easy reporting, which was also adopted by the government

LESSONS LEARNED: By September 2019, 45,489 private facilities were mapped of which 27,899 were found to be eligible and 94% were enrolled in the program. Of these,16,648 facilities registered in HIV Pulse, and 86% reported to the national programs. Consequently, HIV counseling and testing coverage in the private sector in 22 states increased from 37% in December 2017 to 65% in September 2019. Furthermore, the program detected 3,800 HIV+ pregnant women and linked them to treatment contributing to the overall reduction of the EMTCT coverage gap by 15%.

CONCLUSIONS/NEXT STEPS: Saturation of the private sector is possible with an enabling policy framework, ongoing technical assistance, simplified reporting mechanism, effective referral mechanisms, and strong coordination with the government.

APPROACHES TO SCALE AND THE OPTIMIZATION OF SERVICE DELIVERY

PEE1495

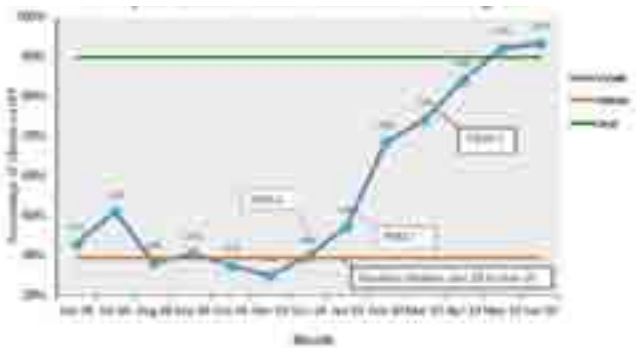
SCALING UP ISONIAZID PREVENTIVE THERAPY UPTAKE AMONG HIV CLIENTS IN KOGI STATE, NIGERIA: A QUALITY IMPROVEMENT APPROACH

S. Balogun[1], I. Orogbemi[1], Z. Rufai[1], E. Nwabueze[1], E. Ijezie[1]
[1]*AIDS Healthcare Foundation, Abuja, Nigeria*

BACKGROUND: Tuberculosis is the leading cause of death among people Living with HIV (PLHIV). However, PLHIV who receive 6 months of Isoniazid can prevent tuberculosis by up to 90%. Despite this knowledge, Isoniazid Preventive Therapy (IPT) coverage is less than 40%. A project reported an increase in median IPT uptake from 40% to 87% among new clients within 10 months. The aim of the project was to replicate this and scale-up to include both new and old clients.

METHODS: Baseline data was collected over 6 months by auditing care cards of clients across six HIV sites with a combined number of 795 active clients shows a median IPT uptake of 39%. The target was to achieve at least 90% IPT uptake over a 6-month period. Root causes identified were knowledge gap on current guidelines, lack of commitment of facility staff, and commodity stock-out. Implementation was conducted in 3 Plan -> Do -> Study -> Act (PDSA) cycles at two months intervals starting with structured capacity building for focal persons in December 2018 followed by identification of facility champions, and isoniazid commodity security.

RESULTS: A total of 2415 encounters were documented during the intervention phase. Children accounted for 7% (n = 163) and adults 93% (n = 2252), women represented 61% (n = 1478) and men 39% (n = 937). Following the first PDSA cycle, there was an increase in IPT uptake from the baseline score of 39% to 48% which rose to 74% after the second cycle and to 94% in the last month of the project. Overall, there was consistent rise in IPT optimization with a shift in median value from 39% to 74%.



[Figure. IPT optimization percent in clients attending clinics]

CONCLUSIONS: Implementation of three PDSA cycles focusing on addressing knowledge gap, having a facility champion and commodity management has shown replicability and scalability in addressing IPT optimization.

PEE1496

COMMUNITY AND FACILITY BASED MODEL INTEGRATION IN NEEDLE AND SYRINGE EXCHANGE PROGRAM IN A SUB SAHARAN SETTING

R. Kansiime[1], W. Musinguzi[1], J. Lule[1], G. Pande[1], P. Kyambadde[1], T.R. Muwonge[2]
[1]*Most at Risk Populations Initiative, Kampala, Uganda,* [2]*Makerere University Infectious Diseases Institute, Kampala, Uganda*

BACKGROUND: World health organization (WHO) has recommended practical strategies and ideas aimed at reducing negative consequences associated with drug use in response to HIV. The needle and syringe exchange program (NSP) is a harm reduction intervention targeting people who inject with Drugs (PWIDs). Uganda as a country does not have specific policies and guidelines for implementation of Needle and syringe Exchange programs. Most at Risk populations' initiative (MARPI) since 2008 has been the forefront of building resilient health systems that are key to access and utilization of integrated Sexual and Reproductive Health Services (SRHS) and HIV services for key and priority populations in Uganda. MARPI is a pioneer organization in direct provision of integrated SRHS and HIV services for key and priority populations and has built capacity for other institutions-small and big to take lead on integrated SRHR and HIV services for most at risk populations. The period March – September 2018, MARPI piloted NSP in Kampala and Wakiso in collaboration with the Uganda Harm Reduction Network to assess the feasibility of NSP among PWIDs in Uganda.

METHODS: This pilot study MARPI used two delivery models (Facility based Model and community-based Model).

Use of facility based model; clients picked new needles and syringes and returned the used ones as they received other SRH services.

Community model; This was divided in to two approaches, Peer-to-peer; where peers delivered new and collected used needles and syringes from the PWIDs and community outreach where health service providers delivered new and collected used needles and syringes to the PWIDs in the community.

RESULTS: Up to 780 needles and syringes were distributed. 236 (30.2%) facility model and 544 (69.7%) community model with, 220 (28.2%); community outreach and 348(44.6%) peer-to-peer. Overall return of used needles and syringes was 305 (56%); direct return to the facility by users 207 (67.8%), 23 (7.5%) peer-to-peer and 75 (24.5%) at outreach.

CONCLUSIONS: This pilot revealed that the distribution of needles and syringes to PWIDs was feasible with community delivery model being the most preferred by PWIDs. Guidelines should be put in place to streamline this program at national level.

PEE1497

"ONLY TWICE A YEAR": A QUALITATIVE EXPLORATION OF SIX-MONTH ANTIRETROVIRAL TREATMENT REFILLS FOR PEOPLE LIVING WITH HIV IN KHAYELITSHA, SOUTH AFRICA

C. Keene[1], N. Zokufa[1], E. Venables[2,3], L. Wilkinson[4,5], R.M. Hoffman[6], T. Cassidy[1], L. Snyman[1], A. Grimsrud[4], J. Voget[7], E. von der Heyden[7], S. Zide-Ndzungu[7], V. Bhardwaj[1], P. Isaakidis[3]
[1]Médecins Sans Frontières, Cape Town, South Africa, [2]University of Cape Town, Division of Social and Behavioural Sciences, School of Public Health and Family Medicine, Cape Town, South Africa, [3]Médecins Sans Frontières, Southern African Medical Unit, Cape Town, South Africa, [4]International AIDS Society, Cape Town, South Africa, [5]University of Cape Town, Centre for Infectious Epidemiology and Research, Cape Town, South Africa, [6]University of California, Division of Infectious Diseases, Department of Medicine, David Geffen School of Medicine, Los Angeles, United States, [7]Western Cape Department of Health, Cape Town, South Africa

BACKGROUND: Longer intervals between routine clinic visits and medication refills are part of patient-centred, differentiated service delivery (DSD), and have been shown to improve patient outcomes as well as optimise health services – vital as 'universal test-and-treat' targets increase numbers of HIV patients on antiretroviral treatment (ART). We performed a qualitative study to explore the experience and acceptability of six-month refills in adherence clubs in Khayelitsha, South Africa.

METHODS: In-depth interviews were conducted in isiXhosa with purposively selected patients and in English with healthcare workers and key informants. The participants had been involved in a randomised controlled trial evaluating multi-month ART dispensing in adherence clubs in Khayelitsha, comparing six-month and two-month refills. All transcripts were audio-recorded, transcribed and translated to English, then manually coded and thematically analysed.

RESULTS: Twenty-three patients (16 in six-month and seven in two-month clubs), seven healthcare workers and six key informants were interviewed between June and November 2019. Patients found six-month refills increased convenience and flexibility to meet other obligations, and reduced unintended disclosure by offering privacy in the community. Contrary to key informant concerns about patients' responsibility to manage larger quantities of ART, patients receiving six-month refills were highly motivated and did not face challenges transporting, storing or adhering to their treatment. All participants felt that strict eligibility criteria were necessary for patients to realise the benefits of extended refills.

Six-month refills were felt to increase the health system's efficiency. However, a significant concern was that the existing drug supply system would struggle to adapt to six-month ART refills at scale, and that a precarious supply chain would both limit the feasibility of implementation and be threatened by the additional stress longer ART refills would place on to the system.

CONCLUSIONS: Patients, healthcare workers and key informants found six-month refills within adherence clubs acceptable and beneficial, but concerns were raised about the reliability of the supply chain to manage extended multi-month dispensing. Stepwise, slow expansion could avoid overstressing supply and allow time for the health system to adapt, permitting six-month ART refills to enhance current DSD options to be more efficient and patient-centred within current health system constraints.

PEE1498

IMPROVING SAME DAY ART IN BOTSWANA: A HEALTH SYSTEM STRENGTHENING APPROACH

M. Montebatsi[1], R. Marima[1], M.-C. Lavoie[2], N. Blanco Herrera[2], J. Kabengele[1], K. Keapoletswe[1], M. Ogbuabo[1], K. Sebina[1], O. Ntwayagae[1], D. Ramaabya[3], M. Ramotsababa[3], N. Ndwapi[1]
[1]Botswana University of Maryland School of Medicine Health Initiative, Gaborone, Botswana, [2]University of Maryland School of Medicine, Baltimore, United States, [3]Ministry of Health and Wellness, Gaborone, Botswana

BACKGROUND: Timely linkage to treatment is critical to reach the 95-95-95 UNAIDS targets and optimize client's health outcomes. Botswana Partnership for Advance Clinical Education (BPACE), a program funded by PEPFAR through CDC, implemented an intensive intervention called Reboot that meant to ensure that HIV-positive individuals were initiated on ART within 7 days, preferably on the same day. This abstract aims to evaluate the effect of Reboot on Same Day and Fast-track linkage to treatment.

METHODS: We conducted a retrospective cohort analysis of patients aged 18 years or older who were newly HIV diagnosed from October 2018 to September 2019 across 41 high HIV burden health facilities. Starting on February 2019, BPACE implemented the following interventions as part of Reboot: 1) introduction of a policy where clients could be transferred to preferred facility following ART initiation; 2) availability of 14 days starter packs of ART at multiple service points; 3) introduction of on-call clinicians after-hours and weekends; and 4) training of 49 prescribers who acted as facility champions to spearhead this initiative; and 5) fast-track peer counseling following HIV diagnosis. We used logistic regression models adjusting for clustering by facility to assess the association of the Reboot with same day or within seven days ART initiation.

RESULTS: From October 2018 to January 2019, 1990 newly identified clients initiated treatment of these 35% were initiated the same day of diagnosis and 71% within 7 days. Following the launch of the reboot (February to September 2019), 3308 newly identified clients were initiated on ART, 65% were initiated the same day of diagnosis and 86% within 7 days. A client was 3.7 (OR 95% CI 3.3-4.2) times more likely to be initiated the same day of diagnosis or 2.5 (OR 95% CI 2.1-2.8) times more likely to be initiated within 7 days than before reboot. The strong associations remain even after controlling by sex and age.

CONCLUSIONS: The multi-level strategies deployed as part of Reboot demonstrated to facilitate ART initiation the same day or within seven days of diagnosis. We recommend scaling up of these interventions to support linkage to treatment.

PEE1499

DELAYING COURIER SPECIMEN COLLECTION TIME IMPROVES PATIENT ACCESS TO VIRAL LOAD TESTING, GAUTENG SOUTH AFRICA

S. Girdwood[1], T. Crompton[2], F. Olsen[3], P. Sejake[4], N. Cassim[3,4], K. Diallo[5], L. Berrie[5], D. Chimhamhiwa[2], W. Stevens[3,4], B. Nichols[1,6]
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Right to Care, Johannesburg, South Africa, [3]National Health Laboratory Service, Johannesburg, South Africa, [4]University of the Witwatersrand, Department of Molecular Medicine and Haematology, Faculty of Health Sciences, Johannesburg, South Africa, [5]Centers for Disease Control and Prevention, Pretoria, South Africa, [6]Boston University, Department of Global Health and Development, School of Public Health, Boston, United States

BACKGROUND: South Africa currently uses a courier network for transporting specimens from primary healthcare facilities to centralized testing laboratories managed by the National Health Laboratory Service. After specimens have been collected from the clinic by the courier network for the day, patients not yet attended to are unlikely to receive same-day blood-draw. This could mean a delay in viral load (VL) testing for HIV patients. Only 69% of patients undergo VL testing according to the guideline-recommended schedule. We first aimed to determine whether a relationship between courier specimen collection time and VL access existed and, if so, whether the courier network could be optimized to delay specimen transport times.

METHODS: For a convenience sample of clinics (n=74) in Gauteng, South Africa, we used number of patients on ART, number of VL tests, and courier pick-up times from 2019. We used logistic regression to assess the relationship between specimen transport time and VL testing access (adjusting for clinic size), defined as the number of annual VL tests performed per ART patient. Using a geospatial model, we optimized the specimen transport network, subject to costs, pre-defined working hours, and minimum servicing requirements, to improve courier routing and delay the average time of specimen collection. Finally, we compared our specimen transport times from the optimized model with current pick-up times to determine the percent change in access to same-day blood-draws based on different assumptions regarding the underlying distribution of patient flow at clinics.

RESULTS: The number of annual VL tests per ART patient (1.14, standard deviation [SD] 0.28) is higher at facilities that have courier collection after 14:47 (the average latest Gauteng collection time) than those that have collection before 14:47 (1.04, SD 0.18), even when adjusted for clinic size (p=0.09). Through specimen network optimization in Gauteng, the average time for specimen transport was delayed to 15:10. We expect this delay to increase patient access to same-day blood-draws by 5%-9% across Gauteng, depending on the patient flow distribution at clinics.

CONCLUSIONS: Delaying specimen pick-up times at clinics by as little as half an hour can improve patient access to laboratory services and increase the demand for VL.

PEE1500

DEVELOPING THE ADAPT (ALTERNATIVE DELIVERY OF ART OPTIMIZATION) MODEL FOR THE PLANNING OF DIFFERENTIATED CARE IN SUB-SAHARAN AFRICA

B. Nichols[1,2,3], S. Kuchukhidze[1], N. Lekodeba[2,3], R. Cele[2,3], S. Pascoe[2,3], L. Long[1,2,3], A. Huber[2,3], S. Rosen[1,2,3]
[1]Boston University, Global Health, Boston, United States, [2]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]University of the Witwatersrand, School of Clinical Medicine, Department of Internal Medicine, Johannesburg, South Africa

BACKGROUND: As countries in sub-Saharan Africa rapidly expand differentiated service delivery (DSD) models for HIV treatment, guidance is needed on the appropriate model mix to maximize the potential benefits of DSD expansion while minimizing cost. ADAPT is an Excel-based mathematical model designed to provide this guidance and identify optimal national DSD implementation strategies.

DESCRIPTION: Under ADAPT, users complete four main components:
a) define the national ART patient distribution for multiple patient strata by setting, sex, age, and proportion considered stable on ART(Fig.1-1);
b) describe each DSD model (both for stable and non-stable patients) to be considered by its location, frequency of interaction, cadre of staff, and services included (Fig.1-1);
c) identify multiple national DSD implementation scenarios by specifying number of models and each model's characteristics (setting [urban/rural]), target population, coverage)(Fig.1-2,3,4); and
d) weigh each outcome (e.g. suppression, patient cost, etc.) by user-defined relative importance(Fig.1-5,7). ADAPT outputs are national and stratum-specific health outcomes and costs for each scenario (Fig.1-5,8). Scenarios are ranked based on expected model outcomes and user-defined values for each outcome to provide the optimal scenario, constrained by the user-defined budget and human resource availability (Fig.1-6).

[Figure 1. ADAPT model structure, by data-source type]

LESSONS LEARNED: To operationalize the model, we identified data sources on DSD cost and effectiveness. These include interviews with program implementers to obtain detailed descriptions of existing DSD models; national electronic medical records (EMR) to estimate stratum-specific health outcomes for patients on DSD and DSD uptake; EMR and national aggregate health datasets to map the national distribution of ART patients; and primary data collection and review of existing studies to estimate provider and patient costs for each model.

CONCLUSIONS/NEXT STEPS: ADAPT provides a decision-making framework for evaluating policy choices related to DSD model scale-up in sub-Saharan Africa. It will allow users to make data-driven decisions on patient health, health system, and budgetary impact of DSD implementation.

PEE1501

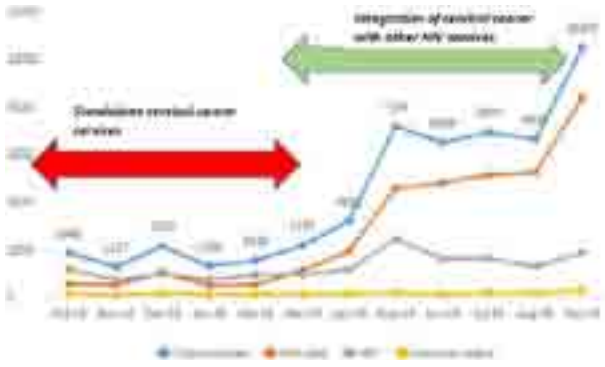
INTEGRATION OF CERVICAL CANCER WITH HIV SERVICES IMPROVES THE UPTAKE OF CERVICAL CANCER SCREENING AMONGST HIV POSITIVE CLIENTS: LESSONS LEARNT FROM ZAMBIA

W. Kanjipite[1], D. Dixon[2], C. Madevu-Matson[3], M. Osborne-Smith[3]
[1]JSI SAFE/Zambia, Strategic Information, Lusaka, Zambia, [2]JSI SAFE/Zambia, Chief of Party, Lusaka, Zambia, [3]JSI, Boston, United States

BACKGROUND: Women living with HIV (WLWH) are 6 times more likely than uninfected women to develop cervical cancer, a leading cause of death among women in Zambia, and should be targeted for screening and treatment. With funding from USAID, USAID SAFE supports Ministry of Health to scale-up cervical cancer services with a specific focus on WLWH.

DESCRIPTION: USAID SAFE operates in 43 facilities providing free cervical cancer services. Screening is conducted through Visual Inspection using Acetic acid (VIA) and immediate treatment using cryotherapy, thermal coagulation or referral for Loop Electrosurgical Excision Procedure for further evaluation. USAID SAFE trained 94 providers in cervical cancer screening using VIA, procured supplies to provide cervical cancer services, and provided supportive supervision for standalone and then integrated cervical cancer services.

LESSONS LEARNED: Initially (Oct-2018 to Feb-2019), WLWH were referred to standalone cervical cancer services after receiving ART services. The volume of all clients screened (an average of 1,699 women per month) was low and less than half (n=693; 41%) were WLWH. During the integration phase (Mar to Sep-2019), health education and referral for cervical cancer screening was provided prior to receiving HIV services. In addition to integration, supportive supervision visits were also intensified. As a result, the average increased to 6,810 per month, close to three-quarters (4,994; 73%) being WLWH (Figure 1). Integration and supervision resulted in a four-fold increase (from 10,195 to 40,858) in the number of clients screened, and a seven-fold increase (from 4,159 to 29,962) in reaching WLWH.



[Figure]

CONCLUSIONS/NEXT STEPS: Integration of cervical cancer into HIV services coupled with intensive supportive supervision is an effective strategy to increase access to screening for cervical cancer among WLWH. USAID SAFE will adopt this model in newly supported facilities in 2020 to reduce the burden of cervical cancer among WLWH.

PEE1502

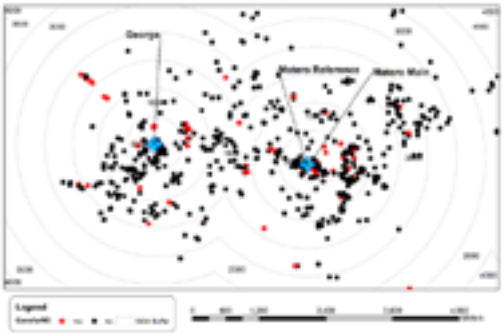
THE OPTIMUM REFERRAL DISTANCE FOR VOLUNTARY MEDICAL MALE CIRCUMCISION SERVICE DELIVERY: GEOSPATIAL ANALYSIS IN LUSAKA DISTRICT

R. Kamboyi[1], M. Kabila[2], O. Chituwo[3], C. Toledo[4], L. Aladesanmi[2], C. Sikazwe[2]
[1]Ministry of Health, Health Services, Lusaka, Zambia, [2]Jhpiego, Affiliate of Johns Hopkins University, Jhpiego, Lusaka, Zambia, [3]Centers for Disease Prevention and Control, CDC/DDPHSIS/CGH/DGHT, Lusaka, Zambia, [4]Centers for Disease Prevention and Control, CDC/DDPHSIS/CGH/DGHT, Atlanta, United States

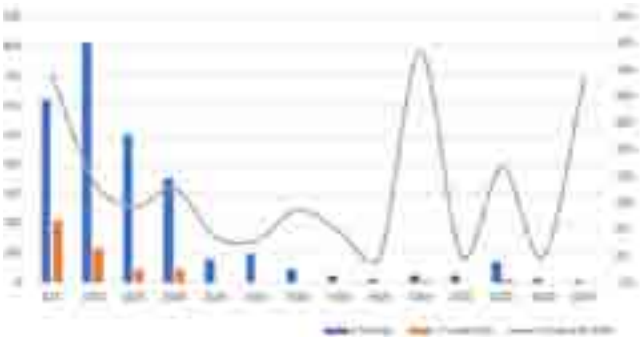
BACKGROUND: Male circumcision prevalence in Lusaka Province, Zambia, is 23%, and HIV prevalence is the highest in the country (16%). Only 85% of the 2018 voluntary medical male circumcision (VMMC) target was achieved in Lusaka District (52,355/61,590). A barrier to uptake of VMMC is distance required to travel for VMMC services. Geospatial analysis was done to determine the optimal referral distance from demand creation to health facility for VMMC.

DESCRIPTION: The project implemented a 2-phased outcome evaluation of an enhanced demand creation strategy and financial compensation/distant mapping approach to assess the hypothesized increase in VMMC uptake among high-risk men in Lusaka District. A total of 10554 eligible men aged ≥18 years, uncircumcised, and who self-reported ≥1 HIV risk factor in the past 6 months were recruited by health promoters at community venues. Health promoters used Android mobile devices, which also recorded geospatial coordinates. The VMMC conversion rate (% high-risk men circumcised ≤3 months of enrollment) and recruitment distances (straight line distances to health facility) were compared using Pearson chi-square.

LESSONS LEARNED:



[Figure. Enrolled vs circumcised clients by distance from facility]



[Figure. Referral distance vs VMMC rate]

The VMMC rate and number of men recruited decreased with increase in distance. Geospatial analysis revealed the optimum distance for demand creation referrals for Lusaka to be 2Km.

CONCLUSIONS/NEXT STEPS: This optimal referral distance allows programs to use resources efficiently by geo-fencing health promoters and to determine prime outreach locations to achieve high VMMC rates in places with low coverage.
The project plans to collect additional spatial data to improve the model for districts where VMMC coverage is low and which have different settlement patterns.

PEE1503

RAPID TRANSITION TO DOLUTEGRAVIR IN A FRAGILE CONTEXT

N. Mahachi[1], M. Awet[1], A. Abuk[1], D. Watkins[2], S. Stender[3]
[1]Jhpiego, Juba, South Sudan, [2]Jhpiego, Baltimore, United States, [3]Jhpiego, Cape Town, South Africa

BACKGROUND: South Sudan has a national HIV prevalence of 2.5%, however, only 24% of people living with HIV (PLHIV) know their status, and only 16% are on antiretroviral therapy (ART). With funding from PEPFAR/USAID, Jhpiego implements the Strengthening the Provision of Primary Health Care HIV Services in South Sudan (SPPHC) Project to provide comprehensive HIV services in Juba and Tambura States.
DESCRIPTION: Conflict and displacement complicate HIV service delivery in South Sudan: more than a third of the population has been displaced since 2013, presenting a major obstacle for diagnosis and retention, and decades of under-investment in health make implementing policy changes challenging. In July 2019, the SPPHC project in South Sudan began transition to dolutegravir (DTG)-based ART and standardization of multiple month dispensing (MMD). The project sought to leverage the PHC system in South Sudan and overcome site-level barriers, while strengthening client-level adherence efforts through MMD in eight PHC clinics in Juba (6) and Tambura state (2). Following the adaptation of guidelines, a detailed facility-level transition plan was developed and included capacity building, weekly tracking through use of a dashboard, and tracking stock status of the fixed-dose combination of tenofovir/lamivudine/DTG (TLD).
LESSONS LEARNED: In November 2019, 68% of eligible PLHIV receiving ART have been transitioned to TLD (72% female; 28% male), and 81% were dispensed three or more months of ART. Site-specific planning and follow-up contributed to taking the more effective regimen to scale in SPPHC-supported sites and job aids have been an important aspect of supporting healthcare providers to properly educate clients on TLD, including ensuring women of reproductive age are aware of potential risks and offered modern family planning methods. Close monitoring of weekly stock levels has ensured adequate drug supply, and mentor mothers have been fundamental in educating clients on benefits of transitioning to the new regimen.
CONCLUSIONS/NEXT STEPS: Despite unique challenges in infrastructure and mobility arising from a fragile setting, the project has been successful in leveraging the primary health care system in South Sudan to implement a major health policy change through mentorship and planning informed by daily and weekly use of data.

PEE1504

VIRTUAL INTERVENTION FOR HIV PREVENTION AMONG MSM - AN ONLINE TO OFFLINE HIV SERVICE DELIVERY MODEL FOR MSM IN DELHI, INDIA

J. Misra[1]
[1]Delhi State AIDS Control Society, Delhi, India

BACKGROUND: A study on use of mobile phone and social media in sex work client solicitation amongst clients of HIV Targeted Interventions (TIs) Projects conducted by DSACS found that, 83% of MSM involved in sex work reported use of mobile phone in soliciting clients. Mobile apps, websites and social media platforms are commonly used in solicitation. Use of technology has change the operation of sex work and made them invisible in physical hotspots. In turn, the TIs with peer led approach were not able to locate and mobilize community for HIV prevention services. In order to reach out and provide HIV prevention services to MSM, DSACS has initiated virtual intervention.
DESCRIPTION: A web portal www.safelovers.in with features like HIV service point locator, self risk assessment, online counselling, chatting, book appointment and order free condom was designed. It allows community to create own user ID and log in to seek anonymous and confidential HIV services at nearby centre as per their convenient day and time anywhere in the city. Community members were trained on virtual mapping, promotion of web portal and online outreach. The intervention started in June 2019 with promotion of web portal and online outreach to locate and mobilize target population to take HIV services. The real time program data captured through inbuilt dashboard as part of the web portal.
LESSONS LEARNED: During six month, 159 virtual sites and apps have been listed. Approximately, 10984 MSMs have been estimated to be active on virtual platforms. 507 virtually active MSM have been mobilised to sign up on web portal. The mean age of the MSM, who signed on web portal was 23 years. About 233 MSM booked an appointment for HIV related services.210 (90%) of them screened for HIV and 3 were tested positive and linked with nearby antiretroviral therapy centre.
CONCLUSIONS/NEXT STEPS: Virtual intervention appears to be a promising approach to locate and mobilize invisible and virtually active young MSM to seek HIV services at nearby HIV clinic as per their convenient time. The next phase of the project will link self HIV testing and PrEP services and strengthen treatment adherence.

PEE1505

EFFECTIVENESS OF ASSISTED PARTNER NOTIFICATION SERVICES TO HIV TEST AND TREAT EN IN WESTERN KENYA: (APS SCALE UP STUDY)

H. Lagat[1], E. Kariithi[2], C. Farquhar[3], S. Masyuko[4], B. Wamuti[3], M. Sharma[3], R. Bosire[3]
[1]PATH, aPS Study Deapartment/Research, Kisumu, Kenya, [2]PATH, aPS Study PI-Kenya, Nairobi, Kenya, [3]University of Washington, Global Health, Seattle, United States, [4]Ministry of Health, NASCOP, Nairobi, Kenya

BACKGROUND: Assisted partner services (aPS) or provider notification for sexual partners of persons diagnosed HIV-positive can increase HIV testing and linkage in sub-Saharan Africa (SSA) and is a high yield strategy to identify HIV-positive persons.
METHODS: We offered assisted partner services (aPS) scale up services in health facilities in Western Kenya. The findings on effectiveness of aPS implementation from an ongoing scale up study in

Western Kenya. aPS was scaled up since May 2018 by the Ministry of Health in collaboration with AfyaZiwani Program. The aPS scale-up study took place in 31 health facilities in Western Kenya. Newly diagnosed HIV-positive females15 years and above were screened for eligibility, consented and offered aPS. The participants who made eligibility criteria and accepted participation provided contact and locator information for all male sexual partners. Male sexual partners who test HIV seropositive received aPS and the female sexual partners elicited were notified and offered HIV testing.

RESULTS: In total, 28075 women were tested and 1260 (yield of 4.5%) were newly diagnosed. The participants were screened for eligibility and 1051 (83%) were enrolled into the study. The female index were elicited for sexual partners reported 1825 male sexual partners (index ratio=1.7). The male partners identified by the female index were traced and offered HIV testing services. Overall, 1340 (73%) of male partners named were contacted and tested for HIV. Of partners enrolled, 588(56%) were known positives and newly diagnosed HIV-positive. The male partners identified who were new positives were 227 (38%) and 361(61%) were known HIV-positive. Majority of partners who were known positive were already on ART (95%).

CONCLUSIONS: This scale up program provides evidence of the effectiveness of a partner notification program implemented in real-world settings. Testing of male sexual partners of newly diagnosed HIV-positive female clients is a high yield strategy to reaching newly diagnosed HIV positive persons. aPS is feasible and acceptable and identified a high proportion of newly diagnosed HIV-infected participants previously unaware of their status, aPNS therefore is an effective strategy to increasing uptake of partner HIV testing within routine healthcare settings.

PEE1506

EFFECTIVE COMMUNITY ENGAGEMENT AND PARTICIPATION, KEY TO NIGERIA ACHIEVING THE ELIMINATION OF MOTHER TO CHILD TRANSMISSION (EMTCT) BY 2021

G.S. Okorie[1]
[1]*National Agency for the Control of AIDS, Community Prevention and Care Services, Abuja, Nigeria*

BACKGROUND: Nigeria contributes 30% world burden of MTCT. From 2017 Nigeria eMTCT data, of the estimated nine million yearly pregnancies, 60% accessed HTS at health facility; 165,474 estimated mothers needing PMTCT, 64.811 (39.2%) have been identified and of those identified, 24,026 (47.2%) delivered at facility offering PMTCT; Nigerian body of Obstetrics are opposed to any interface with community providers of ANC services e.g. Traditional Birth Attendants (TBA). This intervention aimed at finding sustainable solution to challenges of pregnant women not accessing HIV services at health facility and to cub attritions along eMTCT cascade.

DESCRIPTION: A draft framework to strengthen interface between the community and health service providers for PMTCT was designed by National stakeholders coordinated by FMoH. 21 districts with high burden of HIV were selected. A high level advocacy to state, and community stakeholders and technical sessions ensured understanding of staff of SMoH of the need to interface with TBAs on the provision of PMTCT services. TBAs were identified, trained on HIV basics and referrals; their facilities mapped and linked to formal health facilities for referrals. Baseline PMTCT data were collected from 42 PHC that received referrals from the TBAs. Testing was provided at the mapped TBA by health facility personal for 9 months. Identified positives were referred to health facilities for HIV care. Data set have been validated by National M&E system.

LESSONS LEARNED: A total of 104,576 pregnant women were reached within 9 months across the 42 PHCs; 789 were HIV positive (0.75 positivity). This represents 40% increase of access to HTS across the districts; 95% facility delivery by identified positives was recorded. The number of infants who accessed HIV prophylaxes increased by 5% indicating community deliveries referred by TBAs. The TBAs engaged in this exercise now have interface with personnel from facilities. This also popularized the existence of network groups with resultant reduction in stigmatization and improved uptake of PMTCT services.

CONCLUSIONS/NEXT STEPS: This intervention demonstrated that pregnant women patronize TBAs. It also shows that strengthening interface between community and health service providers improved uptake of PMTCT services. Next step is the adoption and dissemination of the framework as policy in Nigeria.

PEE1507

USING THE NATIONAL OTC TOOL TO ESTIMATE ART COSTS FOR DIFFERENTIATED CARE

L. Bollinger[1], A. Adesina[1]
[1]*Avenir Health, Glastonbury, United States*

BACKGROUND: Estimating costs for delivering ART using a differentiated service delivery (DSD) model can be complicated, as there are many different dimensions that are changing: different service delivery visit types and schedules, task-shifting within the visits, and different ARV and laboratory regimens. The National Optimized Treatment Costing (OTC) tool calculates the unit costs and generates the total (or scale-up costs) of differentiated care scenarios to help policymakers undertaking national strategic planning estimate potential savings.

METHODS: The OTC tool compares the cost of a "Current" scenario with the cost of up to three different user-specified differentiated care scenarios. First, the "Current" practice scenario is specified for each of five policy dimensions (Task allocation for facility-level provider visits, Visits, Laboratory tests, Antiretroviral drugs (ARVs), and Other commodities). Then, up to three optimized treatment scenarios are specified for each of the five policy dimensions. Finally, in the "Inputs-Scenario selection" tab, the user can mix and match among the five policy levers to create up to three different overall scenarios. This allows for a great deal of flexibility, as there are many different combinations possible among the five policy levers. The outputs from the three overall scenarios are then compared with the outputs from the "Current" scenario. Outputs includes unit cost/expenditure and total/scale-up cost, disaggregated by key components and by patient type (newly initiating, stable, unstable for each of adults, children, PMTCT clients, and key populations).

RESULTS: An application of the OTC tool in Nigeria showed a potential savings after four years of $170 million reducing overall costs from $1.45 billion to 1.28 billion. In this scenario, designed by policymakers, the source of cost savings was primarily due to the different number of service delivery visits required by the new differentiated care protocol.

CONCLUSIONS: The publicly available National OTC tool provides a user-friendly tool to help policymakers evaluate potential costs savings of various differentiated service delivery models, including con-

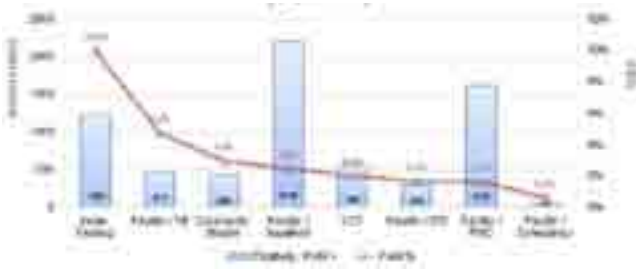
sidering alternate scenarios of different service delivery schedules and types, task-shifting, different ARV regimens, and different laboratory test schedules. Outputs includes unit cost and total/scale-up costs disaggregated by key components and by patient type.

PEE1508

MOST EFFECTIVE TESTING STRATEGIES IN TERMS OF POSITIVITY VOLUME AND YIELD: LESSONS LEARNED FROM NATIONAL-SCALE HEALTHLINK PROJECT IN UKRAINE

O. Vlasiuk[1]
[1]*CO - All-Ukrainian Network of people living with HIV/AIDS, Innovative Programs Unit, Kyiv, Ukraine*

BACKGROUND: Ukraine remains the country with the second-largest HIV epidemic in Eastern Europe. To ensure Ukraine's progress towards the 90–90–90 targets, a national-scale HealthLink Project was launched in 2018. The Project's primary goal is to increase the number of people who know their HIV status through introducing new HIV testing strategies at both community and facility levels.
DESCRIPTION: In 2018-2019, HealthLink introduced HIV testing in 460 healthcare facilities and 180 community sites within 12 high burden regions of Ukraine. Program design envisioned the provision of HIV-related services in primary, outpatient, and specialized healthcare settings, where HIV testing was not provided prior to the Project start or occurred in very limited numbers. Testing models included PITC, VCT, Community-based testing as well as Index Testing, which was not implemented in Ukraine on a routine basis before HealthLink. In total, 268 293 persons were tested for HIV, 6821 of whom received positive results.
LESSONS LEARNED: Testing at in-patient departments and primary facilities provided the highest numbers of newly identified cases with relatively low yields of 2.5% and 1.7% respectively. The most effective strategy was Index Testing, which resulted in a 10% yield and the third-largest number of new HIV cases among all other strategies. TB-clinics and community sites demonstrated high yields but low volumes, and the least effective appeared testing at emergency hospitals and STI clinics.



[Figure. Positive tests and yield by testing modality, 2018-2019 (HealthLink program data)]

CONCLUSIONS/NEXT STEPS: Increased testing at in-patient departments and primary settings resulted in high numbers of new cases, but the next steps should be aimed at more targeted testing in these settings. Index Testing is the most optimal strategy in terms of both positivity volume and effectiveness. HealthLink experience will be most valuable in planning the allocation of program resources for countries with a similar epidemic landscape, particularly in countries of Eastern Europe and Central Asia.

PEE1509

KNOWLEDGE ON HIV & CARE AND SUPPORT SERVICES FOR ROHIGYA POPULATIONS THOSE HAS BEEN DISPLACED

A.J.A. Chowdhury[1]
[1]*The Asia Foundation, Program, Dhaka, Bangladesh*

BACKGROUND: After starting of attacking in Rakhain state of Myanmar by Myanmar Army, till now 1.2 million Rohigya population has been displaced from Myanmar to Bangladesh. Considering the HIV/AIDS scenario, Bangladesh government took initiative to provide treatment to Rohingya PLHIV support by the 'World Health Organization.' Up to 2018 about 300 PLHIV has been identified those are taking ART treatment from DGHS (Director General of Health Services) supported by WHO.
DESCRIPTION: Seventy Rohingya PLHIV has been interviewed to know their present social, physiological status, knowledge of HIV and it's treatment and also their plan for treatment after going back to Myanmar. The respondents has been selected based on the availability in hospital when they come to collect ART. So, all has been selected for interview who came to collect ART on the specific period.

LESSONS LEARNED: # The financial condition is very poor, they have no income source except relief
The PLHIV had no idea on their HIV status
The PLHIV did not get counselling support in any where except in Cox's Bazar hospital
Almost 90% Rohingya PLHIV has no minimum idea about HIV/AIDS
Among them 100% have no specific caregiver and they have no idea on caregiver
Very limited individuals (12%) thought that they will get ART support when they will return in Myanmar
CONCLUSIONS/NEXT STEPS: * All identified PLHIV should be oriented on HIV/AIDS
* VCT services can be available in camp area
* All should have a specific caregiver and the caregiver should be trained on HIV/AIDS and his/her role
* STI/STD services should be ensured including drugs
* At the time of return back in Myanmar, the PLHIV should be transferred through the specific agency/organization considering confidentiality issue

PEE1510

THE "VOICE OF WOMEN" TO INTEGRATE HIV AND SYPHILIS TESTING IN ANTENATAL CARE: A SYSTEMATIC REVIEW OF QUALITATIVE RESEARCH

Y. Zhang[1], R. Guy[1], T. Applegate[1], L. Laffety[1], V. Wiseman[1], C. Treloar[2]
[1]Kirby Institute, UNSW, Sydney, Australia, [2]UNSW, Sydney, Australia

BACKGROUND: Effective integration of HIV and syphilis rapid tests into antenatal care, requires a comprehensive understanding of the health system building blocks, and views from all stakeholders involved. We conducted the first synthesis of qualitative studies which have evaluated the acceptability rapid testing for HIV and STIs among pregnant women.

METHODS: We searched six databases from 1998 to 2018, using PRISMA guidelines. Qualitative studies conducted with pregnant women, health workers, and stakeholders were included. Data were extracted from the direct quotes from participants and interpretation data by publication authors. We used thematic analysis and used findings to generate explanatory thematic domains.

RESULTS: We identified a total of 3548 citations from 7 databases, of which 60 papers were eligible for inclusion (35 papers included pregnant women, 41 papers included health worker and 20 papers included stakeholders; 58 were from low-middle income countries, 2 high-income countries).

We organized the findings into three thematic domains:

(i) social-cultural influences;

(ii) service provision; and,

(iii) personal consideration and support.

The ability of healthcare workers to deliver high-quality care depends on well-developed health system infrastructure, guidelines, sufficient recourses and staffing, usability of the tests, and well-organized organizational tasks. Sustaining high-quality testing required ongoing training, support from supervisors and other peers, as well as a stable and adequate salary.

For women, initial acceptance of the test and their continuation in care depends on the perception that doing so will be a beneficial experience for their baby and themselves, influenced by the provision of services that are supportive, gender-sensitive, caring, confidential, respectful, flexible, and consider their longer life plan. Women's perceptions of the value of tests depend on local socio-cultural beliefs about pregnancy and diseases, their awareness of tests, as well as their gender roles in society.

CONCLUSIONS: In addition to the multiple health system factors that need to be addressed when integrating HIV and syphilis rapid testing into ANC, we found women's preferences need to be strongly considered, and care should be more holistic, and not just about the test.

PEE1511

LESSONS LEARNT FROM IMPLEMENTATION OF BEST PRACTICES IN ADDRESSING DEMAND CREATION CHALLENGES IN THE KINGDOM OF ESWATINI

K. Ndlovu[1]
[1]Centre for HIV and AIDS Prevention Studies, Technical, Mbabane, Eswatini

BACKGROUND: The Kingdom of Eswatini is among the 14 priority countries where VMMC for HIV prevention has been scaled up for public health impact. It is not a traditionally circumcising country and as such when VMMC for HIV prevention was introduced the coverage was about 9%. The VMMC programs aim to circumcise at least 80% of the sexually active men for public health impact and Eswatini currently has a coverage of 40%. This varies regionally where some areas have done over 80% while some are significantly lagging.

DESCRIPTION: The VMMC national program is largely funded by PEPFAR in Eswatini and CHAPS has implemented this program in Eswatini from 2015 to 2019. The program in Eswatini has been marred by demand creation challenges over the years and that meant that CHAPS as an organization had to institute certain strategies as part of turning the program around. CHAPS embarked on a learning program from their South African office to try and adopt demand creation strategies that had succeeded. The two main strategies that were then implemented during the year of implementation starting in July were the zonal saturation and blitz campaigns. These population targeted high density areas through use of census data and MC coverage rates and were implemented concurrently.

LESSONS LEARNED: The period (Q4-2019) when the strategies were implemented yielded 3818 circumcisions in two regions where CHAPS was implementing. This was a 54.7% increase in the numbers from the 2468 done in 2018 which had been the highest performance for the same region. This increment was the highest year on year change and it translated to a 157.8% percent increase in Q4 numbers compared to numbers at inception. The overall CHAPS Q4 results from the two regions in 2019 were the highest ever figures from two regions since program inception.

CONCLUSIONS/NEXT STEPS: The adopted strategies yielded positive outcomes that had never been realized and as such if the program continues to intensify these strategies the program will be on track to achieving the targets. There is a room for collaboration between countries in an effort to overcome demand creation challenges.

PEE1512

OPTIMIZING VIRAL LOAD (VL) TEST AMONG PEOPLE LIVING WITH HIV (PLHIV) USING CONTINUOUS QUALITY IMPROVEMENT (CQI) APPROACH IN 13 HIGH-VOLUME SITES IN FIVE SUPPORTED STATES, NORTHCENTRAL NIGERIA

F. Eluke[1], A. Etsetowaghan[2], M. Umoren[3], K. Onyealisi[4], J. Ezekiel[5], D. Ogundehin[5], A. Omoluabi[6]
[1]Management Sciences for Health, Technical Services, Abuja, Nigeria, [2]Management Sciences for Health, Technical Sciences, Abuja, Nigeria, [3]Management Sciences for Health, Laboratory System Services, Abuja, Nigeria, [4]Management Sciences for Health, MEL, Abuja, Nigeria, [5]USAID, Care and Treatment, Abuja, Nigeria, [6]Management Sciences for Health, Program Management, Abuja, Nigeria

BACKGROUND: Despite the increased availability of resources to ensure uninterrupted access to VL test in Sub-Saharan Africa, access to VL testing remains a challenge, particularly in resource-constraint settings. Program data and structured assessment using site improvement through monitoring systems (SIMS) tool revealed suboptimal VL coverage. This study was conducted to determine whether facility-based Quality Improvement (QI) activities could significantly increase uptake of VL test and suppression.

METHODS: In July 2018, routine program data and standard-of-care evaluation conducted in 13 high-volume sites revealed a baseline VL coverage of 43% and a similar assessment using SIMS-tool yielded coverage of 40%. These assessments followed the international standards for sampling and selection of charts for auditing. Addi-

tionally, a survey was conducted using questionnaires administered to healthcare providers and end-users to identify root causes of the poor VL coverage which include:

Fear of venepuncture-associated pain

Difficulty navigating sites

Having specific days for sample collection

Negligence by healthcare providers

Based on these findings, the following interventions were carried out as QI projects over eleven months:

Use of task-shifting to strengthen request, sample collection, and result documentation.

Intensified health education, incentivized clients and Support groups engagement in health education.

Established clinic-side phlebotomy units for VL sample collection within the ART clinics to eliminate barriers related to difficulty navigating the facilities and reduce client waiting time.

Routinely identify eligible clients using QoC checklist.

Routine program data and charts of clients who attended clinic were reviewed and data analyzed to evaluate VL coverage and suppression among PLHIV at different time-periods.

RESULTS: Data analysis showed remarkable improvement in VL coverage and suppression. After 6months, VL coverage and suppression were 59% and 67% respectively, and after 11months 92% and 88% respectively. Fundamentally, this work provides good insight into the understanding of effectiveness of CQI interventions and shows excellent potential for use of CQI in improving HIV/AIDS program quality

CONCLUSIONS: CQI interventions are effective in improving uptake of VL test for ART monitoring among PLHIV as demonstrated in these sites. This study clearly indicates that CQI interventions are effective in bridging program implementation gaps and deserve been used in other health program areas requiring quality.

PEE1513

BRIDGING THE GAP IN VIRAL LOAD TESTING COVERAGE AND SUPPRESSION AMONG PATIENTS ON ANTI-RETROVIRAL TREATMENT IN ETHIOPIA

D. Habte[1], Y. Tedla[1], A. Kebede[2], A. Mekonnen[1], S. Becknell[1], S.A. Abayneh[1]
[1]Centers for Disease Control and Prevention (CDC), Addis Ababa, Ethiopia, [2]Ethiopian Public Health Institute, Addis Ababa, Ethiopia

BACKGROUND: Ethiopia adopted the three-90 UNAIDS targets for controlling HIV by 2020. The Country subsequently introduced viral load (VL) testing for monitoring the 3rd 90, towards viral load suppression (VLS) among 90% of people on treatment. National scale-up of VL testing started since 2016 which includes actively increasing demand for and access to testing, establishing an external quality assurance scheme, and creating a specimen transport network linking 19 referral testing laboratories with over 1,200 anti-retroviral treatment (ART) clinics. We present the trend of VL coverage (VLC) and VLS by region and age following VL scale up activities.

METHODS: We used aggregate national VL data from Data for Accountability, Transparency and Impact (DATIM) for 2018 and 2019 to describe the trend in VLC and VLS over time.

RESULTS: VL testing increased by 75,887 tests (263,819 to 339,706) between 2018 and 2019, with coverage expanding from 58.4% to 73.1% of all PLHIV on treatment during 2018 Quarter 4 to 2019 Quarter 4. The most recent VLC report ranged from 54% to 82% for all 11 regions in Ethiopia. Three of 11 regions, providing VL testing services for 214,222 PLHIV on treatment (45.7% of national cohort), achieved VL coverage above 80% each in 2019 Quarter 4. Coverage is the lowest (54-57%) for three of four regions that refer specimens outside administrative boundaries to two other regional laboratories. During 2019 Quarter 4, 10 of 11 regions reported VL suppression (<1000 viral copies/ml) above 90%. There is no significant difference in VL testing coverage between children below 15 years of age (67-74%) and adult (53-73%) clients. However, VL suppression was relatively lower among children (75-79%) as compared with adults (89-93%).

CONCLUSIONS: The country made significant improvement in VL testing coverage following the scale-up. There is a relatively good overall VLS with lower performance among children. Understanding the root causes for low VLS among children on ART and devising targeted interventions are recommended. In countries like Ethiopia with large cohort size and reaching epidemic control, sub-national level analysis in VLC and VLS is critical in identifying the gap and providing tailored sub-national level intervention.

PEE1514

EXPANDING ACCESS TO CERVICAL CANCER SCREENING AND TREATMENT AMONG HIV+ WOMEN IN MOZAMBIQUE

M. Urso[1], D. Correia[1], J. Greenberg Cowan[1], M. Torres[1], C. Lorenzoni[2], C. Moreira[2], E. Baker[3], K. Schmeler[3], H. Watts[4]
[1]Centers for Disease Control and Prevention, Maputo, Mozambique, [2]Mozambique Ministry of Health, Maputo, Mozambique, [3]MD Anderson, Houston, United States, [4]US Department of State, Washington DC, United States

BACKGROUND: Mozambique is a country with high prevalence of HIV (13.5% IMASIDA) and large numbers of women living with HIV (WLHIV); of 820,124* patients on HIV treatment between July and September 2019, 70.8% (580,474) were women. According to the Mozambican 2015-2017 cancer registry, cervical cancer is the most common cancer among women and primary cause of cancer-related deaths among WLHIV. As documented by the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) programmatic data, access to cervical cancer screening and treatment among WLHIV has been historically low in Mozambique. There have been two initiatives supported by PEPFAR to increase cervical cancer screening and treatment services in Mozambique, the Pink Ribbon Red Ribbon Initiative in 2015 and the Central initiative in 2018.

DESCRIPTION: In collaboration with Ministry of Health, the U.S. Centers for Disease Control & Prevention (CDC) implemented an integrated approach to improve access to screening and linkage to treatment in seven CDC-supported provinces. An integrated workplan was developed that ensured implementing partners would acquire equipment for screen and treat approach (colposcopes, cryotherapy and Loop Electrosurgical Excision Procedure machines), procure essential supplies and support training cascades with a monthly e-learning component. CDC and the Ministry of Health put in place an enhanced cervical monitoring approach to monitor and map provincial monthly progress. Technical experts from MD Anderson collaborated to provide distance mentoring, quarterly trainings for LEEP and complex surgeries and technical support for training. Between July and September 2018 8,253 women were screened, 8.8% (727) women had positive results, 60.5% (440) women were treated. After the integrated approach between October 2018- September 2019, 68,338 WLHIV who were receiving ART treatment had been screened, 9% (6,208) screened positive and 63% (3,920) received treatment (either cryotherapy or LEEP).

LESSONS LEARNED: A focused, performance based collaboration between donors, implementing partners and the Ministry of Health markedly improved cervical cancer screening access among women living with HIV in Mozambique.

CONCLUSIONS/NEXT STEPS: Linkage to treatment remained incomplete despite a multi-focal approach and requires ongoing innovation.

PEE1515

OPTIMIZING HIV TESTING AT THE FAMILY PLANNING CLINIC OF A TERTIARY-CARE HOSPITAL IN LUANDA, ANGOLA

R. Nhanombe[1], C. Laudari[1], J. Pires[1], J. Maria[1], A. Cruz[1], A. Ukuahamba[2], M. Fonseca[2], C. Barros[3], L. Furtado[3], A. Jha[4], M. A. Mahdi[4], R. Sutton[4], S. Zidana-Ndovi[4], J. Soares Linn[4]

[1]ICAP at Columbia University in Angola, New York, United States, [2]Cajueiros General Hospital in Luanda, Luanda, Angola, [3]National Institute for the Fight against AIDS in Angola, Luanda, Angola, [4]ICAP at Columbia University, New York, United States

BACKGROUND: Angola has a generalized HIV epidemic with 2% prevalence. Since 2015, ICAP at Columbia University has supported the Ministry of Health with HIV prevention and control efforts, including providing high-quality technical assistance to Hospital Geral dos Cajueiros (HGC) in Luanda province. A tertiary-care hospital with large catchment area, HGC had consistently demonstrated high-volume HIV testing with low yield at its family planning (FP) services, with nearly 70% of women being offered HIV re-testing as per national guidelines without any risk assessment. In an effort to better achieve epidemic control, a more targeted approach to the offer of HIV testing services (HTS) within FP services was explored.

DESCRIPTION: In order to optimize HTS at the FP clinic, ICAP developed and implemented a risk assessment tool to assess eligibility for re-testing. The tool focused on screening for signs and symptoms of sexually transmitted infections and TB, and assessment of partner's HIV status, history of unprotected sex, breastfeeding, and engagement in sex work. Implementation of the tool started in July 2018. All new FP clients with unknown HIV status, as well as clients returning for a follow-up appointment after 3 months with a negative HIV status, were screened using the risk assessment tool and if eligible, offered HTS. ICAP mentored FP nurses in use of the tool, and provided support through weekly data reviews to identify and address challenges.

LESSONS LEARNED: During the pre-implementation period (April-June 2018), among 1,427 FP clients tested for HIV, 428 (30%) were new patients while 999 (70%) were re-tests. Only 7 (0.5%) clients were found to be HIV-positive. In a sharp contrast, in the post- implementation period (January-March 2019), among 391 patients receiving HTS, 377 (96.4%) were new FP clients. 5 clients (1.3%) were identified as HIV-positive.

CONCLUSIONS/NEXT STEPS: The early results of the targeted HV testing strategy using a risk assessment tool were shared with the National Aids Institute, and the authorities are currently considering including this approach as part of the national guidelines. ICAP is also advocating adaptation of this tool in related services that require repeat testing, like among HIV/TB co-infection patients.

PEE1516

SOCIAL MARKETING OF HIV TESTING THROUGH THE PRIVATE SECTOR IN SRI LANKA TO ACCELERATE HIV EPIDEMIC CONTROL

G. Weerasinghe[1], D. Ranatunga[2], S.C. Ghosh[3], B. George[3]

[1]National STD/AIDS Control Program, STD, Colombo, Sri Lanka, [2]FHI360, Colombo, Sri Lanka, [3]FHI360, New Delhi, India

BACKGROUND: In Sri Lanka, HIV testing services are primarily delivered through government-run sexually transmitted disease clinics. Only about 16% of the 1.18 million tests conducted in 2018 were delivered through the private sector, but they contributed to 22% of the 350 PLHIV newly diagnosed during the year. The relatively high case-detection rates associated with private sector testing suggest opportunities for this approach to accelerate achievement of epidemic control in Sri Lanka.

DESCRIPTION: The USAID- and PEPFAR-supported LINKAGES project collaborated with Sri Lanka's National STD/AIDS Control Program (NSACP) to implement social marketing of HIV screening through 146 general practitioners in the private sector. The project strengthened provider capacity to promote and provide HIV screening, make referrals to confirmatory testing and treatment services, and use a mobile application to monitor and improve performance. Around 30% of the providers charged clients USD 3.5 – 5.0 per HIV screening test – as compared to the market rate of USD 10-15 per test – and the remaining 70% provided the screening free of charge.

LESSONS LEARNED: Between October 2018 and September 2019, 1,684 individuals received HIV screening through the socially marketed private sector network. About 60% of clients actively sought HIV screening, while the remaining 40% participated in screening at the recommendation of the provider after presenting at the clinic for other reasons. Participants were predominantly male (60%) and between the ages of 18-25 years, and 68% of them reported previously engaging in high-risk behavior. The proportion of screening participants who were diagnosed with HIV was 0.11%, about ten times higher than the national adult HIV prevalence of 0.01%. All of those diagnosed were linked to confirmatory testing and treatment.

CONCLUSIONS/NEXT STEPS: The Ministry of Health has endorsed this approach and is scaling it up in two new districts with domestic funding. As individuals facing HIV risks increasingly seek services in the private sector, the inclusion of PrEP and HIV treatment services may add value. Social marketing of private sector HIV screening could provide a sustainable and preferred path for many previously undiagnosed PLHIV to access testing and treatment services and reduce the burden on government facilities.

PEE1517

DARUNAVIR IS COST-EFFECTIVE COMPARED TO LOPINAVIR FOR SECOND-LINE TREATMENT IN SUB-SAHARAN AFRICA: A MODELING ANALYSIS

J. Campbell[1], C. Middlecote[2], Z. Panos[2], J. Harwell[3], L. Nyambe[4], S. McGovern[5], V. Prahbu[2], P. Domanico[6], C. Amole[2]
[1]Clinton Health Access Initiative, Analytics and Implementation Research Team, Boston, United States, [2]Clinton Health Access Initiative, HIV Access Program, New York, United States, [3]Clinton Health Access Initiative, Clinical Sciences Team, Boston, United States, [4]Clinton Health Access Initiative, Lusaka, Zambia, [5]Clinton Health Access Initiative, HIV Access Program, Pretoria, South Africa, [6]Clinton Health Access Initiative, Global Health Sciences, Boston, United States

BACKGROUND: The ritonavir-boosted protease inhibitor (PI) darunavir plus ritonavir (DRV/r) is clinically superior to other marketed PIs, including ritonavir-boosted lopinavir (LPV/r); however, it is more expensive compared to other generic alternatives. Low and Middle income countries may not invest in DRV/r without a compelling cost-effectiveness and outcomes research analysis.

METHODS: Health outcomes and costs of DRV/r versus LPV/r over 5-years using a closed cohort Markov state transition model. Inputs were taken from country and region-specific sources and the published literature modeled for a sub-Saharan African country setting assuming 70,000 patients on a second-line PI. Patients can fail treatment, move to third-line (3L), become lost to follow-up, or die at each annual cycle. Mortality, adverse events, opportunistic infections (OI), secondary horizontal infections, and quality-adjusted life years (QALY) outcomes were measured. Costs of ARVs, laboratory tests, human resources, and OI treatment were included. Both incremental (ICER) and average cost-effectiveness (ACER) ratios were evaluated.

RESULTS: DRV/r yielded the following improvements over LPV/r: a 33% reduction in mortality, 32% fewer sexual HIV transmissions, an increase of 23,710 QALYs (10%). Further, 62% of the patient years were spent virally suppressed on DRV/r versus 48% on LPV/r. While overall costs were higher for DRV/r ($116 million) than for LPV/r ($108 million), this was predominantly driven by more patients remaining on treatment longer. The ICER was $330, less than a common standard threshold of $500/QALY, and the ACER was lower for DRV/r scenario ($424/QALY) versus for LVP/r ($432/QALY). The ACER reached equilibrium when 3L coverage for failed 2L patients was reduced to 50% of need, when regimen cost of 3L was reduced by 30%, or when drug failure rates for DRV/r increased by 10% from default values.

CONCLUSIONS: While PI use in 2L treatment may decline in the short-term from transitions to dolutegravir in this population, PI demand is expected to increase in the medium-to-long-term. DRV/r provides a cost-effective alternative to LPV/r with improved clinical outcomes for patients without TB co-infection.

PEE1518

FIRST COMMUNITY LED TRANSGENDER CLINIC IN THE PHILIPPINES SCALE UP ITS REACH TO MORE TRANSGENDER PEOPLE

J.D. Ruanto[1], R. Pagtakhan[2], F.E. Arana[3], J.D.M. Dela Cruz[4]
[1]LoveYourself Inc., Grants Program Department, Mandaluyong City, Philippines, [2]LoveYourself Inc., Board of Trustees, Mandaluyong, Philippines, [3]Victoria By LoveYourself, HIV Operations Department, Pasay City, Philippines, [4]Victoria By LoveYourself, Treatment Hub Department, Pasay, Philippines

BACKGROUND: In 2017, Victoria By LoveYourself the first community led transgender clinic in Philippines opened. It aims to provide HIV testing, treatment services, STI diagnosis, management, transitioning counseling and HRT consultation for the transgender people in the Philippines (Manila).

Victoria developed two level services for its clientele: The first level of services (Level 1) is comprised of HIV screening and counselling services on transgender concerns, basic physical health check-ups, basic baseline laboratory procedures, screening and treatment for sexually transmitted infections (STIs), and referrals to specialists. The second level of services (Level 2) includes hormone management, advanced laboratory procedures, and pre-SRS (sex reassignment surgery) assessment and counseling. It also introduced same day test result, test and treat and ART for PLHIVs.

DESCRIPTION: Victoria offers all level 1 and level 2 services free of charge such as HRT consultation and transitioning counseling.

For 2019, Victoria reached 3,344 individuals through its outreach and community center efforts and tested/counselled 789 transgender clients for both HRT and HIV testing since it opened. 90% of who tested reactive was link to care and 92% who are on treatment is already undetectable.

Victoria in partnership with government agencies, companies, school and universities were also able to deliver SOGISC seminars and workshops to Young Key Population at risk for HIV/AIDS and other STI.

LESSONS LEARNED: Access to healthcare services is a basic right. Everyone is entitled to avail and enjoy the health services that public institutions provide. These services must be given to every individual, regardless of sexual orientation, gender identity, and gender expression (SOGIE).

Transgender people have constantly defined access to health and well being services as one of their top priorities. These range from the simplest and most basic services to the most complicated realms of LGBT psychology, transitioning and gender confirmation surgery.

CONCLUSIONS/NEXT STEPS: Victoria aims to have a sustainable financing for the community center through PhilHealth in 1-2 years time based on the experience of LoveYourself's other community centers – LoveYourself Anglo. Victoria also aims to have their own laboratories and to be a one stop shop ensuring linkage to care for clients who test reactive to HIV.

PEE1519

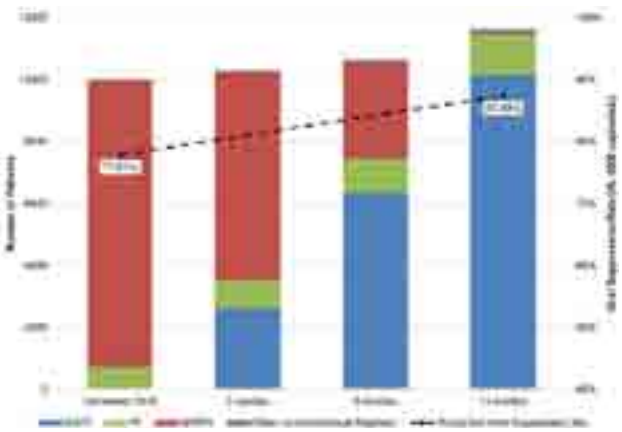
DRAMATIC EFFECT OF MASSIVE DOLUTEGRAVIR IMPLEMENTATION ON VIROLOGIC SUPPRESSION RATES AT THE LARGEST HIV CARE CENTER IN HAITI

B. Liautaud[1], Y. Macius[1], J.E. Mathon[1], A. Dai[2], A. Sanchez[2], R.-I. Verdier[1], C. Guitheau[1], M.A. Jean-Juste[1], F. Homeus[1], K. Sévère[1], J. Bonhomme[1], J.L. Mathurin[1], C. Torrilus[1], S. St Preux[1], A. Apollon[1], M. Cadet[1], S. Pierre[1], P. Sévère[1], R. Secours[1], G. Céus[1], G.P.-L. Florestal[1], L. Pierre[1], J.R. Jeremie[1], H. Théodore[1], M.E. Bélizaire[1], A. Marcelin[1], S. Koenig[3], P. Crémieux[2], M.M. Deschamps[1], J.W. Pape[1], P. Joseph[1]
[1]GHESKIO Centers, Research, Port-au-Prince, Haiti, [2]Analysis Group, Boston, United States, [3]Brigham Women Hospital, Boston, United States

BACKGROUND: In November 2018, the single tablet regimen of tenofovir disoproxil fumarate, lamivudine, and dolutegravir (TLD) became available in Haiti, with a target of 80% implementation at 12 months.

DESCRIPTION: Starting in November 2018, all patients were offered TLD, except for virologically suppressed patients on second-line PI regimens. Counseling was provided for women of childbearing potential, including foetal risks and contraceptive options. Viral load testing was conducted for those with no viral load within 6 months prior to initiation of TLD. After TLD initiation, viral load was conducted at 6 and 12 months. Change in viral suppression rates was compared at GHESKIO at the time when TLD became available and 11 months later.

LESSONS LEARNED: 11,612 active patients (59% female) were potentially eligible for TLD. By 11 months after TLD availability, 10,182 (88%) had initiated TLD. Of these, 1255 (12%) initiated TLD as first-line; 8479 (83%) switched from a first-line NNRTI regimen; and 436 (4%) switched from a second-line PI. During the TLD scale-up period, PI use increased from 7% to 11% of patients, and NNRTI use declined from 92% to <1%. In November 2018, 5398/7377 (73%) of patients at GHESKIO had HIV-1 RNA <40 copies/mL on the most recent viral load test, and 78% had HIV-1 RNA <200 copies/mL (see Figure). In September 2019, 80% of patients had HIV-1 RNA <40 copies/mL and 87% had HIV-1 RNA <200 copies/mL. Among patients with virologic failure, mean HIV-1 RNA was 13,753 copies/mL in November 2018, and 8086 copies/mL in September 2019. The proportion of patients failing ART with HIV-1 RNA >100,000 copies/mL decreased from 11.5% to 6.4% during this period.



[Figure. Change in ARV regimen distribution (November 2018 to September 2019)]

CONCLUSIONS/NEXT STEPS: It is feasible to rapidly implement the TLD regimen. At GHESKIO, 88% of patients were receiving TLD within 11 months after it became available, with dramatic improvements in the proportion of patients with viral suppression

PEE1520

INCREASES IN LINKAGE AND SAME-DAY INITIATION OF ANTIRETROVIRAL THERAPY: FINDINGS FROM THE "SIYENZA" APPROACH IN SOUTH AFRICA

J. Grund[1], S. Porter[1], M. Patton[1], V. Da Costa[1], R. Overmeyer[2], M. Briggs-Hagen[1], R. Lacson[1], J. Paterson[3], D. Rech[4], Y. Pillay[2], A. Herman-Roloff[1]
[1]CDC South Africa, Division of Global HIV & TB, Pretoria, South Africa, [2]National Department of Health, Pretoria, South Africa, [3]Health Systems Trust, Durban, South Africa, [4]The Aurum Institute, Johannesburg, South Africa

BACKGROUND: South Africa (SA) has the largest antiretroviral therapy (ART) program globally, supporting approximately 4.8 million people living with HIV (PLHIV), and it is estimated that there are an additional 3 million PLHIV in need of ART. In February 2019, the President's Emergency Plan for AIDS Relief (PEPFAR) SA launched "Siyenza," an intensive, facility-level surge strategy focused on linkage and retention involving staff from PEPFAR, SA Department of Health (DOH), and PEPFAR-funded District Support Partners (DSPs). A primary goal of Siyenza is to increase linkage from HIV diagnosis to ART initiation. CDC-SA's Siyenza program began in 89 public health facilities in 3 districts.

DESCRIPTION: We analyzed weekly data reported by DSPs in 78 Siyenza facilities during two reporting periods, including the number of PLHIV who tested HIV-positive, the number and proportion of PLHIV who newly initiated ART ever, and the number and proportion of PLHIV who initiated ART on the same day as their HIV diagnosis. Data are reported in two eight-week periods in the beginning of Siyenza (February 8–March 29, 2019; baseline) and during October 4–November 22, 2019 (endline).

LESSONS LEARNED: In the baseline period, 10,720 new PLHIV were identified; of those, 9,999 (93%) ever initiated ART and 7,927 (74%) initiated ART on the same day as diagnosis. In the endline period, 9,493 new PLHIV were identified; of those, 9,142 PLHIV initiated ART (96%) and 7,570 (80%) initiated ART on the same day. Among PLHIV who ever initiated ART, same-day initiation significantly increased from 79% in the baseline period to 83% in the endline period ($p<.05$).

CONCLUSIONS/NEXT STEPS: Using a hands-on, intensive approach was associated with an increased proportion of PLHIV initiating ART on the same day as their HIV diagnosis in CDC-supported Siyenza facilities. Prioritization of same-day ART initiation at Siyenza facilities by all stakeholders—CDC, DSPs, and DOH clinical staff—resulted in rapid improvement. Scaling up this intensive approach helps programs reach epidemic control in settings with large HIV epidemics. Additional interventions are needed to identify additional PLHIV not on ART and to initiate them on to life-saving ART in SA.

PEE1521

I-SURGE STRATEGY IN SOUTH SUDAN: IMPROVING HIV CASE IDENTIFICATION AND ART ENROLLMENT ACROSS HEALTH FACILITIES IN SOUTH SUDAN

H. Ayalneh[1], S. Aragaw[1], F. Bayoa[1], K. Hartsough[1], S. Michaels-Strasser[1]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States

BACKGROUND: Improved HIV service provision for people living with HIV (PLHIV) and, ultimately, achievement of epidemic control can be met through reaching program targets. ICAP implemented an intensive strategy to improve identification of PLHIV and linkage to antiretroviral therapy (ART) services in health facilities (HF) in South Sudan.

DESCRIPTION: In March 2018, ICAP implemented an intensive human resources and data management approach, the ICAP surge (I-Surge) strategy, in 14 HF located in high and medium HIV priority locations across South Sudan to rapidly improve program performance and meet program targets around case finding and linkage to ART.

Components of the I-Surge strategy included: an ICAP point of contact (POC) assigned to each HF to support activities, daily monitoring of key performance indicators vis-à-vis facility-level program targets, sharing of daily achievements, experiences, challenges via WhatsApp to aid real time discussions on effective strategies, management of challenges as they emerge and feedback on key program issues and resolutions. Tools were developed to break down daily activities into discrete steps and decision trees. Weekly and monthly performance reviews were conducted with ICAP and HF staff to identify performance gaps and develop resolutions.

LESSONS LEARNED: Challenges at I-Surge onset were shifting the mindset of staff at all levels to adapt to the intensive granular site management approach, and support for internet connectivity for daily data sharing. I-Surge resulted in increased staff involvement at facility level, identification of site-specific gaps, prompt institution of corrective measures on emerging challenges, greatly improved data management and tracking of program performance, and improved strategic onsite mentorship visits to supported HF. In six months across the 14 sites, case identification increased by 10% (from 1,093 to 1,182), yield increased from 2.8% to 4.5%, new ART initiations increased by 42% (829 to 1,177), and linkage to ART from 61% to 91%.

CONCLUSIONS/NEXT STEPS: The I-Surge approach, a new model of site support, improved case identification and linkage to ART, and showed that real time data reporting and data driven decision-making improves program performance. ICAP is working to apply the same approach to improve ART retention through rapid identification of missed clients and initiation of tracking activities.

PEE1522

TURNING THE TIDE IN REACHING MALES 15-29 YEARS-OLD USING A MULTIFACETED DEMAND CREATION APPROACH - WESTERN PROVINCE, ZAMBIA, 2018-2019

O. Chituwo[1], B. Jere[2], M. Daka[3], L.-L. Liyabola[2], C. Bolton[2], J.Z. Hines[1]
[1]Center for Disease Control and Prevention, Lusaka, Zambia, [2]Centre for Infectious Diseases Research in Zambia, Lusaka, Zambia, [3]Ministry of Health, Mongu, Zambia

BACKGROUND: Voluntary Medical male circumcision (VMMC) prevents male acquisition of HIV by 60% (Auvert B et al 2005). To maximize the impact on the HIV epidemic, Zambia has implemented the 'age pivot' prioritizing males 15-29 years-old for VMMC. Western Province, Zambia, has faced a challenge implementing the age pivot because some tribes practice traditional circumcision of younger boys (i.e., <10 years). In 2019, a multifaceted strategy for improving uptake in 15-29-year-olds—consisting of engaging traditional structures, implementing a human-centered design demand creation approach, increasing the number of trained mobilizers and providing them with individual targets, and offering regular service hours rather than employing a school holiday-based campaign strategy—was undertaken. An analysis was conducted to determine if this approach coincided with improved achievement of the age pivot in Western Province.

DESCRIPTION: The US Presidential Emergency Plan for Aids Relief (PEPFAR) supports two implementing partners— Centre for Infectious Disease Research in Zambia (CIDRZ) and the Western Provincial Health Office (WPHO) — to perform VMMCs in 10 and 5 districts in Western Province, respectively. These partners report age-disaggregated VMMC data to CDC quarterly. A difference-in-difference analysis of the proportion of VMMC clients aged 15-29 years in 2018 and 2019 was conducted between CIDRZ and WPHO using repeated measures ANOVA.

LESSONS LEARNED: From 2018 to 2019, the number of VMMCs performed by CIDRZ increased from 5,918 to 20,140 (this was despite no increase in targets for CIDRZ). Over this time period, the performance of WHPO declined from 10,560 to 4,725. The proportion of men aged 15-29 years increased for CIDRZ (51% to 70%, p<0.01) and WPHO (43% to 49%, p<0.01) from 2018 to 2019. The difference in increase between CIDRZ and WPHO from 2018 to 2019 was statistically significant (p=0.02).

CONCLUSIONS/NEXT STEPS: A multifaceted approach to creating demand for VMMC in the community among men 15-29 years old was associated with an increase in overall VMMC performance and uptake among this target age group. Further scaling of this approach to other areas and partners may result in similar improvements, helping to reach overarching VMMC program targets.

PEE1523

IMPROVEMENTS IN HIV CASE FINDING, ART INITIATION, AND TOTAL PATIENTS ON ART FOLLOWING SITE-LEVEL "SIYENZA" INTERVENTION IN CDC-SUPPORTED SOUTH AFRICA HEALTH FACILITIES – FEBRUARY-SEPTEMBER 2019

S. Porter[1], J. Grund[1], M. Patton[1], M. Briggs-Hagan[1], R. Overmeyer[2], R. Taback-Esra[1], M. Ndlovu[1], R. Machava[1], A. Ochieng[1], R. Lacson[1], J. Paterson[3], D. Rech[4], H. Hausler[5], Y. Pillay[2], A. Herman-Roloff[1]
[1]Centers for Disease Control and Prevention (CDC), Pretoria, South Africa, [2]South Africa National Department of Health, Pretoria, South Africa, [3]Health Systems Trust, Durban, South Africa, [4]The Aurum Institute, Johannesburg, South Africa, [5]TB HIV Care, Cape Town, South Africa

BACKGROUND: In February 2019, the President's Emergency Plan for AIDS Relief (PEPFAR) in South Africa (SA) launched an intensive site-level support and monitoring initiative ("Siyenza") to improve HIV case finding, ART initiation, and retention, supporting the SA National Department of Health (NDOH) goal of adding 2 million PLHIV on ART by 2020. CDC-SA implements the Siyenza package in a subset of facilities that comprise 45% of the people living with HIV (PLHIV) on antiretroviral therapy (ART) supported by CDC-SA. The Siyenza package includes placement of additional CDC-supported district support partner (DSP) staff focusing on ART initiation, treatment retention, and data quality, augmented by weekly supportive visits by CDC-SA and DSP staff and daily monitoring of site performance.

DESCRIPTION: We analyzed aggregate quarterly facility data reported to CDC-SA in large (>1,000 PLHIV on ART) Siyenza facilities, comparing growth from the pre-intervention reporting quarter (October 1-December 31, 2018) to the quarter nine months later (July 1-September 30, 2019). We excluded facilities in which a CDC-supported DSP did not report in both periods and facilities with partial (

LESSONS LEARNED: Data from 127 Siyenza facilities were included in this analysis. In these facilities, all measured outcomes increased in the measurement period. Cases identified increased from 17,915 to 24,682 (38%), ART initiations increased from 17,735 to 25,196 (42%), and PLHIV on ART increased from 410,262 to 490,800 (20%).

CONCLUSIONS/NEXT STEPS: Performance improved overall during the measurement period on all outcomes assessed. Placement of additional staff, focus on ART initiation and retention, and daily reporting with immediate course correction likely contributed to the improvements observed in Siyenza facilities. PEPFAR SA and the NDOH continue to collaborate on the national HIV response through expanded implementation of this site-focused support strategy.

PEE1524

DESIGN, IMPLEMENTATION, AND MONITORING OF HIV SERVICE PACKAGES FOR FEMALE SEX WORKERS: A FIELD ASSESSMENT OF 19 NATIONAL PROGRAMS

L. McCallum[1], H. Falkenberry[1], D. Parsons[1], D. Burrows[1], S. Wedmedyk[1], J. Zhao[2]
[1]APMG Health, Washington, United States, [2]The Global Fund, Geneva, Switzerland

BACKGROUND: In order to prevent, diagnose, and treat HIV among sex workers (SW), many countries worldwide have outlined national service packages. APMG Health, with funding from The Global Fund, conducted field evaluations on the design, implementation, and monitoring of HIV service packages for SW and other key populations (KP) in 19 countries: Angola, Armenia, Benin, Cameroon, Guyana, Haiti, Indonesia, Kenya, Kyrgyz Republic, Madagascar, Malawi, Mali, Morocco, Papua New Guinea, Sierra Leone, South Africa, Sudan, Togo, and Uzbekistan.

METHODS: A preliminary desk review was conducted, followed by a five to ten-day in-country field visit by international and local consultants. Data was collected through: document review; key informant interviews with national stakeholders; visits to sites where packages are implemented, including observation of service delivery; interviews with staff; focus group discussions with SW receiving services; and examination of monitoring forms, methods, and databases.

RESULTS: All assessed countries have designed and implemented specific service packages to best serve SW according to World Health Organization (WHO) guidelines; however, not all countries could successfully implement or monitor the delivery of all or most elements of the packages. Coverage rates, quality of services, and outcomes on programming targets are not consistent. While all countries provide HIV testing services, antiretroviral therapy (ART), and the provision of male condoms, other recommended activities such as mental health services, community empowerment, and addressing stigma and violence are seldom addressed or non-existent. Most countries suffer from insufficient and/or problematic client tracking systems for monitoring the provided services.

CONCLUSIONS: Through all aspects of the design, implementation, and monitoring of national HIV strategies, many countries fail to uphold the standards outlined in their packages of services, revealing large gaps in their fundamental design. Efforts for effective monitoring of services are threatened by issues with data quality, inefficiency of reporting methods, and poor data security. For improved adherence to WHO guidelines for packages of services for SW, countries should focus on implementation and data quality and consistency while redesigning packages to emphasize often neglected services.

PEE1525

ACHIEVING EPIDEMIC CONTROL: THE 95-95-95 OUTCOMES OF DAILY DATA REVIEW AND USE IN ZAMBIA'S EASTERN AND WESTERN PROVINCES

T. Mukwa Malebe[1], P. Kasonde[1], P. Koni[1], L. Parmley[1], F. Ndagije[1], S. Michaels-Strasser[1]
[1]ICAP at Columbia University, Mailman School of Public Health, New York, United States

BACKGROUND: Reaching the last mile in achieving HIV epidemic control requires innovative and active data use which allows for immediate identification of missed opportunities and service gaps. While progress toward reaching the UNAIDS 95-95-95 targets has been made in recent years, health facilities continue to face challenges in utilizing data and monitoring program performance to reach the last mile. ICAP in Zambia, through CDC funding, and in partnership with the provincial health offices in Eastern and Western provinces, supported the implementation of daily data review for performance tracking and real time action in 35 high-volume sites.

DESCRIPTION: ICAP supported daily data review of select key indicators mapped to 95-95-95 objectives at 35 sites between October 2018 – September 2019, with the aim to reduce missed opportunities for HIV testing, linkage, treatment, and retention in care. Health care workers at site-level were supported to review and monitor indicators daily for real time corrective actions with ICAP focal point persons who led data review, while provincial health teams reviewed site-level data weekly. Daily feedback on performance reporting and sharing of results and lessons learned with site, district, and provincial health teams were facilitated via WhatsApp groups.

LESSONS LEARNED: After implementing daily data review, both provinces saw marked improvements in 95-95-95 indicators. In one year of implementation, positivity yield increased from 4.6% to 14.7% and from 3.1% to 6.1% in Western and Eastern provinces respectively. The number of patients newly initiated on antiretroviral therapy increased from 239 to 636 and 486 to 648 and viral load suppression among patients with a documented viral load increased from 62% to 86% and from 84% to 94% in Western and Eastern provinces respectively.

CONCLUSIONS/NEXT STEPS: Daily data review and use for real time decision making at site-level is feasible and appears to play an important role in improving program performance toward reaching 95-95-95. Other concurrent interventions such as the use of new screening tools and community-based interventions may also play a role. Further study is warranted. Replication in other settings to reduce missed opportunities is strongly encouraged.

PEE1526

GEENIUS HIV 1/2 SUPPLEMENTAL ASSAY POINT-OF-CARE TESTING REDUCES TIME TO INITIATE ANTIRETROVIRAL THERAPY

J. Broussard[1], P.-C. Crouch[2], B. Taylor[1], J. Alvarez[1], M. Chavez[1], R.M. Grant[1,2]
[1]San Francisco AIDS Foundation, San Francisco, United States, [2]University of California, San Francisco, United States

BACKGROUND: Point of care HIV tests are an essential part of HIV screening but due to false positives, confirmatory testing is needed to provide an accurate diagnosis prior to starting HIV antiretrovirals (ARV). At Magnet, a nurse-led clinic in San Francisco with a moderate complexity lab, a 2nd generation rapid test for initial screening

was used with a standard HIV confirmatory test panel having a 3-day turn around. To address this delay, an HIV 1/2 supplemental assay was implemented as a point of care confirmatory test.

DESCRIPTION: Individuals who have a positive point of care 2nd generation result immediately received an HIV 1/2 supplemental assay (Geenius, Bio-Rad), and a specimen is sent to a central public health laboratory for standard confirmatory testing (lab based 4th generation HIV-1 Ab/Ag). Individuals with a positive HIV 1/2 supplemental assay were offered immediate initiation of ARVs. Individuals with a negative result were not started on ARVs and received a follow-up phone call with the confirmatory result.

LESSONS LEARNED: From July 2017 to December 2019, there were 118 positive 2nd generation tests. Among these, the HIV supplemental assay was positive in 61, negative in 52, and indeterminant in 5. The HIV supplemental test was 100% concordant with the gold standard lab based confirmatory test. The average age of Geenius test clients was 34; 25% were white, 25% Latinx/Hispanic, 20% multiple races, 11% Asian, 8% black, 11% other/unknown. Implementing the point of care HIV 1/2 supplemental assay reduced the time to a confirmatory result from 3 days to 0 days. The majority of persons who had a positive supplemental test result accepted the offer of immediate ARVs.

CONCLUSIONS/NEXT STEPS: Using confirmatory point of care testing decreases the number of false-positive second generation HIV test results disclosed to individuals, and shortens the time to initiation of antiretroviral therapy from 3 days to zero days. More rapid definitive results also reduced anxiety for clients.

PEE1527

OPTIMIZING TESTING INCREASES YIELD IN HIV CASE FINDING IN THE DEMOCRATIC REPUBLIC OF THE CONGO (2018-2019)

E. Mukinda[1], E. Shahul[2], F. Kitenge[1], V. Makwelebi[1], H. Longuma[1], M.-L. Batumbula[1], M. Mpingulu Bila[1], P. Fonjungo[1], C. Kabwe[1], R. Ewetola[1], P. Raghunathan[1], L.-F. Kamanga[3], R. Chuy[3], S. Behel[2], F. Malele[4], T. Tchissambou[4], A. Loando[5], V. Ilunga[5], D. Matshifi[6], L. Yabadile[6]
[1]US Center of Disease Control and Prevention (CDC), Kinshasa, Congo, Democratic Republic of the, [2]US Center of Disease Control and Prevention (CDC), Atlanta, United States, [3]Programme National de Lutte contre le VIH (PNLS)/MOH, Kinshasa, Congo, Democratic Republic of the, [4]Columbia University-ICAP DRC, Kinshasa, Congo, Democratic Republic of the, [5]Elisabeth Glaser Pediatric AIDS Foundation (EGPAF), DRC, Kinshasa, Congo, Democratic Republic of the, [6]Santé Rurale (SANRU), DRC, Kinshasa, Congo, Democratic Republic of the

BACKGROUND: In compliance with U.S. President's Emergency Plan for AIDS Relief (PEFAR) recommendation for boosting the first 90 target (90% of people living with HIV know their HIV status) of the UNAIDS strategy, the US Center for Diseases Control and Prevention (CDC) in DRC adopted the optimization of provider-initiated testing and counseling services in 2018. We assessed the impact of these changes in HIV-testing modalities

DESCRIPTION: We used routine HIV testing data from 314 PEPFAR/CDC facilities that reported, Fiscal Year (FY) 2018 and 2019. We compared fourth quarter (Q4) of FY 2018 and Q4 of FY 2019 and calculated the number of HIV tests and the yield (percentage of HIV-positive tests) by testing modality

LESSONS LEARNED: Overall, HIV test volume increased by 6.8%, and the number of HIV-positive results increased by 23.4%, whereas overall yield increased by 18% (3.9% to 4.6%). In 2019, the 5 modalities that contributed to most (85%) of the HIV test volume were routine PITC in outpatient departments (OPDs; excluding emergency rooms, and tuberculosis and sexually transmitted infection clinics; 39.8%), prenatal clinics (28.8%), mobile clinics (6.7%), Inpatient (5.3%) and contact testing (3.8%) Between 2018 and 2019, test volume increased in PMTCT, inpatient, mobile clinics and others, but decreased in Other PITC and contact testing (Table). PITC in OPDs remained the leading contributor to the number of HIV-positive results, but the contribution of this modality to overall HIV-positive results decreased from 56% in 2018 to 44% in 2019. By modality, contact testing had the highest yield (15.6%, 2018; 25.8%, 2019) and was the second largest contributor to overall HIV-positive results (4,215/20,326 [20.7%]) in 2019. Increased test volume in antenatal clinics (28.8% of all tests in 2019) did not increase yield (2018,0.95%; 2019, 0.90%). Nevertheless, increase in mobile clinics testing (6.7% of overall 2019 tests) resulted in increase of 69% yield

CONCLUSIONS/NEXT STEPS: Overall, optimization of HIV testing services enabled DRC to achieve relative increases in case finding between 2018 and 2019. Both yield and absolute number of cases should be considered in assessing the impact of scale-up of contact testing and optimization of case-finding approaches

METHODS TO IMPROVE SERVICE QUALITY, SUPPORT AND TAILORING OF SERVICES

PEE1528

IMPROVING EARLY RETENTION RATES AMONG NEW HIV POSITIVE CLIENTS INITIATING ART THROUGH QUALITY IMPROVEMENT APPROACHES AT FORT PORTAL REGIONAL REFERRAL HOSPITAL (FPRRH)

L. Abesiga[1], G. Kisitu[2], W. Akobye[2], F. Tugumisirize[1], C. Kamusiime[1]
[1]Fort Portal Regional Referral Hospital, Medical, Kampala, Uganda, [2]Baylor, Medical, Kampala, Uganda

BACKGROUND: With the launch of intensified HIV case identification in Uganda in 2019, people living with HIV (PLHIV) were identified and rapidly initiated on anti-retroviral therapy (ART) at facility and community level. In February-2019, only 35% of PLHIV returned within one month of initiating ART. This presented a risk of poor adherence to care, lost opportunity for pharmacovigilance, and a risk of drug resistance. We set out to improve early retention (proportion of clients newly enrolled on ART returning to the facility within one month) from 35% in February-2019 to 85% by January-2020 at Fort Portal Regional Referral Hospital.

DESCRIPTION: We conducted brainstorming sessions with representatives from health facility, expert clients, volunteers, community based organization and People Living with HIV Network at FPRRH for root causes on low early retention. Using the focusing matrix, we prioritized interventions to address complex clinic flow, lack of health education talking points on retention, poor documentation in the appointment registers, incomplete/outdated client locator information and inadequate counseling. Interventions included; labeling all rooms in the clinic, escorting new PLHIV to the enrolment office to avoid long queues, coaching on use of client locator forms, appointment reminders, disseminating counseling messages and health education talking points, weekly tracking of progress. Data was extracted from appointment registers and analyzed as proportions using Microsoft spreadsheets.

LESSONS LEARNED: 668 patients were rapidly initiated on ART between February and August 2019. Early retention increased from 35% in Feb-19 to 97% in Oct-19 as shown in figure 1. Weekly tracking

caused the biggest rise in retention rates. Escorting clients to points of care, phone call reminders and introduction of early retention track counter book worked as well, as shown in figure 1.

[Figure 1. Percentage of newly enrolled clients who return within a month of initiating ART at FPRRH.]

CONCLUSIONS/NEXT STEPS: Early retention among new clients on ART improved with concerted quality improvement initiatives. We recommend proactive tracking to support clients to remain in care.

PEE1529

PROGRESS TOWARDS 90-90-90 FOR PRISONERS IN PRISONS PROVIDING DIRECT HIV SERVICES VERSUS SERVICES VIA REFERRAL, UGANDA: A CASCADE ANALYSIS FOR 2017-2018

G. Bahizi[1], A. Mubiru[2], S. Sendagala[2], S. Kabwama[1], Y. Wibaraba[1], B. Kwesiga[1], A.R. Ario[1], J. Kisambu[3], L.A. Mills[2]
[1]Uganda Public Health Fellowship Program, Ministry of Health, Kampala, Uganda, [2]Centers for Disease Control and Prevention, Kampala, Uganda, [3]Uganda Prisons Services, Ministry of Internal Affairs, Kampala, Uganda

BACKGROUND: Ugandan prisoners have higher-than-national HIV prevalence (14% v. 6.2%) and are a key population for epidemic control efforts. Uganda's prisons provide HIV testing and Antiretroviral Therapy (ART) through in-house models (testing and ART directly provided within prisons by prison health staff) or referral models (services from external providers entering the prison or at nearby public health facilities with or without prisoners). We characterized the cascade of HIV care among prisoners for the two models and described barriers to favorable outcomes at key cascade steps.

METHODS: We conducted a retrospective cohort analysis from January 2017 to December 2018. Data were collected from four prisons, two with referral services and two with in-house services. Prisoners were identified in HIV testing registers and ART registers. Viral loads (VL) were obtained from patient files and the Uganda national VL database. HIV cascade achievements measured at year-end were: Testing completeness (proportion of all inmates who knew their HIV status), Treatment initiation completeness (proportion of HIV-positive inmates who had initiated ART), and VL suppression (proportion of HIV-positive inmates on ART with ≥1 VL result who were virologically suppressed (<1000 copies/mL)). Structured interviews were conducted in the 4 facilities with health workers charged with HIV service provision to identify barriers to HIV care for prisoners.

RESULTS: Barriers in prisons operating both models included inadequate clinic space, staffing, and staff training, and uncoordinated prisoner releases and transfers (often before ART initiation or VL testing; limited paper records inaccessible to future providers). For referral-model prisons, limited outside organization funding and staffing, security challenges in transporting prisoners to outside clinics, and limited opportunities for outside organization staff to enter prisons were also identified.

Cascade step	All prisoners N=6803	In-House Testing & Treatment N=5922	Referral Testing & Treatment N=881
HIV Testing Completeness	87% (5924)	91% (5380)	62% (544)
HIV-Positive	12% (717/5924)	10% (546/5380)	31% (171/544)
Treatment Initiation Completeness	70% (503/717)	79% (429/546)	43% (74/171)
Viral Load Testing Completeness	30% (151/503)	32% (137/429)	10% (8/74)
Viral Load Suppression	92% (139/151)	98% (135/137)	50% (4/8)

[Table]

CONCLUSIONS: In-house services yielded better performance than referral. Both had gaps in VL testing. Limited human resources and uncoordinated prisoner transfers and releases were barriers to comprehensive HIV services. We recommend in-house testing and ART in all prisons where possible, and electronic medical records to improve continuity of care.

PEE1530

PEER NAVIGATION IMPROVES UPTAKE OF ANTIRETROVIRAL THERAPY FOR KEY POPULATIONS IN BOTSWANA

W. Dikobe[1], O. Komotere[1], V. Ranebennur[2], R. Kereng[1], M. Gilbert-Lephodisa[1], T. Dima[1], C. Akolo[2]
[1]FHI 360, Linkages Across the Continuum of HIV Services for Key Populations Affected by HIV (LINKAGES) Project, Gaborone, Botswana, [2]FHI 360, Linkages Across the Continuum of HIV Services for Key Populations Affected by HIV (LINKAGES), Washington, United States

BACKGROUND: Fast-tracking members of key populations (KPs) to antiretroviral therapy (ART) reduces onward transmission of HIV to their clients by ensuring immediate access to treatment and, ultimately, viral suppression. Poor linkage to treatment challenges epidemic control. Factors contributing to non-linkage include passive referrals for initiation, lack of psychosocial support, and stigma and discrimination. Peer-led approaches have been shown to be effective in successful linkage and retention of individuals on treatment. We report the impact of peer navigation on prompt linkage of HIV-positive KP individuals to ART in Botswana.

DESCRIPTION: Between October 2015 and September 2019, the PEPFAR/USAID-funded LINKAGES project implemented interventions to address the HIV epidemic among KPs in Botswana. Peer navigation was introduced toward the end of the third year of implementation as an additional intervention to improve access to HIV care and treatment services. Peer navigators were trained on interpersonal skills and motivational communication to help build rapport with peers and navigate them to treatment facilities. They acted as case managers, sharing their experiences on living with HIV, and providing psychosocial support and treatment literacy to peers newly diagnosed with HIV. They continued to provide support through regular phone check-ups and home visits to ensure long term adherence and retention on ART.

LESSONS LEARNED: Over the life of project, a total of 1,758 FSWs and MSM were diagnosed with HIV, and more than 80% were successfully initiated on treatment. Following the introduction of peer navi-

gation, treatment initiation improved from 49% in year three to 89% in year four for MSM. For FSWs, treatment initiation increased from 54% in year three to 105% in year four, as peer navigators successfully linked both new and previously diagnosed FSWs to treatment.

CONCLUSIONS/NEXT STEPS: Peer-led strategies, such as peer navigation are effective in linking KPs to care and treatment. This strategy has been integrated into the KP programs nationwide to help people living with HIV link to treatment early and remain on treatment.

PEE1531

MYSTERY MEN: DO WE KNOW ENOUGH ABOUT THE MALE SEXUAL PARTNERS OF AGYW? DOCUMENTING MALE CHARACTERISATION RESEARCH TO TARGET AND INCLUDE MEN IN HIV PREVENTION PROGRAMMING

S. Magni[1], T. Fellows[1], S. Chan[1], J. Michalow[1], G. Dallabetta[2], S. Johnson[1]
[1]Genesis Analytics, Health Practice, Johannesburg, South Africa, [2]Bill and Melinda Gates Foundation, Seattle, United States

BACKGROUND: HIV prevention programming for adolescent girls and young women increasingly aims to involve their male sexual partners (MSPs). Research to characterise MSPs is needed to tailor services effectively. We aimed to document the extent to which this has been done, the methods used, and the use of results to inform programming in ten high-burden countries in sub-Saharan Africa.

METHODS: In order to identify studies, document findings, and describe how these have informed programming, our methods comprised desktop reviews and stakeholder interviews. We reviewed existing MSP-related research from all ten countries. We conducted 133 interviews with key informants and 29 focus group discussions with 245 programme implementers. Thematic content analysis was conducted.

RESULTS: Thirteen formal studies, which specifically aimed to characterise MSPs of AGYW, were identified in nine of the ten countries (all but Tanzania). Methods used varied considerably. Nine programmatic studies were identified in four countries (Kenya, Malawi, Tanzania, and Uganda). These studies made use of Population Council's ASERT™ (Ascertaining Sexual Relationship Types) tool.

Research to characterise MSPs of AGYW exists, but it was not being conducted consistently, and results were not being presented in a user-friendly manner and lacked clear programme recommendations for tailoring services. Most programme implementers were not aware of the formal research conducted in their own countries, nor were they aware of research other organisations had undertaken. Few were able to clearly articulate the findings or how they have been (or should be) used to inform programming. Some implementers had used research findings to inform where they reach men, rather than who they target.

CONCLUSIONS: Several methods have been used across countries to characterise MSPs, although the use of the results for tailoring programming has been varied. Recommendations for building capacity to improve male characterisation research include: use of ASERT™ tool across countries with guidelines on analysing and presenting data in user-friendly formats; inclusion of psycho-behavioural information to develop personas; and identification of priority MSP segments. The population size of these priority segments should be estimated.

PEE1532

VIKELA EKHAYA: A NOVEL STRATEGY TO ENHANCE HOUSEHOLD TB CONTACT MANAGEMENT IN THE HHOHHO REGION, ESWATINI

G. Mtetwa[1], M. Sandoval[2], T. Devezin[2], M. Matsenjwa[1], G.S. Dube[3], J. Sibanda[3], S. Masuku[3], N. Thivalapill[4], B. Lukhele[1], M. Mkhabela[1], B. Ndlovu[1], H. Gama[1], A. Mandalakas[2], A. Kay[2,1]
[1]Baylor Children's Foundation, Mbabane, Eswatini, [2]Baylor College of Medicine, Pediatrics, Houston, United States, [3]Eswatini National Tuberculosis Program, Manzini, Eswatini, [4]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States

BACKGROUND: In Eswatini, 71% of TB cases are HIV-positive and TB preventive therapy (TPT) uptake among children under-five is less than 12%. Vikela Ekhaya (Protect the Home) aims to deliver home-based HIV/TB diagnostics and TPT among household contacts of TB cases in the Hhohho region of Eswatini.

DESCRIPTION: Mobile Outreach Teams (MOTs), consisting of nurses and HIV Testing Services (HTS) officers, coordinate with Basic Management Units (BMUs) through a mobile application to locate and provide home-based care to household contacts of TB cases. Eligible contacts are provided with HTS, TB screening and TPT using new shorter rifampicin-based regimens. Presumptive TB cases are referred to BMUs for further evaluation. Families who decline household-based care are given the option for clinic-based evaluation and follow-up.

LESSONS LEARNED: Between May 2019 to September 2019, 166 community homes had been visited by MOTs, with 367 follow-up visits. 160/164 (98%) of eligible under-five contacts were initiated on TPT with 98% retention or completion. 41/42 eligible PLHIV initiated TPT with 93% retention. 639 total household contacts were evaluated, 55 with presumptive TB from which three TB cases were diagnosed. 48 of 68 contacts with an unknown HIV status accepted testing, four of whom tested positive and were linked to care. Qualitative interviews with project participants revealed that household-based care abated some of the largest structural challenges. associated with TB contact management. Transport, out of pocket expenditures and clinic access were some of the barriers identified. Interviews with project members revealed personal and professional fulfillment in identifying those most at risk for TB, and operational challenges associated with community implementation.

CONCLUSIONS/NEXT STEPS: Findings revealed that TB screening, initiation and completion of TPT for contacts under-five and HIV positive contacts of TB cases is greatly enhanced when home-based contact management is offered. Shorter rifampicin based TPT may also increase uptake and completion of TPT. In addition, previously unknown HIV positive persons can be identified with this strategy. Implementation within public health programs, enhanced communication and reporting strategies, and assessments of cost effectiveness are now needed to more comprehensively evaluate the potential of home-based TB contact management.

PEE1533

EVIDENCE OF A QUALITY IMPROVEMENT-GUIDED INTERVENTION TO IMPROVE AVAILABILITY OF VIRAL LOAD RESULTS AMONG PREGNANT AND LACTATING WOMEN RECEIVING CARE AT A LARGE HIV CLINIC IN RURAL ZAMBÉZIA, MOZAMBIQUE

S. Van Rompaey[1], R. Pinto[2], J.A. Tique[1], B. Tadeu[2], C. Cabsela[2], J. Fataha[2], A. Inácio[3], W. Silva[1], J. Matsimbe[2], P. Gonzalez[2], J. Greenberg-Cowan[4], A. Nguimfack[4], C. De Schacht[1], C.W. Wester[5,6]

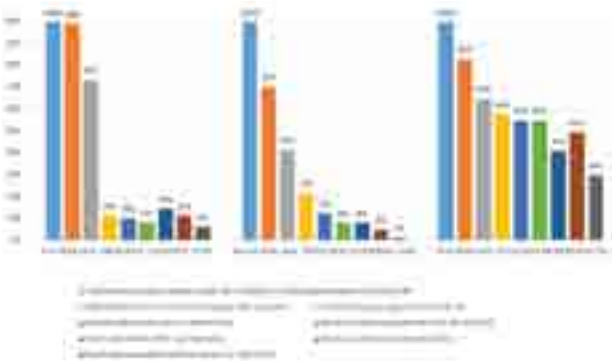
[1]Friends in Global Health, Maputo, Mozambique, [2]Friends in Global Health, Quelimane, Quelimane, Mozambique, [3]Provincial Health Directorate, Quelimane, Mozambique, [4]Centers for Disease Control and Prevention (CDC), Maputo, Mozambique, [5]Vanderbilt Institute of Global Health, Nashville, United States, [6]Vanderbilt University Medical Center (VUMC), Department of Medicine, Nashville, United States

BACKGROUND: In Mozambique, routine viral load (VL) testing for pregnant/lactating women (PLW) is performed three months following antiretroviral therapy (ART) initiation and thereafter on a yearly basis. To improve availability of VL results, Quality Improvement (QI) activities included mentoring of clinicians and counselors on a bi-weekly basis and placement of VL request reminders within clinical files (CF). In May 2019, a specific VL result tracking tool was introduced along with real-time provision of feedback to HF personnel regarding performance towards weekly targets.

DESCRIPTION: To identify bottlenecks, we evaluated steps along the prevention of mother-to-child transmission (PMTCT) VL continuum, from test request through result communication to patients in Namacurra Sede health facility (HF). We report results from three Plan-Do-Study-Action (PDSA) cycles.

LESSONS LEARNED: Data included all HIV-positive PLW, eligible for initial VL testing within three PDSA cycles (Cycle 1: September 21–December 20, 2017; Cycle 2: September 21–December 20, 2018; Cycle 3: March 21–June 20, 2019). Eligibility for initial VL testing was defined as having consistent ART pick-ups for 3 months.

Descriptive analysis was performed on indicators including VL requisition, results entry into electronic patient tracking system, placement of results into CF, and communication of results to the patient.



[Figure 1. Namacurra health facility pregnant and lactating women viral load continuum]

Initially, clinicians significantly under-requested VL among PLW eligible for their first VL test. Subsequent barriers included problems with result availability in CF and limited communication of results to patients.

Following introduction of the third QI PDSA Cycle, improvements were seen in VL requisitions (from 22% to 58%), insertion of VL results into the CF (5% to 49%) and communication of results to patients (1% to 30%).

CONCLUSIONS/NEXT STEPS: Intensive monitoring of process measures targeting observed constraints within the PMTCT VL continuum led to improvements crucial for PMTCT. Based on these preliminary successes, we have expanded this approach to 20 high-volume HF in Zambézia Province.

PEE1534

HOW DO WE TAILOR SERVICES TO MEET YOUNG PEOPLE'S NEEDS? A DISCRETE CHOICE EXPERIMENT TO DETERMINE PREFERENCES OF HIGH SCHOOL STUDENTS IN GAUTENG FOR ACCESSING HIV AND CONTRACEPTIVE SERVICES

S. Pascoe[1,2], C. Govathson[1,2], S. Mngadi[1,2], A. Moolla[1,2], C. Mongwenyana[1,2], N. Ngcobo[1,2], L. Long[1,2,3]

[1]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Internal Medicine, Johannesburg, South Africa, [3]Boston University School of Public Health, Department of Global Health, Boston, United States

BACKGROUND: The South African government has implemented the Integrated School Health Policy and related programmes to address HIV prevention and reproductive health needs among adolescents. To improve uptake of these services it is important to understand the preferences of students for how these programs are delivered so that implementation strategies can reflect this.

METHODS: A discrete choice experiment (DCE) was used to estimate preferences. The DCE was conducted in 10 high schools situated in neighbourhoods of varying socio-economic status (SES) in Gauteng (South Africa). Students aged ≥15 years(Grades 9-12) were consented and enrolled in the DCE. Mixed effects logistic regression was used to determine preferred attributes for HIV and contraceptive service delivery. Results were stratified by gender and the neighbourhood SES (where quintile 1=Low SES and 5=High SES)

RESULTS: The DCE was completed between 07/2018-09/2019; 805 students were enrolled (68% female; 66% 15-17 years; 51% in grades 9-10). 54% of students in quintile 1 schools had no monthly income; 38% in quintile 5 schools had access to> USD7 per month. Preferences were similar for male and female students. Students strongly preferred services provided by friendly, non-judgemental staff (Odds ratio 2.66; 95% Confidence Interval: 2.47-2.87) where confidentiality was ensured(1.79; 1.66-1.93). They preferred services offered after school (1.15; 1.03-1.27) with value-added services like free Wi-Fi(1.18; 1.00-1.38), food(1.23; 1.11-1.37) and youth-only waiting areas (1.18; 1.06-1.31). Students did not have a specific location preference, but preferred not to receive services within the community(0.83; 0.74-0.92). Students attending schools in high SES neighbourhoods expressed a preference for private care(1.27; 1.06-1.53). Costs to access services were a deterrent for most students irrespective of school neighbourhood; female students were deterred by costs ≥USD3 (0.79; 0.70-0.91); males by costs ≥USD7 (0.80; 0.67-0.95)

CONCLUSIONS: Preferences that encourage utilisation of services do not significantly differ by gender or SES of school neighbourhoods. Staff attitude and confidentiality are key issues affecting students' decisions to access HIV and contraceptive services. Addressing how healthcare providers respond to young people seeking HIV-testing, contraceptives and sexual and reproductive health, and close monitoring of comprehensive sexuality education implementation in schools is critical for improving adolescents' uptake of these services.

PEE1535

ACHIEVING THE "THIRD 90" FOR ADOLESCENTS AND YOUNG PEOPLE ON ANTIRETROVIRAL THERAPY IN EASTERN KENYA: A QUALITY IMPROVEMENT COLLABORATIVE (QIC) TO IMPROVE VIRAL LOAD TEST UTILIZATION

G. Dougherty[1], D. Achwoka[2], S. Akoth[3], R. Boccanera[4], T. Gantt[4], M. Hawken[3], I. Leting[3], C. Madevu-Matson[1], R. Mutei[3], C. Ngugi[5], D. Naitore[3], B. Senyana[1], F. Tsiouris[1], A. Wakoli[3], L. Walker[1], M. Rabkin[1]
[1]ICAP at Columbia University, New York, United States, [2]University of Nairobi Institute of Tropical and Infectious Diseases (UNITID), Nairobi, Kenya, [3]ICAP Kenya, Nairobi, Kenya, [4]U.S. Health Resources and Services Administration (HRSA), Bethesda, United States, [5]Ministry of Health, National HIV/AIDS and STI Control Program, Nairobi, Kenya

BACKGROUND: Scaling up routine HIV viral load (VL) testing for adolescents and young people (AYP) is a priority for Kenya's National AIDS Control Program (NASCOP). Kenya's 2018 national guidelines recommend that everyone on antiretroviral therapy (ART) with unsuppressed VL (UVL) (≥401 copies/mL) receive 3 enhanced adherence counseling (EAC) sessions and a repeat VL test within 3 months. Despite marked expansion of VL testing coverage and rollout of national policies, guidelines and training, VL result utilization, especially for AYP, has been suboptimal.

METHODS: In April 2019, ICAP Columbia University partnered with NASCOP, HRSA and CDC Kenya to launch a 12-month QIC at 22 health facilities (HF) in Eastern Kenya, designed to optimize VL utilization for AYP on ART with UVL. Following training on QI methods and VL management, each HF team identified contextually appropriate interventions and applied QI methods to conduct rapid tests of change and analyze monthly progress using run charts. HF's receive monthly coaching visits and convened quarterly to exchange best practices and lessons learned. We analyzed aggregate performance compared to a 12-month pre-intervention baseline.

RESULTS: In the first 6 months, the HF QI teams tested interventions targeting: client education, workflow modifications, commodity management, and improved documentation. Provision of EACs has improved from a baseline median of 64% (n=479) to 91% (n=350) while provision of EACs and repeat VL testing improved from baseline median of 16% (n=479) to 62% (n=350). VL re-suppression on repeat testing improved from a baseline median of 34% (n=273) to 50% (n=314).

[Figure]

CONCLUSIONS: The QIC has helped HF teams to identify and prioritize local, contextually appropriate innovations that have led to swift improvement in critical indicators of VL utilization and re-suppression. The QIC concludes in April 2020 when final results will be analyzed and a validated "change package" of successful interventions will be disseminated nationally.

PEE1536

TOWARD INCREASED CONTINUITY OF HIV CARE: PREDICTORS OF ELIGIBILITY INTERRUPTION AFTER FIRST ENROLLMENT AMONG CALIFORNIA AIDS DRUG ASSISTANCE PROGRAM (ADAP) CLIENTS

D. Aulakh[1], A. Nakamura[1], K. Wu[1]
[1]California Department of Public Health, Sacramento, United States

BACKGROUND: Publicly funded AIDS Drug Assistance Programs (ADAPs) provide access to life saving medications for uninsured and underinsured people living with HIV. To enroll, clients must provide proof of identity, residency, income, and HIV status. Federal requirements specify that clients must recertify their eligibility biannually and re-enroll annually. Preventing ADAP eligibility disruptions is critical to continuity of care, particularly for newly diagnosed clients. However, little is known about which clients are most vulnerable to ADAP eligibility interruption.

METHODS: We examined length of uninterrupted eligibility after initial enrollment using California ADAP enrollment records for adults enrolled between March 4, 2017 and September 4, 2019 (n = 12,867). Kaplan-Meier analyses and parametric regression log-survival time models were used to test for differences and identify significant predictors of uninterrupted eligibility duration.

RESULTS: The percent of days of eligibility covered by ADAP was high (median 100%, IQR 72-100%). However, 37% of clients experienced at least one day of interrupted eligibility after initial enrollment. Kaplan-Meier analyses revealed the risk of an eligibility interruption coincided with clients' first eligibility deadlines at 1, 6, and 12 months. The median length of interruption was 28 days. Gender, race, insurance status, and age were associated with initial eligibility duration. Black/African American clients experienced 2.3 fewer months of uninterrupted eligibility than non-Black/African American clients (p<.0001). Uninsured clients experienced 1.3 fewer months of uninterrupted eligibility than insured clients (p<.0001). Each year of increase in age was associated with a 2 day increase in uninterrupted ADAP eligibility (p < .001). Average uninterrupted eligibility duration for cisgender men, cisgender women, and transgender people, at age 18, was 6.0, 6.1, and 5.1 months, respectively.

CONCLUSIONS: These findings suggest that young, transgender, Black/African American people living with HIV face barriers to providing supporting eligibility documentation at initial ADAP enrollment and are at increased risk of care disruption. Policy changes that reduce enrollment disruptions for new ADAP clients, particularly for vulnerable populations, could improve client health and lower administrative program costs.

PEE1537

IMPROVING HIV VIRAL LOAD (VL) SUPPRESSION AND ISONIAZID PREVENTIVE THERAPY (IPT) COMPLETION THROUGH A QUALITY IMPROVEMENT INITIATIVE AT SCALE: EXPERIENCE FROM UGANDA'S IMPLEMENTATION PROCESS

C. Katureebe Mbojjana[1], H. Kadama[1], E. Karamagi[2], E. Magongo[1], S. Sensalire[2], J. Nabwire[2], T. Chimulwa[1], P. Namuwenge[1], J. Sendiwala[3], V. Nabitaka[4], J. Calnan[5], J. Musinguzi[1]

[1]Ministry of Health, STD/AIDS Control Program, Kampala, Uganda, [2]Ministry of Health, National Disease Control, Kampala, Uganda, [3]Makerere University School of Public Health, Monitoring and Evaluation Technical Support Program, Kampala, Uganda, [4]Clinton Health Access Initiative, Kampala, Uganda, [5]United States Agency for International Development, Kampala, Uganda

BACKGROUND: In 2018, although Uganda had made progress towards achieving the third 90 targets set by the UNAIDS it was not certain that the target would be achieved by 2020. Ministry of Health (MOH) designed and implemented a National Quality Improvement (QI) initiative from Jan 2019 to take to scale high impact interventions and close gaps along care cascades. Of priority was the improvement in the three processes of care for the virally non-suppressed patients; intensive adherence counselling, repeat VL testing and switching as well as completion of IPT. The initiative was implemented through the existing National QI structures that provide regular coaching, tools and support to QI regional and health facility teams that test and implement changes to close the performance gaps. We assess outcomes associated with three processes of care across the VL cascade as well as Isoniazid prevention therapy (IPT).

METHODS: A longitudinal cohort of 42092 non-suppressed patients (≥1000 copies of viral RNA/ml) from 1110 national QI initiative participating health facilities in Uganda were followed up for VL outcomes between January to September 2019. We analyzed data on Intensive adherence Counseling sessions, adherence, repeat VL test results, 2nd non-suppression VL and switch for the general cohort, children and pregnant and lactating mothers. Analysis was done for IPT completion for patients initiated on INH in January 2019.

RESULTS: The proportion of patients who had 3 consecutive IAC sessions increased by 17%, repeat viral load tests increased by 20% and switching to second-line increased by 22% by Sept 2019 for the general cohort. VL suppression outcomes improved for both children and pregnant and lactating mothers. Switching to second line regimen for pregnant and lactating mothers increased by 30% and 25% for VL suppression. Switching for children improved by 22% and suppression by 7%. IPT completion among patients initiated on INH was high at 89%.

CONCLUSIONS: National QI collaborative is feasible and it improved patient outcomes along the viral load cascade to suppression and achieving 90-90-90 targets.

PEE1538

COMMUNITY LED ASSESSMENT OF CLIENT SATISFACTION WITH OST SERVICES: PILOT STUDY IN KYIV AND KYIV OBLAST REGION, UKRAINE

M. Plotko[1], A. Dmitrieva[2], V. Stepanov[2]

[1]Eurasian Harm Reduction Association, Vilnius, Lithuania, [2]Support Research and Development Center, Kyiv, Ukraine

BACKGROUND: OST programmes in Ukraine were originally introduced to respond to the rapidly increasing rates of HIV. As OST have been implemented for more than 10 years, the study of patient satisfaction with treatment gives new opportunities for a better understanding of OST service development prospects in the long run as well as treatment trajectories and changing needs on a patient level.

METHODS: In 2019 EHRA gathered a team of professional researchers and 4 national community organizations to develop a tool to assess treatment satisfaction in the context of the quality of life (QoL) among OST patients. Our approach to this study was based on the principles of equal partnership with the community of people who inject drugs and/or receive OST. The study was conducted using the mixed-method approach. The quality component was implemented through 16 semi-structured interviews, sampling for the quantitative component was performed using publicly available data from the Center for Public Health. 376 OST patients took part in the pilot assessment in Kyiv and Kyiv Oblast region, 178 structured interviews were conducted with patients who get OST for free at state-funded OST sites, 198 - with patients who buy OST in pharmacies after getting prescription at OST sites based in private clinics.

RESULTS: The research showed that although a formally designated range of services is provided, their content and quality are not satisfactory, mostly aimed at monitoring the patient's behavior, rather than providing patient-centered support, and do not improve patients' QoL. HIV positive status and diagnosed hepatitis C are associated with lower levels of QoL indicators in physical and psychological domains. Gathered data also suggests that overall high satisfaction with OST (72%) could be explained by the fact that the perception of treatment is narrowed to the medication (89% said that OST is a vital need for them).

CONCLUSIONS: For improved understanding of goals and outcomes in treatment of chronic diseases, such as drug addictions, we recommend advocating the assessment of patients' QoL as an indicator of treatment efficiency. Special focus should be made on patients primarily targeted by OST programmes, such as people with dual diagnoses (HIV/hepatitis C coinfection).

PEE1539

RISK FACTORS AND MANAGEMENT OF ADVERSE EVENTS ASSOCIATED WITH VOLUNTARY MEDICAL MALE CIRCUMCISION PROGRAMS IN NAMIBIA: OCTOBER 2016 TO SEPTEMBER 2017

A. Cheng[1], M. Ochieng[2], S. Rana[1], Z. Mwandi[3], V. Kiggundu[1], D. Mali[4], E. Mlanga[5], A. Christenson[6], C. Sayikanmi[1], R. Ferris[1], R. Eakle[7,1], S. Kellerman[8]
[1]US Agency for International Development, Office of HIV/AIDS, Washington, United States, [2]Christian Community Healthcare Foundation Kenya, Nairobi, Kenya, [3]Jhpiego, Nairboi, Kenya, [4]US Agency for International Development, Windhoek, Namibia, [5]US Agency for International Development, Lilongwe, Malawi, [6]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [7]London School of Tropical Hygiene and Medicine, London, United Kingdom, [8]Management Sciences for Health, Medford, United States

BACKGROUND: Voluntary Medical Male Circumcision (VMMC) is effective in preventing HIV but limited information is available on VMMC-associated adverse events (AEs) program impact. To better understand how AE reporting and management by VMMC programs, USAID evaluated practices for identifying, reporting, and preventing AEs within the PEPFAR project through USAID called AIDSFree, in Namibia between October 2016 and September 2017.

METHODS: Medical record data abstraction from all 12 AIDSFree-supported VMMC clinics in Windhoek, Namibia from November 2018 to February 2019, and from the AIDSFree program dataset containing data from all VMMCs performed during that time. Qualitative semi-structured interviews were conducted with providers and program managers in four VMMC clinics in Namibia.

RESULTS: The AIDSFree program reported 69 moderate and severe VMMC-associated AEs during the study period but medical record abstraction revealed an additional 44 (113 total: under-reporting rate 44%): 83% moderate, 17% severe and 72% occurred postoperatively. Most circumcisions were performed using the forceps guided method and most AEs (64%) were associated with this procedure, significantly higher than AEs associated with Dorsal slit and sleeve resection procedures (OR 1.5 (1.00 – 2.21), p-0.04). Clients aged 15-19 years had the most AEs (35). Intraoperative AE rate was highest among those aged 15 – 19 years (1.2%) while those aged 15 – 24 years had the highest postoperative AE rate (2.6%), with postoperative AEs significantly higher in this age group (OR=2.5, CI (1.6 – 3.9), p<0.001). Prevention strategies focused on post-operative AEs as they rely on patient's often limited understanding of wound care and hygiene and a recognition that patients often lack the necessary resources to comply; a growing issue as programs increasingly expand outreach to rural and remote locales. Some staff respondents voiced concerns that AE reporting might exclude them from future VMMC work or reflect poorly on their skills.

CONCLUSIONS: Training of clinic staff should emphasize documentation/charting of AEs, along with VMMC clinical skills and AE management. VMMC implementing partners should conduct routine data quality assessment with data validation to improve documentation. Postoperative wound management, care, and hygiene should be emphasized and new strategies considered for increasingly rural client populations.

PEE1540

QUALITATIVE FINDINGS FROM A MULTI-COUNTRY EVALUATION OF ADVERSE EVENTS IN VMMC PROGRAMMING

R. Eakle[1,2], S. Kellerman[3], M. Ochieng[4], S. Rana[1], Z. Mwandi[5], V. Kiggundu[1], D. Mali[6], E. Mlanga[7], A. Christenson[8], C. Sayikanmi[1], A. Cheng[1]
[1]USAID, Washington DC, United States, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Management Sciences for Health, Medford, United States, [4]Christian Community Healthcare Foundation Kenya, Nairobi, Kenya, [5]JSI, Nairobi, Kenya, [6]USAID, Windhoek, Namibia, [7]USAID, Lilongwe, Malawi, [8]Jhpiego, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: More than 18 million men have been reached and more than 230,000 new HIV infections prevented in sub-Saharan Africa, since Voluntary Medical Male Circumcision (VMMC) was proven safe and efficacious in 2007. As programs evolve, continuous evaluation of quality and safety is essential. We present findings from the qualitative component of a multi-country evaluation of safety monitoring among USAID VMMC programs.

METHODS: As part of a larger evaluation effort, semi-structured interviews were conducted with key informants (KIs) purposively sampled to ensure representation from relevant staffing and ministry levels within country programming supported by AIDSFree, a PEPFAR program through USAID, in Namibia, Tanzania, and Malawi. Data collection was conducted between November 2018 and February 2019. Interview guides were informed by literature and expert input. Interviews were conducted by the study team and lasted up to 1.5 hours in English in Malawi and Namibia, and in English and Swahili in Tanzania. A thematic analysis approach was employed to analyse the data. All participants completed informed consent.

RESULTS: Twenty-six interviews were conducted across the three countries. Discussions explored participants' understanding of the VMMC process and preventing, recognizing, reporting, and clinical follow-up of clients with identified adverse events (AEs). Programming differed between the contexts where VMMC program maturity and design varied. All participants acknowledged the need for the VMMC intervention and support provided by AIDSFree, credited with fostering new paradigms in HIV prevention among men. Three additional thematic areas emerged from the data: Balancing service quality and provider empowerment in managing AE reporting; The need for ongoing provider support; and, Providers and clients holding the responsibility of AE prevention. Many participants expressed conflicting motivations to report AEs and avoid potential punitive actions, the need for ongoing technical training and support, and how both providers and clients are responsible for prevention and addressing AEs.

CONCLUSIONS: This research highlighted VMMC as an important intervention for men, as well as areas of program quality vulnerability and how they should be addressed. Providers need protected support to maintain clinical skills and be able to report AEs. Clients should be empowered to ensure their post-operative care is well-maintained.

PEE1541

CONNECTING THROUGH SMART-LYNCAGES: ASSESSING THE LINKAGE OF VOLUNTARY MEDICAL MALE CIRCUMCISION CLIENTS TO ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH (ASRH) SERVICES IN ZIMBABWE

T.M. Moyo[1,2], P. Thukur[3], K.T. Takarinda[4], S. Xaba[4], A. Mangombe[4], N. Zwangobani[4], S. Mabaya[2], W. Ameyan[5], J. Sumuelson[5], O. Mugurungi[4]
[1]Ministry of Health and Child Care, AIDS and TB Unit, Harare, Zimbabwe, [2]World Health Organisation, Zimbabwe Country Office, HIV Prevention, Harare, Zimbabwe, [3]The International Union Aganist TB and Lung Disease, Research, Harare, Zimbabwe, [4]Ministry of Health and Child Care, AIDS and TB, Harare, Zimbabwe, [5]World Health Organisation, Epidemiology, Geneva, Zimbabwe

BACKGROUND: The Smart-LyncAges project was piloted in Bulawayo city and Mt Darwin district of Zimbabwe, to increase the utilization of Adolescent Sexual Reproductive Health (ASRH) services through referral of Voluntary Medical Male Circumcision (VMMC) clients to youth centres. Since its inception in 2016, there has been no assessment of performance of the referral system. Thus, this study aimed to assess the proportion of VMMC clients getting 'successfully linked' to ASRH services and factors associated with not being linked.

METHODS: This was a cohort study using routinely collected secondary data. All VMMC clients (aged 10-24 years) referred for ASRH services during October-November, 2018 were included. Those participants registered for ASRH services within three months of referral were considered as 'successfully linked'. The proportion of 'successfully linked' was summarized as percentages with 95% confidence interval (CI). Adjusted relative risks (aRR) using generalized linear model was calculated as a measure of association between client characteristics and not being linked.

RESULTS: Of the 1478 VMMC clients referred, 463 (31.3%, 95% CI- 30.0-33.8) were 'successfully linked' to ASRH services and the median (IQR) duration for linkage was 6 (0-56) days. Receiving referral from Bulawayo Metropolitan Circumcision Clinic (aRR-1.4 (95% CI1.2-1.7)) and getting VMMC services at outreach facilities (aRR1.2 (95% CI 1.1-1.3) were independently associated with not registering for ASRH services.

CONCLUSIONS: Linkage to ASRH services from VMMC is possible as one-third referred VMMC clients were successfully linked. However, there is need to explore the reasons for not accessing ASRH services and taking corrective actions to improve the linkages especially for VMMC clients assessing services in the metropolitan clinic and outreach centres. intergration and linkages between HIV prevention and ASRH reduce missed opportunitites for adolescents and are complimentary in nature, resulting in the neccessary efficencies especially in resourse limited settings.

PREP: LESSONS LEARNED FROM DELIVERY

PEE1542

FACTORS ASSOCIATED WITH ACCESSING FREE PREP SERVICES IN THAILAND

T. Chinbunchorn[1], O. Nampaisarn[1], R. Ramautarsing[1], S. Janyam[2], T. Sangprasert[3], P. Chanlearn[4], M. Avery[5], S. Mills[5], R. Vannakit[6], P. Phanuphak[7], N. Phanuphak[1]
[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Service Workers in Group, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Mplus, Chiang Mai, Thailand, [5]FHI 360 and LINKAGES, Bangkok, Thailand, [6]Office of Publich Health, USAID Regional Development Mission Asia, Bangkok, Thailand, [7]Thai Red Cross AIDS Research Centre, Bangkok, Thailand

BACKGROUND: Pre-exposure prophylaxis (PrEP) is a highly effective HIV prevention tool. Little is known about client preferences for different models of PrEP services. We describe differences in clients accessing PrEP through fee-based and free services in community-based clinics in Thailand.

METHODS: From January 2016-July 2019, data was obtained from the two largest PrEP programs in Thailand: a free "Princess PrEP" program available in 9 community-based clinics in 6 provinces in Thailand and a fee-based "PrEP-15" program at the Thai Red Cross Anonymous Clinic in Bangkok, Thailand. Demographics and risk behaviors were self-reported, and multivariable regression was used to determine factors associated with engaging in free PrEP services.

RESULTS: A total of 5,687 clients were enrolled, 66.7% through Princess PrEP (82.7% men who have sex with men – MSM, and 12.8% transgender women – TGW) and 33.2% through PrEP-15 (76.3% MSM, 3.1% TGW). Mean age for clients in Princess PrEP and PrEP-15 was 28.8 and 31.5, respectively, p<0.001. Among Princess PrEP and PrEP-15 clients, 61.2% and 54.8% reported multiple partner (p<0.001), 65.3% and 86.4% had inconsistent condom use (p<0.001), 6.7% and 7.1% used amphetamine (p=0.609), and 18.2% and 6.6% reported sex work (p<0.001), respectively.

In the multivariable linear regression model, being MSM (adjusted odds ratio -aOR: 7.17; 95% confidence interval -CI 4.18-12.28, p<0.001), TGW (aOR: 5.9; 95% CI 2.8-12.45, p<0.001), having multiple partners (aOR 1.42; 95% CI 0.98-2.06, p<0.05), and reporting sex work (aOR: 5.03; 95% CI 2.69-9.42, p<0.001) were associated with accessing free PrEP.

Clients who earned more than 1,600 USD per month were less likely to access free PrEP (aOR: 0.38; 95%CI 0.23-0.63, p<0.001), as well as clients who reported inconsistent condom use (aOR: 0.01; 95%CI 0-0.03, p<0.001), and clients who used drugs during sex (aOR: 0.73; 95%CI 0.57-0.94, p<0.05).

CONCLUSIONS: In order to optimize PrEP uptake, accessibility should be diversified to accommodate for the needs of different populations. Factors that we found can be used to tailor service delivery models to different populations. While some clients may choose to pay out of pocket, PrEP should be available under universal health coverage, particularly for key populations such as MSM, TGW, and sex workers.

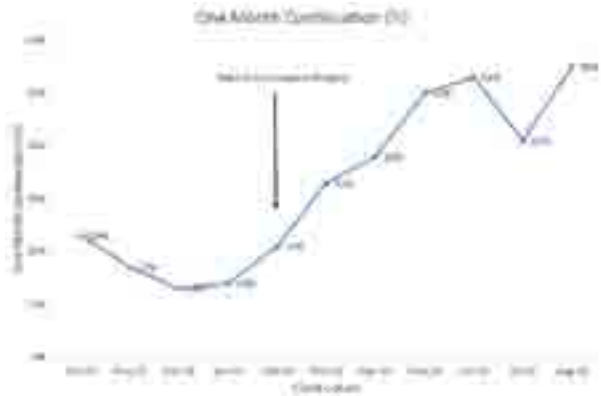
PEE1543

IMPROVING PREP CONTINUATION RATES THROUGH CLIENT-CENTERED INNOVATIONS IN LESOTHO

T. Chakare[1], M. Ramapepe[1], J. Berg[1], A. Rozario[1], M. Motaba[1]
[1]Jhpiego, TSEPO, Maseru, Lesotho

BACKGROUND: Lesotho, with an adult (15-59 yrs) HIV incidence rate of 1.5/100 person years began scaling up PrEP in 2018 as part of comprehensive HIV prevention response. Despite proven effectiveness, many PrEP programs experience high client attrition rates during early use.
DESCRIPTION: Programmatic data from community-based PrEP services registers in Lesotho revealed that only 20% of those starting PrEP for the first time between October 2018 and January 2019 returned on time (defined as within 37 days) for first refill. In response, PrEP users and service providers were engaged to prototype solutions to mitigate refill delays. Between February and October 2019, five parallel innovations were implemented in Maseru and Berea districts. Routinely collected prescription data was monitored for changes in timeliness of first refill by innovation beneficiary group.
LESSONS LEARNED: All five continuation improvement efforts led to improved continuation of PrEP at one month when compared to the baseline 20% October 2018-January 2019 average. See Figure; 1.

[Figure 1. PrEP Continuation Innovations and Results]



[Figure 2. One Month PrEP Continuation by Monthly Enrollment Cohorts]

Figure 2 shows a steady increase in overall one month continuation rates since the inception of continuation improvement projects in February 2019.
CONCLUSIONS/NEXT STEPS: Implementation of all client-centered innovations were followed by improvements in first refill, including a rapid increase in overall program monitoring and evaluation data by enrollment month. Adaptation to different contexts is required to ensure beneficiaries remain protected for as long as they need PrEP. Nuances of PrEP use among those at intermittent and episodic risk warrant further evaluation.

PEE1544

EARLY SEROCONVERSION AMONG NEW ORAL PRE-EXPOSURE PROPHYLAXIS (PREP) USERS: OBSERVATIONS FROM LESOTHO

T. Chakare[1], S. Leluma[1], T. Mabote[1], R. Phate[2], M. Ramapepe[1]
[1]Jhpiego, TSEPO, Maseru, Lesotho, [2]Ministry of Health, Disease Control, Maseru, Lesotho

BACKGROUND: Oral pre-exposure prophylaxis (PrEP) provides greater than 90% protection against HIV acquisition. Lesotho is among countries hardest hit by the HIV epidemic and is scaling up PrEP as an HIV prevention option for individuals at substantial risk. Seroconversion following PrEP initiation in the context of routine implementation is not well documented.
DESCRIPTION: After starting PrEP, clients in Lesotho are retested for HIV at month-one, month-three and every three months thereafter. Serial HIV testing is the standard of care using three antibody based, third generation assays. Screening for HIV exposure in the 72 hours preceding PrEP initiation to determine Post-Exposure Prophylaxis (PEP) eligibility, was routinely implemented from October 2018. All seroconversions reported in Lesotho's community programme from January 2018 - November 2019 were evaluated for the performance of PEP eligibility screening, time on PrEP and adherence. Information was drawn from service registers and reports.
LESSONS LEARNED: Eight seroconversions following PrEP initiation were reported among 12 462 users in the period under review. Seven tested positive at the month-one post-initiation retest, and one at the month-four visit. Good adherence was reported for all but two clients. The month-four client had 70% adherence and one of the month-one clients took 60% of prescribed doses. Only three of the seroconverters were screened for PEP before starting PrEP. Seventy-eight percent (78%) of new PrEP users during the period reviewed did not return for their first refill and were subsequently not retested.
CONCLUSIONS/NEXT STEPS: Almost all seroconversions (87.5%) in our case series were detected at the first retesting opportunity, suggesting HIV infection just before or soon after initiating PrEP. Early seroconversion on PrEP may be an unavoidable consequence of successfully reaching at-risk individuals. All new PrEP clients in high incidence settings should be counselled to return for repeat testing one month after initiation regardless of continuation intentions. Equally important is the need for PrEP providers to diligently screen for PEP versus PrEP eligibility.

PEE1545

THE UTILITY OF RENAL FUNCTION SCREENING FOR PRE-EXPOSURE PROPHYLAXIS (PREP) USERS: A REVIEW OF BASELINE CREATININE CLEARANCE RESULTS IN LESOTHO

T. Chakare[1], S. Leluma[1], T. Mabote[1], T. Tarumbiswa[2], R. Manda[3], M. Ramapepe[1]
[1]Jhpiego, TSEPO, Maseru, Lesotho, [2]Ministry of Health, Disease Control, Maseru, Lesotho, [3]USAID, Biomedical Prevention, Maseru, Lesotho

BACKGROUND: Tenofovir (TDF), recommended for PrEP, is associated with long-term side effects during HIV treatment. The WHO recommends routine creatinine monitoring for PrEP clients at baseline and 6 monthly thereafter. PrEP is contraindicated when estimated creatinine clearance (CrCl) is below 60 ml/min. Less frequent monitoring is suggested when baseline CrCl is above 90 ml/min. While

implementation of creatinine screening has obvious cost implications, phlebotomy has also been flagged as a possible access barrier. PrEP clients are generally younger, healthier and exposed to TDF for shorter periods than clients on TDF for HIV treatment. PrEP use is typically transient and only 4% of clients in Lesotho's community program continue PrEP beyond six months.

DESCRIPTION: Using data from service registers, we analyzed baseline CrCl results for clients assessed for PrEP eligibility through Lesotho's community PrEP project between June and November 2019. CrCl was estimated using the Cockroft-Gault equation. Analysis of renal function was done by age, sex and weight.

LESSONS LEARNED: Of 2622 client records, 247 were eligible for analysis by virtue of completeness of age, sex, weight and creatinine data. There were 219 females and 28 males. Clients were mostly young with an average age of 22.8 years (range 15-68 years). At 135 ml/min, average CrCl was high, with a range of 46-319 ml/min. One client, a 68 year old hypertensive man, had CrCl less than the 60 ml/min PrEP eligibility threshold. Ninety-three percent (219/236) of clients below 40 years of age had an estimated CrCl above 90 ml/min in contrast to only 36% (4/11) of older clients. Comparison by weight was less remarkable as 84% (43/51) of clients weighing less than 50kg had CrCl above 90 ml/min compared to 92% (180/196) of clients with higher weights.

CONCLUSIONS/NEXT STEPS: Except for one client with renal disease risk factors, creatinine screening did not add value to clinical decisions. In addition, a large majority of clients younger than 40 years had high baseline CrCl estimates (>90 ml/min). To offset costs and reduce access barriers for young PrEP users free of renal stigmata, we recommend serum creatinine screening after six months of use rather than at initiation.

PREP INITIATION AND CONTINUATION AMONG PREGNANT WOMEN ARE ASSOCIATED WITH CO-DELIVERY OF HIV SELF-TESTS FOR AT-HOME MALE PARTNER TESTING: RESULTS FROM AN IMPLEMENTATION PROGRAM IN KENYA

J. Pintye[1], E. Begnel[1], J. Kinuthia[2], F. Abuna[2], J. Sila[2], G. Owiti[2], J. Dettinger[1], A.L. Drake[1], A.D. Wagner[1], K. Mugwanya[1], J.M. Baeten[1], G. John-Stewart[1], PrEP Implementation for Young Women and Adolescents (PrIYA) Program
[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya

BACKGROUND: Programmatic provision of HIV self-tests to antenatal care (ANC) attendees for secondary distribution to male partners is scaling up in Kenya and could influence PrEP decision-making. We evaluated PrEP outcomes among ANC attendees at clinics delivering PrEP alone or with self-test distribution in the PrEP Implementation for Young Women and Adolescents (PrIYA) Program.

DESCRIPTION: The PrIYA Program approached HIV-uninfected pregnant women seeking routine ANC at 16 clinics in Kisumu, Kenya from 11/2017-06/2018. ANC attendees were screened for PrEP per national guidelines and those eligible were offered PrEP at the same visit. Eight clinics were purposively assigned to also distribute HIV self-tests to women for at-home partner testing; women could accept either self-tests, PrEP, or both. Self-test acceptors received instructions on use and a minimum of 2 OraQuick Advance kits. We used Poisson regression models, clustered by site, to evaluate the relationship between self-test distribution and PrEP initiation and continuation among women with partners of unknown HIV status. In a subset, we conducted in-depth interviews (IDIs) to elucidate reasons for PrEP discontinuation.

LESSONS LEARNED: We screened 4912 HIV-uninfected pregnant women for PrEP, of whom 1446 (29%) had partners of unknown HIV status and were included in the analysis. Overall, 593/1446 (41%) women were from clinics co-delivering PrEP and self-tests. Median age was 24 years (IQR 21-28), median gestational age was 26 weeks (IQR 20-31), and 84% were married. PrEP initiation was more frequent in clinics distributing self-tests compared to PrEP-only clinics (36% vs. 29%, prevalence ratio[PR]=1.23, 95% CI 1.02-1.48, p=0.027). At clinics co-delivering PrEP and self-tests, 60% of women accepted self-tests to distribute to partners; PrEP uptake was similar among self-test decliners and acceptors (36% vs. 39%, p=0.384). Among PrEP initiators at clinics co-delivering PrEP and self-tests, those who accepted self-tests more frequently discontinued PrEP at 3-months (89% vs. 78%, PR=1.14, 95% CI 1.00-1.25, p=0.003) and 6-months (97% vs. 89%, PR=1.09, 95% CI 1.00-1.19, p=0.05). In IDIs, women commonly reported discontinuing PrEP after their partners self-tested HIV-negative.

CONCLUSIONS/NEXT STEPS: Distributing self-tests for male partners in ANC may influence PrEP decision-making. Comprehensive HIV prevention should be offered in ANC to meet the diverse needs of pregnant women.

PEE1547

QUALITATIVE ASSESSMENT OF BARRIERS AND FACILITATORS OF PREP USE BEFORE AND AFTER IMPLEMENTATION OF A PREP PROGRAM FOR KEY POPULATIONS IN RAKAI, UGANDA

W. Ddaaki[1], P.T. Yeh[2], J.G. Rosen[2], G.M. Bua[1], J. Jackson[3], S. Stromdahl[4], S.J. Reynolds[5], M.K. Grabowski[3], R. Gray[2], G. Kigozi[1], J. Kagaayi[1], G. Nakigozi[1], L.W. Chang[3], F. Nalugoda[1], N. Nakyanjo[1], A.M. Ekstrom[1], C.E. Kennedy[2]
[1]Rakai Health Sciences Program, Kalisizo, Uganda, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]Johns Hopkins School of Medicine, Baltimore, United States, [4]Karolinska Institutet, Solna, Sweden, [5]National Institutes of Health, Washington DC, United States

BACKGROUND: Uganda began providing HIV preexposure prophylaxis (PrEP) through selected PEPFAR-funded implementation projects in 2017. We explored perceptions of PrEP before its rollout and user experience after it was introduced to understand programmatic barriers and facilitators in Rakai, Uganda.

METHODS: We collected qualitative data before (2016-2017) and after (2019) PrEP rollout in hyperendemic fishing communities and trading centres in south-central Uganda. We conducted 75 in-depth interviews, and 93 individuals participated in 12 focus group discussions. We purposively selected female sex workers, fishermen, healthcare providers, HIV-discordant couples and community members to explore PrEP awareness, hypothetical uptake and adherence before roll-out. After rollout, we further selected individuals who had started, discontinued, and refused PrEP to describe experiences along the PrEP cascade. Interviews were audio-recorded and transcripts were thematically analysed using a team-based framework analysis approach.

RESULTS: Early concerns about unskilled/untrained volunteers distributing prescriptions, price gouging, and manipulation by community distributers were no longer described as concerns after program implementation. However, despite community sensitization, some participants felt rollout occurred too quickly and reported poor knowledge and rumours about PrEP after rollout. Both before and

after program rollout, study participants described medical mistrust and stigma (fear of being perceived as promiscuous or HIV-positive) as barriers to PrEP use. After rollout, community stigma influenced adherence to daily pill intake (e.g. desire for secrecy led to missed doses), adherence to refill schedules, relationship consequences, and partner support for uptake and adherence. Mobility and pill fatigue were additional barriers. Desire to remain HIV-negative while having an HIV-positive/unknown partner was consistently considered to be the main benefit of PrEP. After rollout, additional facilitators of PrEP uptake and adherence included support from opinion leaders and greater control over HIV risk in high-risk occupations (e.g. sex work) and social contexts (e.g. fishing communities).

CONCLUSIONS: While the PrEP program in Rakai addressed many early concerns, HIV stigma and rumours remain barriers to PrEP uptake and adherence. Community-initiated communication about PrEP with successful PrEP users as opinion leaders may promote uptake and adherence by addressing fears and rumours, while flexible delivery and refill models may facilitate PrEP continuation.

PEE1548

PEER POWER: HARNESSING PEER MOBILISERS TO IMPROVE UPTAKE OF PREP AMONG ADOLESCENT GIRLS

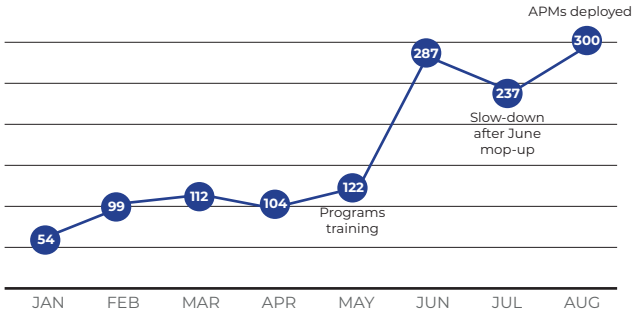
K. Chatora[1], V. Mabhunu[1], T. Mawoyo[1], M. Munjoma[1], N. Taruberekera[1]
[1]Population Services International, Harare, Zimbabwe

BACKGROUND: Nearly 1,000 Adolescent Girls and Young Women are infected by HIV daily in Sub Saharan Africa. Factors predisposing young women to HIV include early sexual debut and unprotected sex. Adolescent Girls (AGs) in Zimbabwe as in many African countries, face provider and community stigma preventing them from accessing HIV prevention services. Against this backdrop, PSI Zimbabwe deployed 23 former DREAMS club facilitators to mobilize and improve uptake of PrEP among AGs; 15-19 years in 6 DREAMS districts.

DESCRIPTION: Between July and August 2019, we deployed twenty-three Adolescent Peer Mobilisers (APMs) to recruit and refer AGs in selected high HIV- burden urban and rural areas for PrEP services. The APMs discussed the menstrual health and pregnancy link, positioning MHM as a 'socially acceptable' hook in promoting the uptake of PrEP. They integrated PrEP mobilization with other HIV prevention programs such as Voluntary Medical Male Circumcision and Condoms. Mobilization was implemented concurrently with service outreach to offer immediate access to AGs. Before deployment, the APMs accessed services as mystery clients to identify opportunities for provider youth friendliness. They formed a Youth Advisory Board, to mentor providers on youth friendliness.

LESSONS LEARNED: Using program data for the period January and August 2019, we observed a sustained uptake of PrEP among AGs between June and August (Fig 1). The increase in PrEP uptake between May and June is explained by improved program fidelity. This increase was sustained by the introduction of APMs in August.

CONCLUSIONS/NEXT STEPS: Using APMs to recruit AGs for PrEP, while positioning menstrual health as an entry point and program implementation fidelity is associated with increased uptake of PrEP. APMs provide safe spaces for AGs. Bringing PrEP services to where AGs feel most comfortable and messaging from whom they desire can increase uptake. Programs seeking to improve PrEP uptake among AGs need to consider these elements.



[Figure 1. AGs PrEP enrolment 2019]

PEE1549

ACADEMIC DETAILING INSTITUTES AS A NOVEL CAPACITY BUILDING STRATEGY FOR UNITED STATES HEALTH DEPARTMENTS SEEKING TO EXPAND PREP PRESCRIBING

G. Naja-Riese, MSW[1], A. Decker, NP[2], M. Fischer, MD, MS[3], J.D. Fuchs, MD, MPH[1]
[1]San Francisco Department of Public Health, Population Health Division, Center for Learning and Innovation, San Francisco, United States, [2]San Francisco Department of Public Health, Population Health Division, Disease Prevention and Control, San Francisco, United States, [3]Brigham and Women's Hospital, Department of Medicine, Division of Pharmacoepidemiology & Pharmacoeconomics, Boston, United States

BACKGROUND: PrEP is a core prevention strategy of the U.S. plan to end the HIV epidemic. However, only 10% of the estimated 1.2 million individuals eligible for PrEP are receiving it. Clinician capacity to offer PrEP limits access, with less than a third of primary care providers reporting comfort with PrEP prescribing. Using HIV and sexually transmitted disease surveillance data, public health departments (HDs) are uniquely poised to engage clinicians with a significant number of PrEP eligible patients. Academic detailing (AD) is a research-proven strategy that uses targeted one-on-one educational visits with providers to encourage adoption of evidence-based practices. We developed AD Institutes (ADIs) and evaluated their impact in helping HD staff establish and sustain PrEP AD programs.

DESCRIPTION: In 2018 and 2019, a team of national capacity building assistance (CBA) programs recruited two cohorts from 18 local and 15 state HDs interested in implementing AD for PrEP. Using a Knowledge-to-Action implementation framework, each cohort participated in 2.5-day highly interactive face-to-face skills building workshops, which reviewed the conceptual and practical aspects of AD programming and offered technical assistance to HDs crafting their jurisdictional plans. A longitudinal 6-12-month post-Institute assessment tracked program implementation and challenges faced.

LESSONS LEARNED: ADI evaluations indicated significant increases in knowledge and self-efficacy to conduct provider visits, with the peer feedback received during mock-detailing practice sessions being the most highly valued aspect of the training. All participants would recommend the workshop to colleagues. Among post-Institute assessment respondents, a majority (70%) of jurisdictions implemented PrEP AD programs; primary barriers included staff turnover, funding cuts, and clinical provider resistance. Unanticipated challenges included acknowledgment of social media campaigns spreading misinformation about PrEP safety, as well as recent FDA approval of Descovy® as an oral PrEP agent which could alter already-developed key messages for providers.

CONCLUSIONS/NEXT STEPS: ADIs are a highly effective and replicable capacity-building strategy to support HDs seeking to expand the number of PrEP prescribers. Post-Institute peer-to-peer learning collaboratives may support ADI participants over time as they refine plans, confront challenges, and integrate new information about PrEP and advances in HIV prevention.

PEE1550

REACHING KEY AND PRIORITY POPULATIONS WITH PREP: LESSONS FROM EASTERN UGANDA

C. Karutu[1], H. Nandudu[1], N. Matsiko[1], C. Luzze Julius[1], M. Arinaitwe[1], I. Mirembe[1], C. Mejia[2], S. Aldridge[2]
[1]IntraHealth International (RHITES-E), Mbale, Uganda, [2]IntraHealth International, Chapel Hill, United States

BACKGROUND: Oral PrEP, when taken consistently and correctly, can reduce the risk of HIV infection to near-zero and is recommended as a prevention choice for people at substantial HIV infection risk. In August 2017, the Ministry of Health (MoH) Uganda adopted the WHO policy on Pre-Exposure Prophylaxis (PrEP) for HIV negative key and priority populations (KPs/PPs). In August 2018, the USAID-funded Regional Health Integration to Enhance Services in Eastern Uganda (RHITES-E) Activity collaborated with the MoH to roll out PrEP services in Mbale Regional Referral Hospital and Namatala Health Centre IV.

DESCRIPTION: PrEP eligible clients were provided with a 30-day supply of daily oral tenofovir-emtricitabine and instructed to return for follow-up after a month. Those that returned were provided with a three-month supply and instructed to return for quarterly follow-up and refills, including HIV risk screening and testing, PrEP side effects, STI screening and adherence counseling, and every 6 months creatinine clearance testing. RHITES-E reviewed monitoring data on project-supported PrEP services provided to different groups of KPs and PPs through the two facilities from October 2018 to September 2019 to inform programmatic delivery and scale-up.

LESSONS LEARNED: Of 1203 HIV-negative individuals assessed for PrEP from key and priority populations at the two facilities, 398 (33%) were eligible for PrEP, 56% (222/398) were initiated, and 30% (66/222) returned for follow-up within 6 months. Client-reported reasons for discontinuing PrEP were: voluntary stoppage by clients due to low perceived risk; stoppage by clinicians after indications of reduced risk; and mobility/frequent change in location (mostly female sex workers). Challenges observed by peer navigators included stigma associated with PrEP drug packaging being similar to antiretroviral drug packaging; fear of side effects; and health workers being too busy to initiate PrEP due to burdensome documentation requirements.

CONCLUSIONS/NEXT STEPS: In response, the project has strengthened peer engagement, adopted a differentiated service delivery model and is mentoring facility health workers to reduce initiation and discontinuation challenges and improve PrEP retention. Despite deploying peer navigators, PrEP discontinuation remains a challenge. Evidence from this work will inform the next steps for wider delivery of PrEP in Uganda and other programs in resource-limited settings globally.

TESTING AND TREATMENT AT SCALE: ISSUES AND LESSONS

PEE1551

CASE STUDY OF EFFECTIVE IMPLEMENTATION OF ASSISTED PARTNER NOTIFICATION SERVICES IN OBER KAMOTH SUB-COUNTY HOSPITAL, KISUMU COUNTY, KENYA

I.D. Odhiambo[1], H. Alwang'a[1], H. Lagat[1], J. Onsomu[1], D. Oketch[2], B. Adiedo[2]
[1]PATH, Kisumu, Kenya, [2]Ministry of Health, Kisumu, Kenya

BACKGROUND: Assisted partner notification services for index patients with HIV infections involves elicitation of information about sex partners and contacting them to ensure that they test for HIV and link to care. Current HTS approaches are not enough to get to the first 90.Assisted partner notification services (aPNS) has been shown to be effective in improving HIV testing yield and augmenting HIV case finding among individuals exposed to HIV.

DESCRIPTION: Assisted partner notification services from May 2018 was scaled up by the Ministry of Health in 16 health facilities in Kisumu county in collaboration with Afya Ziwani Program and Kisumu County department of Health. Findings based on implementation of aPNS from a selected facility implementing aPNS in Kisumu County, Western Kenya was analysed.

LESSONS LEARNED: During the period May 2018 to 10th November 2019, 1037 females were tested at Ober Kamoth Hospital in Kisumu. The newly diagnosed HIV-positive females ≥15 years of age were screened for eligibility, consented and offered aPS. Those who accepted provided contact information of their male sexual partners in the past 3 years. Healthcare providers notified partners of their potential HIV exposure and provided HIV testing and referral services.The program identified 53 (yield of 5.1%) newly diagnosed females of whom 50 were reached for aPNS (94%) and reported 75 male sexual partners (partner to index ratio=1.2). The male partners identified by the female index were traced and reached for aPNS 66 (88%) . Overall, 66 (88%) of male partners named were contacted and tested for HIV 100%(N=66). Of partners tested, 16 (24%) were newly diagnosed HIV-positive and 19 (29%) were known HIV-positive. The majority of partners who were known positive were already on ART (95%).

CONCLUSIONS/NEXT STEPS: Tracing and testing of male sexual partners of newly diagnosed HIV-positive female clients is a high yield strategy to reaching newly diagnosed HIV positive persons. Most male partners preferred to be tested outside of the clinic, highlighting the importance of community-based testing options.Use of eligibility screening tools improves the positivity rates. aPNS therefore is an effective strategy to increasing uptake of partner HIV testing within routine healthcare settings.

PEE1552

LEVERAGING ON INDEX CLIENT TESTING TO OPTIMIZE HIV CASE IDENTIFICATION IN UGANDA. A COUNTRY PROGRESS

M. John Bosco Jr[1], L. Marvin[2], T. Geoffrey[1], M. Peter[1], M. Joshua[1]
[1]Ministry of Health, STD/AIDS Control Program, Kampala, Uganda, [2]Clinton Health Access Initiative (CHAI), HIV Prevention, Kampala, Uganda

BACKGROUND: Index client testing using the Assisted Partner Notification (APN) approach was introduced in Uganda in 2018 through feasibility pilot studies. By September 2019, 1,225 out of the 2,800

targeted health facilities were implementing APN. We present a 12 months (July 18-June 2019) APN implementation successes, challenges and next steps.

DESCRIPTION: The country adopted WHO APN guidelines in 2017. Data capture and reporting tools (HMIS) were developed together with the APN training curriculum. Capacity building through national and regional trainings was conducted in Mid-July 2017 and implementation started same month, using a scale up approach. We conducted 3 days' facility based trainings of health workers in APN and implementation at trained facilities started same week. APN data was analysed quarterly at Ministry of health level, dis-aggregated by gender.

LESSONS LEARNED: A total of 152,512 index clients (58% females, 42% males) were eligible for APN, of these, 65% (n=99,155, 59% females, 41% males) were interviewed, enlisting 146,961 (48% females, 52% males) sexual contacts in the last 12 months. Of the enlisted sexual contacts, 82% (n=124,391, 42% females, 58% males) were notified about their potential exposure to HIV and of these 75% (n=92,624, 50% females, 50% males) were tested for HIV with 22,970 (55% females,45% males) clients testing HIV positive hence a yield of 25% (28% in females, 22% in males. Of the newly identified HIV positive, 94% (n=21,224, 91% females and 95% males) were linked to care. Up to 12%(n=15,338) of all those that had been contacted were found to be already in care.

[Figure]

CONCLUSIONS/NEXT STEPS: Index client testing (APN) is a novel strategy in identifying the diagnosed people living with HIV. Next steps shall focus on curbing losses along the cascade.

PEE1553

CHARACTERISTICS OF CHILDREN LIVING WITH HIV WHO DIED BEFORE ART INITIATION IN UGANDA

C. Ngonzi Muhangi[1], D. Kajjumba[1]
[1]Makerere University, School of Public Health, Kampala, Uganda

BACKGROUND: Early HIV testing and immediate initiation on ART is critical for the survival of children living with HIV. The objective of this study was to describe characteristics of children who died before ART initiation and to learn where gaps and needed progress lie.

METHODS: Data was abstracted from facility records for children aged 0–18 months diagnosed with HIV between April 2018 and December 2019 from 14 health facilities providing Early Infant Diagnosis (EID) for HIV in selected facilities in Central Uganda. For this analysis, we included all children that ever-tested HIV-positive, including those lost to follow-up. Data were abstracted from patients' testing forms, facility HCT and ART registers and mother-infant records.

RESULTS: At the selected study facilities, 107 children tested HIV-positive; 87 (81%) were initiated on ART. Of 20 (19%) children not initiated on ART, 8 (38%) died before ART could be initiated despite a policy of counseling and offering ART on the same day of diagnosis. Of those who died, 63% had their initial test at age 6-8 weeks; 75% of deaths occurred before age 12 weeks. The median age at HIV testing among children who died before ART initiation was 7.6 weeks compared to 7.8 weeks for those who did not die; 6/8 (75%) children who died had received their HIV results before death. The median time from sample collection to caregiver receipt of results was 0 days in these sites; median time from testing to death was 7 days. Among infants who died before ART initiation, 38% of mothers were not receiving ART themselves.

CONCLUSIONS: Death was not associated with delayed EID testing, lack of caregiver receipt of results, or lack of access to ART. Thirty-eight percent of women whose children died before ART initiation were not on ART themselves; it is unclear if this had a negative influence on the decision for their children to receive ART. Further data are needed to assess how to enhance the policy of counselling for same-day ART initiation in children.

PEE1554

UNDISCLOSED ART USE AT PRIMARY HEALTH CARE CLINICS IN RURAL UMKHANYAKUDE, KWAZULU NATAL, SOUTH AFRICA: A CROSS SECTIONAL STUDY

N. Sithole[1], M. Moshabela[2], R. Gunda[1], O. Koole[1], M. Seidner[1], M. Krows[3], T. Schaafsma[3], C. Celum[3], R.V. Barnabas[3]
[1]Africa Health Research Institute, Mtubatuba, South Africa, [2]University of KwaZulu-Natal, School of Public Health and Nursing, Durban, South Africa, [3]University of Washington, Seattle, United States

BACKGROUND: People living with HIV (PLHIV) who present for HIV testing to primary health clinics (PHCs) are typically presumed to be antiretroviral therapy (ART) naïve. However, recent data have suggested that undisclosed ART use might be common. Non-disclosure of ART is not often measured in routine ART care programmes and can increase costs and decrease quality of care. . We assessed the prevalence of viral load suppression (VLS) and non-disclosure of ART among people testing for HIV in the public healthcare setting in South Africa.

DESCRIPTION: The Delivery Optimization of ART (DO-ART) clinical trial recruited PLHIV who self-reported as ART naïve or having defaulted for the past 3 months. Dried Blood Spots (DBS) were used to measure viral load. After identifying a frequent occurrence of VLS amongst participants screened for the study between February to November 2018 at 2 PHC clinics in uMkhanyakude, we pursued additional testing of DBS samples for tenofovir (TDF) and emtricitabine(FTC). We summarized the data about VLS, antiretroviral (ARV) use, and prior HIV testing from the DO ART study questionnaire.

LESSONS LEARNED: A total of 62 of 202 (30%) participants screened for the DO-ART study had an undetectable viral load. Of these 37/62 (60%) had ARVs detected in DBS samples. To answer the question have you ever tested for HIV, 1/62 answered don't know (ARVs detected), 29/62 answered no – I found out today (18/29(62%) had ARVs detected), 31/62 answered yes – I knew my status(17/31(55%) had ARVs detected), 1 No answer (ARVs detected).

CONCLUSIONS/NEXT STEPS: Undisclosed ART use among people presenting to care at PHC clinics appears to be common in rural KwaZulu-Natal. It can lead to a duplication of ART prescriptions and

mis-estimation of HIV diagnosis and treatment data. Future research should explore reasons for non-disclosure to identify solutions to this issue.

Participant responses to the question: "Ever tested for HIV"	N=62	ARVs detected in DBS
No, I found out today	29 (47%)	18/29 (62%)
I knew my status but am not on ART	31 (50%)	17/31 (55%)
I don't know	1 (2%)	1/62 (2%)
No answer provided	1 (2%)	1/62 (2%)

[Table 1. Self reporting HIV status versus ARV detection]

Godbole[1], Impact Evaluation of ART in India (ART-IE) study team

[1]ICMR-National AIDS Research Institute, Pune, India, [2]ICMR-National AIDS Research Institute (Formerly), Pune, India, [3]ICMR-National Institute of Epidemiology, Epidemiology, Chennai, India, [4]ICMR-National Institute of Medical Statistics, Delhi, India, [5]ICMR-National Institute for Research in Tuberculosis, Chennai, India, [6]ICMR-National Institute of Cholera and Enteric Diseases, Kolkata, India, [7]ICMR-National Institute for Research in Environmental Health, Bhopal, India, [8]National Chair (Medical Statistics), ICMR-National Institute of Medical Statistics, Delhi, India, [9]Ex-Prof. & Head, Dept. of PSM, Banaras Hindu University & Ex-NPO (HIV/AIDS), WHO, Lucknow, India, [10]National AIDS Control Organization, Delhi, India, [11]Indian Council of Medical Research, Delhi, India

BACKGROUND: India's free antiretroviral (ART) program initiated in 2004, was rapidly scaled-up with 355 ART-centers (ARTC) by 2012 and another 176 in 2017, serving 10,50,326 People Living with HIV (PLHIV) 'on-ART'. ART was provided at CD4 count ≤350/mm^3 during 2012-16, ≤500/mm^3 during July 2016–June 2017 and regardless of CD4 thereafter (test-and-treat). PLHIV registered but not qualifying for ART (Pre-ART PLHIV), were called back every six months, till the CD4 dropped to ART initiation cut-off, while PLHIV 'on-ART' visited monthly for drug pick-up. PLHIV missing scheduled visits for 3 consecutive months and untraceable were defined as lost to follow-up (LFU).

Sustainable success of large-scale treatment programs depends upon regular engagement with PLHIV in care, posing an implementation challenge. We estimated ART retention rates and its determinants among PLHIV registered during 2012-2017.

METHODS: Records of PLHIV aged ≥15 years and registered between April 2012 and March 2017 in 81/396 ARTC distributed across 33 Indian states/Union territories were reviewed. Life-table method, Cox proportional hazards model, Chi-square test helped estimate retention probability and potential determinants.

RESULTS: Of 154154 registered PLHIV, 82.3% received ART ('on-ART') during 2012-18. LFU proportions were significantly higher among 'pre-ART' PLHIV [28.9% vs 11.1% p<0.001)]. LFU was maximal at higher CD4 counts among 'pre-ART' PLHIV, while it was greatest at lower CD4 among PLHIV 'on-ART'. Five-year retention probability for 'pre-ART' and 'on-ART' PLHIV was 57% and 81%, respectively (overall). It was 46% when CD4 at registration was 351-500/mm^3 among 'pre-ART' PLHIV. LFU incidence was 4.3/100 and 12.9/100 person-years among PLHIV 'on- ART' & 'pre- ART', respectively. Overall, 'pre-ART' PLHIV had significantly higher chances of being LFU (Adjusted HZ 2.95, 95% CI 2.85-3.05) as compared to 'on-ART'. Other determinants of becoming LFU (Adjusted HZ, 95% CI) included PLHIV being 'male' (1.08, 1.05-1.11); having CD4 count 351-500/mm^3 (1.21, 1.16-1.26); and having tuberculosis (1.15, 1.10-1.19).

CONCLUSIONS: Offering ART immediately upon linkage to care, irrespective of CD4 count seems to be the key intervention to retain PLHIV in large-scale treatment programs, especially at CD4 counts >350/mm^3. Other innovative interventions to enhance PLHIV engagement with ARTCs is recommended.

PEE1556

SURGE STRATEGIES IMPROVE HIV TESTING EFFICIENCY AND LINKAGE TO TREATMENT AMONG FEMALE SEX WORKERS IN NAIROBI, KENYA

S. Mwangi[1], J. Gacheru[1], R. Mwenda[1], A. Olawo[2], C. Agunga[2], N. Njuguna[2], C. Akolo[3]

[1]Bar Hostess Empowerment and Support Program, Programs, Nairobi, Kenya, [2]FHI 360, Meeting Targets and Maintaining Epidemic Control (EpiC) Project, Nairobi, Kenya, [3]FHI 360 Kenya, Washington DC, United States

BACKGROUND: Kenya has made significant progress in the fight against HIV/AIDS but is unlikely to achieve epidemic control by 2020—hence, the need for accelerated optimized testing and treatment strategies. We sought to optimize case finding and linkage to treatment among female sex workers (FSWs) in Nairobi, Kenya through the implementation of surge strategies.

DESCRIPTION: Bar Hostess Empowerment and Support (BHESP), a key population (KP)-led organization working with the USAID/PEPFAR-funded LINKAGES project led by FHI 360, implements KP programming for FSWs by providing comprehensive HIV services at the drop-in center (DIC) or through outreach as part of differentiated service delivery models. In July–November 2019, the program initiated a surge strategy to accelerate case identification through the adoption of risk network referral (RNR), whereby FSWs at high risk for or living with HIV were asked to mobilize members of their social networks with similar risk profiles to access HIV testing at the organization's DIC or outreach locations. To ensure prompt linkage to HIV treatment among those testing HIV positive, service providers undertook individualized follow-up through phone calls and escorted referrals to the linkage facilities/DIC.

LESSONS LEARNED: BHESP increased HIV case-identification rates from 2.1% (64/3,043 FSWs who tested January–June 2019) to 9.7% (220/2,275 FSWs who tested July–November 2019), representing a four-fold increase in the case-identification rate. Of the 220 new cases identified, 193 (88%) resulted from RNR and 12% from routine outreach and testing. During the same period, the linkage rate increased from 65% to 98%. Creating buy-in from the FSWs living with HIV in identifying their higher-risk social networks was instrumental in identifying more cases. Involvement of clinical staff was also key, as the staff took ownership of the surge strategy, including setting weekly targets and reviewing results.

CONCLUSIONS/NEXT STEPS: Surge approaches enable programs identify implementation gaps and put in place more effective approaches. The lessons learned from these approaches should be built into routine program activities, thus optimizing outcomes. BHESP will continue to use these approaches with the aim of further improving case identification and linkage to HIV treatment.

[1]University of Washington, Seattle, United States, [2]PATH, Kisumu, Kenya, [3]Ministry of Health, Nairobi, Kenya, [4]Kenya Medical Research Institute, Nairobi, Kenya

BACKGROUND: HIV assisted partner services (aPS) has been recommended as a strategy to increase awareness of HIV positive status among HIV exposed individuals and link persons living with HIV (PLWH) to care. As the Ministry of Health (MOH) in Kenya scales up aPS into HIV testing services (HTS) nationally, understanding the main barriers and facilitators can help optimize integration, defined as the degree of coordination, collaboration, and consolidation of an intervention as it occurs.

METHODS: We conducted qualitative interviews with key aPS stakeholders in Kenya in 2018 (August, September) in Kisumu, and 2019 (January to June) in Homa Bay using semi-structured interview guides. Using an organizational systems model, aPS integration was analyzed across five HTS subsystems: adaptive (planning), supportive (procurement), maintenance (recruitment, training), production (service delivery) and managerial (monitoring, evaluation). We categorized aPS integration into three phases: introduction, routine aPS provision, and sustained aPS service delivery. Interviews were audio-recorded, transcribed, coded - both inductively and deductively - and analyzed using thematic content analysis with Dedoose software.

RESULTS: Twenty qualitative interviews were conducted (MOH policy-makers: 4 [20%], HIV implementing organizations: 5 [25%], county/sub-county AIDS coordinators: 4 [20%], facility in-charges: 7 [35%]). aPS integration activities were ongoing across the five HTS sub-systems, were predominantly at the introductory phase, and included development of aPS guidelines and training materials (adaptive), procurement of test kits (supportive), hiring and training HTS providers on aPS (maintenance), aPS service delivery (production), and monitoring of aPS indicators (managerial). Key challenges were limited HTS funding, weak legal frameworks, and human resource shortages to hire and train HTS providers, and to support phone and physical tracing of sexual partners.

CONCLUSIONS: Overall, lack of funding was noted to be a major barrier to aPS integration, while government involvement was a key facilitator. As aPS is scaled up and integrated into routine HIV testing services across sub-Saharan Africa, decision makers will require adequate resources to recruit and train HTS counselors in aPS, and to support tracing of sexual partners.

PEE1558

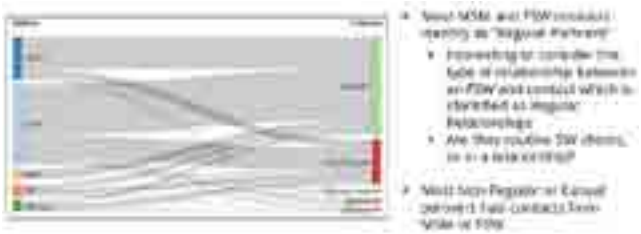
RELATIONSHIPS TYPES, AGE DISPARATE AND SEXUAL NETWORK TREES AMONG KEY POPULATIONS IN ZIMBABWE

N. Taruberekera[1], S. Leuschner[2], B. Mutede[2], B. Maponga[2], J. Mavudze[2], M. Munjoma[2], N. Madidi[2]
[1]Population Services International, Harare, Zimbabwe, [2]PSI, Harare, Zimbabwe

BACKGROUND: HIV index case testing (ICT) is increasingly an important approach for finding the remaining HIV positives given that such cases have become isolated. Zimbabwe is embracing this approach through a large national HIV program funded by USAID. To strengthen ICT it is important to routinely analyze sexual networking data to actively inform better programming.

DESCRIPTION: We used 798 index cases recruited through both private and public sector facilities and 1380 contacts for the period of June to August 2019 to examine relationships present in ICT sexual network trees using descriptive analysis and logistic regression modeling using R. Logistic regression predicted HIV positive status as explained by age mixing. High risk groups comprised men who have sex with men, female sex workers and their clients.

LESSONS LEARNED: We found that sexual networks among high risk populations are not isolated to high risk populations (Fig 1). As many as 38% and 4.4% of female sex worker indices are linked to the general population and high risk males (MSM) respectively. We also observed considerable age differences. About 5% of ages 15 to 24 years indices or contacts were partnered with ages over 45 years. Furthermore, we found that men had 1.85 times more positive contacts than women (OR=1.85; 95% CI 1.55-2.20) and that older ages were more likely to be positive (OR=1.015; 95% CI 1.01-1.03) while contacts in age-disparate relationships (younger or older) had 1.38 times greater odds of a positive test (OR=1.38; 95% CI 1.01-1.88).



[Figure 1. Characteristics of relationships - risk groups & relationship status]

CONCLUSIONS/NEXT STEPS: These findings suggest that index testing can be better yielding if targeted based on relationship type, inter-alia age disparate between the indices and contacts.

PEE1559

IMPROVING TARGETED HIV TESTING SERVICES (HTS) THROUGH AN HIV RISK ASSESSMENT QUESTIONNAIRE IMPLEMENTED AT SELECTED HEALTH FACILITIES IN HAITI: ISSUES, LESSONS LEARNED AND IMPLICATIONS FOR THE NATIONAL AIDS CONTROL PROGRAM

M.L. Excellent[1], D. Lauture[1], S.T. Omero[1], E. Emmanuel[1], F. Jean Louis[1], J.W. Domercant[1]
[1]*Institut pour la Santé, la Population et le Développement (ISPD), Pétion-Ville, Haiti*

BACKGROUND: The UNAIDS set a goal of delivering HIV testing services (HTS) to 95% of people infected. In Haiti, only 86% of the people living with HIV are aware of their HIV positive status. To achieve the UNAIDS goal, the National Control AIDS Program (PNLS) revised the National HIV testing guidelines and recommended targeted HTS. However, patients' risk factors for HIV infection are not assessed by providers prior to ordering HTS. Consequently, HTS report showed an over-testing of HIV negative individuals and a low positivity yield. We present here the outcomes of an intervention aiming at improving targeted HTS and HTS yield at selected health facilities in Haiti.

DESCRIPTION: In response to HIV over-testing reported during FY19Q3 (April-June2019), EQUIP developed and implemented a HIV-risk assessment questionnaire at 46 selected health facilities to foster reduction of routine HIV-testing practices and the adoption of targeted HTS. Targeted HTS implies the offer of HTS to people found to be at risk for HIV. We conducted training sessions on the revised HTS guidelines for providers followed by regular technical assistance (TA) visits to ensure providers' compliance and implementation of provider-initiated testing (PITC). Additionally, we conducted weekly review of HTS data to monitor progress and address challenges timely.

LESSONS LEARNED: Initially, the results of HTS-yield with the over-testing were as follows: In FY19Q1 the HTS yield was reported at 2.24% (N=872/38797) then at 2.05% (N=786/38265) in FY19Q2. After the implementation of the HIV-risk assessment questionnaire, HTS yield increased at 2.58% (N=921/35685) in FY19Q3 and reached 2.62% (N=798/30400) on FY19Q4. The implementation of the questionnaire resulted in an uptake of provider-initiated testing and counselling (PITC). Continuous onsite TA visits are critical for standardized implementation of targeted HTS. Overall, our interventions have helped address the HIV over-testing while improving HIV-positivity rate (HTS-yield).

CONCLUSIONS/NEXT STEPS: The implementation of a HIV-risk assessment questionnaire, led to an increase in the proportion of individuals newly tested positive for HIV while the overall number of persons tested decreased. HTS strategies targeting at risk populations can help PNLS/MOH in reaching the first 95 of the UNAIDS goal in Haiti.

PEE1560

RETENTION WITH SAME-DAY ART INITIATION AMONG HIV POSITIVE PEOPLE WITHIN TEST AND TREAT SETTINGS IN KIAMBU COUNTY, KENYA: A RETROSPECTIVE COHORT STUDY

E.O. Obat[1], C. Odhiambo[1], E... Mugambi[1], J... Mechi[1]
[1]*University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya*

BACKGROUND: Universal test and treat of newly-diagnosed PLHIV was envisioned to improve the retention of PLHIV in care.
This study assessed if time to ART initiation, within routine test and treat settings, among newly diagnosed PLHIV affected their retention at 12 months post ART initiation.

METHODS: Medical records of PLHIV aged ≥ 16 years, diagnosed HIV positive and started on ART between January and December 2017, at four public health facilities in Kiambu County were retrieved from the Electrical Medical Records (EMR) platform and analyzed. Transfer-ins and incomplete records were excluded from the analysis. Kaplan-Meier survival methods were used to determine the probability of being retained in care at 1-year post ART initiation. Multi-variate analysis was performed using cox regression. The study's significance level was set at $p \leq 0.05$.

RESULTS: Of 772 records reviewed, 661(86%) were eligible for analysis. Of these, 458 (69%) were females, 75.9% (502) were aged between 25-50 years while 17% aged 16-24 years. Of the 661, 252 (38.1%) began ART on the same day of diagnosis,31% began between day 1- 14 post-diagnosis while 30.8% took more than 14 days post-diagnosis before starting ART.
Among those who were lost to follow-up at 12 months, 75 (51.3%) were from for same-day ART group. Taking longer than 14 days after diagnosis to start ART was associated with a higher likelihood (0.85) of retention in care at 1-year post initiation, than starting on the same-day of diagnosis (0.65) or between day 1-14 (0.75), [P(log rank)= 0.000, 2 d.f]. Sex, marital status, residential settings, baseline WHO stage and age were not associated with an increased hazard of attrition post ART start.

CONCLUSIONS: Uptake of test and treat was sub-optimal and 1-year retention in care was poorer among those who opted for the same-day of diagnosis treatment as compared to those who took a day or longer before starting ART. This is contrary to findings that informed the test and treat policy. Therefore, factors behind the poor retention with same-day ART initiation should be explored contextually with a view of improving the retention of PLHIV in the area and informing practice locally, regionally and internationally.

PEE1561

TARGETING DIVORCED, SEPARATED AND WIDOWED PARENTS TO MAXIMIZE HIV CASE FINDING AMONG CHILDREN AND ADOLESCENTS IN ETHIOPIA

K. Delele[1], M. Mecha[1], G. Mayanja[1], T. Medrano[2]
[1]*FHI 360, OVC, Addis Ababa, Ethiopia,* [2]*FHI 360, IDHS, Washington, United States*

BACKGROUND: The USAID Caring for Vulnerable Children (CVC) Activity is a five-year project (2018-2022) implemented by FHI 360 in Ethiopia. As a PEPFAR-funded project, one of CVC's priorities is to identify new cases of children living with HIV in the community and link them to antiretroviral treatment.

DESCRIPTION: In Ethiopia, the HIV testing positivity rate among children/adolescents <18 is below 1% making it difficult to identify HIV positive cases. CVC implemented a six-month initiative to accelerate HIV case finding among children and adolescents <18 in Addis Ababa (July-December, 2019) . Given that Divorced, Separated and Widowed (DSW) adults have shown a higher HIV positivity rate, we tested a new case finding strategy of using DSW parents as an entry point to identify new HIV cases among children/adolescents.

In addition, the project's regular case finding strategy of identifying children based on the following risk factors was used: being an AIDS orphan, double orphan, sexually active adolescent, chronically sick, sibling of infected child, or sexual partner(s) of adolescents with HIV. We used community peer mobilizers and social service workers to identify eligible parents and their biological children for HIV testing.

LESSONS LEARNED: A total of 3,245 DSW parents were tested for HIV, of which 175 (5.4%) tested HIV+. All 382 children of these newly diagnosed women were tested for HIV using ICT (Index Case Testing) of which 22 tested HIV+ (5.8% positivity rate). For children tested based on the regular risk factors, the following positivity rates were found: 2.6% (13/500) for AIDS orphans, 1.2% (3/260) for double orphans, 1% (9/880) for sexually active adolescents, 0.7% (1/146) for chronically sick children. No cases were detected among 32 siblings of HIV infected children and 49 sexual partners of HIV infected adolescents. The odds of HIV positivity from ICT was 4.3x (95% CI 2.3-8.0) higher compared to testing at risk children with the regular approach.

CONCLUSIONS/NEXT STEPS: The HIV positivity rate of 5.8% among children of newly diagnosed DSWs indicates that ICT among this population is an effective HIV case finding strategy for children and adolescents. Family centered HIV testing targeting DSWs should be prioritized to identify HIV positive children.

PEE1562

DIFFERENTIATED HIV TESTING TO REACH THE MALE SUB-POPULATION IN MUBENDE REGION-UGANDA

A. Mugisa[1], B. Nakibuuka[1], J. Baluku[1], J. Nakaweesi[1], C. Ssenyimba[1]
[1]Mildmay Uganda, Health Systems Strengthening, Kampala, Uganda

BACKGROUND: According to the Uganda Population HIV/AIDS (UPHIA) survey 2016, the HIV prevalence of men is 4.7%. It is approximated that 126,341 males greater than 15 years need to be initiated on ART in Uganda (PEPFAR, Uganda 2019).

With a primary objective of ensuring that 65% of the total positives identified in the region are men, Mildmay Uganda has implemented differentiated HIV testing(HTS) approaches tailored towards reaching men. Here we present the impact of the different testing approaches in the project implementation area from October 2018 to September 2019.

DESCRIPTION: With PEPFAR support, Mildmay Uganda has been implementing a 5-year project aiming at "Accelerating Epidemic control in Mubende Region" since April 2017. The geographical scope for this project is 8 districts in the central region of Uganda (Luwero, Nakaseke, Nakasongola, Mityana, Mubende, Kiboga, Kassanda & Kyankwanzi).The Differentiated HTS approaches for men included Assisted Partner Notification (APN) through female index clients, Social Network strategy(SNS) testing at 55 facilities, Flexi Hour testing in the late evenings at 25 designated high volume facilities, HIV Self-testing targeting spouses of pregnant and lactating women and workplace HTS in communities using male champions targeting plantation workers, brick layers, cattle keepers and fisher folks.

LESSONS LEARNED:

- Two thousand eight hundred ninety-eight (2,898) men tested positive from the above testing approaches, contributing 44% of the total positive identified in COP18
- The highest yielding testing approaches have been APN at 20% and SNS at 18%
- The lowest yielding approaches were flexi hour testing at 4% and work place testing at 5%

CONCLUSIONS/NEXT STEPS: Scaling up high yielding testing approaches like APN and SNS is important in identifying HIV positive men.

PEE1563

UTILIZATION OF SURGE STRATEGY TO ACCELERATE HIV CASE FINDING THROUGH INDEX PARTNER TESTING: LESSONS LEARNT FROM IRINGA AND MOROGORO REGIONS IN TANZANIA

B. Msongole[1], J. Gamaliel[1], J. Kimario[1], M. Kamonga[1], B. Christian[2], J. Bisimba[3], C. Jones[4], E. Okechukwu[1], M. Njelekela[4]
[1]FHI 360, Dar es Salaam, Tanzania, United Republic of, [2]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [3]USAID, Dar es Salaam, Tanzania, United Republic of, [4]Deloitte Consulting Limited, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Reaching the first 90 in Tanzania is still a challenge, according to Tanzania HIV impact survey in 2016, only 61% of PLHIV in Tanzania were aware of their HIV status. USAID Boresha Afya Southern Zone Program implemented surge approach in its two supported regions with high HIV burden. Surge was conducted for a period of six weeks and index testing among sexual contacts was one of the main strategies for HIV case finding.

DESCRIPTION: Surge was implemented in Iringa and Morogoro regions in 83 priority high volume facilities but was scaled in facilities with hotspots as catchment areas. Implementation index testing through surge involved listing PLHIV enrolled between April and August 2019 and initiating elicitation campaigns. Index contacts with missed opportunity for testing were actively tracked through assisted partner notification methods. Program technical staff were assigned as facility backstops and sensitization of the regional, district, and facility-level management teams was done. PLHIV peers volunteering at HIV clinics were actively engaged in tracking index contacts. In facilities with limited human resources, additional testers were deployed to overcome the deficit. Index elicitation and testing was extended beyond working hours and during weekends.

LESSONS LEARNED: A total of 20,363 sexual contacts were tested during the surge implementation period, three times increase compared to pre surge period (6,073). Positive cases identified among sexual contacts tested were 6,381, males were 2,969 (47%) and females were 3,412 (53%). Positive sexual contacts identified during surge period were 2.5 times higher compared to pre surge period (2,592) and contributed to 76% of the total positive cases identified (8,319) in the two regions.

A decrease in yield from 43% in pre -surge period to 31% during surge period was due to increased testing coverage. The yield for females during surge was significantly high 33% (p=.00001, 95%CI 32% -34%) compared to male positive yield of 30%.

CONCLUSIONS/NEXT STEPS: The results showed effectiveness of surge approach in accelerating HIV case finding through index sexual partners testing. Further, close site monitoring, involvement of regional and district health management teams and daily data monitoring for continuous improvement were key to the success of surge implementation.

PEE1564

CHANGES IN PRE-TREATMENT LABORATORY MONITORING PRACTICES UNDER "TREAT-ALL" GUIDELINES IN 28 COUNTRIES

E. Brazier[1,2], O. Tymejczyk[1,2], E. Zaniewski[3], M. Egger[3], K. Wools-Kaloustian[4], C.T. Yiannoutsos[4], A. Jaquet[5,6], K.N. Althoff[7], J. Lee[7], Y. Caro[8], P.M. Luz[9], J. Tanuma[10], T. Niyongabo[11], D. Nash[1,2], International epidemiology Databases to Evaluate AIDS (IeDEA) consortium

[1]City University of New York (CUNY), Institute for Implementation Science in Population Health (ISPH), New York, United States, [2]City University of New York (CUNY), Graduate School of Public Health and Health Policy, New York, United States, [3]University of Bern, Institute of Social and Preventive Medicine (ISPM), Bern, Switzerland, [4]Indiana University, School of Medicine, Indianapolis, United States, [5]Centre Inserm 1219 & Institut de Santé Publique d'Épidémiologie et de Développement, Bordeau, France, [6]Université de Bordeaux, Bordeaux, France, [7]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [8]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Departamento de Infectología, Mexico City, Mexico, [9]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [10]AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan, [11]Centre National de Reference en Matiere de VIH/SIDA (CNR), Bujumbura, Burundi

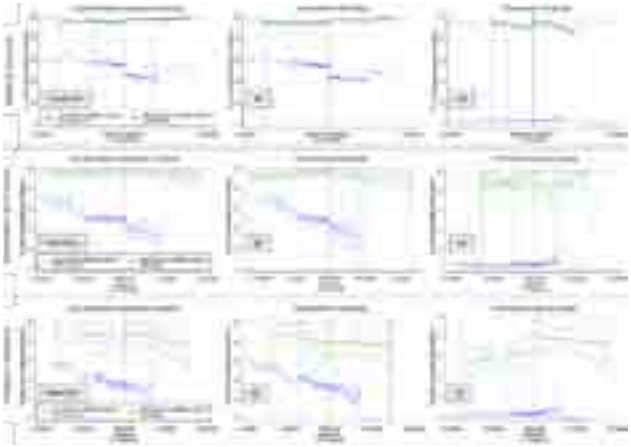
BACKGROUND: While antiretroviral therapy (ART) has expanded rapidly, the effect of Treat-All policies on pre-treatment laboratory monitoring practices is under-researched.

METHODS: We examined the effect of Treat-All policies on pre-treatment CD4 and viral load (VL) testing using a regression discontinuity design with data-driven bandwidths and data from 523,854 patients enrolling in HIV care and initiating ART between 2006 and 2018 in 28 countries at 434 sites participating in the International epidemiology Databases to Evaluate AIDS (IeDEA) consortium. Changes in the proportion of patients with any pre-ART laboratory monitoring, along with CD4- and VL-specific proportions, were estimated among adults (aged ≥20 years), adolescents (aged 10-19) and children (aged <10) in low-/lower-middle income countries (L/LMICs) and in high/upper-middle income countries (H/UMICs).

RESULTS: In L/LMICs, national adoption of Treat-All policies was followed by an immediate decrease in the proportion of adult patients with any pre-treatment laboratory monitoring [Panel A(1)], from 54.4% to 47.8% (-6.7 percentage points [pp]; 95%CI: -8.4 to -4.9), with a comparable change observed among adolescents [Panel B(1)], from 50.7% to 43.3% (-7.4pp; 95%CI: -12.4 to -2.4), and no change observed among children [Panel C(1)].

Changes in the proportion of adults and adolescents with any pre-treatment laboratory monitoring were largely due to decreases in pre-treatment CD4 testing [Panel A(2) and B(2)]. In H/UMICs, the proportion of patients with any pre-treatment laboratory monitoring was very high prior to national adoption of Treat-All, and increased slightly among adult patients.

CONCLUSIONS: There are major disparities in pre-treatment laboratory monitoring by country income group. A concerning proportion of patients in L/LMICs start ART without any pre-treatment laboratory tests, and this has been exacerbated by Treat-All policy implementation. Current policies and practices in L/LMICs should be revised, especially around pre-treatment CD4 monitoring, to ensure the ability to provide differentiated care and adequately monitor progress toward earlier diagnosis and treatment initiation.



[Figure]

PEE1565

IMPROVING LINKAGE TO ANTIRETROVIRAL TREATMENT USING A PEER ATTACHMENT MODEL IN SELECTED FACILITIES IN THE SOUTHERN HIGHLAND ZONE, TANZANIA

A.w. Ngwalle[1], E. Akom[2,3], K. Samoel[1], J. Mgaya[4], D. Maganga[1], F. Ndossi[1], H. Wazee[4], A. Adetosoye[5], E. Churi[1]

[1]HJF Medical Research International (HJFMRI), Medical Department, Mbeya, Tanzania, United Republic of, [2]U.S. Military HIV Research Program (MHRP), Walter Reed Army Institute of Research, Medical Department, Silver Spring, United States, [3]Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, Medical Department, Silver Spring, United States, [4]HJF Medical Research International (HJFMRI), Medical Depertment, Mbeya, Tanzania, United Republic of, [5]HJF Medical Research International (HJFMRI), Program Management, Mbeya, Tanzania, United Republic of

BACKGROUND: Linkage of HIV positive individuals to antiretroviral therapy (ART) remains a challenge in Tanzania, reducing progress towards epidemic control. In April 2019, the PEPFAR Tanzania program launched a national intervention targeting 241 high volume facilities to boost performance in key indicators, including linkage and early retention on ART. To address this gap in the Southern Highlands, we sought to build on evidence from the Bukoba Combination Prevention Evaluation study, which had previously demonstrated good outcomes for linkage and early retention through a Peer Attachment Linkage Case Management (LCM) model.

DESCRIPTION: HJFMRI, an implementing partner of the U.S. Military HIV Research Program, adopted LCM in 54 high volume health facilities. All newly identified and consenting PLHIV are assigned and attached to a case manager, a trained expert client. The case manager provides escort and ART clinic navigation, in-person meetings or phone calls for psychosocial support and appointment reminders. During the meetings, they offer counselling on the importance of same-day ART initiation, remaining on ART for life and disclosure of status. The expert clients assess and resolve enrollment and retention barriers during each session. They closely manage clients through their second ARV refill. LCM activities are monitored through a dedicated register, while linkage and retention information is extracted from the facilities' routine monitoring system.

LESSONS LEARNED: During the first six months, 13,050 of the 13,656 adult PLHIV newly diagnosed in the 54 facilities consented to be attached to expert clients for LCM. Of these, 12,034 (92%) consented for

rapid ART initiation, including (88.6%) who were initiated on ART on the day of diagnostic. After six weeks, 10,661 (88.6%) were retained on treatment. In these facilities, the intervention increased linkage to 90%, compared to 84% before the introduction of LCM. The LCM model also had a significant impact on index testing, increasing the percentage of acceptance of index testing from 77% to 96%, while the average number of elicited contacts increased from 0.9 to 2.

CONCLUSIONS/NEXT STEPS: LCM is a successful strategy for active linkage and early retention amongst adult PLHIV and is likely to improve program performance if implemented in other PEPFAR countries.

PEE1566

GAPS AND BARRIERS FOR HIV DNA PCR TESTING AT REGIONAL REFERENCE LABORATORIES (RRLS) ACROSS INDIA UNDER EARLY INFANT DIAGNOSIS (EID) PROGRAMME

S. KAMBLE[1], N. GAWDE[2], N. GOEL[1], M. THORWAT[1], D. Jagtap[3], S. Kurle[4], S. Gadhe[5], V. VERMA[6], R. GANGAKHEDKAR[7], S. Rajan[6]
[1]ICMR-National AIDS Research Institute, Epidemiology and Bio Statistics, Pune, India, [2]Tata Institute of Social Sciences, Pune, India, [3]ICMR-National Institute of Research in Reproductive Health, Mumbai, India, [4]ICMR-National AIDS Research Institute, Pune, India, [5]ICMR-National AIDS Research Institute, Epidemiology and Communicable Division, Pune, India, [6]National AIDS Control Organisation, New Delhi, India, [7]Indian Council of Medical Research, Epidemiology and Communicable Division, Pune, India

BACKGROUND: Regional Reference Laboratories (RRLs) play crucial role for HIV DNA PCR testing on Dried Blood Spot (DBS) samples under Early Infant Diagnosis (EID) programme of India. We assessed the gaps for testing of DBS samples pertaining to total Turn Around Time (TAT) from sample collection till receipt of result,sample rejection, infrastructure and logistic issues.

METHODS: Programme RRL data (2013-2016) was analysed and facility survey was conducted across four RRLs along with data collection. In Depth Interviews (IDI) were conducted among service providers to assess implementation gaps.

RESULTS: TAT for DBS testing had declined from 53 median days (2013) to 29 days (2016) due to reduced sample processing time; however there was no improvement in transport and dispatch time. There was interstate variation with median TAT from 16 days in Karnataka state to 63 days in Odisha state. Sample transportation time was high for states of Odisha (33 days) and West Bengal (27 days) while processing and testing time was more in Southern Indian states (28 days).

Two of four RRLs were nationally accredited. At all RRLs personal protective equipment, biomedical waste management procedures and calibrated equipment were available. Overall discordant result on confirmatory testing was observed for 11% to 19% samples. Overall 2.6% (414) samples were rejected mainly because of inadequate quantity (164) and delay in receipt of DBS (125) at RRL. After rejection, repeat samples were received only from 55 cases (13.4%) after a median delay of 141 days, of which 4 samples later on turned as positive. Qualitative data revealed testing challenges like inadequate collection and storage of DBS, discrepancy in sample and data form, missing information of child and labelling issues. Improper postal or email address, long waiting for postage, receipt of result courier during non-working hours were communication challenges. Inadequate collection and packing of DBS and ART initiation before confirmatory diagnosis were quoted reasons for discordant results. Inadequate funds and human resources were leading to delayed testing and increasing work load.

CONCLUSIONS: The observed gaps highlight the need for decentralization of HIV diagnostic DNA PCR testing, capacity building of laboratory personnel and for national accreditation of existing laboratories.

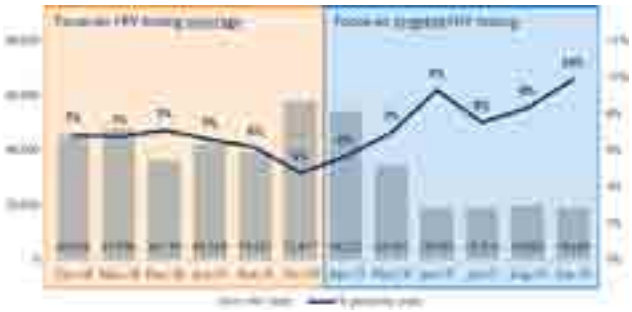
PEE1567

TARGETED HIV TESTING IMPROVES POSITIVITY YIELD AND REDUCES TESTING VOLUMES AMONG THE GENERAL POPULATION IN ZAMBIA

M. Sichamba[1], B. Kafulubiti[2], M. Goma[1], W. Kanjipite[1], D. Dixon[1], C. Madevu Matson[3], M. Osborne - Smith[3]
[1]JSI, USAID SAFE Project, Kabwe, Zambia, [2]JSI, USAID SAFE project, Kabwe, Zambia, [3]JSI, USAID SAFE Project, Boston, United States

BACKGROUND: HIV testing is critical to ensure early diagnosis and treatment of people living with HIV (PLHIV) which reduces transmission to others. As we move towards HIV epidemic control, index testing and HIV screening tools have been shown to be efficient and effective targeted testing strategies to identify the remaining undiagnosed PLHIV.

DESCRIPTION: The USAID SAFE program supports the Ministry of Health (MOH) in 114 health facilities in Central Province, Zambia to implement HIV case identification, treatment and retention services since October 2018. Initially, widespread testing focused on increasing coverage but led to high numbers of HIV test kits being used and declining yields. USAID SAFE shifted to targeted HIV testing: (1) Enhanced index testing through administering an Index Interview Guide to all newly identified PLHIV and those already on ART each time they came to the facility to determine sexual risk behaviors and assess eligibility for partner notification services, (2) Enhanced use of MOH HIV screening tool in all testing points to screen all (except antenatal women) seeking HIV testing, only clients with one or more risk factors or HIV defining condition were offered an HIV test.



[Figure]

LESSONS LEARNED: The initial focus on increasing HIV testing coverage led to declining positivity yield from 7% in Oct-2018 to 5% by Mar-2019, while targeted testing increased yield to 10% in Sep-19. HIV testing volumes reduced remarkably by 67% (from 57,817 to 19,064) representing a potential savings of over 35,000 HIV test kits in one month.

CONCLUSIONS/NEXT STEPS: Targeted HIV testing through enhanced index testing and HIV screening tools improve the positivity yield while reducing the testing volumes. As we progress toward HIV epidemic control, MOHs and implementing partners should embrace effective and efficient testing techniques to identify the remaining pockets of HIV to avert new infections and attain epidemic control.

PEE1568

FINDING PEOPLE LIVING WITH HIV AND AIDS IN THE SOUTHERN HIGHLAND ZONE, TANZANIA: STRATEGIC USE OF A NATIONAL HIV ELIGIBILITY SCREENING TOOL

A.W. Ngwalle[1], E. Akom[2,3], K. Samoel[4], E. Churi[1], J. Mgaya[1], D. Maganga[1], F. Ndossi[1], H. Wazee[1], A. Adetosoye[5]

[1]HJF Medical Research International (HJFMRI), Medical Department, Mbeya, Tanzania, United Republic of, [2]U.S. Military HIV Research Program (MHRP), Walter Reed Army Institute of Research, Medical Department, Silver Spring, Tanzania, United Republic of, [3]Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, Medical Department, Silver Spring, United States, [4]HJF Medical Research International (HJFMRI), Research Department, Mbeya, Tanzania, United Republic of, [5]HJF Medical Research International (HJFMRI), Program Management, Mbeya, Tanzania, United Republic of

BACKGROUND: Chronic HIV over testing has been a major challenge in Tanzania. To avoid this, HJFMRI, an implementing partner of the U.S. Military HIV Research Program, aims to increase targeted HIV testing and to reduce repeat testing of low-risk individuals. The program adopted the standardized national screening tool to identify individuals at high risk of HIV infection among outpatient department (OPD) attendees in the Southern Highlands Zone. The goal of the HIV screening tool is to decrease the number of people needed to test to identify one positive individual, thereby improving testing efficiency and yield.

DESCRIPTION: Group pre-test counseling was offered to all OPD patients in waiting areas. All patients were referred for screening on HIV testing eligibility, and screening outcomes were documented in a register. All OPD patients were given a testing slip and routed to a provider-initiated testing and counselling (PITC) room for opt-out testing. Those eligible were tested for HIV while maintaining their place in the clinic queue. Testing was conducted by clinicians, nurses and counselors. Screening and testing data were monitored weekly, and regular supportive supervision visits ensured the quality of the services provided in the facilities.

LESSONS LEARNED: Between April 1 to September 30, 2019, 535,616 patients attended the OPDs for various services in 132 health facilities. Of these, 448,317 (83%) were screened for eligibility of HTS and 113,392 (25%) of those screened were eligible. HIV testing was successfully provided to 108,288 (95.5%) of the eligible clients and 5,721 (5.3%) were diagnosed HIV positive. This is a 1.9-fold increase in testing yield compared to the previous 6 months, when PITC yielded 2.8% positivity rate.

CONCLUSIONS/NEXT STEPS: Eligibility screening is a successful strategy for targeted HIV testing in medical entry points and has substantially improved testing yield amongst adults and children visiting health facilities for treatment. Remaining challenges to be addressed include: a shortage of human resources in facilities, inadequate knowledge and accountability of the testers, and lack of space for screening and OPD testing. In tandem with these improvements, the eligibility screening strategy should be extended beyond PEPFAR-supported facilities in Tanzania for maximal impact.

PEE1569

FACILITATORS AND BARRIERS TO KNOWLEDGE ON 'UNDETECTABLE VIRAL LOAD IS UNTRANSMITTABLE' AMONG SEXUALLY ACTIVE ADULTS ON ANTIRETROVIRAL THERAPY IN LUSAKA, ZAMBIA

F. Ngwenya[1], M. Simuyaba[2], T. Banda[3], J.M. Zulu[4], H. Halwiindi[1], M. Makasa[5,6]

[1]University of Zambia, Department of Community and Family Medicine, Lusaka, Zambia, [2]Zambart, University of Zambia, School of Public Health, Lusaka, Zambia, [3]Centre for Infectious Diseases Research in Zambia, Lusaka, Zambia, [4]University of Zambia, Department of health policy and Management, Lusaka, Zambia, [5]University of Zambia, Biostastitics and Epidemiology, Lusaka, Yemen, [6]University of Zambia, Public Health,Department of Epidemiology and Biostatistics, Lusaka, Zambia

BACKGROUND: In Zambia, sub-optimal adherence to antiretroviral treatment (ART) is among the main reasons deterring attainment of the 90% viral load (VL) suppression among adults. Limited knowledge about 'undetectable VL is untransmittable' is envisaged as a barrier for optimal adherence to ART especially among asymptomatic people living with HIV (PLHIV). In order to attain at least 90% of sustained VL suppression rate, it is inevitable that PLHIV are knowledgeable about 'undetectable VL is untransmittable'. Thus, the study explored the barriers and facilitators on knowledge about 'undetectable VL is untransmittable' among PLHIV on ART in Lusaka.

METHODS: Data were collected between December 2018 and January 2019, in three busy ART facilities in Lusaka. Semi-structured interview schedules were used to explore PLHIV's perceptions and knowledge on 'undetectable VL is untransmittable'. Purposive sampling was used to select a mix of PLHIV with suppressed (n=41) and unsuppressed (n=14) VLs. A total of (n=25) men and 35 women, aged 18-58 years participated in the study. All the participants were on ART for at least nine months. Data were analysed thematically.

RESULTS: We identified facilitators and barriers to knowledge on 'undetectable VL is untransmittable'. The facilitators were: (1) Various sources of knowledge including friends on ART, learning by being in a discordant relationship, self-taught through internet, radio, health care providers, and through enhanced adherence counseling especially among those with unsuppressed VL, and (2) benefits of 'undetectable VL is untransmittable' consisting of reduced stigma and worry-free sexual relationship due to negligible risk to infect partner. The barriers comprised: (1) inadequate literacy on VL and its implication on HIV transmission but with more emphasis on CD4 count literacy, (2) waiting time affected follow up of VL results and to attend literacy sessions, (3) extended fast track short-visits limited interaction with literacy sessions, and (4) undetectable VL is perceived transmittable.

CONCLUSIONS: Achieving a sustained third 90 goal requires increased knowledge of the efficacy of 'undetectable VL is untransmittable' among PLHIV. Therefore, there is need to prioritise health literacy on 'undetectable VL is untransmittable' to both virally suppressed and unsuppressed PLHIV, and to address barriers of waiting time and extended fast track short-visits.

PEE1570

MISDIAGNOSIS OF HIV INFECTION AND THE DILEMMA OF THE INDETERMINATE RESULT: A COMMUNITY CROSS-SECTIONAL STUDY AMONG HIV-POSITIVE WOMEN AND CHILDREN IN SOUTHERN MOZAMBIQUE

L. Fuente-Soro[1,2], L. Paroni[1], S. Fernández-Luis[1,2], E. López-Varela[1,2], O. Augusto[2], T. Nhampossa[2], I. Cuamba[2], E. Bernardo[3,4], H. Guambe[5], K. Tibana[5], B. Ngeno[6], M. Urso[6], D. Naniche[1,2]
[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Manhiça Health Research Center (CISM), HIV, Manhiça, Mozambique, [3]Manhiça District Health Services, Manhiça, Mozambique, [4]Vanderbilt Institute for Global Health, Tennessee, United States, [5]Ministério de Saúde (MISAU), Maputo, Mozambique, [6]Centers for Disease Control and Prevention (CDC), Maputo, Mozambique

BACKGROUND: Universal "Test and Treat" in pregnant women began in 2012 to prevent HIV mother-to-child transmission (MTCT). In most sub-Saharan African settings, HIV rapid diagnostic tests (RDT) are the main diagnostic tool, and yet there is limited data on women and children misdiagnosed . During surveillance campaigns, there is also a lack of standardization on how indeterminate lab-confirmatory results (ILCR) are classified. While WHO excludes ILCR, the Mozambican population-based survey considered ILCR HIV-negative. We aimed to estimate the magnitude of HIV misdiagnosis among women and children, applying three ILCR interpretation scenarios, in Manhiça, Mozambique.

METHODS: This analysis was nested in a cross-sectional household HIV-testing survey conducted between October 2017 and April 2018 to measure community MTCT among children under-4. A total of 5000 mother-child pairs were randomly selected for participation. HIV serostatus of all pairs was ascertained through documentation or age-appropriate testing following national guidelines for RDT using serial Determine and Unigold for mothers and children >18-months. For the purpose of this analysis, only children>18-months were included. HIV-positive participants provided a dry blood spot sample (DBS) for a laboratory-confirmatory test (Bio-Rad Geenius HIV 1/2) which provided one of three possible results: positive (HIV-true-positive), negative (HIV-false-positive) or indeterminate. For analysis we considered three potential scenarios, varying in how ILCR was classified. Classification as 1) HIV-true-positive in the study-scenario, 2) HIV-negative in the Surveillance-scenario and 3) excluded in the guideline-scenario. Prevalence of misdiagnosis was calculated as HIV-false-positives/all-positives for all scenarios.

RESULTS: Overall, 3069/5000 (61.4%) mothers-child pairs were recruited. Among them, 864 mothers and 30 children were identified as HIV-positive and provided a DBS sample. Lab-confirmatory testing identified 808 (93.5%) of mothers as HIV-true-positive, 18 (2.1%) as HIV-false-positive and 38 (4.4%) with ILCR. Estimates of prevalence of misdiagnosis in mothers was 2.1% (95% CI 1.2-3.3) in the Study-scenario, 2.2%(95% CI 1.3-3.4) in the Guideline-scenario and 6.5%(95% CI 4.9-8.3) in the Surveillance-scenario. Among children, no ILCR were obtained, thus prevalence of misdiagnosis was 6.7% (95% CI 0.8-22.1).

CONCLUSIONS: To avoid HIV-false-positive results and unnecessary ARV-exposure, systematic confirmatory testing should be done, however a unified approach to classify indeterminate confirmatory-results is needed to better monitor true prevalence of HIV-misdiagnosis.

PEE1571

SUPPORTING SCALED-UP OPTION B+: LESSONS FROM MALAWI'S PREVENTION OF MOTHER-TO-CHILD HIV TRANSMISSION (PMTCT) COMMUNITY FACILITY LINKAGE (CFL) MODELS

S.M. Topp[1], N. Carbone[2], J. Tseka[2], L. Kamtsendero[2], G. Banda[2], M.E. Herce[3]
[1]James Cook University, Townsville, Australia, [2]UNC Project, Lilongwe, Malawi, [3]University of North Carolina, Chapel Hill, United States

BACKGROUND: In Malawi, several large community facility linkage (CFL) models support the national prevention of mother-to-child HIV transmission (PMTCT) and antiretroviral (ART) programmes to strengthen engagement and retention in care and treatment. Training lay health workers to carry out clinic and community-based activities, Malawi's CFL programmes (e.g. Mentor Mothers, Expert Clients, Tingathe Community Health Workers) are currently largely NGO-financed and administered. We explore the nature and sustainability of current governance arrangements and implications for future programming.

METHODS: Using a case-based design, we conducted eight in-depth facility assessments comprising a facility/CFL model survey; 43 semi-structured interviews with PMTCT clients; 30 focus group discussions with Ministry-employed professional and lay providers and CFL providers; between 2-4 hours of onsite observation per site; and in-depth interviews with 13 CFL program coordinators and Ministry officials. Thematic analysis was used, drawing on institutional governance theories that promote relational analysis.

RESULTS: Although Ministry stewardship of health services was universally acknowledged by NGO partners, the donor-driven priorities of NGOs were often noted as dominant. Multiple district stakeholders described NGO's need to demonstrate impact and resultant preference for operating in high-performing sites as detrimental to district attempts to strengthen service quality or improve coverage in poorer performing sites. The burden of coordinating multiple NGOs to enable CFL scale-up placed strain on district human resource capacity and was inefficient. Moreover, the largely project-based nature of CFL programmes saw cyclical defunding of trained CFL providers weakening motivation and impacting service consistency. While acknowledging the much-needed contribution CFL models make retention and engagement outcomes and recognising that Government of Malawi cannot currently absorb programme costs, stakeholders at facility, district, provincial and national levels nonetheless characterized the current CFL governance arrangements as sub-optimal.

CONCLUSIONS: In the era of Option B+ and 'treat all' policies for HIV effective strategies to strengthen engagement and retention in care are critical. However the embeddedness and sustainability of those strategies is also important. Short term and duplicative programs absorb scarce resources and risk demotivating precious human resources on whom retention and engagement programmes rely. Findings point to the importance of innovating governance models that support Ministry-led, donor financed human resource strategies.

PEE1572

TEST AND TREAT, THE DILEMMA OF THE WOMAN IN ANC IN MALAWI

J.M. Tseka[1], N. Carbone[1], L. Kamtsendero[1], S.M. Topp[2], M.E. Herce[3]
[1]UNC Project, Lilongwe, Malawi, [2]James Cook University, Townsville, Australia, [3]University of North Carolina, Chapel Hill, United States

BACKGROUND: Malawi's introduction of Option B+ policy improved uptake and retention in prevention of mother to child transmission (PMTCT) and resulted in impressive gains in the number of pregnant and breastfeeding women initiating antiretroviral therapy (ART). Despite this, retention-in-care of women has remained a key challenge. In the context of a study examining the impact of linkage-programs on PMTCT outcomes, we sought to understand key factors that continue to influence women's engagement in care.

METHODS: Across five districts and eight clinics we interviewed 43 PMCTC-enrolled mothers, and conducted 30 focus groups with professional, lay and NGO health workers. Thematic inductive analysis was used to identify and synthesis findings.

RESULTS: Findings revealed complex interaction between social, structural and individual motivations for starting and remaining in care. However a dominant theme in both client and health worker accounts was the tension between women's socially-sanctioned motivation to engage in PMTCT to '*protect my unborn child*' and their equally socially driven fears that treatment would result in their '*being accused of being the one who brought the virus into the home*' resulting in abandonment by (particularly) husbands. While many emphasized initial engagement in care as driven by a desire to 'save' the life of the child, some mothers felt pressured by the system to comply with government policy despite ongoing fears about the consequences for their own social security. In the context of this dominant narrative, facilities' capacity to respond to women's fears, through provision of counselling, community follow-up and psychosocial and peer support were often predictive of improved long-term engagement and retention.

CONCLUSIONS: While preserving their child's life remains a key motivation for enrolling in PMTCT for pregnant and breastfeeding women, it does not remain a strong motivation for remaining engaged in ART once the child is born. For Option B+ to deliver on its promise, health facilities must be able to respond to women's need for counselling, linkage and support in the critical post-partum phase, and PMTCT and ART programmes must further engage with social programming to address still-prevalent, gendered, community-based HIV stigma.

PEE1573

OUTCOMES OF HIV INFECTED CLIENTS WHO PRESENT WITH ADVANCED DISEASE AT ENROLLMENT INTO CARE WITHIN PACT TIMIZA-SUPPORTED FACILITIES IN WESTERN KENYA

C. Ngeno[1], H.O. Ramadhani[2], E. Amadi[1], N. Blanco[2], A. Ndaga[1], R. Oyuga[1], F. Ogero[3], E. Owino[4], A. Aoko[5], E. Koech[1]
[1]University of Maryland, CIHEB, Nairobi, Kenya, [2]University of Maryland, CIHEB, Baltimore, United States, [3]Kisii County, Department of Health, Department of Health, Kisii, Kenya, [4]Migori County, Department of Health, Department of Health, Migori, Kenya, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Kisumu, Kenya

BACKGROUND: Globals trends indicate that median CD4+ count at antiretroviral therapy(ART) initiation is <350cells/mm^3 across all income groups indicating late presentation despite implementation of Test and Start guidelines. Studies have focused on trends, reasons for late presentation and mortality amongst those with advanced disease and less on, viral suppression(VS, viral load<1000copies/ml), and lost to follow up(LTFU, >30days missed doses) which may influence patient management.

METHODS: A retrospective cohort analysis of patients initiated on ART between October 2017-September 2018 was undertaken to evaluate association between late presentation and VS and retention among patients >15 years in 4 UMB-supported facilities in Kisii and Migori counties. Participants with a baseline CD4+ count<200cells/mm^3 were classified as having advanced disease. Multivariate logistic regression models were used to evaluate the association between advanced disease and VS at 6 and 12 months on ART at 95% significance level. Kaplan Meier Survival Curves were used to assess LTFU.

RESULTS: Overall, 609 clients were initiated on ART and at 12 months of follow-up 28(4.6%) had transferred out, 32(5.3%) were LTFU and there were no documented deaths. Of 533 individuals with VL results, only 326(53.5%) had baseline CD4+ count and VL results, and therefore included in this analysis. Participants median age was 32(interquartile range 26–40)years and 67/326(20.6%) had advanced disease. VS at 6 and 12 months was 91.6% and 93.7% respectively. Patients presenting with advanced disease had decreased odds of VS at 6 months on ART, [adjusted odds ratio (aOR) 0.23(CI 0.10 – 0.55)]. There was no difference in VS between those with and those without advanced disease at 12 months (aOR of 0.6(CI 0.22 – 1.65).
Cumulative incidence of LTFU at 6 and 12 months was 2.7% and 7.1% respectively among those with advanced disease compared to 0.7% and 3.4% among those classified as well (log rank test p = 0.07).

CONCLUSIONS: Patients with baseline CD4 count<200copies/ml were less likely to be VS at 6-months of follow-up compared to those with CD4≥200copies/ml and more likely to be LTFU even beyond 6-months of follow up. This finding highlights the utility of a baseline CD4 count and need for differentiated, individualized care at HIV diagnosis.

PEE1574

CONTRIBUTION OF ASSISTED PARTNER NOTIFICATION TO IDENTIFICATION OF UNDIAGNOSED HIV INFECTION AMONG SEXUAL PARTNERS OF HIV POSITIVE INDEX CLIENTS IN MID-WESTERN UGANDA: A RETROSPECTIVE REVIEW OF PROGRAM DATA

E. Mugisa[1], R. Ssebunya[2], M. Apolot[3], J. Lubwama[4], L.A. Mills[5], W. Amutuhaire[6], D. Damba[2], D.J. Birungi[1]
[1]Baylor, HIV Prevention, Fort Portal, Uganda, [2]Baylor, Monitoring and Evaluation, Fort Portal, Uganda, [3]Centers for Disease Control, HIV Testing Services, Kampala, Uganda, [4]Centers for Disease Control, HIV Prevention, Kampala, Uganda, [5]Centers for Disease Control, HIV care and treatment, Kampala, Uganda, [6]Baylor, HIV care and treatment, Fort Portal, Uganda

BACKGROUND: In order to reduce the proportion of people with undiagnosed HIV infection, it is vital to implement effective and efficient HIV case identification strategies. There was limited data on the successes of Assisted Partner Notification (APN) in identification of undiagnosed HIV infections and its contribution to overall HIV case identification. We documented the contribution of APN to HIV case identification in eight districts of mid-western Uganda.

DESCRIPTION: In May 2018, the Ministry of Health adopted Assisted Partner Notification (APN) as an effective HIV case identification strategy. In eight districts of mid-western region, scale up of APN began in June 2018 with training of 60 regional trainers of trainees

(TOTs) who thereafter were facilitated to train lower level health workers. With funding from CDC-Uganda, a total of 145 peripheral health facilities received onsite didactic training in APN with focus on identification of eligible HIV positive clients, elicitation of their sexual partners and delivery of HIV testing services. By October 2018, 131/145 (90.3%) health facilities had initiated APN services to eligible HIV positive individuals. We conducted a retrospective review of facility APN reports for the period October 2018 to September 2019 to ascertain the contribution of APN to HIV case identification.

LESSONS LEARNED: Of the 14,879 individuals who tested HIV positive, 9826 HIV positive individuals aged 15 years or older were interviewed and accepted to receive APN services. Majority (55.7%) were female. Following enrollment into APN, 18,217 sexual partners were elicited translating to an index client to sexual partner ratio of 1:2. Ninety one percent (16,721/18,217) of elicited sexual contacts were followed up and offered HIV testing services. Of these, 21.4% (3,476/16,271) tested HIV positive translating to a 23.4% (3,476/14,879) contribution to overall HIV case identification during the twelve months period. Fifty five percent (2,052/3,746) of HIV positive sexual partners were female and of these, 57% (1,165/2,052) were aged 15-29 years. Among the HIV positive male sexual partners, 65% (1121/1694) were aged between 30 and 49 years.

CONCLUSIONS/NEXT STEPS: APN was feasible in a rural setting and significantly contributed to overall HIV case identification.

PEE1575

EXPANDING TO ELIMINATE: INCREASED ACCESS OF PMTCT SERVICES TO PREGNANT WOMEN IS PAVING THE WAY TO EMTCT. EXPERIENCE FROM GLOBAL FUND SUPPORTED AHANA PROJECT IN INDIA

k. Biswas[1], R. KB[1], S. Kanoujia[1], M. Kumar[1], D. Nirwal[1], R. Mitra[2]
[1]Plan India, Monitoring & Evaluation, New Delhi, India, [2]Plan India, Programme, New Delhi, India

BACKGROUND: India is aiming to achieve EMTCT with highest number of annual estimated pregnancies (29 million) in the world by 2020. While, 94% of the estimated pregnancies are registered for ANC package of services the evidence suggests that the access to HIV testing remained at 18% during 2014-15 in the 14 states contributing 14 million annual pregnancies. Complementing Govt. of India's response, Ahana project funded by The Global Fund aimed to saturate all pregnant women with HIV testing and facilitate treatment provision.

DESCRIPTION: A longitudinal study of pregnant women receiving HIV testing recorded in Strategic Information Management System of Govt. of India and a cohort of 13 thousand HIV positive pregnant women received treatment and care services was analysed along with desk research of Public health service facilities to conclude on the findings.

LESSONS LEARNED: Based on the situational analysis a 360 degree approach was adopted to increase the testing and treatment facilities at scale. While, testing earlier was only limited at the 6 thousand district hospitals; with expansion of service provision through project intervention, HIV testing made available at more than 25 thousand village level Primary Health Clinic (PHC) and at the community level through Village Health Sanitation and Nutrition Committee (VHNSC). This increased access immediately resulted in improving results for HIV testing among pregnant women increased from 18% during 2014-15 to 44% during 2017-18 and to 73% (against estimated pregnancies) during 2018-19 in the intervention states. The access has resulted in more than 6 million pregnant women receiving HIV testing, and identification of additional 2,100 HIV positive pregnant women and linkages with treatment services during last year.

CONCLUSIONS/NEXT STEPS: Without community involvement it is impossible to attain the saturation of pregnant women with HIV testing or reaching out to first 90. The programme model demonstrate the rapid scale up of community level testing at the village level has ensured to scale up HIV testing exponentially. Taking HIV testing services at the doorstep of pregnant women has resulted in improved health seeking behaviour resulting in identification of HIV positive cases for treatment and care and support.

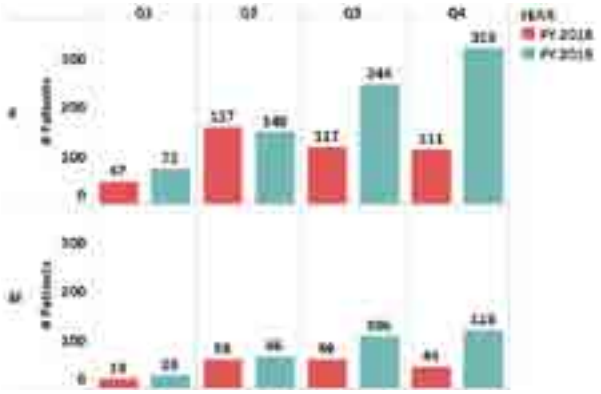
PEE1576

MAXIMIZING SAME-DAY ANTIRETROVIRAL TREATMENT (ART) INITIATIONS BY IMPLEMENTING AN HIV TESTING AND ART INITIATION ESCALATION PLAN

E. VanderWal[1], W. Benzerga[2], N. Lukhele[3]
[1]Kettering College of Medical Arts, Kettering, United States, [2]American University, Washington, D.C., United States, [3]University of Zimbabwe, Harare, Zimbabwe

BACKGROUND: The Luke Commission (TLC) provides free HIV/AIDS testing and treatment in Eswatini as part of a comprehensive healthcare platform reaching 95,000 underserved clients annually. UNAIDS 2019 estimates for Eswatini suggest that across all ages, 92% of people know their status and 86% of PLHIV are on ART. Those untested or HIV+ yet not on treatment often prove difficult to engage. When junior-level staff attempt to assist, these late adopters frequently resist testing or ART initiation. In March 2019 (close of FY19Q2), TLC implemented an escalation plan to bring together patients and senior-level staff trained to advocate for HIV testing and ART initiation.

DESCRIPTION: TLC implemented an escalation plan to connect clients to senior-level staff at the first sign of resistance to testing or ART initiation. Male and female staff champions were selected to interact with resistant clients for HIV testing, ART initiation, and follow-up. In addition, counselors and clinical staff were retrained on the importance of encouraging testing and same-day initiation, especially in key age/sex bands. In all cases, the decision to test or to initiate rested solely with the client.



[Figure. ART initiations (reporting quarters - gender)

LESSONS LEARNED: Implementation of the escalation plan significantly increased the number of newly identified HIV+ clients and ART initiations. Implementation resulted in percentage increases in ART initiations for female clients of 109% (from 117 to 244) in FY19Q3

and 188% (from 111 to 319) in FY19Q4. For male clients, the escalation plan resulted in respective percentage increases in ART initiations of 80% (from 59 to 106) and 168% (from 44 to 118).

CONCLUSIONS/NEXT STEPS: Providing immediate access to senior-level staff for late adopters significantly increased testing and initiation through TLC. It is hoped that this escalation model might be replicated by other health facilities to move more rapidly toward epidemic control.

PEE1577

HIGH LINKAGE RATES FROM COMMUNITY HIV INDEX TESTING PROGRAM IN NAMIBIA

I. Pietersen[1], B. Seolwane[2], E. Dzinotyiweyi[3], N. Hamunime[3], L. Ashipala[3], L. Bikinesi[3], S. Hong[1], E. Dziuban[1], C. Fischer Walker[1], G. Mutandi[1], D. Cockburn[2], A. Besa[2], K. Moeller-Jensen[2]
[1]Centers for Disease Control and Prevention, Windhoek, Namibia, [2]Development AID from People to People, Windhoek, Namibia, [3]Ministry of Health and Social Services, Windhoek, Namibia

BACKGROUND: Namibia adopted the Test and Treat Policy and scaled up country wide in 2016. This policy requires linking all newly-diagnosed HIV positive individuals to ART treatment services within seven days after a confirmatory HIV diagnosis. Development Aid from People to People-Namibia (DAPP) is a PEPFAR implementing partner providing community index partner testing (IPT) by recruiting consenting index clients at health facilities and testing their sexual partners who provide consent in the community. Index clients are primarily newly diagnosed HIV positive individuals aged >18 years and patients on antiretroviral therapy (ART) with unsuppressed viral loads. HIV-positive individuals diagnosed within communities are then physically escorted by DAPP field workers to the nearest health facility for ART services. Repeat home visits are made to enroll those individuals that are not linked the same day.

METHODS: DAPP program data were analyzed from seven high HIV burden regions for the period of October 2018-September 2019. Linkage rates were calculated by time from date of initial HIV diagnosis to date of linkage to ART services.

RESULTS: A total of 1,619 index partners were identified positive during the period under review. The total number linked to ART were 1,586 which is a 98% linkage rate. Of these, 1,017 (64%) were linked within the same day of initial HIV diagnosis, 449 (28.3%) within seven days, 89 (6%) within 30 days, 31 (2%) after 30 days, and 33 (2%) were not linked. Within seven days 92% were linked to ART.

CONCLUSIONS: These results show that very high linkage rates within seven days can be achieved by community-based testing providers through the provision of physical escorting as well as continued follow ups through home visits.

PEE1578

TRANSITIONING WOMEN OF CHILD BEARING AGE TO DOLUTEGRAVIR BASED REGIMEN COUPLED WITH INTEGRATION OF FAMILY PLANNING (FP) AND HIV SERVICES: LESSONS LEARNT FROM ZAMBIA-COPPERBELT, CENTRAL, AND NORTHWESTERN PROVINCES

M. Simwenda[1], W. Kanjipite[1], M. Chanda[1]
[1]JSI USAID SAFE, Lusaka, Zambia

BACKGROUND: The USAID-funded Supporting an AIDS Free Era (SAFE) works with the Ministry of Health (MOH) in Copperbelt, Central, and North-Western Provinces in Zambia to enroll and transition clients on ART to the Dolutegravir based regimen (TLD). SAFE employs an integrated approach in the implementation of services at facility level which includes the integration of family planning into HIV services.

DESCRIPTION: The transitioning of women on ART to TLD in the three SAFE supported regions was greatly affected by the Tsepamo study findings which led to clinicians initially not enrolling women of child bearing age on TLD. USAID SAFE intensified the integration of FP services into the HIV program at all supported facilities to increase the confidence of clinicians to enroll more women on TLD. Retrospective program level data was reviewed and analyzed to evaluate the trend of transitioning of women of child bearing age by clinicians coupled with the integration of FP services in the ART clinics.

LESSONS LEARNED: The proportion of women to men enrolled on TLD increased from 20% in October 2018 to 48% in August 2019 (almost 1:1 ratio between men and women enrolled on TLD). A three-fold increase (26%==>77%) among women of child bearing was also observed which was mainly due to the intensification of integration of FP services into the ART clinics and increased number of HIV+ women accessing FP services from 1659 in October 2018 to 28,000 in October 2019.

[Figure]

CONCLUSIONS/NEXT STEPS: This is a clear demonstration that even in the midst of the challenges of transitioning women of child bearing age, upon intensification of integration of FP services in the HIV program, the SAFE project supported the MoH and saw an exponential increase in the enrolment of women of child bearing age on TLD. SAFE will continue enrolling and transitioning women of child bearing age to TLD.

PEE1579

HIV CASE FINDING AMONG SEXUAL CONTACTS OF CLIENTS WITH HIGH VIRAL LOAD AT KILOSA DISTRICT HOSPITAL IN MOROGORO TANZANIA: RESULTS FROM TARGETED INDEX TESTING STRATEGY

B. Msongole[1], M. Kamonga[1], P. Kitali[2], J. Gamaliel[1], B. Christian[2], J. Bisimba[3], C. Jones[4], E. Okechukwu[1], M. Njelekela[4]
[1]FHI360, Dar es Salaam, Tanzania, United Republic of, [2]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [3]USAID, Dar es Salaam, Tanzania, United Republic of, [4]Deloitte Consulting Limited, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: In Tanzania, an estimated 1.6 million people are living with HIV however only 61% are aware of their HIV status. In 2018, Tanzania scaled up implementation of index testing as one of the targeted testing strategies in order to reach the first 90. Index partner testing focused on partners of newly identified positives and new on treatment patients. Other potential target groups for index testing such as partners of clients with high viral load (≥ 1000 c/ml) and partners of lost to follow up clients with unknown HIV status were often forgotten.

DESCRIPTION: At Kilosa District Hospital, USAID Boresha Afya Southern Zone Program introduced sexual contacts of clients with high viral load as one of the targeted groups for index testing in August 2019. In addition to other target groups, health care workers were sensitized on elicitation and testing of eligible sexual contacts of clients with high viral load . After receiving viral load results, all unsuppressed clients were listed in a dedicated index register and elicitation of the listed clients was incorporated in first enhanced adherence session. HIV testing of the listed contacts was conducted at clients' preferred location and time mostly done during extended working hours and weekends.

LESSONS LEARNED: Between August and October 2019 index partner elicitation was done to 108 patients who had high viral load (≥1000 c/ml) . Elicited index clients had 151 sexual contacts listed and contacted for HIV testing, 90 were males (median age 39 years) and 61 were females (median age 39 yrs). Out of 151 sexual contacts tested, 59 were found to be HIV positive which was equivalent to 39% yield, a high yield compared to overall program yield for index testing (33%). Of the positive cases identified, 30 were males and 29 were females with high yield among females (48%) as compared to males (33%).

CONCLUSIONS/NEXT STEPS: The findings show high HIV case finding among sexual contacts of clients with high viral load highlighting the need to scale index testing in this group. Targeting high viral load clients' sexual contacts with unknown HIV status is important in reaching the first 90 therefore eliminating treatment gap.

PEE1580

TESTING ONLY THOSE WHO REALLY NEED TESTING: USE OF HIV RISK ASSESSMENT TOOL IN THE USAID DISCOVER-HEALTH VOLUNTARY MEDICAL MALE CIRCUMCISION PROGRAM IN ZAMBIA

J. Kashitala[1], C. Madevu-Matson[2], A. Fullem[2], M. Chikuba-McLeod[1]
[1]JSI Research & Training Institute, Inc., Lusaka, Zambia, [2]John Snow, Inc., Boston, United States

BACKGROUND: The USAID DISCOVER-Health Project (DISCOVER), implemented by JSI Research & Training Institute Inc (JSI), supports the Ministry of Health to improve access to and utilization of quality HIV services in Zambia. Support incorporates SBCC and service delivery to ensure that groups most vulnerable to HIV, including males 20-34 (key to HIV epidemic control goals) are effectively reached with information/programs/services, including VMMC. Zambia VMMC guidelines include pre-surgery HIV testing as part of the minimum service package, with at least 95% of clients tested, nationally, with HIV positivity yield of around 0.1% (general male population average yield is 5%). Using the HIV-risk screening tool in this population would identify those at high HIV-risk and reduce unnecessary/costly HIV testing.

DESCRIPTION: With a five-year life-of-project VMMC target of 360,000, we introduced the intervention, the HIV-risk screening tool, in the VMMC program in April 2019. The screening tool was administered by a trained HIV counsellor during pre-surgery counselling. HIV risk was determined based on client responses to six questions including: HIV testing within 3months; unprotected sexual contact; sexually transmitted infection symptoms; and alcohol/drug use. We analysed VMMC HTS pre-intervention (July-December 2018) and post-intervention (July-December 2019), comparing HTS numbers and computing estimated cost savings.

LESSONS LEARNED: The table below summarizes the findings:

Indicator	Pre-intervention July to Dec 2018	Post-intervention July to Dec 2019
VMMC_CIRC	11,885	17,878
VMMC_CIRC Tested	11,594	5,057
VMMC_CIRC Tested HIV+	20	14
% Tested	98%	28%
%Yield Rate	0.17%	0.28%

[Table]

Implementation of the HIV-risk screening tool led to: significant reductions in testing volumes from 98% to 28%; significant increase in positivity yields from 0.17% to 0.28%; and more effective HIV counselling (with reduced volume HTS counsellors spent more time with at-risk clients). Using a $7 cost-rate/HIV testing/person, the estimated program cost-saving is $62,741.

CONCLUSIONS/NEXT STEPS: In VMMC programs in resource-limited settings, using the HIV-risk screening tool increases HTS efficiency, significantly reducing HTS volumes, increasing HIV positivity yields, and providing significant cost-savings that can allocated to other uses. With a higher VMMC_CIRC volume post-intervention, the reduction in absolute HIV+ raises concerns about sensitivity and specificity. DISCOVER will evaluate these aspects to inform future implementation.

HIV SELF-TESTING FOR HIV AND LINKAGES TO PREVENTION AND CARE

PEE1581

HOW DO LOCAL DRUG SHOPS SELL AND PRICE HIV SELF-TEST KITS? DESCRIPTIVE EVIDENCE FROM TANZANIA

C. Chiu[1], L.A. Hunter[1], S.I. McCoy[1], R. Mfaume[2], P. Njau[3,4], J.X. Liu[5]
[1]School of Public Health, University of California, Berkeley, United States, [2]Shinyanga Regional Medical Office, Shinyanga, Tanzania, United Republic of, [3]Health for a Prosperous Nation, Dar es Salaam, Tanzania, United Republic of, [4]National AIDS Control Programme, Ministry of Health, Community Development, Gender, Elderly, and Children, Dar es Salaam, Tanzania, United Republic of, [5]Institute for Health and Aging, Bixby Center for Global Reproductive Health, University of California, San Francisco, United States

BACKGROUND: Drug shops are an underutilized channel to distribute HIV prevention products like HIV self-testing to hard-to-reach populations. However, little is known about how owners set prices on new products, how much prices vary both within and across shops, and whether HIV self-test kits are commercially viable. We observed how drug stores set prices for self-test kits and tested for evidence of price discrimination.

METHODS: From August to December 2019, we provided free self-test kits to 26 Accredited Drug Dispensing Outlets (ADDOs) and pharmacies in Shinyanga, Tanzania to sell to the local community in a setting where oral-fluid self-test kits were not yet available. We collected data on sales quantity, price, and customer characteristics (age and sex) using shop records, cross-validated with anonymous customer feedback forms. We calculated descriptive statistics on sales and price variation over time and across shops. Using a multiple linear regression model, we conducted F-tests to determine whether shop, age, sex, and time (week) respectively were associated with (log) price.

RESULTS: A total of 324 self-test kits were sold over the study period; 69% of purchasers were male, 40% were aged 25-34 and 30% aged 35-44. Retail prices set by shops ranged from 1,000 to 10,000 Tsh (mean 3,500 Tsh; ~$1.50 USD) and followed a bi-modal distribution that clustered around 2,000 Tsh (26% of sales) and 5,000 Tsh (39% of sales). Prices varied little by age (p=0.60), sex (p=0.42), or over time (p=0.43). Although shop significantly (p<0.001) predicted price, price variation within shop was concentrated among 6 (23%) shops, and 7 (27%) shops sold at a uniform price over the study period.

CONCLUSIONS: Contrary to our expectations based on existing qualitative literature, there was limited variation in prices and no evidence of price discrimination by age or sex in Shinyanga. Given that observed retail prices were below the current global negotiated wholesale price ($2 USD or ~4,600 Tsh, excluding various delivery costs), further demand creation and/or cost-reduction is required before self-test kits may become a commercially viable product in this setting. Further research is required to understand pricing strategies over a longer period and outside of an experimental setting.

PEE1582

UNASSISTED PEER-BASED DISTRIBUTION OF HIV ORAL SELF-TESTING FOR THE HARD TO REACH IN RURAL KWAZULU NATAL, SOUTH AFRICA

M.K. Kitenge[1], C. Laxmeshwar[1], E. Bermudes Aza[2], L. Trivino Duran[3], E. Ford-Kamara[1], G. Van Cutsem[4,5], N. Gcwensa[1], K. Hlophe[6], L. Ohler[1]
[1]Médecins Sans Frontières (MSF), Eshowe, South Africa, [2]Médecins Sans Frontières(MSF), International Office, Amsterdam, Netherlands, [3]Médecins Sans Frontières (MSF), Cape Town, Cape Town, South Africa, [4]Médecins Sans Frontières (MSF), Southern African Medical Unit, Cape Town, South Africa, [5]Centre for Infectious Disease Epidemiology, University of Cape Town, Cape Town, South Africa, [6]Department of Health, King Cethswayo District, Eshowe, South Africa

BACKGROUND: A population-based survey conducted by Médecins Sans Frontières (MSF) in Eshowe, KwaZulu Natal, South Africa reported the achievement of the UNAIDS 90-90-90 targets in 2018. Innovative delivery models with HIV oral self-tests (OST) provide an opportunity to reach the hard-to-reach population (young men aged 15-24 years and those never tested). We present preliminary results from a study evaluating peer distribution of OST to scale–up HIV testing under programmatic conditions.

METHODS: In this single arm, uncontrolled study, counsellors provided OST kits to peers for distribution to their sexual partner, anyone in their social network or for self-testing (termed secondary recipients) from September 2018 to October 2019. The study was conducted at 25 MSF-supported HIV testing sites in Eshowe/Mbongolwane area, rural KwaZulu--Natal. A structured questionnaire was administered during recruitment and follow-up, when people came for confirmatory HIV testing.

RESULTS: Among 31,746 people approached, 7,904(24.9%) accepted to be peer-distributors; 24,491 OST kits were distributed, a median of three (IQR: 2-4) per peer. Median age was 28 years (IQR: 23-36) and 5540(70.1%) were women. Peers were recruited through waiting room talk (43.0%), HIV testing and counselling services (27.1%), self-referral (24.5%), and services at mobile clinics (5.4%).

During the study period, 886(3.6% of tests distributed) individuals reported OST use. Median age was 28.5 years (IQR: 23.4-35.5) and 606(67%) were women. Furthermore, 86(29.5%) of men were aged 18-24 years, 164(55.8%) were aged 25-40 years and 44(15%) were above 40 years. Among these, 533(60.1%) tested themselves, while 353(39.9%) received kits from peer-distributors. Fourteen (1.6%) reported testing for the first time and 713(81.4%) people came back even after testing negative on OST. HIV positivity among people coming for follow-up was 17.7%(157/886). Among these, 75.1%(118) were initiated on ART during the study period.

CONCLUSIONS: These preliminary data suggest distribution of OST among general population is acceptable with 1 out of 4 accepting to be peer-distributors. Few of those secondary recipients who reported were first time testers or young men, suggesting that these populations remain hard to reach. This distribution strategy warrants further study to explore motivators and barriers for peer-distributors and experiences while engaging with whom they distributed OST kits to.

IRANIAN FEMALE SEX WORKERS PERCEPTION AND ATTITUDE TOWARD USING OR DISTRIBUTING HIV SELF-TEST: A QUALITATIVE STUDY

L. Taj[1], M. Vameghi[2], D. Ali[2], A. Esmeili[3], M. Nasirian[3], Z. Boroumandfar[4], T. Amiri[1], N. Abedinzadeh[1], M. Mohraz[1], P. Afsar Kazerooni[5], A. Mirzazadeh[6]
[1]Iranian Research Center for HIV/AIDS, Iranian Institute for Reduction of High-Risk Behaviors, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Social Welfare Management Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Islamic Republic of, [3]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [4]Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic of, [5]Shiraz HIV/AIDS Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [6]Department of Epidemiology and Biostatistics, Institute for Global Health Sciences, University of California, San Francisco, United States

BACKGROUND: HIV self-testing has potential to be reached by key populations who would otherwise not access to or use routine HIV testing services. We aimed to assess perception and attitudes of using and distributing HIV self-test among Female Sex Workers (FSW), as the first population ever used HIV self-test in Iran.

METHODS: This qualitative study was conducted among 37 FSW in two cities (Tehran and Isfahan) in Iran, spring 2018. Eligible participants were aged 18 + years and sold sex in the last month. Data collection was conducted through semistructured interviews and Focus Group Discussions based on purposive and theoretical sampling until data saturation. Content analysis was utilized to analyze the transcribed interviews.

RESULTS: Participants were 35.8±7.7 years of age, 36.1% reported drug use in the last year, 83.9% were tested for HIV recently, and 12.9% were HIV positive. About half find their clients at street/park locations and had experienced violence by their husband, boyfriend and clients in 38.1%, 32.4% and 36.4% of the cases, respectively.

Majority indicated how important it is for a FSW to know her HIV status, and high acceptance of HIV self-testing. Being able to do the test in private, find out the result rapidly, and to receive HIV self-test free of charge would be strong motivators for FSW to use HIV self-test. There were concerns of finding out the positive result by themselves which would be frightening in their opinion. Majority mentioned they would accept HIV self-test if offered by a peer, and it is more likely to suggest self-test to their husband or permanent partners rather than casual clients. However, participants believed most clients would not accept HIV self-test and FSW may lose their clients upon the offer and would be at risk for violence.

CONCLUSIONS: Results suggested that Iranian FSW would be willing to use HIV self-test. They had some concerns about distributing the HIV self-test to their clients/partners. To have FSW offer the HIV self-test to their clients successfully, training about self-tests and skills such as marketing and negotiations are required.

PEE1584

DEMOGRAPHIC CHARACTERISTICS OF HIVST USERS AND PREDICTORS OF USING HIVST AMONG PRIORITY POPULATIONS IN ZAMBIA

T. Kipingili[1], L. Nkhoma[1], S. Besa[1], K. Tembo[1], M. Siwela[1], E. Mteba[1], V. Kapotwe[1], W. Chisanga[1], A. Phiri[2], G. Lingenda[2], A. Oakley[3], M. Wright[3], E. Kuhlink[3]
[1]Pact Zambia, Lusaka, Zambia, [2]USAID, Lusaka, Zambia, [3]Pact, Washington Dc, United States

BACKGROUND: As a critical intervention for HIV epidemic control, HIV Self-Testing complements other testing modalities to reach difficult-to-reach populations with HIV services. Successful implementation of HIVST, which started in Zambia in 2015, has the potential to contribute to achieving the UN's 95-95-95. This abstract investigates demographic characteristics of HIVST users and predictors of using HIVST in priority populations (AGYW and their sexual partners, mobile populations, discordant couples and other hotspots populations) reached by the USAID-Z-CHPP program in Zambia to uncover dynamics of HIVST use that can be used for improved targeting.

METHODS: Routine HIVST program data from the PEPFAR/USAID–funded Z-CHPP program were analyzed. Between October 2018 and September 2019, 4,964 people categorized as priority populations in community hotspots and in DREAMS centers were recruited and offered HIVST from the program. Cross–tabulations with a Chi–square test for associations were performed, along with multivariate analysis using binary logistic regression to identify factors associated with using HIVST.

RESULTS: Of the 4,964 people recruited in the program,51% were 20-29 years of age and 52.5% were males. Mobile populations comprised 62.5% followed by AGYW and their sexual partners at 34.8%. 4,699 (94.7%) received HIVST. Assisted HIVST modality accounted for 51% of all HIVST with 64.7% for mobile populations and AGYW with their sexual partners at 32.3%. Using HIVST was significantly associated with population category, with the highest proportion (96.7%) among AGYWs and their sexual partners and the lowest among other populations (91.9%) ($p<0.001$). Multivariate logistic regression analysis showed that compared to females, males were nearly three times more likely to receive HIVST (aOR 2.91, $p<0.001$). In terms of population category, compared to AGYW and their sexual partners, mobile population were 59% less likely to receive HIVST (aOR 0.41, $p<0.001$). Although 40-49 years age group were 94% more likely to receive HIVST than under 20 years group, the effect was not statistically significant (aOR 1.94, $p>0.05$).

CONCLUSIONS: HIVST is an effective and convenient modality to reach hidden populations. HIVST program should be tailored to reach more mobile populations who are at an elevated risk of contracting HIV and subsequently link them to care.

PEE1585

LESSON LEARNED FROM IMPLEMENTING ASSISTED PARTNER NOTIFICATION SERVICES AMONG GAY, BISEXUAL, AND TRANSGENDER PEOPLE IN COASTAL KENYA

K.S. Mohamed[1], T. Mumba[1], M. Shally[1], N. Mukuria[1], W.K. Kazungu[1], A. Wesonga[1], A. Kigoro[1], E. van der Elst[1], M. Dijkstra[1], E. Sanders[1], Khamisi Mohamed
[1]Kenya Medical Research Institute, IAVI, Kilifi, Kenya

BACKGROUND: Assisted partner notification services (APNS) have great potential in finding undiagnosed HIV infections. However, data are limited on how to offer APNS to gay, bisexual, and transgender people (GBT) in Sub-Saharan Africa (SSA). We present our lessons learned from implementing APNS among GBT in coastal Kenya.

DESCRIPTION: Since April 2019, APNS has been offered to GBT testing HIV positive (index cases) in two research clinics in coastal Kenya. For each sexual partner, index cases could choose a notification strategy: extension of an oral HIV self-test (OraQuick) by the index case, index referral, or provider referral. For a subset of index cases (n=18) potential social harms were assessed with a questionnaire one month after initiating APNS.

LESSONS LEARNED: APNS was offered to 37 index cases and was accepted by 73.0% (27/37). Out of 78 unique partners with contact details, index cases opted for an index-extended self-test to 18.0% (14/78) of partners, index referral to 9.0% (7/78) of partners, and provider referral to 73.1% (57/78) of partners. Proportions of partners presenting for HIV testing were 14.3% (2/14) for partners who were provided a self-test, 42.9% (3/7) for partners through index referral, and 64.9% (37/57) for partners through provider referral. In total, 21.4% (9/42) partners were newly diagnosed with HIV. Notifying partners with the WHO recommended message "You might have been exposed to HIV" did not solicit partner testing. The message "We would like to discuss important health related issues" was received better and enabled partner testing. Furthermore, one notification phone call by the provider was not sufficient for most partners, approximately 2-3 follow-up calls were necessary to build rapport before partners presented at the clinic for HIV testing. Among partners who did not own a phone, multiple field visits from providers and GBT peers were necessary to successfully engage partners. No social harm was reported after completion of APNS.

CONCLUSIONS/NEXT STEPS: Majority of partners were notified through intense provider follow-up, supported by GBT peers, which enabled HIV testing. Delivering culturally tailored messages and building rapport with partners is an ongoing process necessary to achieve partners coming forward for HIV testing.

PEE1586

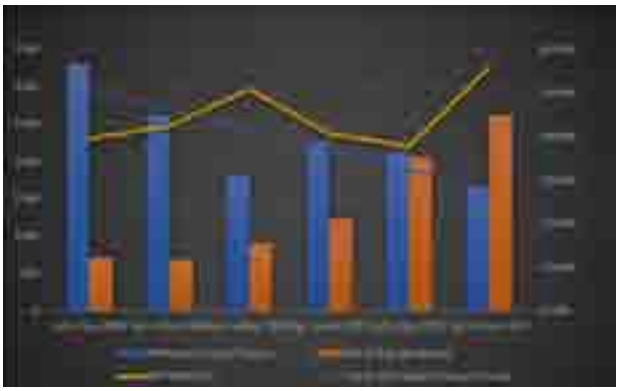
TAKING HIV PROGRAMMING TO SCALE BY IMPROVING THE EFFICIENCY OF COMMUNITY INDEX TESTING THROUGH USE OF HIV SELF TESTING ON THE USAID/FHI360 ZIMBABWE HIV CARE AND TREATMENT (ZHCT) PROJECT

A. Muchedzi[1], R. Dhliwayo[1], T. Zulu[2], F. Mudzengerere[2], T. Mavimba[2], T. Nyagura[3], G. Ncube[4], T. Tafuma[2]
[1]FHI 360, Technical, Harare, Zimbabwe, [2]FHI 360, Harare, Zimbabwe, [3]USAID, Harare, Zimbabwe, [4]MOHCC, Harare, Zimbabwe

BACKGROUND: In Zimbabwe, of the 1.4 million people living with HIV (PLHIV), 74.2% know their status. Finding the remaining PLHIV, with limited resources, requires innovative and efficient approaches. FHI360 in Zimbabwe is implementing HIV self-testing (HIV-ST) in the context of community-index testing towards epidemic control in the country.

DESCRIPTION: In June of 2018, FHI360 introduced HIV-ST in the (ZHCT) project, whose goal is to increase access of HIV-testing-services (HTS), primarily at community-levels to sub-populations that would not ordinarily access HIV services at the health facility. The project is implemented in eight districts across three provinces. FHI360 supported community cadres, known as expert patients, working closely with the health-facilities, line-list all newly diagnosed-PLHIV and contacts that opt for community testing. The expert patients, after obtaining consent, visit the household of contacts to prepare them for HTS and provide HIV-ST. The specialized nurse then provides confirmatory HIV testing to contacts with a reactive HIV-ST. Program data was captured using District-Health-Information-Software2.

LESSONS LEARNED: The project reached 20,495 people with HIV-testing services from Jul 2018 when HIV-ST was introduced as a forerunner to community index-testing. Figure 1 shows the reduction in the specialized nurses' testing volume with the introduction of HIV-ST. The testing volume per quarter decreased from 3307 in Jul 2018 to 1655(50%) by Dec 2019 while the number of HIV-ST kits that were distributed through community index-testing steadily increased. The FHI360 project continued to achieve and sustain high HIV yields rates of an average of 39%. Of the 7,993 PLHIV identified, 7,433(93%) were linked to ART.



[Figure 1. FHI360/ZHCT project testing volume and sustained high yields with introduction of HIV ST, Jul 2018 - Dec 2019]

CONCLUSIONS/NEXT STEPS: HIV-ST improved the efficiency of community index-testing in identifying the missing by reducing the testing volume. The project achieved and sustained high HIV yields rates with HIV-ST introduction. The scale-up of HIV-ST conducted by expert patients, as a forerunner for community index-testing, is recommended in Zimbabwe towards epidemic control.

PEE1587

PEER-LED HIV SELF-TESTING SUCCESSFULLY REACHES KEY POPULATIONS IN RURAL EASTERN UGANDA

C. Mejia[1], C.L. Julius[2], H. Nandudu[2], P. Wandawa[2], K. Odong[2], S. Aldridge[1], C. Karutu[2]
[1]IntraHealth International, Chapel Hill, United States, [2]IntraHealth International, Mbale, Uganda

BACKGROUND: Key populations (KPs) in Uganda, including female sex workers (FSWs), men who have sex with men (MSM), transgender women (TG), people who inject drugs (PWID), and incarcerated men are disproportionately affected by HIV. Uptake of testing remains low. HIV self-testing (HIVST) is a discreet, convenient way to reach KPs who don't know their status. In 2017, the government introduced an oral HIVST kit to complement existing strategies in the fight against HIV. In 2018, peer-led HIVST was introduced and evaluated by USAID's Regional Health Integration to Enhance Services (RHITES-E) in Eastern Uganda Activity led by IntraHealth International. Using monitoring data, RHITES-E assessed effects of HIVST on uptake, identification of HIV-positive persons, and linkage to care.

DESCRIPTION: Between October 2018-September 2019 KPs were offered HIVST by peer-leaders at 12 health facilities. Self-testers were given the choice to test with or without assistance. HIVST kits were distributed directly to individuals from facilities and attached community distribution points. Those receiving kits were provided information on performing the test; meaning of test results; need for confirmatory testing for a reactive test, and test result feedback to service providers. Clients were provided with appointment cards to a facility of their choice and a counselor's phone contact. Those testing HIV-positive were advised to go to a facility for a confirmatory test.

LESSONS LEARNED: 2,640 HIVST kits were distributed from October 2018-September 2019 (1326 clients opted for directly assisted and 1314 for unassisted HIVST). 14 clients were confirmed HIV-positive (4 females, 10 males) and initiated on ART. Clients who opted to confirm their results included MSM (139), FSWs (322), TG (12), PWIDs (55), and incarcerated men (32). The majority of FSWs preferred assisted self-testing while MSMs opted for unassisted self-testing. During the first quarter, there was a low return rate from unassisted testers. In following quarters, RHITES-E developed guidance for peer-leaders to contact within 2 days all who had taken kits.

CONCLUSIONS/NEXT STEPS: Peer-led HIVST successfully reached KPs; including those never tested. Offering HIVST with different support may increase testing uptake among KPs. Unassisted HIVST may be particularly beneficial for reaching MSM but rates of return were low.

APPROACHES TO VIRAL LOAD MONITORING AT SCALE

PEE1588

MAKING HIV VIRAL LOAD ACCESSIBLE IS NOT ENOUGH, OPP-ERA PROJECT!

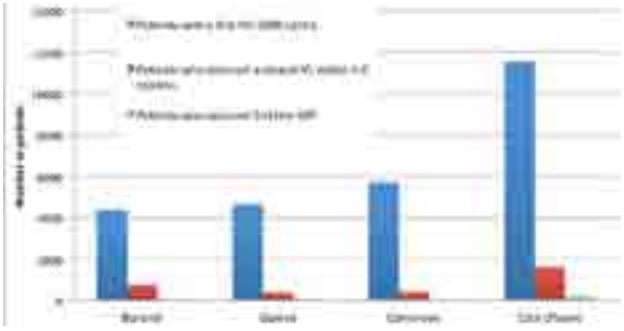
G. Breton[1,2], F. Karemera[3], T.K. Tonguino[4], E. Lumia[1], D. Yapo[1], E. Guichet[1], N. Dubois-Cauwelaert[1], Y. Koita[5], S. Karemangingo[3], D. Zana[6], E. Temgoua[7], O. Sylla[8], S. Ouvrard[1], L. Maloto[9], R. Tubiana[2,1], Y. Madec[10], OPP-ERA study group
[1]SOLTHIS, Paris, France, [2]Pitié Salpêtrière Hospital, Infectious and Tropical Diseases, Paris, France, [3]PNLS/IST, Bujumbura, Burundi, [4]SOLTHIS, Conakry, Guinea, [5]PNLSH, Conakry, Guinea, [6]PNLS, Abidjan, Cote D'Ivoire, [7]CNLS, Yaoundé, Cameroon, [8]Sidaction, Paris, France, [9]Expertise France, Paris, France, [10]Pasteur Institute, Paris, France

BACKGROUND: In resource-limited countries, access to HIV viral load (VL) has increased, providing information to the "third 90%". From a clinical point of view, is VL prescribed and are VL results used by prescribers? We took advantage of the OPP-ERA project, which enabled the implementation of VL through open polyvalent platforms in 4 countries in West and Central Africa (Burundi, Cameroon, Cote d'Ivoire, Guinea) to study these issues.

METHODS: Access to VL and the implementation of national recommendations for monitoring virological failure were studied from the databases for the 13 OPP-ERA laboratories from 2014 to 2019.

RESULTS: In total, nearly 230,000 VL measurements were performed between 2014 and 2019. The median number of VLs per patient was 1.3 (1.1-1.5 depending on the country) for the period 2016-2019. In the medical facilities benefiting from the project, the proportion of patients who received at least one viral load averaged 32% in 2018 (19-42% depending on the country) with a great variability between facilities. Overall 81% (78-89% depending on the country) of patients were in virological success (VL<1000 cp/mL), this rate has remained stable over time.

Among the 26268 patients with a first VL>1000 cp/mL between 2014 and 2018, a control VL was performed in 12% of patients within the recommended time frame of 3 to 6 months. The rate of switch in the 2nd line ART regimen was estimated at 3%.



[Figure. Virological failure management cascade, OPP-ERA project (2014-2019)]

CONCLUSIONS: Despite the availability of VL for a period of 6 years, the prescription and use of VL appears to remain limited as evidenced by the low number of VL measurements per patient, the virological failure management cascade and the lack of impact on the virological success rate.

The reasons for the low use of VL and its results need to be further explored in order to make access to VL more beneficial to patients.

PEE1589

FACTORS ASSOCIATED WITH VIRAL NON-SUPPRESSION AFTER ENHANCED ADHERENCE COUNSELLING AMONG PATIENTS WITH PERSISTENTLY ELEVATED VIRAL LOADS IN MILITARY ART CLINICS IN UGANDA

J. Akao[1], E. Lugada[2], T. Rwegyema[3], D. Bwayo[3], C. Wamundu[4]
[1]US Embassy Kampala, Department of Defence, Kampala, Uganda, [2]University Research Co. LLC, DHAPP, Kampala, Uganda, [3]University Research Co., LLC, DHAPP, Kampala, Uganda, [4]Uganda Peoples Defence Forces (UPDF), Directorate of HIV/AIDS, Kampala, Uganda

BACKGROUND: The national HIV/AIDS treatment guidelines recommend enhanced adherence counselling (EAC) to persistently non-suppressing persons with elevated viral load before a decision to change antiretroviral regimen due to treatment failure is made. The PEPFAR funded URC-Department of Defense HIV/AIDS Prevention Program (DHAPP) provides technical support to 28 military health facilities in comprehensive HIV/AIDS care. We undertook an assessment to determine the proportion of and factors associated with persistent non-suppression despite EAC procedures.

DESCRIPTION: A retrospective review of patient files was conducted for all patients with high HIV viral loads (VL) ≥1000 copies/ml in all 28 ART prescribing military between April 2018 and April 2019. Data on initial VL test results, EAC sessions, repeat VL test results, and documented barriers to adherence from a sampled group were abstracted for detailed analysis using logistic regression.

LESSONS LEARNED: A total of 1,433 (7.3%) of 20,001 patients enrolled on ART had had at least one viral load above 1000 copies/ml over the study period. Average time on ART was 2.5 years. A sample of 168 of those with a detectable VL who had completed the recommended three EAC sessions and had a repeat VL test were sampled from 9 facilities for detailed analysis. Overall, only 41% (68/168) achieved viral suppression following EAC. Factors associated with subsequent suppression were having good adherence at the 1stEAC session (OR 0.3, p 0.005) while being less than 19 years (OR 2.5, p0.001) was associated with persistent non-suppression. Common barriers to adherence cited were lack of adequate food (25%); alcohol abuse (20%); other social problems (10%); transport barriers (10%) and stigma/disclosure challenges was reported by 8%.

CONCLUSIONS/NEXT STEPS: EAC among non-suppressing persons achieved sub-optimal results and may not be sufficient to guide treatment failure management. Additional screening techniques and targeted structural interventions to address nutritional challenges and alcohol abuse are warranted in the management of potential treatment failure. Exploration of additional interventions beyond EAC is also recommended especially in the management of childhood treatment failure.

PEE1590

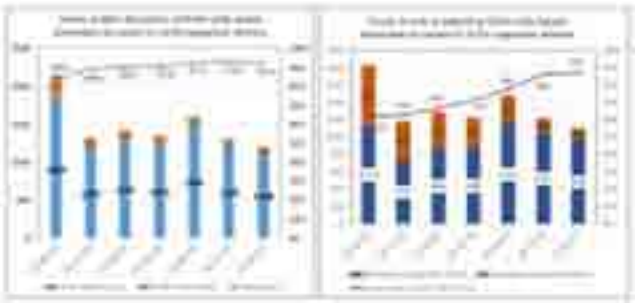
IMPROVING MANAGEMENT OF PEOPLE LIVING WITH HIV ON FIRST-LINE ART REGIMENS WITH VIRAL NON-SUPPRESSION IN 19 DISTRICTS SUPPORTED BY INFECTIOUS DISEASES INSTITUTE IN UGANDA

M.G. Nabukenya-Mudiope[1], I. Senteza[1], L. Ssekiswa[1], P. Kavuma[1], A. Muganzi[1], J. Kigozi[1]
[1]Infectious Diseases Institute, College of Health Sciences, Makerere University, Outreach, Kampala, Uganda

BACKGROUND: Delayed switching of people living with HIV (PLHIV) on first-line ART regimens with virologic failure is a challenge in Uganda. We aimed to improve rates of regimen optimization among PLHIV on 1st ART from 62% to 90% in 19 districts of Kampala, mid-Western and West Nile regions of Uganda. We report program interventions undertaken to achieve this aim.

DESCRIPTION: Infectious Diseases Institute (IDI) with support from PEPFAR through CDC, implemented district level viral load (VL) interventions including; functionalization of district mentorship teams; monthly visits to all ART facilities, targeted visits to poorly performing facilities and quarterly district VL sharing sessions. Facility level interventions included: functionalization of existing multidisciplinary teams (MDT) and formation of new ones where they were missing; peer-peer mentorship during MDT switch discussions and twinning of health workers at better performing facilities, provision of VL job aides for management of non-suppressed clients, review of VL non-suppressed cascades and implementation of improvement projects to address identified gaps, functionalization of PLHIV peer support groups, improving linkage to available orphaned and vulnerable services (OVC) and home-based support by para-social workers for challenging cases.

LESSONS LEARNED: The rates of switching eligible PLHIV on 1st line ART to optimal ART regimens increased from 62% in the quarter January-March 2018 to 87% in July-September 2019. The proportion of PLHIV with two consecutive detectable VL results not switched decreased from 38 percent (695/1828) in January-March 2018 to 13 percent (140/1108) in July-September 2019. Discussion of PLHIV with consecutive detectable VL results in MDT increased from 84% in January-March 2018 to 93% in July-September 2019.



[Figure]

CONCLUSIONS/NEXT STEPS: Timely switching of PLHIV with virologic failure is feasible but requires ongoing capacity building and addressing of psychosocial challenges to affected families. There is need to scale up this package of interventions to bridge the remaining gaps in regimen optimization.

PEE1591

PROVIDING TAILORED SERVICES FOR UNSTABLE CLIENTS: ADAPTING DIFFERENTIATED SERVICE DELIVERY MODELS AND LESSONS FROM THE LANGO SUB-REGION IN NORTHERN UGANDA

G.E. Sangadi[1], S. Maher[2], N. Brady[3], A. Austin[4], S. Bauman[3], M. Makumbi[5], P. Donggo[1]
[1]USAID RHITES North Lango Project/John Snow Inc, Programs - Care and Treatment, Lira, Uganda, [2]John Snow Inc, Programs - Key Populations Programing, Boston, United States, [3]John Snow Inc, Programs, Boston, United States, [4]John Snow Inc, Programs - Monitoring and Evaluation, Boston, United States, [5]USAID RHITES North Lango Project/John Snow Inc, Lira, Uganda

BACKGROUND: In Uganda, HIV care services, including antiretroviral therapy (ART) are provided through differentiated service delivery models (DSDM) to improve prevention, identification, diagnosis, treatment, and support for people who require HIV services. The models adapt the location, providers, frequency, and intensity of services to meet client needs and desires. Though usually reserved for stable clients, the USAID Regional Health Integration to Enhance Services-North, Lango project uses some of these approaches for clients with unsuppressed viral load (VL) results to improve client outcomes. Unstable clients, defined as ART-naive clients, are those newly initiated on ART and those with unsuppressed VL results (over 1,000 copies/mL).

DESCRIPTION: From March to September 2019, the project supported health care providers to identify and line-list all non-suppressed clients identified between September 2018 and June 2019 in 54 health facilities. They designated a clinic day for these clients and trained service providers on age appropriate psychosocial support. The listed clients were mobilized to attend the designated clinic days during which intensive adherence counselling (IAC) was provided.

LESSONS LEARNED:

Age	unsuppressed	returned for 1st IAC	completed 2nd IAC session	completed 3 IAC sessions	received 2nd VL test	unsuppressed after IAC	Switched to 2nd line
0-14 years	1683	1152	1078	853	517	243	218
		80%	80%	79%	61%	47%	90%
15-24 years	1353	492	421	324	196	81	59
		36%	86%	77%	60%	41%	73%
25 and above	5516	3775	2952	2478	1576	506	378
		68%	78%	84%	64%	32%	75%
All	8552	5619	4451	3655	2289	830	655
		66%	79%	82%	63%	36%	79%

[Table. Non suppressed cascade from 54 health facilities March to September 2019]

8,552 clients with unsuppressed clients enrolled on IAC over four months. Overall 5,619 (66%) clients started intensive adherence counseling (IAC); 78% completed three recommended sessions of IAC with a good adherence, and 63% of these clients had a repeat viral load test and 64% had a suppressed VL result after a repeat VL test and 79% of the unsuppressed switched to second line. Although re-suppression was lowest among those below 15 years (53%) and 90% were switching to second line.

CONCLUSIONS/NEXT STEPS: Designating specific days for one-stop clinics provides an opportunity for increased peer support and tailored comprehensive IAC, service delivery, and VL suppression.

TIME TO REPEAT VIRAL LOAD TESTING FOLLOWING AN UNSUPPRESSED VIRAL LOAD AMONG ADOLESCENTS AND YOUNG ADULTS IN KENYA

C. Mugo[1], K. Wilson[2], A. Onyango[1], I. Njuguna[3], C. Mburu[1], B. Richardson[2], L. Oyiengo[4], I. Inwani[5], G. John-Stewart[6], D. Wamalwa[1], P. Kohler[7]
[1]University of Nairobi, Pediatrics and Child Health, Nairobi, Kenya, [2]University of Washington, Global Health, Seattle, United States, [3]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [4]Ministry of Health, National AIDS/ STI Control Programme, Nairobi, Kenya, [5]Kenyatta National Hospital, Pediatrics and Child Health, Nairobi, Kenya, [6]University of Washington, Global Health, Epidemiology, Pediatrics and Medicine, Seattle, United States, [7]University of Washington, Global Health, Psychosocial and Community Health, Seattle, United States

BACKGROUND: Viral load (VL) information is key in determining success and changes required in HIV care for adolescents and young adults (AYA). We assessed VL data to determine its utilization in the care of AYA on ART in Kenya.

METHODS: VL data for AYA ages 10-24 years in the period April 2017 to May 2019 in 117 sites in 28 counties were abstracted from the Kenya national HIV program database. Eligible records included being on ART for at least 6 months with at least 6 months of follow-up time following the first monitoring VL in the dataset. We summarized demographics, treatment after first VL, and repeat testing following unsuppressed VL (≥1000 copies/ml). Among records with unsuppressed VL, we calculated the proportion with any repeat VL, a repeat VL within 6 months, and median (interquartile range [IQR]) number of months between first unsuppressed VL and the repeat VL.

RESULTS: We abstracted 40,928 VL records for 23,969 AYA, of whom 16,722 (70%) were eligible for this analysis. Of those, 11,845 (71%) were female, median age 19 (IQR: 13-23), with 6105 (37%) from counties with a HIV prevalence ≥10%. Median ART duration was 39 months (IQR: 18-77), while 13,830 (83%) were on a nevirapine/efavirenz based regimen and 2,539 (15%) on a protease inhibitor.

Among 16,722 eligible AYA, 3,928 (23%) had an unsuppressed VL at first measurement. Only 2,268/3928 (58%) had any repeat VL in the dataset. Further, only 1,397 (36%) had a repeat VL within 6 months after the unsuppressed VL. Among the 2,268 with a repeat VL, the median time between unsuppressed and the repeat VL was 5 months (IQR: 4-8). Among 1,303 AYA with 2 consecutive unsuppressed VL, 715 (55%) had information on ART regimen after their second VL, with 483 (68%) indicating no change of regimen.

CONCLUSIONS: A substantial proportion of AYA on ART had unsuppressed VL, with less than half receiving a repeat VL assessment within 6 months, and less than half of those with persistent VL failure having a change of regimen. Strategies to improve VL testing practices among health care workers are needed to improve outcomes of AYA on ART.

ASSESSMENT OF ROUTINE VIRAL LOAD TESTING INTERVALS AMONG VIRALLY SUPPRESSED AND UNSUPPRESSED ART PATIENTS IN CENTRAL AND NORTHERN CÔTE D'IVOIRE

K.E. Kemper[1,2], O. Augusto[1,2], S. Gloyd[1,2], D.A. Akoku[3,2], G. Ouattara[3], L.A. Perrone[4,2], P.H. Assoa[5], C. Akoua-Koffi[6,7], A. Koné[1,2]
[1]Health Alliance International, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Health Alliance International, Abidjan, Cote D'Ivoire, [4]International Training and Education Center for Health (I-TECH), Seattle, United States, [5]International Training and Education Center for Health (I-TECH), Abidjan, Cote D'Ivoire, [6]Université Alassane Ouattara, Bouaké, Cote D'Ivoire, [7]University Teaching Hospital, Ministry of Health and Public Hygiene, Bouaké, Cote D'Ivoire

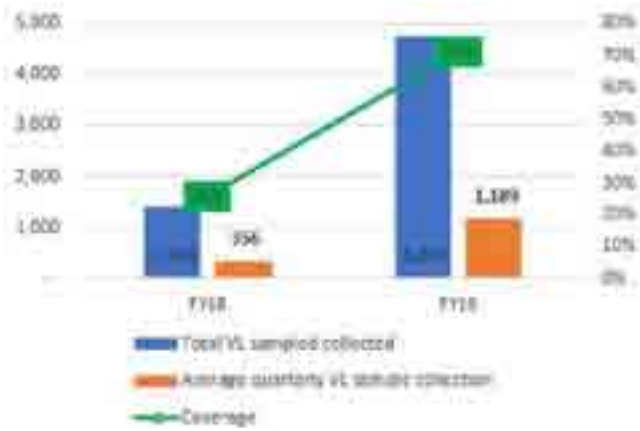
BACKGROUND: Viral load (VL) monitoring can play a substantial role in improving HIV care in Côte d'Ivoire, as it can be used to evaluate treatment outcomes and diagnose treatment failure. Côte d'Ivoire adopted the Test and Treat approach in February 2017. We sought to determine if time between VL tests aligns with differentiated guidelines for virally suppressed or unsuppressed patients.
METHODS: We analyzed laboratory data for ART patients who received a viral load test processed at three regional laboratories in Bouaké, Abengourou, and Korhogo between 2015-2018. Patient-level data and validated VL results from paper-based forms were entered into the OpenELIS Global laboratory software system by trained data clerks. We merged data for patients who received multiple VL tests by matching on unique patient ID. We excluded patients who initiated ART 6 months before the first VL test in the database or who were missing ART initiation dates. We defined viral suppression as a VL test result of <1,000 copies/mL. We used the Kaplan-Meier survival estimator to analyze time between first and second VL tests following ART initiation.
RESULTS: 12,469 patients from 17 districts and 223 clinics were included in the analysis. 9,081 (72.8%) were females, 11,737 (94.1%) were 15 years or older. 3,704 (29.7%) patients received a second VL test during the 4-year study period. The median time from ART initiation to first sample collection for VL testing was 7.8 months (IQR: 6.2 to 13.4). The median time between the first and second VL test was 24.9 months (IQR: 14.7 to >40). Of the 2,545 (20.4%) who were not virally suppressed within 12 months of ART initiation, 9 (0.4%) had a second test within 6 months; 485 (19.1%) had a second test within 12 months.
CONCLUSIONS: We identified poor follow-up of testing in accordance with national guidelines between the first and second VL tests among patients who were not virally suppressed between 2015 and 2018. VL monitoring should strengthen targeted efforts to reach virally unsuppressed patients for routine testing and potential ART regimen change. OpenELIS is a useful tool to assess viral load suppression and the quality of ART.

PEE1594

IMPROVING HIV VIRAL LOAD COVERAGE IN RESOURCE LIMITED SETTINGS THROUGH ELIMINATION OF PATIENT AND STRUCTURAL BARRIERS: THE CASE OF THE CAMEROON MILITARY HIV PROGRAM

A. Che Gilbert[1], G.T. Mumbari[1], L.M. Dapremont[2], J.C.A. Aba[3], G.A. Dion Ngute[1]
[1]DOD HIV/AIDS Prevention Program (DHAPP), Yaounde, Cameroon, [2]DOD HIV/AIDS Prevention Program (DHAPP), San Diego, United States, [3]Metabiota Inc, Yaounde, Cameroon

BACKGROUND: HIV viral suppression improves patient health outcomes and reduces deaths and new infections. Persons living with HIV (PLHIV) have better outcomes when they are on ART and are virally suppressed. Therefore, understanding HIV viral load suppression rates is crucial to ending the HIV epidemic, but impossible without enough viral load coverage. During fiscal year 2018 (October 2017 to September 2018), viral load coverage within the Cameroon Military program was 25.9%.
DESCRIPTION: From site visits, several barriers were identified: patient level were:
(1) official and unofficial fees
(2) time away from work or other duties to attend multiple HIV appointments a month; and at the structural level:
(1) limited days for sample collection due to lack of storage options, and
(2) infrequent and unreliable transportation.
Successful negotiations with military leadership to overcome financial barriers resulted in eliminated HIV patient user fees.
LESSONS LEARNED: Improvements included patient level: (1) improved identification of patients due for viral load testing by healthcare providers, (2) direct linkage by healthcare providers walking the patient to the sample collection unit when onsite, (3) scheduling viral load testing on ART pickup dates; and at the structural level: (4) daily viral load sample collection, (5) improvement in sample storage conditions to ensure viable samples, and (6) more frequent transportation of samples from healthcare facilities to the military laboratory. Viral load coverage increased from 26% in 2018 to 71% at the end 2019.



CONCLUSIONS/NEXT STEPS: The substantial increase in viral load coverage shows that a comprehensive approach was successful. The Cameroon military HIV program will build upon these accomplishments to further increase viral load coverage in 2020 and be able to utilize viral load results to identify stable verses non-stable patients in order to better tailor their HIV care accordingly.

PEE1595

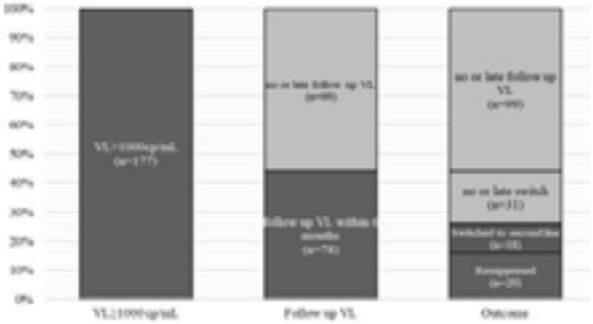
ASSESSING THE VIRAL LOAD MONITORING CASCADE FOR CHILDREN IN RURAL LESOTHO: A CHALLENGE TO DECENTRALIZED CARE

J. Muhairwe[1,2], J. Brown[3,4], L. Motaboli[1], B. Nsakala[1], M. Lerotholi[5], A. Amstutz[3,4,6], T.I. Lejone[1], T.R. Glass[3,4], N.D. Labhardt[3,4,6]
[1]SolidarMed, Swiss Organisation for Health in Africa, Butha-Buthe, Lesotho, [2]University of Geneva, Institute of Global Health, Faculty of Medicine, Geneva, Switzerland, [3]Swiss Tropical and Public Health Institute, Clinical Research Unit, Department of Medicine, Basel, Switzerland, [4]University of Basel, Basel, Switzerland, [5]Ministry of Health, Maseru, Lesotho, [6]University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland

BACKGROUND: The World Health Organization (WHO) identifies HIV infected children taking antiretroviral therapy (ART) as a priority group for routine viral load (VL) monitoring. In 2016, Lesotho decentralised routine VL monitoring to the districts. We assessed the VL cascade for children with unsuppressed VL in the 12 health clinics in Butha-Buthe district.

METHODS: Data derived from a prospective cohort of children (< 15 years) attending one of the 12 health clinics. VL results are defined as suppressed (<1000 copies/mL) and unsuppressed (≥1000 copies/mL). As per WHO guidelines, children with unsuppressed VL should receive adherence counseling and follow-up VL within 3-6 months. Virologic failure (VF), i.e. two consecutive unsuppressed VLs, should trigger switch to second-line ART within 3 months.

RESULTS: From January 2016 until June 2019, 687 children of median age 10 years (interquartile range 7-13) received 2,525 VL tests. 57% were female, and 51% attended rural health clinics. Figure 1 displays the care cascade of the 26% (177) with an unsuppressed VL: 44% (78/177) received a follow-up VL within 6 months, of these, 62% (49/78) had confirmed VF and 18 were switched to second-line within 3 months. Overall, only 27% (47/177) were managed according to guidelines (i.e. follow up VL within 6 months and subsequent resuppression or switch to second-line within 3 months). Children attending rural clinics were less likely to have follow up VL (81% vs 93%), more likely to have VF (66% vs 54%) and less likely to be switched to second line (35% vs 52%).



[Figure 1. Viral load cascade of children with a first unsuppressed VL]

CONCLUSIONS: Despite access to VL monitoring, management of children with unsuppressed VL was not optimal because of delayed follow-up and untimely regimen switch in children with confirmed VF. Delays were particularly marked in rural clinics. Programs should employ models of care that ensure timely action after VL results, especially in rural settings with decentralized care.

PEE1596

ACHIEVING HIGH VIRAL LOAD UPTAKE AND SUPPRESSION WITHIN PACT TIMIZA SUPPORTED FACILITIES IN WESTERN KENYA

C. Ngeno[1], N. Blanco[2], M.C. Lavoie[2], E. Amadi[1], A. Ndaga[1], R. Oyuga[1], K. Abuya[3], D. One[4], E. Katiku[5], E. Koech[1]
[1]University of Maryland, CIHEB, Nairobi, Kenya, [2]University of Maryland, CIHEB, Baltimore, United States, [3]Kisii County, Department of Health, Department of Health, Kisii, Kenya, [4]Migori County, Department of Health, Department of Health, Migori, Kenya, [5]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Kisumu, Kenya

BACKGROUND: In 2017, Migori and Kisii Counties had a respective viral suppression(<1000copies/ml) of 67% and 74%. In collaboration with the county governments, the University of Maryland Baltimore (UMB)-Center for International Health, Education and Biosecurity (Ciheb) implemented a bundle of interventions to improve viral load (VL) uptake among all eligible clients on ART for at least 6 months and suppression towards the last mile of the 95-95-95 UNAIDS targets in Kisii and Migori. This activity was part of PACT Timiza, a PEPFAR-CDC funded program. We examine outcome trends since the implementation of this intervention across 182 facilities in Kisii and Migori from January 2017 to September 2019.

METHODS: We conducted a cross-sectional analysis of routinely collected and aggregated programmatic data from adults>15 years and across 182 facilities in Kisii and Migori Counties between January 2017 and September 2019. The bundle of interventions included five strategies:

1) reviewing patient flow to ensure the entry point included VL monitoring;

2) developing a tracking system for VL testing;

3) training health workers on importance of returning VL results to clients;

4) educating clients on HIV health literacy; and,

5) enhancing management of high VL through viremia clinics including intense adherence support.

We evaluated trends using a non-parametric test of trend and differences in VL uptake and suppression between males and females using linear regression.

RESULTS: We found a statistically significant positive trend in VL uptake from January 2017 at 60% (28,449/47,516) to September 2019 at 97% (61,721/63,323) (p=0.01). Similarly VS increased from 70% at baseline (19,826/28,449) to 96% (59,008/61,721) at September 2019, a statistically significant positive trend in VS (p<0.01). VS within females increased from 71% to 96% and for males from 67% to 94% during the evaluation period. There was no significant difference between VL uptake (p=0.99) or VS (p=0.56) by gender.

CONCLUSIONS: A comprehensive approach focusing on clients, health providers and healthcare system processes resulted in reaching the 3rd 95 target and the approach benefited both genders equally.

PEE1597

ASSESSING FIRST HIV-1 DRUG RESISTANCE TESTING RESULTS AT BAYLOR CLINICAL CENTRE OF EXCELLENCE, LILONGWE, MALAWI

M. Byumbwe[1], P. Kazembe[1], A. Benson[1,2]
[1]Baylor College of Medicine Children's Foundation, Clinic, Lilongwe, Malawi, [2]Baylor College of Medicine, Paediatrics, Houston, United States

BACKGROUND: With more than 15 years of sustained increases in antiretroviral therapy (ART) coverage in Malawi, the country's HIV care and treatment cohort has grown with several earlier initiates switched to second-line ART. However, significant number of second-line ART clients present at clinics with high viral loads (>1000 copies/ml), suggesting second-line ART failure. Management of such clients includes monthly intensive adherence counseling (IAC) for three months followed by viral load testing and genotypic testing of HIV-1 drug resistance for clients who still have high viral load despite good adherence. In 2019, Baylor-Malawi sent five samples for genotypic testing. This study describes the genotypic testing results of the five samples.

DESCRIPTION: The genotypic testing yielded different results across the five samples. One client showed resistance to (first-line) non-nucleoside reverse transcriptase inhibitors (Nevirapine, Efavirenz, Etravirine and Rilpivirin) and intermediate resistance to Doravirine; there was no evidence of resistance to second-line drugs (Tenofovir, Lamivudine, Atazanavir and Ritonavir). Two clients showed no resistance to any ART drugs as they had completely sensitive panels. The remaining two clients showed resistance to their second line ART drugs.

LESSONS LEARNED: While genotypic testing can identify clients with resistance to various ARVs, lack of adherence to ART remains a challenge among second-line ART clients. Questions remain on how best to capture adherence in this population as two clients with good adherence (by pill counts) had high viral loads and not resistant to any ART drugs; and whether IAC delivered at the facility is optimal. It is worth noting that while these clients likely have poor ART adherence, we cannot completely rule out presence of minority resistant viruses in their bodies which, unfortunately, could not have been picked by the genotypic testing that was performed.

CONCLUSIONS/NEXT STEPS: ART clinics should continue delivering IAC to clients on second-line ART presenting with high viral loads even after clients give samples for genotypic testing. Additionally, there's need to find ways to optimally deliver IAC as well as better and cost-effective ways to quantify ART adherence in this population since some of the clients with good adherence (assessed by pill count method) may not be adherent.

PEE1598

LOW ANTENATAL VIRAL LOAD COVERAGE AMONG PREGNANT WOMEN LIVING WITH HIV IN A NESTED COHORT STUDY IN PUBLIC HEALTH SECTOR FACILITIES IN ZIMBABWE

C. Boeke[1], K. Sithole[2], E. Makadzange[2], P. Mangwendeza[2], T. Maparo[2], J. Sacks[1], R. Simbi[3], S. Mukungunogwa[3], A. Mangwiro[2], T. Peter[1], S. Khan[1], A. Mushavi[3]
[1]Clinton Health Access Initiative, Boston, United States, [2]Clinton Health Access Initiative, Harare, Zimbabwe, [3]Ministry of Health and Child Care, Harare, Zimbabwe

BACKGROUND: Viral suppression during pregnancy and at delivery dramatically reduces mother-to-child transmission (MTCT) of HIV and is critical to achieving an HIV-free generation. Zimbabwe's national guidelines (2016) recommend viral load (VL) screening at the first antenatal care visit (ANC1) among pregnant women already on antiretroviral therapy (ART) to identify women with elevated viral load (≥1000 copies/mL) for targeted adherence counseling and if necessary, treatment regimen switch to prevent MTCT. We assessed the extent to which pregnant women in Zimbabwe received a VL monitoring test at their first antenatal care visit.

METHODS: As part of a larger implementation study on VL for prevention of MTCT (PMTCT) initiated in August 2019 at 20 public health facilities across two provinces in Zimbabwe, 889 women were enrolled at delivery during the first four months of the study. Social and demographic information was collected from women at enrollment, and clinical data from the pregnancy were collected retrospectively for those who received antenatal care at the facility using registry data and patient care cards.

RESULTS: In this cohort, the median age was 32 (IQR: 27-36) years; 92.9% (n=826) were married. ANC1 took place during the third trimester for the majority of women (61.5% of those with known gestational age at ANC1; n=491). 729 of the women had received their antenatal care at the same facility as delivery and had been on ART for at least 3 months at ANC1; of those, 8.2% (n=60) received a VL test at ANC1. Among those tested, 13.3% (n=8) had elevated VL (≥1000 copies/mL) and 86.7% (n=52) were suppressed.

CONCLUSIONS: In this large cohort, ANC tended to begin late in pregnancy and less than 10% of pregnant women received a VL test at ANC1. Moreover, among women with a valid VL test result at ANC1, more than 10% had an elevated VL, suggesting that a substantial proportion of women enrolled in ANC in this population are in need of prompt interventions to prevent MTCT. Emphasis on the importance of seeking early antenatal care and further scale-up of VL testing at ANC1 will be critical to achieving elimination of MTCT.

INNOVATIONS AND LESSONS FOR SUPPORTING ADHERENCE

PEE1599

LEAVING NO ONE BEHIND: ASSESSING THE IMPACT OF MSM COMMUNITY-BASED ADHERENCE CLUBS ON RETENTION AND VIRAL LOAD SUPPRESSION IN UGANDA

S. Atuhura[1], D. Weikum[2], C. Ajulong[3], S. Ganafa[1], M. Kimbugwe[1], C. Ndeloa[4], F. Kyomukama[5], F. Okwi[5], S. Alamo[3], C. Martin[6]
[1]Spectrum Uganda Initiatives, Kampala, Uganda, [2]Centers for Disease Control and Prevention, Atlanta, United States, [3]Centers for Disease Control and Prevention, Kampala, Uganda, [4]Frontline AIDS, Hove, United Kingdom, [5]Action Group for Health Human Rights and HIV/AIDS, Kampala, Uganda, [6]US Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: Uganda continues to be a world leader in successfully engaging its HIV-affected and -infected communities in HIV program quality improvement. Atuhura et al. 2017 demonstrated that the community score card (CSC) effectively enables communities to advocate for such improvement. CSC findings have revealed community demand for adherence clubs to support viral load (VL) suppression among HIV-positive men who have sex with men (MSM).

DESCRIPTION: A retrospective observational evaluation of 2017-2018 Spectrum data across 8 facilities representing 3 regions reported that, of the 126 MSM enrolled on ART, only 15 (11.9%) had VL suppression. Between January 2018 to March 2019, clinicians screened 145 MSM, of whom 71 (49.0%) were eligible (VL suppression at screening, on ART for ≥1 year) to join adherence clubs. In this same timeframe, 10 adherence clubs (each consisting of 4 to 11 participants) were formed across the country. Each club's healthcare workers (HCWs) received gender and sexual diversity training, performed medical check-ups, refilled ART, and offered HIV care counseling. Participants were followed monthly from January 2018 through November 2019. The last VL test in November 2019 reported VL suppression among these 71 MSM was 100%.

LESSONS LEARNED: To our knowledge, this is the first time that adherence clubs have been demonstrated to enhance treatment compliance and retention in care among MSM in Uganda. HIV-positive clients, particularly key populations (KP), who continue to experience stigma and discrimination reported overwhelming support for these adherence clubs because accompanying healthcare workers were friendly and compassionate. Members agreed that monthly gatherings were an optimal frequency and qualitative data reveals that clients have reported increase in general confidence, ability to speak openly about their HIV status, and desire to mobilize their HIV-positive peers to strive for treatment adherence and VL suppression. Overall, communities have reported greater ownership and investment into reaching HIV epidemic control.

CONCLUSIONS/NEXT STEPS: ART adherence clubs will continue to expand for MSM clients and will be introduced to other KP groups. Successes with adherence clubs and other community engagement activities (e.g., CSC) continue to underscore the importance of recognizing the community as a critical stakeholder in the fight against HIV.

PEE1600

REACHING THE THIRD 90 IN THE PHILIPPINES: OUTCOMES OF THE CONNECT FOR LIFE MHEALTH ADHERENCE SUPPORT PROJECT

C. O'Connor[1,2,3], K. Leyritana[1], J. Lewis[4], A. Doyle[2], R. Gill[5], E. Salvana[6,7]
[1]Sustained Health Initiatives of the Philippines (SHIP), Manila, Philippines, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [4]Cardiff University, Y Lab, the Public Services Innovation Lab for Wales, School of Social Sciences, Cardiff, United Kingdom, [5]Johnson & Johnson Global Public Health, London, United Kingdom, [6]Institute of Molecular Biology and Biotechnology, National Institutes of Health, University of the Philippines Manila, Manila, Philippines, [7]University of the Philippines College of Medicine, University of the Philippines Manila, Section of Infectious Disease, Department of Medicine, Manila, Philippines

BACKGROUND: The Philippines had a 203% increase in new HIV infections from 2010-2018, with the majority of infections among MSM. In 2018, an estimated 44% of Filipino PLHIV were on antiretroviral treatment (ART) and 39% were virally suppressed. Improving treatment coverage, retention, and adherence, and viral suppression are key to slowing the spread of the HIV in the Philippines.

METHODS: A 48-week cohort study enrolled ART patients in Metro Manila in a mHealth intervention, The intervention Connect for Life™ (CfL),supported by Johnson& Johnson, provided patients with individualized voice/SMS services – pill reminders, appointment reminders, symptom reporting, health tips, and adherence feedback. The analysis tracked changes in individual clinical and adherence outcomes over time. Additionally, visit attendance was compared between patients who received visit reminders and others who opted to not receive the service.

RESULTS: From October 2016 to December 2018, 462 patients received 13,506 voice calls reminding them to take their pills and/or attend their clinic visits. During these calls patients listened to 4,188 health tips. Patients who opted for SMSs received more than 24,000 SMSs including 7,004 visit reminders, 5,049 adherence feedback messages, 10,030 pill reminders and 2,844 health tips.

ART Adherence: The proportion of patients adherent to ART (self-reported >95% of pills in last 30 days) increased from 78.6% at baseline to 90.2% after 48 weeks of the intervention.

Visit Attendance: Patients who received visit reminders attended 38% of visits on the scheduled appointment date, while other patients attended 30% of visits as scheduled (F=9.00, p=0.0028).

Retention in care: 95% of study patients were still in care at SHIP or a transfer site after 48 weeks, 5% were lost to follow up or deceased.

VL Suppression: Among patients who had VL monitoring, the suppression rate was 91% with no significant change over the intervention. Access to laboratory viral load is a challenge in the country, and 21% (95/462) of patients did not have their VL monitored.

CONCLUSIONS: The CfL platform enhanced services for patients. The intervention led to improved visit attendance and pill-taking, sustained high rates of retention and viral suppression, and high levels of patient satisfaction.

PEE1601

PILL-TAKERS AND SUPERHEROES: IMAGE PREFERENCES FOR AN ANTIRETROVIRAL THERAPY (ART) ADHERENCE PICTOGRAM AMONG ADOLESCENTS AND YOUNG PEOPLE LIVING WITH HIV (AYPLHIV)

L. Gittings[1], R. Hodes[1], M. Hargoven[1], R. Dowse[2], L. Cluver[3]
[1]University of Cape Town, Cape Town, South Africa, [2]Rhodes University, Makhanda, South Africa, [3]University of Oxford, Oxford, United Kingdom

BACKGROUND: The HIV epidemic among adolescents is one of the biggest public health challenges facing East and Southern Africa (ESA). AYPLHIV have documented poor adherence to antiretroviral therapy (ART), and AIDS-related illness is the leading cause of death amongst AYP in ESA. Evidence suggests that pictograms can support adherence to medicines amongst adults. Less is known about the efficacy of pictograms amongst AYP, and people living with HIV. Findings report on the piloting of a pictogram to support ART adherence among AYPLHIV.

METHODS: This research was undertaken as part of an intervention component of a longitudinal, mixed-methods study on ART adherence amongst AYPLHIV in South Africa (n=1057). The pictogram was developed based on study findings in collaboration with a graphic designer, a clinician, and two pharmacologists with expertise in visual pharmacology for patients in the Global South. Multiple pictogram options were developed and tested in a series of in-depth semi-structured interviews with AYPLHIV (n=6). Participants interpreted images, physically arranged them, acted out how they would like health workers to use the images, and provided input and advice into the images themselves as well as their use and modes of delivery.

RESULTS: Participants responded well to a 'comic book' style pictogram, colourful images, and imagery reflecting diversity in body sizes and ethnicities amongst young people. They preferred superhero images to demonstrate capability to overcome side-effects over other images of strength and resilience. Interviews revealed participant expertise in modes of administration of ART, facilitated conversations about side-effects and medicines-taking challenges, and the common misperception that ART must be taken with food.

[Figure]

CONCLUSIONS: Pictograms and empowering visual methodologies, in combination with other supportive and resilience-promoting factors may encourage AYPLHIV to take and persevere with their medication. Participatory methods that engage creative, young person-centred imagery can generate rich data that forefronts the expertise, preferences and voices of AYPLHIV.

FACTORS ASSOCIATED WITH SELF-REPORTED ADHERENCE AMONGST HIV POSITIVE PREGNANT AND BREASTFEEDING WOMEN IN AN HIV PEER SUPPORT PROGRAM: A MULTI-COUNTRY, MULTI-LEVEL ANALYSIS

K. Schmitz[1], T. Mhembere[2], C. Metekoua[2], K. Shumba[2], C. Mlandu[2], M. Mbule[1], A. Ronan[1], F. Burtt[1], F. Mpungu[1], A. Chivafa[2], V. Williams[2], E. Musenge[2], E. Scheepers[1], J. Igumbor[2]
[1]mothers2mothers, Cape Town, South Africa, [2]University of the Witwatersrand, Johannesburg, South Africa

BACKGROUND: Consistent adherence to antiretroviral treatment is important for durable viral suppression, prolonged patient survival, and reduction of HIV transmission risk. Peer support programs using HIV positive lay health workers report high adherence amongst HIV positive pregnant and breastfeeding women. This study investigated multi-level factors associated with self-reported adherence amongst these women in an HIV peer support program.

METHODS: We conducted a secondary analysis of data collected from HIV positive pregnant and breastfeeding women in Eswatini, Lesotho and South Africa between 2016 and 2018. We augmented the data with population data from national Demographic and Health Surveys. The sample consisted of 12,551 HIV positive women registered into the mothers2mothers' Mentor Mothers program at health facility level. Adherence was defined as consistently reporting high adherence, 95% of the times they were seen by a Mentor Mother using at least one of two adherence self-reporting tools. We performed multi-level mixed-effects parametric survival analysis to identify factors associated with adherence at every time point in the program.

RESULTS: The median duration in the program in our sample from enrollment was 9 (IQR: 6-15) months. The median number of contact sessions with a Mentor Mother was 6 (IQR: 3-9). Every additional year in age at registration decreased adherence by 3% ($p<0.001$). An increase in the median number of contacts with postpartum women at the health facility increased adherence by 44% ($p=0.009$). An increase in the proportion of Mentor Mothers with high competence in ART initiation support and treatment monitoring increased adherence by 35% ($p=0.019$). An increase in the proportion of babies delivered in public healthcare facilities in a community linked to a health facility increased adherence by 1% ($p=0.004$). An additional month spent between contact sessions with a Mentor Mother, decreased adherence at every time point by 6% ($p<0.001$). Increase in the median daily caseload per Mentor Mother decreased adherence by 19% ($p<0.001$).

CONCLUSIONS: The results highlight the importance of having competent lay health workers in supporting client adherence to HIV treatment. Our findings also underscore the value of an optimum Mentor Mother caseload and an effective frequency and interval between contacts.

ADOLESCENT AND YOUTH PROGRAMMING

PEE1603

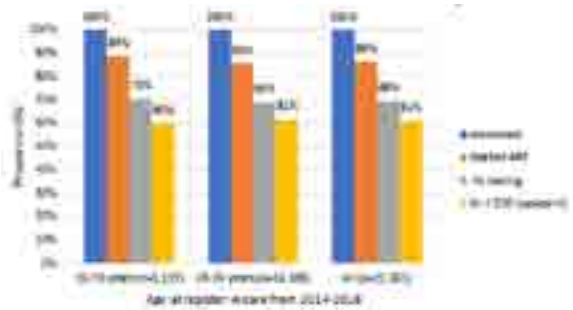
THE HIV TREATMENT CASCADE IN THE ERA OF RAPID ANTIRETROVIRAL INITIATION AMONG BEHAVIORAL HIV-INFECTED YOUTH THROUGH THE NATIONAL AIDS PROGRAM IN THAILAND

S. Teeraananchai[1,2], S.J. Kerr[2,3,4], K. Ruxrungtham[2,4], J. Thammatacharee[5], P. Khananurak[5], T. Puthanakit[2,6,7]
[1]Department of Statistics, Faculty of Science, Kasetsart University, Bangkok, Thailand, [2]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [5]National Health Security Office, Nonthaburi, Thailand, [6]Division of Infectious Diseases, Department of Pediatrics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [7]Research Unit in Pediatric Infectious Diseases and Vaccines, Chulalongkorn University, Bangkok, Thailand

BACKGROUND: Thailand has effective universal coverage through the National AIDS program (NAP). Since 2014, national guidelines recommends antiretroviral treatment initiation at any CD4 level. Here we describe the HIV care cascade in youth and assess factors associated with attrition at each step.

METHODS: HIV-infected youth aged 15-24 years, diagnosed with HIV and registered to the NAP from 2014-2018 were studied. We classified youth into 2 groups: 15-19 years (adolescents) and 20-24 years (young adults). We described the proportion of youth at each cascade step: registration, starting treatment, first viral load (VL) testing, and achieving virological suppression (VL < 200 copies/mL). Subdistribution hazard ratios (SHRs) for predictors of loss to follow-up (LTFU) before ART initiation were calculated, with death considered as a competing risk.

RESULTS: 21,305 patients registered in HIV care (24% adolescent, 76% young adult). Median (interquartile range, IQR) CD4 count at diagnosis was 334 (177-490) cells/mm^3; 70% had asymptomatic HIV infection. A higher proportion of adolescents versus young adults initiated ART (89% vs 86%; P=<0.001, Figure). Overall, 86% started ART, mostly NNRTI-based (30% within 7 days, 62% within 30 days), 647 (3%) did not start ART, 494 (2%) died prior to starting treatment, and 1767 (9%) were LTFU. Youth with less advanced HIV stage (aSHR 1.23, 95%CI 1.06-1.43) and higher CD4 count at registration (≥ 350 vs < 350; aSHR 2.65, 95%CI 2.31-3.03) had a higher chance of LTFU before ART initiation. After starting ART, 14,790 (69%) had a VL test, 13,005 (61%) were virally suppressed and 7% had virological failure > 1000 copies/mL. Of 3,607 (17%) who had no VL test, 2,309 (11%) were LTFU, 351 (2%) died and 947 (4%) recently started ART and were not yet eligible for VL testing.



[Figure. The cascade of HIV care in Thai HIV-infected youth]

CONCLUSIONS: Comprehensive service delivery among Thai youth must be further strengthened to achieve higher rates of virological suppression.

PEE1604

AVAILABILITY AND AGE OF CONSENT FOR ADOLESCENTS' ACCESS TO SEXUAL AND REPRODUCTIVE HEALTH AND HIV PREVENTION SERVICES IN NORTH-CENTRAL NIGERIA

Y. Lachir[1], A. Zhang[1], P. Ohagwu[2], I. Wright[3], T.I. Bisi-Adeniyi[4], L. Ezekwe[4], C. Adirieje[4], N. Torbunde[5], T. Jasper[6], A. Fubara[7], M.O. Folayan[8], N.A. Sam-Agudu[1,5,4]
[1]University of Maryland, School of Medicine, Baltimore, United States, [2]University of Maryland, School of Pharmacy, Baltimore, United States, [3]University of Maryland, School of Social Work, Baltimore, United States, [4]Institute of Human Virology Nigeria, International Research Center of Excellence, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Pediatric and Adolescent HIV Unit, Abuja, Nigeria, [6]Institute of Human Virology Nigeria, Continuous Quality Improvement Unit, Abuja, Nigeria, [7]Institute of Human Virology Nigeria, Pediatric and Adolescent HIV Unit, Rivers State Team, Port Harcourt, Nigeria, [8]Obafemi Awolowo University, Department of Child Dental Health and Institute of Public Health, Ile Ife, Nigeria

BACKGROUND: Nigeria is a youthful country; ~25% of its 200 million people are adolescents 10-19 years old. Comprehensive, accessible sexual and reproductive health (SRH) services are important for all adolescents. We assessed the availability of preventive, adolescent-targeted SRH/HIV services at public health facilities.

METHODS: This cross-sectional survey was conducted at six of the largest hospitals in North-Central Nigeria between June-August 2019. Data on SRH/HIV service availability and costs were collected from healthcare worker interviews. Descriptive statistics were applied.

RESULTS: All six facilities had been delivering HIV services for >10 years, with 4/6 (67%) providing pediatric HIV services for >10 years, and 2/6 (33%) for 5 to <10 years.

For disease prevention: HIV testing, PrEP and male condoms were available at all facilities for free; syphilis screening was available at all facilities for a charge; gonorrhea/chlamydia screening were available and for a charge at 5/6 (83%) sites; genital herpes screening was available, and for a fee at 3 (50.0%) sites. HPV screening was not provided at any facilities surveyed.

Age of consent for access to HIV testing was between 14 and 17 yrs for 4 sites, 18 yrs for one, and no stated minimum for one site. Age of consent for condoms was 18 yrs at 4 sites, 10 yrs at one, and no stated minimum at one site. There was no data on availability for PrEP access to adolescent minors.

For contraception: Pregnancy tests were available at all facilities for a fee. Oral contraceptive pills, implants and injectables were available for free at 3/6 (50%) sites, for a charge at 2/6 (33%) sites, with one site stating no availability. Intrauterine devices were available at 5/6 (83%) sites, all for a charge.

CONCLUSIONS: The range of SRH/HIV services accessible to adolescents is limited by age stipulations, non-universal availability and fees. Age of consent for different services varied. Adolescents' access to PrEP was not institutionalized. Sub-optimal access to SRH/HIV services may limit the achievement of adolescent HIV prevention and treatment goals in Nigeria. There is a need to optimize and integrate adolescent SRH with HIV with respect to policy and service delivery in our study setting.

PEE1605

UPTAKE OF THE DREAMS INTERVENTION PACKAGE FOR HIV PREVENTION AMONG GIRLS IN EARLY ADOLESCENCE: FINDINGS FROM AN IMPACT EVALUATION IN URBAN KENYA

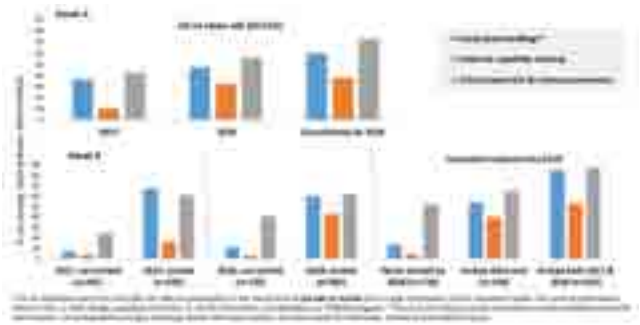
S.N. Mulwa[1,2], J. Osindo[2], E.O. Wambiya[2], A. Gourlay[1], B. Maina[2], B.O. Orindi[3], S. Floyd[1], A. Ziraba[2], I. Birdthistle[1]

[1]London School of Hygiene & Tropical Medicine, Department of Population Health, London, United Kingdom, [2]African Population and Health Research Center, Nairobi, Kenya, [3]Kenya Medical Research Institute (KEMRI)-Wellcome Trust Research Programme, Center for Geographic Medicine Research, Kilifi, Kenya

BACKGROUND: Provision of HIV prevention strategies in early adolescence (10-14 year-olds) may reduce new infections, yet few studies have evaluated programme implementation within this vulnerable population. We examined the extent to which a multi-sectoral complex intervention (the DREAMS Partnership) reached young adolescent girls in Kenya's Korogocho and Viwandani slums, where DREAMS was rolled-out from 2016.

METHODS: We utilized two annual rounds of data from a cohort study established in a sample of 10-14 year-old girls in 2017, randomly-selected from the Nairobi Urban Health and Demographic Surveillance System. We summarised proportions of self-reported invitation into DREAMS and uptake (defined as past 12 months' usage) of three primary interventions that were prioritised in this population. Analysis was restricted to girls followed-up in 2018.

RESULTS: In 2017, 606 10-14 year-old girls were enrolled into the study (response rate of 61% of n=1002 eligible), of whom 516 (85%) were followed-up in 2018. Self-reported invitation to participate in DREAMS increased from 49% (in 2017) to 77% (by 2018). Uptake in selected interventions increased over time: social asset building (37% and 47% uptake reported in 2017 and 2018 respectively (+10% [95%CI 5,16%])); school-based HIV and violence prevention (42% and 56% (+14% [8,20%])); and financial capability training (10% and 33% (+23% [18,27%])). By 2018, 59% had accessed at least two primary interventions, and 28% had accessed all three. Uptake was higher among those invited to DREAMS vs those not invited (e.g. 68% vs 7% for social asset building, and 17% vs 4% for financial capability training in 2017 (Figure 1)).



[Figure 1. Uptake of primary interventions among 10-14 year olds in Nairobi by round of interview overall (panel A), and by invitation to participate in DREAMS (panel B)]*

CONCLUSIONS: Delivery and integration of a multi-sectoral complex intervention is feasible and can reach young adolescent girls in challenging environments such as urban slums in Kenya. Additional time and effort may be needed to deliver the full DREAMS package of 3 priority interventions to targeted adolescent girls.

PEE1606

GROUP ANTENATAL/POSTNATAL CARE: A DIFFERENTIATED SERVICE DELIVERY MODEL OF CARE FOR PREGNANT AND BREASTFEEDING ADOLESCENT GIRLS AND YOUNG WOMEN (AGYW) IN UGANDA

D. Timothy Idipo[1], P. Mudiope[1], L. Nabitaka Kisaakye[1], D. Kintu[2], D. Ondo[1], J. Ssendiwala[3], F. Magala[4], J. Cheptoris[1], J. Nassali[4], I. Lukabwe[5]

[1]Ministry of Health, National Disease Control, Kampala, Uganda, [2]AMREF Health Uganda, Kampala, Uganda, [3]Makerere University School of Public Health - Monitoring and Evaluation Technical Support (MUSPH-METS) Programme, Kampala, Uganda, [4]Makerere University Walter-Reed Programme (MUWRP), Kampala, Uganda, [5]Ministry of Health, Kampala, Uganda

BACKGROUND: About 25 percent of pregnant women in Uganda are teenagers aged 10-19 years. Services delivery at ANC/PNC is homogenous for all, irrespective of mothers' age, needs and preferences. The WHO recommends Group ANC/PNC model as one of the best practices in differentiating pregnancy-care based on context and setting. Evidence around the full benefits of Group ANC in the Ugandan setting has largely been unknown. The 12-month pilot set out to determine G-ANC acceptability, utilization, retention, and preliminary effect on maternal and newborn outcomes among pregnant and breastfeeding AGYWs aged 10-24 years in Uganda.

DESCRIPTION: The G-ANC pilot targeted AGYWs 10-24 years, across 33 sites in 23 districts. The recruitment of eligible mothers was based on informed consent. Groups were made of 6 to 12 members characterized by age-bands (10-19 or 20-24 years), and gestational age, irrespective of their HIV status. Groups were tracked in cohorts that met monthly. The service package provided included group health education sessions, self-care activities and individualized obstetric exams by midwives. Linkages and referrals to other community services were integral to the model design. Midwives received pre-implementation training, on-site mentorships and collaborative learning sessions from peers. Duration in a group was 12 months for negative mothers and 18 for the HIV positive mothers and their infants.

LESSONS LEARNED: Findings: Cumulatively, 1,626 groups of 6-12 members had been formed. 15,219 AGYWs were enrolled. The overall mean length of stay in the group was 4.7 months. Among women who had delivered, the mean number of prenatal visits was 3.6 while each on average spent 6.8 months in the group. From group discussions, the majority of mothers highly approved the intervention recommending its scale-up.

What we have learned: Service differentiation may be more youth-friendly and beneficial for young mothers and a good predictor of skilled- birth attendance and good maternal and newborn outcomes.

CONCLUSIONS/NEXT STEPS: Differentiating services for mothers at high-risk of adverse maternal and newborn outcomes is strongly recommended. The Group-ANC/PNC model may have additional benefits for HIV positive AGYWs because of the retention dividend. There is a need to scale up this in Uganda with lessons learned from the pilot.

PEE1607

A DESIGNATHON TO CO-CREATE COMMUNITY-DRIVEN HIV SELF-TESTING SERVICES FOR NIGERIAN YOUTH: DESCRIPTIVE FINDINGS FROM A NATIONWIDE PARTICIPATORY EVENT

K. Tahlil[1], C. Obiezu-Umeh[2], T. Gbajabiamila[3], U. Nwaozuru[2], D. Oladele[3], A. Musa[3], I. Idigbe[3], J. Okwuzu[3], C. Airhihenbuwa[4], N. Rosenberg[1], W. Tang[1], J. Ong[5,6], D. Conserve[7], B. Kapogiannis[8], J. Iwelunmor[2], O. Ezechi[3], J. Tucker[1,5]

[1]University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]Saint Louis University, St. Louis, United States, [3]The Nigerian Institute of Medical Research, Lagos, Nigeria, [4]Georgia State University, Atlanta, United States, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Central Clinical School, Monash University, Melbourne, Australia, [7]University of South Carolina, Columbia, United States, [8]Maternal and Pediatric Infectious Disease Branch, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, United States

BACKGROUND: Youth have a high risk of HIV infection in many LMICs but are infrequently involved in designing HIV interventions. Increased youth participation in HIV prevention may drive demand for HIV services. The purpose of this study is to describe how a designathon was used to develop HIV self-testing (HIVST) strategies for Nigerian youth. A designathon is an event that brings together diverse individuals, in teams that compete with one another, to solve a problem.

METHODS: We hosted a 48-hour designathon in which young people (aged 14-24 years) from across Nigeria designed HIVST project proposals tailored for youth. Each proposal included details about HIVST kit packaging, method of distribution, promotional strategies, and target population. Teams pitched their proposals on how to increase HIVST uptake and they were assessed based on desirability, feasibility, impact, and teamwork. A seven-member judging panel included youth, government officials, and HIV researchers. Judges ranked each team's proposal and invited teams with promising ideas to a four-week capacity-building program to further develop their ideas. We examined socio-demographic characteristics of participants and summarized themes from their HIVST proposals.

RESULTS: Forty-two youth on 13 teams participated in the designathon. The median team size was 3 participants (IQR: 2 – 4 participants). The median age was 22.5 years (IQR: 21 – 24 years), 67% were male, 47% completed tertiary education, and 50% resided in Lagos State. Themes from teams' proposals included HIVST integration with other health services, digital approaches, and student engagement. Three teams created HIVST proposals that integrated HIVST services with other self-care interventions (e.g. syphilis self-testing or other STD testing, condoms, lubricants, hand soaps), of which two were among the seven teams that planned to use social media to promote their HIVST approaches. Five teams focused on students within schools and outside-of-school settings. Judges identified seven teams with exceptional HIVST strategies; five were supported for further capacity building training.

CONCLUSIONS: Designathons provide a structured method for incorporating youth ideas, preferences, and styles into HIV prevention services. Youth development of HIVST strategies resulted in promising solutions, suggesting that youth have potential to contribute to HIV service delivery in the Nigerian context.

PEE1608

AWARENESS AND UPTAKE OF THE DREAMS HIV PREVENTION PACKAGE OVER TIME AMONG POPULATION-BASED COHORTS OF YOUNG WOMEN IN KENYA AND SOUTH AFRICA

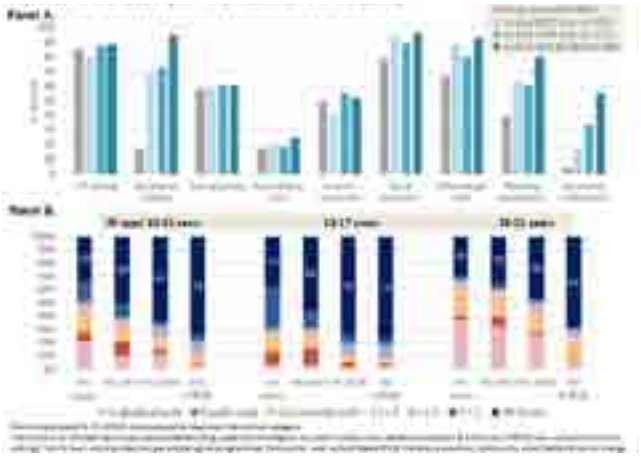
A. Gourlay[1], I. Birdthistle[1], S. Mulwa[1,2], N. Mthiyane[3], F. Magut[4], N. Chimbindi[3], A. Ziraba[2], M. Otieno[4], D. Kwaro[4], J. Osindo[2], V. Kamire[4], M. Shahmanesh[5,3], S. Floyd[1], DREAMS Impact Evaluation Study Team

[1]London School of Hygiene and Tropical Medicine, Faculty of Epidemiology and Population Health, London, United Kingdom, [2]Africa Population and Health Research Center, Nairobi, Kenya, [3]Africa Health Research Institute, KwaZulu-Natal, South Africa, [4]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [5]University College London, Institute for Global Health, London, United Kingdom

BACKGROUND: The DREAMS Partnership promotes a complex, multi-level package to prevent HIV among adolescent girls and young women (AGYW). We sought to identify changes over time in awareness and participation, including how interventions were combined, in three settings where DREAMS was implemented from 2016.

METHODS: Cohorts of ~1500 AGYW were randomly selected from demographic platforms in Kenya (Nairobi and Gem, western Kenya) and South Africa (uMkhanyakude, KwaZulu-Natal). AGYW aged 13/15-22 years were enrolled in 2017 (Nairobi and uMkhanyakude) or 2018 (Gem), with annual follow-up to 2019. We describe awareness of DREAMS, (self-)reported invitation to participate, and uptake of DREAMS interventions by: a) categories and levels of the PEPFAR Core Package; b) number of 'primary' interventions (7 intended for AGYW in Kenya; 5 in South Africa). Analyses were stratified by year invited (cumulative exposure to DREAMS) and age at enrolment.

RESULTS: Proportions aware and invited to DREAMS increased over time across all settings, to >80% aware and >50% invited by 2018 (highest among younger AGYW, e.g., 63% among 13-17s vs 39% among 18-22s in uMkhanyakude). HIV testing, school-based interventions (among younger AGYW), and social protection were the most accessed Core Package categories, while differences in uptake across categories of DREAMS invitation were greatest for novel DREAMS-specific interventions, e.g., social asset building (>75% among those invited in 2017&2018 in all settings, versus <20% among those never-invited) (figure).



[Figure. Uptake of DREAMS Core Package intervention categories (panel A) and 'levels' (panel B) among AGYW aged 13-22 years by invitation to participate in DREAMS (example of uMkhanyakude)]

Receipt of combinations of interventions (across individual, family and community levels) increased by year and cumulative exposure to DREAMS. Few AGYW accessed all intended 'primary' interventions by 2019 (e.g., <10% of 15-17s and ≤15% of 18-22s invited by 2018).

CONCLUSIONS: Over time, DREAMS reached high proportions of AGYW in all settings, particularly younger AGYW. Participation in combinations of interventions improved but uptake of the complete 'primary' packages remained relatively low.

PEE1609

INSIGHTS ON YOUTH LEADERSHIP IN HIV PROGRAMMING FOR ADOLESCENT GIRLS AND YOUNG WOMEN IN SOUTH AFRICA: LESSONS FROM PROGRAMME IMPLEMENTATION

N. Gumede[1], E. Durden[1]
[1]*Johnson & Johnson, Global Public Health, Durban, South Africa*

BACKGROUND: Youth leadership in the HIV response is critical in ending AIDS by 2030. With young women making up 67% of new HIV infections in sub-Saharan Africa, their leadership and participation in the design, implementation, monitoring and evaluation of HIV interventions is paramount. Supported by Johnson & Johnson (JnJ), in partnership with UNFPA South Africa, DREAMS Thina Abantu Abasha (DTAA) is a youth-led, peer-to-peer HIV prevention project, providing adolescent girls and young women (AGYW) aged 14-24 with leadership, employability and sexual and reproductive health and rights (SRHR) information and skills in four high-incidence districts in two provinces in South Africa.
DESCRIPTION: Three Youth Leadership Team (YLT) members conceived, planned and managed the programme in each province. Peer Educators (PEs) use their own community networks to recruit and enrol AGYW in a series of six structured workshops, one-day road shows and career days. Beneficiaries receive a workbook containing key programme content. Youth leadership includes Programme Trainers (PTs) who supervise and mentor PEs through weekly team meetings and Data Capturers (DCs) who capture and record reach. YLT, PTs and DCs meet weekly to monitor progress. YLT, JnJ and UNFPA support staff meet weekly for mentoring and support of youth leaders. DTAA is supplemented with social media and a radio drama.
LESSONS LEARNED: DTAA exceeded targets, reaching 1,198,380 beneficiaries between 2018-2019. Beneficiaries' health-related behaviour improved, with 16 % of sexually active programme participants aged 14-18 reporting having started to use condoms as a result of DTAA. 48% report starting to use contraception, and 41% testing for HIV. 64 % of programme participants aged 19-24 report having started to use condoms as a direct result of DTAA. 88% report starting to use contraception, and 100% testing for HIV. Entrepreneurial activity, employability and leadership increased amongst 19-24 year olds. Project success was attributed to age and geographic proximity of youth leaders. Complex communication chains and implementation logistics challenged programme efficiency. Lack of an exit strategy threatened project sustainability.
CONCLUSIONS/NEXT STEPS: Youth leadership increases the relevance and effectiveness of HIV prevention programmes for beneficiaries. Strengthening youth leadership and management skills and improving partner communication and implementation logistics can ensure greater programme sustainability.

PEE1610

ZAMBIA U-REPORT: STRENGTHENING YOUTH-LED HIV AND LINKAGES RESPONSE IN ZAMBIA THROUGH SMS AND DIVERSIFICATION

G. Chungu[1], N. Tembo[2], S. Diangamo[3], A. Lesa[1], R. Kalamatila[3], E. Lungu[4]
[1]*Bluecode Systems, U-report, Lusaka, Zambia,* [2]*Blucode Systems, U-report, Lusaka, Zambia,* [3]*National HIV/AIDS/TB/STI Council, Knowledge Dissemination Unit, Lusaka, Zambia,* [4]*UNICEF, HIV Unit, Lusaka, Zambia*

BACKGROUND: The Zambia U-report platform was launched in 2016 by the National HIV/AIDS/STI/TB Council with support from UNICEF. Young people around the country do not have an electronic one stop access to health information. Access to applications like WhatsApp, Viber, Facebook, Skype and Twitter for communication using instant messaging or voice calling is on the rise. Close to 4,610,657 of Zambia's youth population are not on the SmS platform. Young people will increasingly access mobile phones over time and will continue to seek advice on health related issues from friends/internet access.
DESCRIPTION: Zambia U-report is a youth-led SMS-based HIV response initiative called that is using the shortcode 878. Initially, U-report is a platform that shares Sexual Reproductive Health (SRH) information with adolescent subscribers to promote behavioral change but the system's diversification over time, has enabled subscribers to have access to SMS information on a variety of topics. The answers and information received are confidential and available around the clock. U-Report in the last six years has proven to increase comprehensive HIV knowledge among adolescents and youths, addressing misconceptions about HIV prevention and treatment - increasing HIV treatment literacy and linkages to HIV services. The Zambia U-report system is able to carry out polls and campaigns through a feature that allows for polling questions to be sent out. This feature is essential for partners as the aggregated reports generated are used to create and implement tailored youth initiatives.
LESSONS LEARNED: Young people have a diverse range of questions and challenges - offering a one stop information center for access to information for integrated services offers for a wider scope. Implementing incentified initiatives is a best practice to increase engagement. Adolescent engagement is key for the platform's continued improvement and performance. Poll and campaign feature used by partners to reach a demographic of their interest.
CONCLUSIONS/NEXT STEPS: Intensify on the ground sensitization with influential young people and peer educators across the country. Maximise on social media engagement on platforms such as twitter and youtube. Create more linkages for specified services on the SMS platform. Increase polls sent out for partners to develop interventions from generated reports.

PEE1611

REACHING YOUNG MEN: EVALUATING THE IMPACT OF DREAMS ON HIV TESTING, CARE AND PREVENTION AMONG YOUNG MEN IN THREE DIVERSE SETTINGS

M. Shahmanesh[1], K. Baisley[2], E. Wambiya[3], S. Khagayi[4], S. Mulwa[2], A. Ziraba[3], N. Mthiyane[5], I. Birdthistle[2], S. Floyd[2], D. Kwaro[4]
[1]University College London, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]African Population Health Research Centre, Nairobi, Kenya, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]Africa Health Research Institute, Durban, South Africa

BACKGROUND: DREAMS promotes combination HIV prevention amongst adolescent girls and young women. Acknowledging the role of young men missing from the care and prevention cascade in HIV transmission, we describe their uptake of HIV testing, care and prevention in three settings where DREAMS rolled-out from 2016.

METHODS: We describe uptake of HIV testing, voluntary medical male circumcision (VMMC) and antiretroviral therapy (ART) among 20-29 year-old men in general population cohorts in uMkhanyakude (KwaZulu-Natal, South Africa), Nairobi (Kenya), and Gem (Siaya, Kenya), following DREAMS roll-out (2016-2019).

RESULTS: In uMkhanyakude, N=1248, 1050, 585, and 1031 men aged 20-29 years participated in the 2015-2018 surveys. VMMC uptake increased steadily from 39.6% to 53.7% and 19.6% to 46.6% in men aged 20-24 and 25-29 respectively. Condom use increased, however by 2018 only 51.8% of 20-29 year olds who were HIV positive (based on anonymous serosurvey) were on ART.

In Nairobi, N=1833, 1902 and 1374 men aged 20-29 years participated in the 2017-2019 surveys. VMMC uptake was was 59.6% in 2017. There is no suggestion that VMMC or condom use improved. HIV testing in the past year was 66.2% in 2017 and 51.2% in 2019. Uptake of ART was low throughout.

In GEM, 994, 1855, and 1152 men aged 20-29 participated in the 2016-2018 surveys. HIV testing and ART almost doubled between 2016 and 2018, e.g. from HIV testing from 41% to 82% and ART from 39% to 80% in 20-24 year olds respectively. There was also an increase in condom use and VMMC, particularly in 20-24 year olds.

CONCLUSIONS: There is some evidence that following the rollout of DREAMS there was improvement in VMMC and condom use in both South Africa and Kenya. Improvements in engagement in the HIV treatment cascade was more heterogeneous with the greatest improvement seen in rural Kenya.

Setting	uMkanyakude, South Africa								Nairobi, Kenya						GEM, Siaya, Kenya

SIERRA LEONE'S FIRST NEEDLE AND SYRINGE PROGRAM: LESSONS LEARNED

A. Scheim[1], H. Kamara[2], K. Mansaray[3], M. Thumath[4]
[1]Drexel University, Epidemiology and Biostatistics, Philadelphia, United States, [2]Social Linkages for Youth Development and Child Link, Freetown, Sierra Leone, [3]National AIDS Secretariat, Freetown, Sierra Leone, [4]Oxford University, Oxford, United Kingdom

BACKGROUND: Sierra Leone has a stable generalized HIV epidemic with a prevalence of ~1.5% and between 2.2-14% among key populations. Among an estimated 1500 people who inject drugs (PWID), HIV prevalence was 8.5% in 2015. Access to sterile syringes is low, with 25% of PWID reporting using sterile equipment at their last injection. To prevent HIV transmission among PWID, Sierra Leone's first Needle and Syringe Program (NSP) was launched in 2019.

DESCRIPTION: The three-year NSP pilot is supported by the Global Fund and implemented by Social Linkages for Youth Development and Child Link, with the support of the National HIV/AIDS Secretariat. The pilot aims to reach 1000 PWID in Freetown and the surrounding rural areas. In 2018, a feasibility assessment was conducted, followed by the development of an implementation plan and operational manual. Thirty staff were trained, and service delivery began in March 2019.

LESSONS LEARNED: PWID and stakeholders from the health, law enforcement, and government sectors were broadly supportive of NSP. Specific barriers to implementing NSP in-country included challenges in medical waste management and procurement and unavailability of drug treatment or medical care for PWID. NSP implementation also benefited from strengths including a well-established PWID peer network, a newly optimized unique identification code for key populations, and relationships with law enforcement. In its first 10 months of operation, the NSP distributed approximately 3000 sterile syringes to 317 unique clients, of whom 20.5% were female or transgender. Used supplies are collected and safely incinerated every two weeks.

CONCLUSIONS/NEXT STEPS: The successful implementation of NSP in Sierra Leone can serve as a model for harm reduction service scale-up in West Africa. Long-term sustainability of NSP in Sierra Leone will require ongoing efforts to align policing and law enforcement with public health goals; police remain hesitant to enter a for-

mal agreement to recognize the NSP. To address the holistic HIV prevention and health needs of PWID, service pathways for sexual and reproductive health, wound care, overdose prevention, and opioid substitution need to be developed with support from diverse funding partners. A 2020 IBBS survey will provide an updated population size estimate and evaluation targets.

PEE1613

FACTORS ASSOCIATED WITH ART DEFAULTING IN HIV PATIENTS THAT STARTED ART DURING THE TEST AND TREAT STRATEGY IN ANGOLA, 2018

A. cruz[1], J. Afonso[2], J. Pires[1]
[1]SPH Angola, Luanda, Angola, [2]NRL, Luanda, Angola

BACKGROUND: Non-adherence to antiretroviral therapy (ART) is related to therapeutic failure, proliferation of drug resistant strains and need for expensive second-line regimens. We aimed to investigate the factors associated with ART defaulting among PLHIV followed in tertiary hospitals in Angola after introduction of Test and Treat (T&T) strategy.

METHODS: A cohort study was conducted in Cajueiros and Sanatorio (National Tuberculosis Reference) Hospitals in Luanda. All HIV patients starting ART in February 2018 were included and followed up for a period of 12 months. The outcome of interest was non-adherence to ART at 12 months. Semi-structured questionnaires and review of clinical files were used for data collection. Significance level was set at $p<0.05$ for all hypothesis tests. Pearson chi-squared ($\chi 2$) tests, followed by multivariable logistic regression modelling were used to identify factors associated non-adherence to ART.

RESULTS: The majority (72%) of our cohort was female, between 29-39 years old (44.4%) and single (48.2%). More than half (54.3%) had advanced disease upon HIV. Over half of the patients (54,3%) were hospitalized at HIV diagnosis and 56.8% started ART on the day of the diagnosis. More than 70% of patients changed doctors during the 12 months follow-up period. Only 39.1% had a VL at 6 months and only 55% at 12 months follow-up.

After 12 months, only 46.4% were being followed and adherent to ART. Younger patients (18-28 years) and Sanatório hospital patients were more likely (OR: 4.5 and OR; 4.3, $p<0.05$, respectively) to be non-adherent.

CONCLUSIONS: Our study is the first in Angola to provide insightful data on factors associated to ART defaulting in Angola. The majority of patients were non-adherent at 12 months, which calls for caution when planning T&T expansion in country. Strategies to improve ART adherence are needed for younger and co-infected (TB/HIV) patients in Angola.

PEE1614

SOCIAL AND SEXUAL NETWORK STRATEGIES FOR TARGETED IDENTIFICATION OF HIV-POSITIVE CLIENTS AMONG KEY POPULATIONS (KP) IN DEMOCRATIC REPUBLIC OF THE CONGO (DRC)

J. Soares Linn[1], A. Jha[1], T. Tchissambou[2], Y. Ilunga[2], S. Dane[1], S. Zidana-Ndovi[1], K. Hartsough[1], F. Malele Bazola[2]
[1]ICAP at Columbia University, New York, United States, [2]ICAP at Columbia University in DRC, Kinshasa, Congo, Democratic Republic of the

BACKGROUND: ICAP at Columbia University has partnered with the Ministry of Health in DRC to increase population access to comprehensive HIV prevention, care and treatment services. Among KP, increasing identification of HIV-positive individuals and linking them to ART is a major goal of ICAP's current work in DRC.

DESCRIPTION: During FY 2018-19, ICAP implemented social and sexual network testing and self-testing at KP-friendly facilities in Kinshasa province to specifically increase programmatic reach among partners of HIV-positive clients, hard-to-reach female sex workers (FSWs, above 35 years age) and men who have sex with men (MSM), and those at higher risk of HIV infection (living with partners having possible HIV infection or those having herpes or condyloma). Under this initiative, each eligible client is given up to 3 coupons to provide to their sexual partners or peers, and coupons are tracked bi-weekly through phone calls or text for 3 months. If the contacts who received coupons do not show up at facility, a team of counselors or providers advocate self-testing to such individuals, and they are then tracked in a similar manner for 3 months. Self-testing is also provided directly to partners and peers if the client is not comfortable using coupons.

LESSONS LEARNED: Between October 2018 and August 2019, 633 FSWs (among 1163 eligible) and 61 MSM (among 134) accepted coupons from ICAP-supported health facilities. 348 contacts of FSWs (36% of the coupons distributed) and 38 contacts of MSM (41%) returned the coupons, resulting in detection of 48 new HIV-positive clients (13.8% seropositivity) from the FSW-network, and 5 from the MSM-network (13.2% seropositivity).

Simultaneously, between December 2018 and August 2019, self-testing kits were provided to 214 FSWs and 90 MSM, resulting in a 47% rate-of-return (101 FSWs and 42 MSM). 24 new HIV-positive FSW clients (23.8% seropositivity) and 18 new HIV-positive MSM clients (42.9% seropositivity) were identified.

CONCLUSIONS/NEXT STEPS: These early results clearly demonstrate that ICAP's strategies for identification of HIV-positive KP clients have the potential to vastly improve programmatic reach among targeted groups. The approach would require further evaluation in terms of linkage-to-care and replication in similar high-burden settings.

PEE1615

OUTCOMES OF TRACKING LTFU IN POST-CONFLICT SETTING WITH HIGH POPULATION MOBILITY

N. Mahachi[1], M. Awet[1], A. Abuk[1], D. Watkins[2], S. Stender[3]
[1]Jhpiego, Juba, South Sudan, [2]Jhpiego, Baltimore, United States, [3]Jhpiego, Cape Town, South Africa

BACKGROUND: South Sudan is the youngest country in the world with a population of 11 million and an estimated HIV prevalence of 2.5%. Fewer than one in four people living with HIV (PLHIV) know their HIV status, contributing to low antiretroviral (ART) coverage (16%). Through the USAID-funded Strengthening the Provision of

Primary Health Care HIV Services (SPPHC) project, Jhpiego has been providing comprehensive HIV services across 8 facilities with a focus on identifying and linking newly identified PLHIV to ART and ensuring they are retained in care and achieve/maintain viral suppression.

DESCRIPTION: The SPPHC team works with community health workers (CHWs) and mentor mothers through civil society organization (CSO) partners to systematically follow-up clients who missed appointments and attempt to re-engage those lost to follow-up (LTFU) back into care. Clinical providers schedule appointments for all ART clients using an appointment book. A list of clients who missed appointments is abstracted weekly and passed on to CHWs for tracing by phone calls or a home visit. Outcomes of follow-up are documented, the data is aggregated into a LFTU database and outcomes are analysed and communicated back to the providers.

LESSONS LEARNED: SPPHC has improved systems to follow-up clients at community level, largely due to engagement of CSOs. Through close coordination with facility-based providers and supportive supervision, there has been an improvement in documentation, weekly reporting and action planning. One-third (29%) of the 994 clients LTFU and successfully traced Jan-Sep 2019 left care due to travel (many to Uganda); 10% self-transferred; 9% had issues with transport; and 8% reported stopping ART due to stigma. Challenges identified in the tracing process include closing of a widely used telecommunications provider leading to inability to phone clients, and inadequate documentation of physical landmarks near client homes.

CONCLUSIONS/NEXT STEPS: High population mobility accounts for a significant number of LTFU in the South Sudan context. Collaboration at country level and across borders is essential if clients are to be assured consistent access to care and treatment.

MENTAL HEALTH AND HIV

PEE1616

HIV/STI AND SOCIO-BEHAVIORAL PROFILES OF MEN WHO HAVE SEX WITH MEN ENGAGING SEXUALIZED DRUG USE BEHAVIOR IN AN INTEGRATED CHEMSEX CARE SERVICE IN TAIWAN

C. Strong[1], N.-Y. Ko[2], Y.-W. Chen[1], W.-L. Chen[1], A.-C. Chung[3], S.-T. Hsu[3], S.-Y. Wei[3], C.-C. Yen[3]
[1]National Cheng Kung University, Department of Public Health, Tainan, Taiwan, Province of China, [2]National Cheng Kung University, Department of Nursing, Tainan, Taiwan, Province of China, [3]Kaohsiung Municipal Min-Sheng Hospital, Healing, Empowerment, Recovery of Chemsex Health Center, Kaohsiung, Taiwan, Province of China

BACKGROUND: The rising trend of sexualized drug use (SDU/chemsex) in men who have sex with men (MSM) in Taiwan has become a critical contributor to the HIV epidemic. HERO integrated service (Healing, Empowerment, Recovery of Chemsex) was established in southern Taiwan in November 2017 to provide care and prevention services for HIV, mental health and substance use. The objective of this study was to describe the HIV/STI and socio-behavioral profiles of MSM engaging SDU at the HERO integrated service.

DESCRIPTION: HERO provided three major SDU-related intervention services: chemsex recovery group, counseling using Chemsex Care Plan, and psychiatric referral and treatment. At each visit, clients filled out a survey including sociodemographics, PrEP history, risk behaviors, depression, and anxiety. Survey data were linked to administrative data that recorded services they utilized at each visit. SDU at the baseline was defined as more than 0% of their sex life involving substance, such as ecstasy, ketamine, methamphetamine, and GHB/GBL.

LESSONS LEARNED: HERO had 1602 visits up to August 2019. There were 115 MSM who reported having SDU at the baseline and 29% were HIV positive, followed by syphilis (26%). One-fifth of HIV-negative SDU clients currently used PrEP. Methamphetamine was the most popular choice of substance (45%), followed by erectile-dysfunction drugs (44%), Rush (36%) and alcohol (24%). Half of the MSM less than 25 years old used methamphetamine. Thirty percent had moderate or severe anxiety and 23% for depression. Ten SDU clients used the psychiatric services at HERO and half of them used more than half a year. Among 115 MSM with SDU, 13% attended our recovery group. For those who participated less than or equal to five times of recovery group (41%), self-reported SDU decreased. Yet, the decreasing trend was not observed among those who attend more than five times.

CONCLUSIONS/NEXT STEPS: Integrated health services for chemsex are necessary and in high demand. Recovery group members stay engaged with our group by continuing to attend them. An alarming trend for methamphetamine use was observed among the younger population and warranted more outreaching services. Besides SDU-related interventions, increasing uptake of PrEP among MSM engaging SDU should also be a priority.

PEOPLE LIVING WITH HIV AND TB

PEE1617

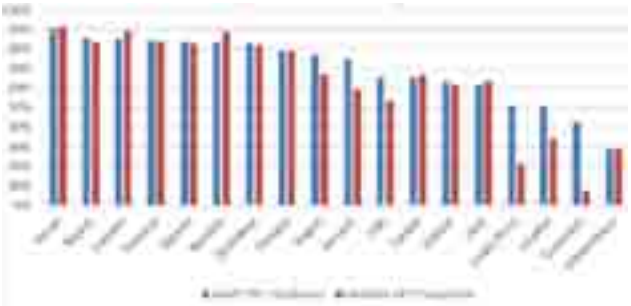
ADULT AND PEDIATRIC TUBERCULOSIS PREVENTIVE THERAPY IN SELECT PEPFAR-SUPPORTED COUNTRIES

P. Vinayak[1], T. Al-Samarrai[1], M. Peterson[2], C. Nichols[3], E. Wong[1], S. Cavanaugh[1]
[1]Office of the Global AIDS Coordinator (OGAC), Washington D.C., United States, [2]Division of Global HIV and Tuberculosis, Center for Global Health, Centers for Disease Control and Prevention (CDC), Atlanta, United States, [3]U.S. Agency for International Development (USAID), Washington D.C., United States

BACKGROUND: Tuberculosis (TB) is the leading cause of death among people living with HIV (PLHIV) worldwide and children with HIV are particularly vulnerable. TB preventive therapy (TPT) has been shown to decrease mortality among PLHIV, however scale-up has been limited. In 2018, the President's Emergency Program for AIDS Relief (PEPFAR) set ambitious targets for PEPFAR-supported countries to treat all PLHIV with TPT by 2021. This report describes the completion rates of TPT in PEPFAR-supported countries among adults and children.

DESCRIPTION: We conducted a descriptive analysis of TPT completion data collected in PEPFAR-supported countries from October 2018 – September 2019. During that time, a total of 24 programs reported TPT data to PEPFAR; five countries and one regional program where less than 5% of patients on ART initiated TPT were excluded. Using country-specific data, we determined TPT completion rates among PLHIV on ART during the one-year analysis period and compared completion rates among adults (≥15 years) and children (<15 years).

LESSONS LEARNED: Among 18 countries, seven had TPT completion rates of >80% for both adults and children. TPT completion rates ranged from 29% to 91% for adults and 8% to 92% among children. Completion rates for adults and children were within 5% of each other in 11 countries, but adults had TPT completion rates ranging from 10-35% higher than children in six countries. The greatest discrepancies between adult and pediatric TPT completion were in Cameroon (adults 43%, children 8%), South Africa (adults 51%, children 21%), and Lesotho (adults 50%, children 34%).



[Figure. TPT completion by age PEPFAR results, October 2018 - September 2019]

CONCLUSIONS/NEXT STEPS: In the majority of PEPFAR-supported countries that have launched TPT programs for PLHIV, completion rates among adults and children were comparable. However, pediatric TPT completion lags significantly behind adult TPT completion in 1/3 countries. Barriers to pediatric TPT should be identified and addressed to reduce TB morbidity and mortality among children.

PEE1618

OPTIMIZATION OF HIV TESTING AMONG PATIENTS WITH RESPIRATORY SYMPTOMS IN A TB CLINIC IN LUANDA, ANGOLA

R. Nhanombe[1], C. Laudari[1], J. Pires[1], C. Teixeira[1], A. Ukuahamba[2], C. Mota[2], M. Cazeia[2], L. Furtado[3], A. Dissadidi[4], A. Jha[5], M. A. Mahdi[5], R. Sutton[5], S. Zidana-Ndovi[5], J. Soares Linn[5]

[1]ICAP at Columbia University in Angola, New York, United States, [2]Cajueiros General Hospital in Luanda, Luanda, Angola, [3]National Institute for the Fight against AIDS in Angola, Luanda, Angola, [4]National Tuberculosis Control Program in Angola, Luanda, Angola, [5]ICAP at Columbia University, New York, United States

BACKGROUND: Angola, with a generalized HIV epidemic and 2% prevalence, is a country with a high burden of TB (estimated 107,000 cases in 2017) and 33% HIV/TB co-infection rate. Since 2015, ICAP at Columbia University has supported the Ministry of Health with HIV prevention and control efforts, including providing high-quality technical assistance in Luanda province. The national HIV counseling and testing guidelines established since 2013 recommend universal HIV testing for all diagnosed TB patients. However, opportunities to optimize and extend HIV testing services (HTS) to additional groups, including symptomatic respiratory patients, remain.

DESCRIPTION: In 2017, ICAP supported establishment of TB management services at the Cajueiros General Hospital (HGC) in Luanda, including the operationalization of the One-Stop Shop Model for TB/HIV co-infection patients. Under this program, HTS were not only offered to all diagnosed TB patients, but ICAP optimized and extended this service to all symptomatic respiratory patients referred for TB assessment and follow-up, as well as those diagnosed TB patients with a prior negative HIV test (within last 3 months) and recognized to be at risk for HIV. Systems were established for in-service mentoring of health providers, and routine monitoring of data with provision of feedback to clinical personnel.

LESSONS LEARNED: Between July 2018 and September 2019, 1,685 patients underwent HIV testing within the TB service at HGC. Of those, 886 (52.6%) were previously diagnosed TB patients who were re-tested, and 43 (4.9%) found to be HIV-positive. The remaining 799 (47.4%) were symptomatic respiratory patients, with 51 (6.4%) testing HIV-positive. Thus, among the 94 patients testing HIV-positive within the TB service during this period, 54.2% were symptomatic respiratory patients without current diagnosis of TB at the time of HIV test.

CONCLUSIONS/NEXT STEPS: These early results demonstrate the impact of expanding the offer of HTS within TB services to all symptomatic respiratory patients, leading to increased identification of new HIV-positive clients. ICAP is currently advocating with the National HIV program for a revision of the current testing guidelines to incorporate this important and impactful testing approach in Angola.

PEE1619

IMPLEMENTATION OF ROUTINE TB SCREENING AND LINKS TO TPT INITIATION IN 24 PEPFAR-SUPPORTED COUNTRIES, OCTOBER 2018-SEPTEMBER 2019

C. Nichols[1,2], P. Vinayak[3], E. Wong[3], J.S. Cavanaugh[3], T. Al-Samarrai[3]

[1]U.S. Agency for International Development, Office of HIV/AIDS, Washington, United States, [2]Interagency Collaboration for Program Improvement (ICPI), Washington, United States, [3]The U.S. Department of State, The Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, United States

BACKGROUND: Tuberculosis (TB) is the leading cause of death for people living with HIV (PLHIV) and routine symptom-based TB screening of antiretroviral (ART) patients and initiation of TB preventive therapy (TPT) are critical health services in countries with dual epidemics. The U.S. President's Emergency Plan for AIDS Relief (PEPFAR) monitors TB screening and TPT initiation efforts to assess program implementation. We analyzed this program data to assess screening and TPT treatment efforts.

DESCRIPTION: We analyzed data from 24 PEPFAR supported countries to determine the number of PLHIV on ART screened for TB symptoms and of those who screened TB negative, how many were initiated on TPT between October 2018-September 2019*.

We compared program results for two 6-month-intervals: October 2018-March 2019 and April 2019-September 2019 and evaluated screening and TB initiation rates by agender and age (<15, and 15+).

[Figure 1. Key TB screening and TPT initiation in 24 PEPFAR-supported countries, October 2018 - September 2019]*

LESSONS LEARNED: As shown in Figure 1, 84.0% of ART patients were screened for TB during period 1 however only 76.4% were screened during period 2. Of those, screened 96.1% and 97.2% were

TB symptom negative for period 1 period 2, respectively. The proportion of those who screened TB negative and were initiated on TPT increased from 6.9% in period 1 to 11.6% in period 2. In terms of subpopulations, for both time periods, the highest percentage of males <15 were screened for ART, and the lowest category was for males 15+. The increase in TPT initiation occurred across all age and sex categories.

CONCLUSIONS/NEXT STEPS: Most PEPFAR-supported programs were routinely screening ART patients, however gaps remain. The proportion of PLHIV on ART screened for TB symptoms decreased during these two time periods. The proportion of PLHIV on ART initiated on TPT increased between periods 1 and 2. Improving rates of TB symptom screening and TPT initiation are necessary as TPT scale-up efforts continue.

DIFFERENTIATED SERVICE DELIVERY

PEE1620

UNDERSTANDING HOW COMMUNITY-BASED ANTIRETROVIRAL DELIVERY INFLUENCES ENGAGEMENT IN HIV SERVICES: A QUALITATIVE ASSESSMENT OF SOUTH AFRICA'S DIFFERENTIATED CARE CCMDD PROGRAMME

J. Dorward[1,2], L. Msimango[1], A. Gibbs[3,4], H. Shozi[1], S. Tonkin-Crine[2,5], G. Hayward[2], C. Butler[2], H. Ngobese[6], P.K. Drain[7], N. Garrett[1,8]
[1]Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [2]University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom, [3]South African Medical Research Council, Gender and Health Research Unit, Pretoria, South Africa, [4]University of KwaZulu-Natal, Centre for Rural Health, School of Nursing and Public Health, Durban, South Africa, [5]University of Oxford, NIHR Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance, Oxford, United Kingdom, [6]Ethekwini Municipal Health Department, Durban, South Africa, [7]University of Washington, Departments of Global Health, Medicine and Epidemiology, Seattle, United States, [8]University of KwaZulu-Natal, Discipline of Public Health Medicine, School of Nursing and Public Health, Durban, South Africa

BACKGROUND: Providing antiretroviral therapy (ART) for millions of people living with HIV requires efficient, patient-centred models of differentiated ART delivery. In South Africa, the Centralised Chronic Medication Dispensing and Distribution (CCMDD) programme allows over 1 million people who are clinically stable to collect ART from community pick-up points and private pharmacies, instead of attending clinics. We aimed to understand how the CCMDD programme influences patients' engagement in HIV care.

METHODS: Between March-August 2018 we conducted in-depth interviews and focus group discussions with patients receiving ART and health-care workers in Durban, South Africa. We audio recorded interviews and discussions which we then transcribed and translated. We used Nvivo software to perform a deductive thematic analysis, with a framework informed by social practice theory, which highlights the *materialities*, *meanings*, *competencies* and *other social practices* that underpin patients' engagement in HIV care.

RESULTS: We conducted 25 interviews and four focus groups with a total of 55 patients (median age 31, 56% women), and interviewed eight healthcare workers (median age 39, all nurses). For standard clinic-based HIV care, participants reported long waiting times, poor confidentiality, and restricted opening hours as major barriers to engagement. In contrast, CCMDD allowed quicker and more convenient ART collection in the community, which reduced disruption to patients' lives. This particularly benefitted some employed patients, helped to normalise HIV, and was seen as a reward for taking ART well. Some patients used this to motivate better adherence. Patients also understood that they would receive less clinical oversight in CCMDD, but could return to the clinic for additional care. At private pharmacies some patients reported receiving inferior treatment compared to paying customers, and some worried about inadvertently revealing their HIV status. Patients and healthcare workers also had to negotiate problems with implementation of CCMDD, including some pharmacies reaching capacity or only allowing ART collection at restricted times.

CONCLUSIONS: In South Africa, the CCMDD programme reduced *material* barriers to attending clinics, changed the *meanings* associated with collecting ART and was less disruptive to *other social practices* in patients' lives. Expansion of community-based ART delivery programmes may help to facilitate and sustain engagement in HIV care.

PEE1621

ASSESSMENT OF CLINICAL OUTCOMES AND RISK OF LTFU AMONG PATIENTS RECEIVING DIFFERENTIATED HIV CARE: RESULTS FROM A PROSPECTIVE COHORT STUDY IN NORTHERN TANZANIA

R. Abdul[1], T. Rinke de Wit[2], G. Martelli[3], M. Maulidi[4], E.C. Kwezi[4], K. Costigan[5], P. Katambi[6], A. Pozniak[7], S. Hermans[2]
[1]Amsterdam Institute for Global Health and Development (AIGHD), Shinyanga, Tanzania, United Republic of, [2]Amsterdam Institute for Global Health and Development (AIGHD), Amsterdam, Netherlands, [3]Doctors with Africa - CUAMM, Padova, Italy, [4]Doctors with Africa - CUAMM, Shinyanga, Tanzania, United Republic of, [5]Missionary Sisters of our Lady of the Apostles, Shinyanga, Tanzania, United Republic of, [6]Diocese of Shinyanga, Shinyanga, Tanzania, United Republic of, [7]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom

BACKGROUND: Provision of HIV services in Tanzania is centred at the facility level. With an increasing number of patients due to the Universal Test and Treat policy and longer survival, facilities become increasingly overwhelmed. Differentiated Care Models (DCM) provide various time-saving care packages to HIV clients, based on their needs as an alternative. It is important to tailor such models to local settings. This study assessed the effectiveness of an ongoing community DCM intervention in Shinyanga, Tanzania, in comparison to the standard of care (SoC, facility-based model), in terms of retention in care, treatment adherence, stability over time and loss to follow-up (LTFU).

METHODS: This prospective cohort study included stable patients (stability defined as adherence >95%, viral load <200cp/ml, on ART >6 months, no pregnancy or opportunistic infections) attending routine HIV care in Bugisi (rural) and Ngokolo (urban) health facilities between July 2018 and September 2019. Eligible patients were offered to participate in the DCM, nurse-overseen and Community Health Worker (CHW)-led. Retention and adherence were compared using Chi-square; logistic and Cox proportional hazards regression models were used to analyse factors associated with patients' stability over time and the risk of LTFU respectively.

RESULTS: Of 2,521 patients, 24.7% received DCM and 75.3% SoC. DCM patients were slightly older (mean 42.6 versus 37.8 years) and less likely to be male (32% versus 36%). One-year retention in care and treatment adherence were better among DCM patients than SoC: 92% versus 82% and 99.2% versus 95.7%, respectively (p=0.001). SoC

patients were more likely to be unstable over time (OR=2.27; 95% CI:1.44-3.55). Urban patients were more likely to become unstable over time than rural (OR= 3.05; 95%CI: 2.05-4.56). There was no difference in LTFU between patients attending SoC and DCM (HR=2.42; 95%CI: 0.71-8.19).

CONCLUSIONS: Patients attending DCM demonstrate better retention in care, treatment stability and good treatment adherence. This highlights the effectiveness of DCM and the potential of CHW in delivering community-based HIV services that fit local Tanzanian context. The risk of LTFU was not different between patients attending SoC and DCM. Results from this study could be used to extend this DCM to other similar settings.

PEE1622

DIFFERENTIATED SERVICE DELIVERY MODEL FOR ADOLESCENTS: EXPERIENCE FROM WESTERN KENYA

C. Ngeno[1], M.C. Lavoie[2], N. Blanco[2], E. Amadi[1], A. Ndaga[1], R. Oyuga[1], P. Obwogo[3], L. Njoki[3], L. Nyabiage[4], E. Koech[1]
[1]University of Maryland, CIHEB, Nairobi, Kenya, [2]University of Maryland, CIHEB, Baltimore, United States, [3]Department of Health, Kisii, Kenya, [4]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Kisumu, Kenya

BACKGROUND: In Kenya, an estimated 133,000 adolescents are living with HIV. As of September 2019, the national estimate for viral suppression (VS) among adolescents was 81%, well-below the program target of 95%. In 2017, HIV care and treatment programs in Kenya initiated a differentiated service delivery (DSD) model designed for adolescents called Operation Triple Zero (OTZ). OTZ focuses on empowering adolecents to maintain zero missed appointments, zero missed drugs/medications, and zero viral load (VL) copies. We examined trends in uptake of VL testing and suppression among OTZ participants.

METHODS: We conducted a cross sectional analysis of routinely collected and aggregated data from January 2018-September 2019 from adolescents (10-19 years) participating in OTZ at 70 sites supported by UMB Timiza program in Kisii and Migori counties. Outcomes of interest were attendance to scheduled appointments, uptake of VL testing and suppression. We evaluated trends in outcomes using a non-parametric test of trend and differences in outcomes between boys and girls using linear regression.

RESULTS: During the study period a total of 2,882 adolescents participated in OTZ including 1,663 (58%) girls and 1,219 (42%) boys. Overall, an average 91% of the enrolled adolescents attended their scheduled appointments, uptake of VL testing was 79% and VS was 82%. Sex was not associated with uptake of VL testing (p=0.29), adherence to scheduled appointments (p=0.33) and VS (p=0.86). For girls and boys, we found a statistically significant positive trend in VS during the course of the program from 80% to 89% (p<0.01). There was no change in appointment adherence (p=0.13) nor uptake in VL testing (p=0.52).

CONCLUSIONS: Among adolescents who participated in the OTZ, there was a significant increase in the proportion of adolescents who were virally suppressed during the implementation of OTZ. Strenghtening VL uptake is needed to capitalize on high adherence to the program.

PEE1623

SMALL CHANGES IN ELIGIBILITY CRITERIA COULD HAVE SIGNIFICANT IMPLICATIONS FOR DIFFERENTIATED SERVICE DELIVERY MODEL UTILIZATION IN ESWATINI, MALAWI, TANZANIA AND ZAMBIA

A. Bardon[1], C. Moucheraud[2], R. Hoffman[2]
[1]University of Washington, Epidemiology, Seattle, United States, [2]University of California, Los Angeles, United States

BACKGROUND: Differentiated service delivery (DSD) models can support adults on ART to achieve optimal clinical outcomes. Given significant variability in definitions of criteria for DSD models, we assessed how differences in criteria could impact the number of participants eligible, to better inform DSD expansion.

METHODS: We estimated DSD cohort sizes under scenarios of differing eligibility criteria using data from the Population-based HIV Impact Assessment Project, nationally-representative, cross-sectional, household surveys. We estimated proportions of adults eligible for DSD in Eswatini, Malawi, Tanzania, and Zambia (among those ≥18 years, on first-line ART regimen, not undergoing evaluation or treatment for tuberculosis, and <5 missed ART doses in prior 30 days) for scenarios: varying viral suppression levels (<40, 200, or 1000 copies/mL), time on ART (≥3, 6, or 12 months), and pregnancy/breastfeeding. All estimates use survey weighting with jackknife variance estimation. We then applied these proportions to UNAIDS 2019 midyear treatment coverage estimates among adults in each country.

RESULTS: The proportion and number of adults eligible for DSD varies greatly based on the definition used. The highest proportion of adults eligible for DSD (65.0%; 95% CI: 56.7-72.6%) would be achieved by including pregnant/breastfeeding women (Model D); and the lowest proportions would result from defining viral suppression as <40 copies/mL (52.3%; 95% CI: 44.8-59.6%) (Model B) or by requiring individuals to be on ART for ≥12 months (53.1%; 95% CI: 44.2-61.8) (Model F). Depending on criteria used, cohort sizes for DSD programs could increase by up to 20-30%, approximately equivalent to an additional 150,000 adults in Tanzania and Zambia, 100,000 in Malawi, and 32,000 in Eswatini.

	Eswatini (n=2369) % (95% CI)	Malawi (n=1569) % (95% CI)	Tanzania (n=1026) % (95% CI)	Zambia (n=1434) % (95% CI)	Overall (n=4964) % (95% CI)
Model A: ≥18 years, on first-line ART regimen at time of survey, on ART ≥6 months, not suspect for TB in prior year (in MW and ZM) or not currently on TB treatment (in ES and TZ), <5 doses of ART missed in prior 30 days, not pregnant or breastfeeding (if female), viral load (VL) <1000 copies/mL	66.4 (64.5-68.3)	62.3 (59.2-65.2)	51.6 (47.6-55.5)	61.4 (58.5-64.3)	58.1 (47.6-68.0)
Model B: same as Model A, but VL <40 copies/mL	58.2 (56.1-60.2)	60.2 (57.2-63.1)	43.9 (40.0-47.9)	54.9 (51.9-57.9)	52.3 (44.8-59.6)
Model C: same as Model A, but VL <200 copies/mL	64.2 (62.2-66.2)	60.9 (57.9-63.9)	50.0 (46.0-53.9)	60.1 (57.2-63.0)	56.6 (47.0-65.8)
Model D: same as Model A, but excluding pregnancy/breastfeeding criteria	71.4 (69.5-73.3)	70.9 (68.3-73.4)	57.0 (52.9-61.1)	69.4 (66.4-72.2)	65.0 (56.7-72.6)
Model E: same as Model A, but on ART ≥3 months	68.9 (66.9-70.8)	64.9 (62.1-67.7)	52.7 (48.8-56.6)	63.6 (60.7-66.4)	58.6 (47.7-68.7)
Model F: same as Model A, but on ART ≥12 months	53.1 (44.2-61.8)	57.5 (54.2-60.7)	46.3 (42.5-50.2)	56.8 (53.6-59.9)	53.1 (44.2-61.8)

[Table 1. Weighted proportion of adults on ART in Eswatini, Malawi, Tanzania, and Zambia eligible for differentiated service delivery models by varying eligibility criteria]

CONCLUSIONS: These estimates may be useful to policymakers for planning resource allocation necessary for DSD expansion. Inclusion of pregnant/breastfeeding women, using a stricter definition of viral suppression, or exclusion of those on ART <12 months may have the greatest impact on DSD coverage, and depending on uptake, may also influence utilization.

PEE1624

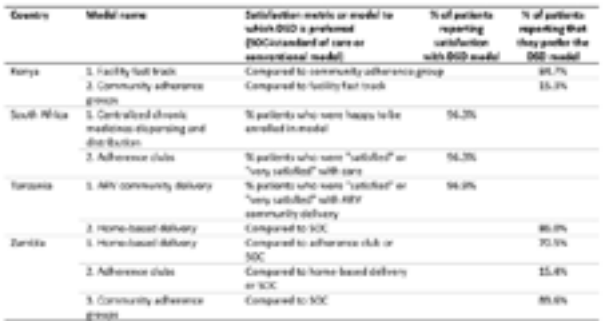
PATIENT COSTS AND SATISFACTION ASSOCIATED WITH DIFFERENTIATED MODELS OF SERVICE DELIVERY FOR HIV TREATMENT IN SUB-SAHARAN AFRICA

S. Kuchukhidze[1], L. Long[1,2,3], S. Pascoe[2,3], A. Huber[2,3], B. Nichols[1,2,3], M. Fox[1,2,3], S. Rosen[1,2,3]
[1]Boston University School of Public Health, Global Health, Boston, United States, [2]Health Economics and Epidemiology Research Office (HE2RO), Johannesburg, South Africa, [3]University of the Witwatersrand, Department of Internal Medicine, School of Clinical Medicine, Johannesburg, South Africa

BACKGROUND: Anticipated benefits of differentiated service delivery (DSD) models for HIV treatment include lower costs to patients and greater patient satisfaction. We reviewed recent sources that reported empirical information on patient costs and satisfaction.
METHODS: We searched PubMed, Embase, Web of Science, and international HIV conferences for peer-reviewed publications/presentations and conducted a targeted web search to identify unpublished reports. Sources were included if they: a) reported primary data on outcomes of a cohort of ART patients enrolled in a DSD model in sub-Saharan Africa since 2016; b) contained estimates of costs (time or money) to patients; or c) reported satisfaction with or preferences for DSD model participation.
RESULTS: Patient costs were reported for 9 DSD models in 4 countries; 5 also provided a conventional care comparison (Table 1).

[Table 1. Patient costs of receiving ART in differentiated service delivery models]

All sources with a comparison showed a substantial reduction in patients' monetary costs and/or time spent obtaining ART. A measure of patient satisfaction or preference was also reported for 9 models in 4 countries (Table 2).



[Table 1. Patient satisfaction with and preference for DSD models]

A large majority of patients were satisfied with their DSD model, and most preferred a DSD model to conventional care; group models (e.g. adherence clubs) were less popular than individual models.
CONCLUSIONS: Only a handful of studies have compared the costs to patients of DSD models to conventional care and/or reported patient satisfaction with DSD models. There is a strong likelihood of publication bias in this literature, but available evidence suggests that such models substantially reduce patient costs of seeking ART and are preferred to conventional care.

PEE1625

"YOU ARE NOT BENEFITING US BY KEEPING US AWAY": WHY DO SOME ELIGIBLE PEOPLE ON ANTIRETROVIRAL THERAPY (ART) DECLINE TO PARTICIPATE IN ETHIOPIA'S APPOINTMENT SPACING MODEL WITH 6-MONTH ART DISPENSING?

J. Mantell[1], T. Assefa[2], M. Molla[3], J. Zech[4], L. Block[4], D. Deguma[5], Z. Melaku[2], P. Preko[6], M. Rabkin[4,7]
[1]Columbia University Irving Medical Center and the New York State Psychiatric Institute, Division of Gender, Sexuality and Health, Psychiatry, New York, United States, [2]ICAP Ethiopia, Addis Ababa, Ethiopia, [3]Addis Ababa University, Addis Ababa, Ethiopia, [4]ICAP at Columbia University, New York, United States, [5]Oromia Regional Health Bureau, Addis Ababa, Ethiopia, [6]ICAP Eswatini, Mbabane, Eswatini, [7]Columbia University Mailman School of Public Health Departments of Medicine & Epidemiology, New York, United States

BACKGROUND: Ethiopia has prioritized the transition of people doing well on antiretroviral therapy (ART) into an appointment spacing model (ASM) with twice-yearly health facility (HF) clinical visits at which 6 months of ART are dispensed. It is one of the first countries in sub-Saharan Africa to take biannual multi-month scripting and delivery (6-MMD) to scale. We conducted a qualitative study to explore why some eligible individuals choose not to enroll in ASM.
METHODS: We convened 12 focus group discussions (FGDs) at three HFs in Ethiopia's Oromia region. The 93 participants were all ASM-eligible and had been on ART for ≥ 1 year; participants in 6 FGDs had chosen to enroll in ASM and participants in the other 6 FGDs had chosen not to enroll in ASM. We conducted inductive and deductive thematic analyses.
RESULTS: Participants' median age was 41 years (IQR 12) and 89% had been on ART > 5 years. Those in ASM were very satisfied. Three key themes emerged when those not in ASM explained their rationales: concerns about medication storage; dissatisfaction with decreased visit frequency; and misunderstandings about ASM. Non-enrolled participants feared that they could not store 6 months of ART safely, securely, and privately, e.g., that the ART would be vulnerable to heat-induced spoilage, access by children, and/or discovery by others leading to forced HIV status disclosure and stigmatization. They also preferred more frequent HF visits which enabled social bonding with providers and other patients, the reassurance of frequent check-ups, and ongoing counseling and adherence support. Concern about synchronizing ART pick-ups with those of an HIV+ partner or child also deterred ASM enrollment. Finally, many non-enrolled participants misunderstood ASM, thinking that they would be limited to twice-yearly HF visits, that they would receive different ART than in the conventional model, and/or that the ART dispensed would expire prior to their next visit.
CONCLUSIONS: Not all intended ASM benefits were viewed as patient-centered, and ASM is unlikely to be the preferred model for everyone. However, some resistance to ASM may be mitigated by

optimizing ART packaging, enhancing pre-enrollment orientation, strengthening community engagement, and/or providing the option of supplemental community-based support services.

PEE1626

ECONOMIC EVALUATION OF DIFFERENTIATED SERVICE DELIVERY MODELS FOR ART SERVICE DELIVERY IN LESOTHO: COST TO PROVIDER AND COST TO PATIENT

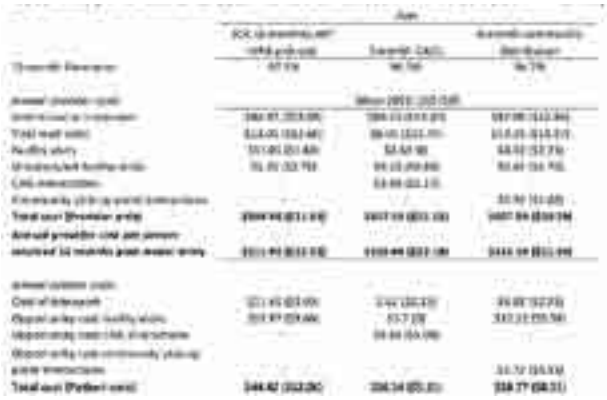
B.E. Nichols[1,2,3], G. Fatti[4,5], R. Cele[2], N. Lekodeba[2], T. Maotoe[6], M.V. Sejana[7], C. Chasela[6,8], I. O Faturiyele[9], B. Tukei[6,7], S. Rosen[1,2,3]

[1]Boston University, Department of Global Health, Boston, United States, [2]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]University of the Witwatersrand, School of Clinical Medicine, Department of Internal Medicine, Johannesburg, South Africa, [4]Kheth'Impilo AIDS Free Living, Cape Town, South Africa, [5]Stellenbosch University, Division of Epidemiology and Biostatistics, Department of Global Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [6]Right to Care, Johannesburg, South Africa, [7]EQUIP Lesotho, Maseru, Lesotho, [8]University of Witwatersrand, Department of Epidemiology & Biostatistics, Johannesburg, South Africa, [9]USAID, Washington DC, United States

BACKGROUND: Lesotho, the country with the second highest HIV prevalence (23.6%) in the world, has made considerable progress towards achieving UNAIDS' "95-95-95" targets. Recent success in improving treatment access to all known HIV positive individuals has severely strained existing healthcare infrastructure and financial and human resources. Lesotho has a largely rural population, creating a significant burden to patients in terms of time and financial costs to visit healthcare facilities. With data from a cluster randomized non-inferiority trial of community-based differentiated models of multi-month ART delivery implemented in 2017-2019, we evaluated the impact of differentiated service delivery (DSD) models for ART delivery on costs to the provider and patient in Lesotho.

METHODS: For this analysis, we estimated the total cost per patient retained 12 months after entry into a DSD model. We evaluated the standard of care (SOC) (quarterly facility visits and ART dispensing), community adherence groups with 3-month dispensing (CAGs), and community ART distribution with 6-month dispensing. We calculated the cost per patient treated from provider and patient perspectives and the cost per patient retained from the provider perspective. Provider costs included medications, laboratory tests, clinical visits, and interactions with DSD models. Patient costs included transport time and opportunity costs to clinical visits and interactions with DSD models. Costs are reported in 2018 USD.

RESULTS: The 12-month retention and average annual cost of providing HIV care and treatment was comparable across all three study arms (Table 1).



[Table 1. Annual provider costs, cost per person retained at 12 months post model entry, and patient costs by study arm]

There was a strong reduction in patient costs, however, for both DSD arms: 63% reduction for CAGs compared to SOC and 58% reduction for 6-month community ART distribution compared to SOC.

CONCLUSIONS: In Lesotho, community-based DSD models for HIV treatment are not likely to reduce costs for providers. They offer a substantial savings to patients, however, and may thereby support long-term adherence and retention in care.

PEE1627

RETENTION IN CARE AND VIRAL SUPPRESSION IN DIFFERENTIATED MODELS OF HIV TREATMENT DELIVERY IN SUB-SAHARAN AFRICA COMPARED TO CONVENTIONAL CARE: SCARCE EVIDENCE, DIVERSE OUTCOMES

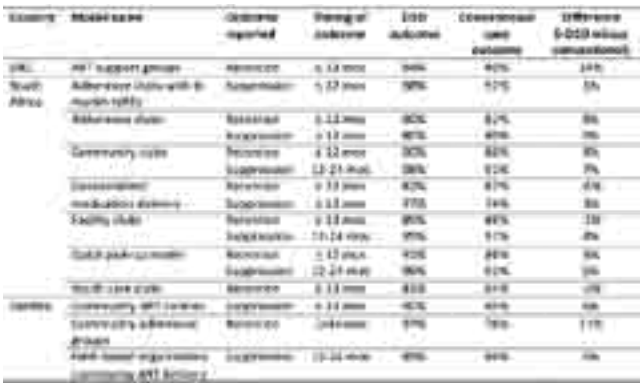
L. Long[1,2], S. Kuchukhidze[1], S. Pascoe[2,3], A. Huber[2,3], M. Fox[1,2], B. Nichols[1,2], S. Rosen[1,2]

[1]Boston University, Global Health, Boston, United States, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]University of the Witwatersrand, Department of Internal Medicine, School of Clinical Medicine, Johannesburg, South Africa

BACKGROUND: For differentiated service delivery (DSD) models of HIV treatment to be successful, they must achieve equivalent or better clinical outcomes for patients, in addition to other anticipated benefits such as reduced costs. We reviewed recent evidence to compare clinical outcomes in DSD models to those in conventional care.

METHODS: We conducted a comprehensive, rapid review of the published literature, conference abstracts, and unpublished reports to identify studies that reported retention in care or viral suppression in DSD models in sub-Saharan Africa measured ≤12 months or 12-24 months after model entry (i.e., within the first or second year of model participation) based on patient data accrued since 2016. Single-arm estimates that did not provide a conventional care comparison or reported outcomes other than retention or suppression were excluded.

RESULTS: For all of sub-Saharan Africa, we identified 8 sources, of 25,932 sources screened, that provided quantitative estimates of the outcomes sought and included comparison data. These sources described a total of 11 DSD models, with 16 clinical outcomes reported (Table).



[Table. Outcomes of DSD models with comparisons to conventional care since 2016]

Three quarters of the estimates (12/16) were from South Africa, with the remainder from Zambia (3) or DRC (1). Most were group models, such as adherence clubs. 10/16 DSD outcomes represented small (≤10%) improvements over conventional care. Two group models

showed large improvements (>20%) in retention over conventional care, while three models had slightly worse retention than conventional care. Our analysis excluded 28 sources that reported 46 clinical outcomes of DSD models without comparison data.

CONCLUSIONS: Despite rapid scale up of DSD models, rigorous evaluations of clinical outcomes are scarce. Available data suggest that many but not all DSD models produce equivalent or slightly better outcomes than conventional care, though publication bias in favor of positive outcomes is likely. More studies that include comparisons to conventional care or other models are needed.

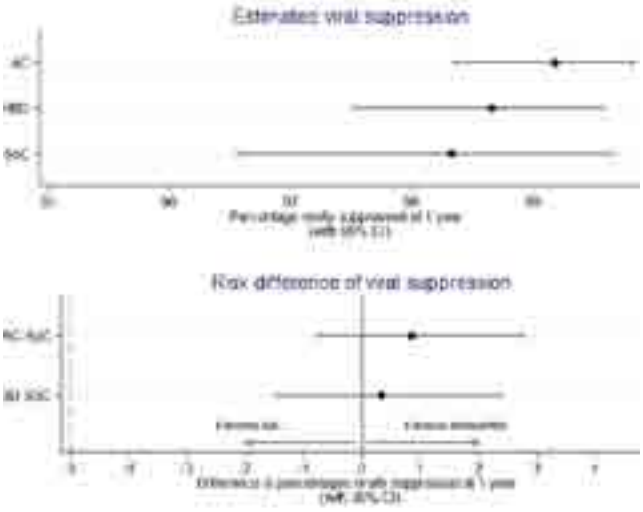
PEE1628

VIRAL SUPPRESSION IN STABLE HIV+ PATIENTS IN TWO COMMUNITY MODELS OF ART DELIVERY: A CLUSTER-RANDOMIZED TRIAL NESTED WITHIN THE HPTN 071 (POPART) TRIAL IN LUSAKA, ZAMBIA

M. Limbada[1], D. Macleod[2], K. Chileshe[1], E. Muhau[1], O. Shibwela[1], S. Floyd[2], A. Schaap[1,2], R. Hayes[2], S. Fidler[3], H. Ayles[1,2], on behalf of the HPTN 071 (PopART) Study Team
[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Imperial College, London, United Kingdom

BACKGROUND: Non facility-based antiretroviral therapy (ART) delivery for stable HIV+ patients may increase sustainable ART coverage in resource-limited settings. Within the HPTN 071 (PopART) trial, two models, Home-Based Delivery (HBD) or Adherence Clubs (AC), were offered to assess whether they achieved similar viral load suppression (VLS) to standard-of-care (SoC).

METHODS: A three-arm cluster-randomized non-inferiority trial, nested in two urban HPTN 071 trial communities in Zambia, randomly allocated 104 zones to SoC (35), HBD (35) or AC (34). ART and adherence support were delivered 3-monthly at home (HBD), adherence clubs (AC) or clinic (SoC). Adult HIV+ patients defined as "stable" on ART, were eligible for inclusion. The primary endpoint was VLS at 12 (+/-3) months, defined as RNA <1000 copies/ml, with a non-inferiority margin of 5%.



[Figure 1. Prevalence and risk difference of viral load suppression AC = Adherence club, HBD = Home-based delivery, SoC = Standard of care, AC - SoC = Risk difference between AC and Soc, HBD - SoC = Risk difference between HBD and Soc, Dashed line = non-inferiority margin]

RESULTS: Between May-December 2017, 2,489 participants were enrolled (781 SoC, 852 HBD, 856 AC). A higher proportion had VL measurements in the primary outcome window in HBD (60.8%) and AC (56.7%) arms than in the SoC (49.9%) arm (p=0.002). Of 1096 missing observations, 152 were attributable to causes (25 deaths, 37 relocations, 90 LTFU), 690 participants had VL results outside the window period and 254 did not have a VL result after 9 months. The prevalence of VLS was estimated to be 98.3% (95%CI: 96.6%-99.7%) in SoC, 98.7% (95%CI: 97.5%-99.6%) in HBD and 99.2% (95%CI: 98.4%-99.8%) in AC (Figure). This gave an estimated risk difference of 0.34% for HBD compared to SoC (95%CI: -1.46% to +2.37%) and 0.85% for AC compared to SoC (95%CI: -0.76% to +2.77%). There was strong evidence (p<0.001) that both community ART models were non-inferior to SoC.

CONCLUSIONS: Community models of ART delivery were as effective as facility-based care in terms of viral suppression.

PEE1629

THE LANDSCAPE OF DIFFERENTIATED SERVICE DELIVERY MODELS IN MALAWI, SOUTH AFRICA, AND ZAMBIA

A.N. Huber[1,2], S. Pascoe[1,2], L. Long[1,2,3], B. Nichols[1,2,3], S. Kuchukhidze[3], I. Mokhele[1,2], N. Lekodeba[1], S. Rosen[1,2,3]
[1]Health Economics and Epidemiology Research Office (HE2RO), Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Internal Medicine, School of Clinical Medicine, Johannesburg, South Africa, [3]Boston University School of Public Health, Global Health, Boston, United States

BACKGROUND: Most countries in sub-Saharan Africa are scaling up ART differentiated service delivery (DSD) models, but the scale of routine implementation and its impact on patients and the health system is poorly understood. Current national data systems do not adequately capture this information, making implementing partner (IP) organizations the best source of current data. We report interviews with all major IPs in Malawi, South Africa, and Zambia.

METHODS: In 2019, we conducted semi-structured interviews with the main NGOs supporting the implementation of DSD models. For each DSD model, we collected population eligible, model characteristics, scale of implementation, data availability, and other information.

RESULTS: We interviewed 28 organizations supporting 94 DSD models in the three countries (Table).

Average months of ARVs dispensed in model*	Number of models described**	Malawi	South Africa	Zambia
1 month	11	6	3	2
2 months	57	1	56	0
3 months	15	7	2	6
1 or 3 months (patients typically start with 1 month, then move to 3 months)	3	1	1	1
6 months	9	3	1	5
5 or 6 months (typically previously dispensed 3 months but transitioning to 6 months in line with national policy)	14	7	0	12
Not reported	5	2	3	0
Total reported in interviews	**94**	**22**	**46**	**26**

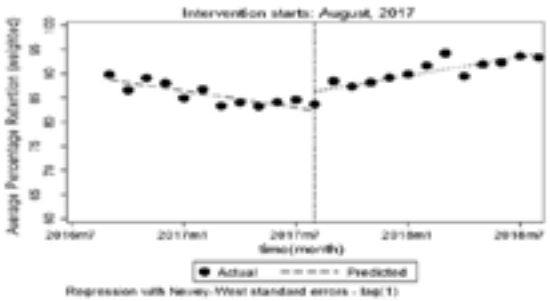
*Includes DSD models for both suppressed and unsuppressed patients, all ages and risk groups, excluding PMTCT programs.
**Specific models of care are present more than once in this table, as each instance of an implementing partner supporting a given model is counted separately. For example, multiple partners in South Africa support FDMOD, each is counted as a separate model in this table.

[Table. Months of ART dispensed, by country]

Of these models, 40% delivered services to individuals outside facilities, primarily medication pickup points; 27% were facility-based individual models, such as fast-track services and specialized key population clinics; 28% were healthcare worker-led group models, predominantly adherence clubs; and 5% were client-led groups such as community ART groups (CAGs). Most (55%) models were limited to "stable," virally suppressed adults, but each country had some mod-

els designed for advanced disease patients and key populations. Six-month dispensing was well established in Zambia and becoming more common in Malawi; 2-month dispensing remained the norm in South Africa. Models for stable patients typically required 2 full clinic visits and anywhere from 0 to 12 additional DSD interactions per year. IPs observed that 6-month dispensing may reduce patient interest in group models and others requiring ≥ 2 interactions/year. Data systems for recording DSD model scale up and participation vary by IP and are not centralized.

CONCLUSIONS: The diversity of differentiated service delivery models for HIV treatment currently being implemented in Malawi, South Africa, and Zambia hampers generalization but offers multiple examples for other countries to consider.



[Figure 1. Net percent retention of those current in care compared with 24 months prior, subtracting out the new on treatment during that time interval. Values are plotted from 12 months prior to differentiated care start to 12 months afterwards. Mean value over the 57 facilities is weighted by patient volume (facility size).]

PEE1630

RETENTION IN HIV CARE AMONG DIFFERENTIATED CARE STABLE PATIENTS IN A PROGRAM SETTING IN KISUMU, KENYA

F. Odhiambo[1], M. Moghadassi[2], J. Lewis-Kulzer[2], R. Onyango[3], J. Kadima[1], ,.E. Bukusi[1], C. Cohen[2], S. Shade[4]

[1]Kenya Medical Research Institute, Center for Microbiology Research-Research Care and Training Program, Nairobi, Kenya, [2]University of California, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [3]Kenya Medical Research Institute, Microbiology Research, Research Care and Training Program, Nairobi, Kenya, [4]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States

BACKGROUND: Kenya adoption of universal treat-all policy in 2016 led to rapid increase in adults on treatment. To relieve the additional burden on impacted health facilities, Kenya`s Ministry of Health (MOH) promoted differentiated service delivery (DSD) for stable patients, including fewer clinic visits and rapid facility drug pick-up (FastTrack). We explore how FastTrack affects retention in HIV care.

METHODS: Fifty-seven MOH facilities in Kisumu County rolled-out FastTrack. Eligible adult patients had six-monthly clinic appointments and three-monthly drug pickup. Sites underwent readiness assessment, training, and patients enrolled in FastTrack on a rolling basis from January to November 2017. We conducted a retrospective chart review to assess retention defined as net on treatment (i.e. current patients, less new on treatment), 12-months after treatment initiation, from 2014 through 2018. An interrupted time-series approach and modeled percent retained among all ~35,554 adult patients, 12-months before and after DSD implementation using weighted generalized estimating equations and moving averages over 5 values was used, p-value=0.05. Models included months before or after DSD implementation.

RESULTS: Patient retention declined slightly from 83.2% to 77.2% (-0.5% per month; 95% CI=-1.0, 0.0) in the 12-months prior to DSD implementation; increased to 83.1% immediately after DSD implementation; with further increase to 89.6% (0.5% per month; 95% CI=0.4, 0.7) in the 12-months after DSD implementation (Figure 1). Pre-Intervention, referral hospital patients had higher retention (5.7%; 95% CI=0.8, 10.5) than dispensary patients. Post-intervention, health center patients had higher retention (6.9%; 95% CI=4.5,9.2) compared to dispensary patients; and facilities in rural sub-counties had higher retention (3.7%; 95% CI=2.1,5.3) compared to facilities in Kisumu City.

CONCLUSIONS: DSD was associated with improved retention in HIV care with greatest improvement demonstrated in moderately sized facilities and rural sub-counties. Additional efforts are required to enhance the benefits of DSD in urban and larger facilities.

PEE1631

OUTCOMES OF THREE VERSUS SIX-MONTHLY DISPENSING OF ANTIRETROVIRAL TREATMENT (ART) FOR STABLE HIV PATIENTS IN COMMUNITY ART REFILL GROUPS: A CLUSTER-RANDOMIZED TRIAL IN ZIMBABWE

G. Fatti[1,2], N. Ngorima-Mabhena[3], E. Mothibi[1], T. Muzenda[1], R. Choto[4], T. Kasu[4], T. Tafuma[5], N. Mahachi[5], K. Takarinda[4], T. Apollo[4], O. Mugurungi[4], C. Chasela[6,7], R.M. Hoffman[8], A. Grimwood[1]

[1]Kheth'Impilo AIDS Free Living, Cape Town, South Africa, [2]Stellenbosch University, Department of Global Health, Cape Town, South Africa, [3]Kheth'Impilo AIDS Free Living, Harare, Zimbabwe, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]FHI360, Harare, Zimbabwe, [6]EQUIP Health, Centurion, South Africa, [7]University of the Witwatersrand, Department of Epidemiology and Biostatistics, Johannesburg, South Africa, [8]University of California, Department of Medicine, Los Angeles, United States

BACKGROUND: Multimonth dispensing (MMD) of antiretroviral treatment (ART) is a differentiated service delivery model aiming to reduce patient-related barriers to care and improve health system efficiency in low-income settings. There is increased interest in MMD models, however, randomized evidence of its clinical effectiveness is lacking. We performed a cluster-randomized trial comparing three and six-monthly MMD in community-based ART refill groups (CARGs) versus standard-of-care facility-based ART delivery in Zimbabwe.

METHODS: A three-arm, unblinded, pragmatic cluster-randomized, non-inferiority trial was performed. Thirty healthcare facilities (clusters) and linked CARGs were allocated to either: ART collected three-monthly at facility (3MF, control); ART provided three-monthly in CARGs (3MC); or ART provided six-monthly in CARGs (6MC). Stable adults receiving ART ≥ six months with baseline viral load (VL) <1000 copies/ml were enrolled. Retention in ART care (primary outcome) and viral suppression (VS) 12 months after enrollment were compared by arm, using regression models specified for clustering. ClinicalTrials.gov, NCT03238846.

RESULTS: 4800 participants were enrolled; 1919, 1335 and 1546 in 3MF, 3MC and 6MC, respectively. Retention was high and similar in all arms, 93.0%, 94.8% and 95.5% in 3MF, 3MC and 6MC, respectively (table). The pre-specified non-inferiority limit (-3.25%, risk difference [RD]) was met for comparisons between all arms; 3MC vs. 3MF, adjusted RD=1.1% (95% CI: -0.5% to 2.8%); 6MC vs. 3MF: aRD=1.2% (95% CI: -1.0% to 3.6%); and 6MC vs. 3MC: aRD=0.1% (95% CI: -2.4% to 2.6%). VL completion at 12 months was 49%, 45% and 8% in 3MF, 3MC and 6MC, respectively.VS in 3MC (99.7%) was high and not different to 3MF (99.1%), relative risk=1.0 (95% CI: 1.0-1.0). VS was marginally reduced in 6MC (92.9%) vs. 3MF, relative risk=0.9 (95% CI: 0.9-1.0).

	Retention (primary outcome)						Viral suppression (secondary outcome)						
	En-rolled	Retained		Adjusted Risk Difference (RD)			Viral load done	Viral load comple-tion	Suppressed		Relative Risk (RR)		
Arm	N	n	%	RD	95% CI	P	N	%	n	%	RR	95% CI	P

[Table]

CONCLUSIONS: Retention in CARGs receiving three and six-monthly MMD was noninferior to standard-of-care facility-based ART delivery in Zimbabwe for stable patients, and is a strategy that can be scaled-up. VS was high in 3-monthly CARGs, but VS in six-monthly CARGs requires further evaluation.

PEE1632

INCREASED SUPPRESSION AND RETENTION RATES AMONG CLIENTS ENROLLED ON THE 6 MONTHS MULTI-MONTH SCRIPTING AND DISPENSATION (MMSD) DIFFERENTIATED SERVICE DELIVERY MODEL (DSD): EXPERIENCES FROM CENTRAL PROVINCE, ZAMBIA

M. Simwenda[1], W. Kanjipite[1], M. Chanda[1], B. Ndango[1], D. Dixon[1], C. Madevu-Matson[2], M. Osborne-Smith[2]
[1]JSI USAID SAFE, Lusaka, Zambia, [2]JSI, Boston, United States

BACKGROUND: In order to improve health outcomes among ART clients, USAID funded Supporting an AIDS Free Era (USAID SAFE) supports the Ministry of Health (MoH) in Copperbelt, Central, and Northwestern provinces in Zambia to implement Differentiated Service Delivery (DSD) models, including Multi-Month Scripting and Dispensation (MMSD). These models aim to improve viral load (VL) suppression and retention rates among ART clients, but drug efficacy and client adherence over a long time period away from the clinic were unknown.

DESCRIPTION: On the MMSD model, stable clients on ART are supplied drugs for 3 or 6 months to reduce the existing burden on the health systems whilst improving other health outcomes such as VL suppression and retention rates. In 2016, 543 clients were enrolled on the 6-months drug dispensation model at Kasanda and Makululu clinics in Central Province of Zambia. Program level data was reviewed and analyzed to determine the outcomes of VL suppression and retention in care of clients at 1, 2, and 3 years after enrolment into the MMSD model and compared to the other ART clients.

LESSONS LEARNED: VL suppression increased from 85% in year 1 to 99% in year 3 of the clients being enrolled on the model. Retention rates remained above 95%. Retention and VL suppression rates among clients on the 6 months MMSD was higher than that of the other ART clients not enrolled on the model (91% and 88% respectively at year 3 of implementation of the model).

CONCLUSIONS/NEXT STEPS: This evaluation demonstrates and confirms that there is good VL suppression rate and retention in care for clients on the 6-months MMSD model. Client adherence and drug efficacy were indirectly assessed through suppression rates. The current guidelines by the MoH in Zambia on enrolling stable clients on the 6-months MMSD should continue and be scaled up in all ART facilities.

PEE1633

CONTINUOUS QUALITY IMPROVEMENT IN IMPROVING PATIENT CATEGORIZATION DOCUMENTATION, FOR DIFFERENTIATED SERVICE DELIVERY IMPLEMENTATION, A CASE OF WESTLANDS HEALTH CENTRE

L. Ombima[1], A. Awadh[1], M. Etole[1], A. Kimani[2]
[1]Nairobi City County Health Department, Health, Nairobi, Kenya, [2]USAID Afya Jijini, Health, Nairobi, Kenya

BACKGROUND: The International AIDS Society defines Differentiated Care as a client-centered approach that adapts HIV services across the clinical cascade to reflect the preferences of various groups of people living with HIV. By providing DC the health system can refocus resources to those most in need. In Westlands Health Center, which has 1356 HIV positive clients, we sought to categorize our clients as stable and unstable to give this care. The problems identified included poor documentation of categorized clients as either stable or unstable.

DESCRIPTION: Following DC recommendations by the National Program, four staffs at Westlands Health Centre went for a training on DC model using CQI. One of the trained staff was appointed as the facility mentor to guide on collection of baseline data. Using a decision matrix, we identified poor documentation of categorized clients in care as the key performance gap.

As part of the improvement process, The clinic team instituted use of categorization checklist and improvising the daily activity register as counter measures. This counter measures were developed after a root cause analysis was done where the staff applied the cause and effect analysis fish bone diagram and 5 whys. The team thereafter identified a change package for the root causes. The best scoring counter measures were implemented using PDSA cycle and the progress was tracked using run charts.

LESSONS LEARNED: After implementing the counter measures at the HIV clinic, the team noted that documentation of categorized, stable clients improved from 9% to 48% in twelve months.

Mon	Jun19	Jul19	Aug19	Sep19	Oct19	Nov19	Dec19	Jan19	Feb19	Mar19	Apr19	May19

[Table. Numerator - Documented stable client Denominator - Clients on ARV >1year seen]

CONCLUSIONS/NEXT STEPS: Use of CQI in differentiated care at the HIV clinic led to improved patient categorization documentation. Scale up of CQI approaches in tackling gaps and challenges across the HIV continuum of care is recommended.

PEE1634

RETENTION IN CARE AMONG PATIENTS IN DIFFERENTIATED MODELS OF HIV CARE IN KWAZULU-NATAL, SOUTH AFRICA

A. Shigayeva[1], N. Gcwensa[1], C. Dlamini Ndlovu[1], N. Ntumase[1], S. Sabela[1], L. Ohler[1], L. Trivino-Duran[2], E. FordKamara[1], K. Hlophe[3], G. Van Cutsem[4,5]

[1]Médecins Sans Frontières, Eshowe, South Africa, [2]Médecins Sans Frontières-South Africa, Cape Town, South Africa, [3]Department of Health, King Cetshwayo District, Richards Bay, South Africa, [4]Southern Africa Medical Unit, Médecins Sans Frontières, Cape Town, South Africa, [5]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa

BACKGROUND: Differentiated Models of HIV care (DMOC) aim to improve health care efficiency in the context of ART scale up. This study in Kwazulu Natal, South Africa, evaluates effectiveness of four DMOC models: counselor-led adherence clubs, community ART groups (CAG), fast lane spaced appointment (FLSA), and community pick up points (PuP). We compared retention between DMOC models, and retention on ART between DMOC patients and patients in normal care at 10 MSF supported clinics.

METHODS: Retrospective cohort study among patients enrolled into DMOC between 1/1/2012 and 31/12/2018, using routine ART data. DMOC was offered to patients >=18 years old, on ART for >= 12 months, and virologically suppressed. Kaplan-Meier techniques were applied. DMOC patients were followed from enrollment till return to clinic care, death or loss-to-follow up (LTFU). Outcomes for ART retention were LTFU or death. Censoring occurred in case of transfer out or database closure on 5/12/2019.

RESULTS: 9501 were enrolled into DMOC; median age was 39 years (IQR 32-48), 2353 (24.8%) were males, time on ART prior enrollment was 3.2 years (IQR 2-5); 1561 (18.1%) returned to clinic care, 657 (6.9%) were LTFU, 109 (1.1%) died. DMOC retention was 89.1%, 82.5%, 77.8% at 12, 24 and 36 months. DMOC retention was lower for CAGs (P=0.006) (Table 1).

	Clinic Care* (N=4188)	CAG (N=179)	Adherence Club (N=3598)	PuP (N=3630)	FLSA (N=2094)
Age (median, IQR)	35 (29-44)	41 (32-49)	39 (32-48)	38 (31-47)	40 (34-49)
Male (N, %)	1236 (29.5%)	38 (21.2%)	759 (21.1%)	942 (26.0%)	614 (29.3%)
Time on ART before enrolment, years (median, IQR)	3.1 (2-4)	3.3 (2-5)	2.9 (1-5)	3.4 (2-6)	4.9 (3-7)
Changed DMOC type (N, %)		63 (35.2%)	1315 (36.5%)	586 (16.1%)	218 (10.4%)
Retention on DMOC					
12M		85.1%	88.4%	90.1%	88.9%
24M		78.4%	82.1%	83.4%	82.5%
36M		72.4%	76.0%	81.0%	76.0%
Retention on ART since DMOC enrollment					
12M	91.9%	94.9%	96.4%	96.6%	97.2%
24M	85.4%	91.7%	92.9%	93.3%	94.0%
36M	79.0%	87.3%	89.3%	91.2%	90.8%
VL completion at 12M	61.0%	64.5%	74.6%	66.0%	53.9%
VL suppression <400 copies/ml	88.3%	89.0%	92.0%	98.2%	97.9%

*Clinic patients who were eligible for DMOC but not enrolled. Two clinic patients were matched to one FLSA patient on closest ART initiation and DMOC eligibility dates. Follow up of matched clinic patients started on DMOC initiation date of a matched FLSA patient

[Table 1. Baseline characteristics and outcomes among stable ART patients, by DMOC participation]

ART retention was 96.6%, 93.2%, 90.2% at 12, 24, and 36 months and did not differ across DMOC types (P=0.09), but was significantly higher compared to clinics (P<0.0001). VL completion was sub-optimal in all models; VL suppression at <400 copies/ml was lower amongst patients at clinics and CAGs (P<0.0001).

CONCLUSIONS: Concurrent implementation of alternative DMOC approaches in a large ART program is feasible, and achieves high long-term retention on ART. In order to address patients' changing needs robust monitoring is essential to assess clinical status, movement between models of care, and return to clinic care.

PEE1635

INTEGRATED POSTNATAL CLUBS SHOW IMPROVED MATERNAL VIRAL LOAD COMPLETION AND INFANT TESTING UPTAKE COMPARED TO HISTORICAL CONTROLS IN KHAYELITSHA, SOUTH AFRICA

K. Lebelo[1], T. Cassidy[1,2], L.T. Duran[3], V. Bhardwaj[1], N. Mantangana[1], L. Mdani[1], N. Malabi[1], K. Buchanan[1], L. Snyman[1], D. Hacking[1], V. de Azevedo[4], S. Patel-Abrahams[4], C. Hofmeyr[5], J. Igumbor[6], A. Nelson[1]

[1]Medecins Sans Frontieres, Khayelitsha, Cape Town, South Africa, [2]University of Cape Town, Division of Public Health Medicine, Cape Town, South Africa, [3]Medecins Sans Frontieres, Cape Town, Cape Town, South Africa, [4]City of Cape Town Health, Cape Town, South Africa, [5]Mothers2mothers, Cape Town, South Africa

BACKGROUND: Despite declining HIV mother-to-child transmission in South Africa, challenges still persist, including 4.3% transmission at 18 months, poor maternal retention and low infant testing uptake. To address these challenges, MSF, City of Cape Town Health and mothers2mothers developed postnatal clubs (PNC) in Khayelitsha, a low-income, high HIV prevalence area in South Africa. The model integrates psychosocial support, early childhood development, and maternal and child health. A mothers2mothers mentor facilitates a group session of 3-11 mother-infant pairs (MIPs) and each MIP consults with a nurse.

METHODS: We included MIPs enrolled in PNCs with 18 months of follow-up from June 2016-December 2018. Controls were recruited at birth for another study in Khayelitsha where infants were tested with birth PCR, mothers counselled on infant testing at birth and traced if infants were not known to have tested. We included MIPs with babies born from November 2015 to June 2016 with a negative 6-week PCR. We report on maternal viral load completion and suppression (<400copies/mL) by 12 months (7-365 days after birth) and 18 months (12-18 months), and infant rapid test completion at 9 months (8-10months) and 18 months (17-19months). For both cohorts, we excluded babies that seroconverted from subsequent testing denominators. We evaluated the additional cost burden to the health facility of PNCs.

	Historical controls	Postnatal clubs	Risk Ratio (95% CI) [PNC/controls]
Infants 9 month rapid completion (8-10mth)	112/221 51%	114/141 81%	1.6 (1.4-1.9)
18 month rapid completion (17-19mth)	70/220 32%	90/140 64%	2.0 (1.6-2.6)
Mothers 0-12 month viral load completion	149/221 67%	140/141 99%	1.5 (1.3-1.6)
0-12 month viral load suppression	141/149 95%	134/140 96%	1.0 (0.96-1.1)
12-18 month viral load completion	65/221 29%	107/141 76%	2.6 (2.1-3.2)
12-18 month viral load suppression	63/65 97%	101/107 94%	0.97 (0.9-1.0)

[Table 1]

RESULTS: In the PNC cohort (N=141), one infant seroconverted (after exiting the PNC) before their 18 months test, while two control group infants (N=221) seroconverted before 18 months. Infant testing

completion rates were higher in the PNC cohort at nine months (81% vs 51%) and 18 months (64% vs 32%) than the historical controls. Mothers' viral load completion rates were higher in the PNC cohort at 12 months (99% vs 67%) and 18 months (76% vs 29%), with similar viral suppression rates (Table 1). PNCs entailed minimal additional cost.

CONCLUSIONS: PNCs provided women with peer support and convenience, and improved maternal viral load monitoring and infant testing.

PEE1636

ACCEPTABILITY AND FEASIBILITY: PATIENT AND PROVIDER EXPERIENCES OF URBAN ADHERENCE GROUPS (UAGS) IN ZAMBIA

S.M. Topp[1], C. Mwamba[2], C. Bolton-Moore[2], A. Sharma[2]
[1]James Cook University, Townsville, Australia, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia

BACKGROUND: Differentiated service delivery has potential for improved service delivery and health outcomes through tailored services that reduce overall costs to providers and people living with HIV. We examined patient and provider experiences of one model, Urban Adherence Groups (UAGs), to distil lessons regarding supply- and demand-side acceptability and feasibility in Zambia.

METHODS: Nested within a matched-pair cluster-randomized effectiveness trial of UAGs in Zambia, we conducted endline focus group discussions with study-enrolled patients (32), professional (16) and lay (16) healthcare workers (HCW); and interviews with 32 study staff, 10 clinic in-charges and 9 provincial or district health directors. Inductive and deductive analysis was used to synthesize findings under the themes "acceptability" (general perceptions about, or experiences with UAGs) "appropriateness" (assessment of clinical or psycho-social impact); and "feasibility" (qualitative evaluation of resources and capabilities required scale-up and sustain UAGs long-term).

RESULTS: Patients and HCW found UAGs to be highly acceptable, with reduced queuing and congestion a key theme. For patients, reduced congestion freed time to meet livelihood needs and lessened concerns about unintentional disclosure from attending public clinics. Routine access to information and meaningful group support also reduced self-stigma. Patients described UAGs as appropriate due to improved accessibility of medication, a preference for group (versus one-on-one) counselling and the "*opportunity to interact with the [UAG-specific] staff*" without fear of being '*shouted at*'. Group size and mixed gender groups were generally viewed as appropriate. HCW, however, expressed concerns about UAG appropriateness due to reduced frequency of clinical checks. Patients and HCW both viewed the UAG model as feasible, contingent on staff and funding inputs. Two preconditions for scaling-up UAGs were commonly mentioned. First, professional HCWs appointed to lead UAGs should be selected for and trained to deliver 'friendly' 'helpful' and efficient care. Second, establishment of formal MOH employment for lay (or community) health care workers was needed, recognising their key linkage, navigation and education roles in UAG success.

CONCLUSIONS: UAGs demonstrate promise as a one mechanism for improving patient experience of, and engagement in HIV treatment in Zambia, but require adequate human resourcing and oversight.

PEE1637

DEVELOPING A MODEL TO PRIORITISE MEN WHO HAVE SEX WITH MEN FOR DELIVERING DIFFERENTIATED PREVENTION SERVICES IN TARGETED INTERVENTIONS IN INDIA

S. Rajan[1], B. Singh Kushwaha[2], J. Kirubakaran[3], B. George[3], G.S. Shreenivas[3], L. Singh Kharayat[2], P. Goswami[3], M. Setia[4], S. Panyam[5], S. Kumar[2]
[1]Ministry of Health & Family Welfare, National AIDS Control Organization, New Delhi, India, [2]National AIDS Control Organisation, Targeted Intervention Division, New Delhi, India, [3]FHI 360, Linkages, New Delhi, India, [4]Consultant, Epidemiologist, Mumbai, India, [5]Consultant, M&E Expert, Hyderabad, India

BACKGROUND: Targeted Innervation (TIs) have been critical component of the National AIDS Control Programme in India, designed for key populations. The TI programme provides standardized services to all KPs. However, to increase the efficiency of these interventions and thereby to reach the 90-90-90 targets, it is important to prioritize Men who have sex with men (MSM) into high/moderate/low categories and to provide differentiated package of services. Thus, the present data modelling was designed to develop a composite indicator for appropriate categorisation of high-risk MSM in India.

METHODS: We used the following data points from 18 TIs from six regions of India from April 2017-September 2018: demographic, sexual behaviours, and biological indicators. The cut-offs for numerical variables were based on Receiver Operating Characteristics curve, area under the curve and Youden's index for optimal cut-offs. These categories generated were used in the regression analysis; the final weights for the composite indicator were based on the final regression model. The outcome for the models was new HIV infections.

RESULTS: The median score of inter quartile range in the National models was 28 (23, 38). The cut-off for classification of scores was High >=28, Moderate 16-27, and Low <15. About 52% MSM were classified as high-risk, 39% as moderate-risk, and 10% as low-risk. HIV incidence was significantly higher in the high-risk MSM compared with moderate risk MSMs (p=0.001). None of the low-risk MSM was HIV-positive. Higher weights for HIV positivity was assigned to the following indicators: Association with TI for <2 years (24%); had an STI (17%); Sexually active with men for less than 5 years (13%), double-decker (typology) (10%). Younger MSM (18-24 years) were significantly more likely to miss a condom in the past 10 sex acts compared with those aged >=31 years (p<0.001).

Categories	Total Data points	HIV Positivity	Associated with TI < 2 years	MSM for < 5 years	Typology – Double-decker	Had an STI/RTI
High (>=28)	17402	32 (0.2%)	5959 (34%)	4604 (26%)	8876 (51%)	416 (2%)
Moderate (16-27)	12957	10 (0.08%)	228 (2%)	212 (2%)	1344 (10%)	36 (0.3%)
Low (<=15)	3270	0 (0%)	0 (0%)	10 (0.3%)	385 (12%)	0 (0%)
P value		<0.001	<0.001	<0.001	<0.001	<0.001

[Table 1: Distribution of behavioural characteristics]

CONCLUSIONS: The composite indicator precisely classified MSM with increased risk for new HIV infections, corroborating the need for differentiated service delivery approach for resource optimization within the concentrated HIV epidemic in India.

PEE1638

EXPANDING ACCESS TO HIV CARE AND TREATMENT THROUGH DECENTRALIZED DRUG DISTRIBUTION IN THE PRIVATE SECTOR

H. Marqusee[1], K. Badiane[1], T. Minior[1], S. Baker[1], J. Tayag[2], M. Hijazi[1]
[1]USAID, Office of HIV/AIDS, Washington, DC, United States, [2]USAID, South Africa, Pretoria, South Africa

BACKGROUND: Public hospitals often manage high volumes of clients with inadequate staffing, resulting in long wait times, overworked staff, poor client satisfaction, and weak retention. The private sector is an untapped resource for decongesting public facilities and increasing access to HIV services. Private outlets can offer clients privacy, convenient locations and scheduling, consistent stock availability, shorter wait times, and greater client-centered care. Most importantly, they are often the preferred place of care for populations who are harder to reach and retain in the public sector, including men, higher income groups, adolescents and key populations.

DESCRIPTION: Through the PEPFAR-funded Sustainable Financing Initiative (SFI), USAID has been expanding access to ARVs through the private sector. In Nigeria, between 2016 and 2019, SFI equipped a network of private outlets to deliver PEPFAR-funded ARVs to patients who chose to receive their medication in a private pharmacy or hospital. Other automated decentralized models, such as "eLockers" and ATM-like dispensing units, also show promise for decongesting public facilities. SFI has documented the successes, challenges and steps needed to scale up these decentralized approaches and has developed a tool to model their epidemiological and economic impact in a number of countries.

LESSONS LEARNED: As a result of SFI work in Nigeria, over 3,000 patients have been receiving ART services from private facilities and nearly 15,000 have been regularly picking up their medication from private pharmacies, with average adherence rates of 95% and pharmacy visit times under 30 minutes. By delegating ARV refill services to private pharmacies, the intervention decongested overburdened public hospitals, reduced staffing requirements, increased their capacity to manage their workload, and improved client satisfaction. This work has been estimated to provide savings of approximately $5 million to PEPFAR due to reduced client load and associated management and human resources costs at public facilities. After deducting investments to establish the program, this represents a return on investment of 5:1.

CONCLUSIONS/NEXT STEPS: Decentralized ARV distribution programs that utilize private sector infrastructure can increase the number of patients on treatment while providing cost savings to donors, governments and patients.

PEE1639

FACTORS THAT INFLUENCE THE SATISFACTION OF PEOPLE LIVING WITH HIV(PLHIV) WITH DIFFERENTIATED ART DELIVERY MODELS IN EAST CENTRAL UGANDA

K. Baleeta[1], N. Tumwesigye[1], A. Muhwezi[1], B. Nsangi Kintu[1], R. Iriso[1], D. Mwehire[1], M. Mbonye[1], S. Riese[2], L. Bailey[3], D. Freitas Lopez[3], L. Nakitende Kiggwe[1], D. Nantamu[4], M. Etukoit[5], B. Tibingana[5], J. Wasswa[1], E. Kayongo[1], D. Byonanebye[6]
[1]University Research Co.LLC, USAID RHITES EC, Jinja, Uganda, [2]Metrics for Management, Washington, United States, [3]University Research Co.LLC, USAID RHITES EC, Chevy Chase, United States, [4]Jinja District Local Government, Health, Jinja, Uganda, [5]The Aids Support Organization, Kampala, Uganda, [6]University of New South Wales, Sydney, Australia

BACKGROUND: The World Health Organization has recommended Differentiated service delivery models (DSDM) as patient-centered ART delivery mechanisms for patients living with HIV/AIDS (PLHIV) who have an undetectable viral load. We sought to determine the level of and factors associated with patient satisfaction with DSDM services.

METHODS: This was a cross-sectional study of a random sample PLHIV accessing ART within DSDMs at eight facilities in East Central Uganda. Eligible patients were adults (≥18 years), on ART and enrolled on either Community Client Led ART Delivery (CCLAD), Community Drug Distribution Points (CDDP) or Fast-Track Drug Refill (FTDR) models for at-least twelve months. Data was collected from June to July 2019. A validated tool was used to measure patient satisfaction with DSDM services along five aspects: health worker confidentiality, psychosocial support received, time for other priorities, health cost and time spent traveling and waiting to receive ART services. Patients were then categorized as either satisfied or not satisfied. Logistic regression was used to identify factors associated with patient satisfaction with DSD services.

RESULTS: Overall 842 (254(30.2%) males; 588 (69.8%) females) were enrolled on the study of whom, 541 (64.2%) were satisfied with DSDM services: 78.7% in CDDP, 42.8% in CCLAD and 36.3% in CCLAD. The factors associated with patient satisfaction were being on CDDP [aOR=3.42, 95% CI :2.15–5.44] and FTDR[aOR=2.92, 95% CI:1.34–6.31] DSDMs relative to CCLAD, greater than three years on DSDM [aOR=2.32, 95% CI:1.12–4.87], lower transport costs (< $ 1.35) per clinic visit [aOR=2.39, 95% CI:1.59–3.60] being employed either in agriculture[aOR=4.41, 95% CI :2.62-7.41] or any other employment sector [aOR=4.22, 95% CI :2.46-7.27]relative to being unemployed, participation of a friend/relative [aOR=1.79, 95% CI :1.22–2.61] and not drinking alcohol [aOR=2.33, 95% CI:1.24–4.29].

CONCLUSIONS: The study showed that 64.2% of the patients are satisfied with DSDM services. Service delivery factors (model type, time-period on DSDM, and having a friend/relative at the same ART point), social factors (employment, and alcohol consumption), and transport costs were all associated with patient satisfaction with DSDM. Implementers need to further tailor services to address these factors to improve odds of satisfaction especially in CCLAD and FTDR DSDMs.

PEE1640

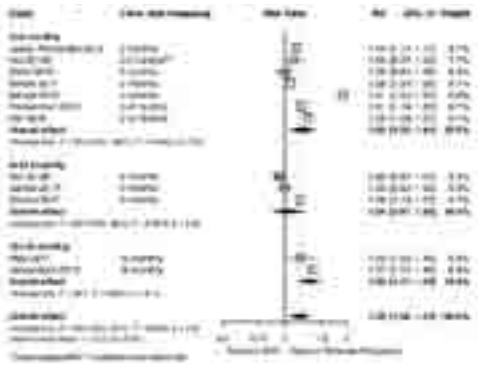
REDUCING FACILITY APPOINTMENT FREQUENCY TO IMPROVE RETENTION IN CARE AMONG CLINICALLY STABLE, HIV POSITIVE PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Le Tourneau[1], R. Thompson[2,3], A. Germann[3], I. Eshun-Wilson[4], E.H. Geng[5,4]
[1]University of California, Division of HIV, Infectious Diseases & Global Medicine, School of Medicine, San Francisco, United States, [2]University of California, Proctor Foundation, San Francisco, United States, [3]Johns Hopkins University, School of Public Health, Baltimore, United States, [4]Washington University at St. Louis, Division of Infectious Diseases, School of Medicine, St. Louis, United States, [5]Washington University at St. Louis, Center for Dissemination and Implementation, Institute for Public Health, St. Louis, United States

BACKGROUND: Global HIV treatment programs have sought to lengthen the interval between clinical encounters for stable patients to reduce the burden of seeking care, but the overall effect of reduced frequencies on retention is unknown. We conducted a systematic review and meta-analysis to evaluate the interventions that reduce the frequency of clinic visits, including clinical assessments and/or ART collection at the facility, for stable patients living with HIV.

METHODS: We searched seven databases and reference lists through April 2019. Eligible studies included HIV+ patients in low- and middle-income countries who were stable on ART (ex. ≥3 months on ART, 95% adherence). We extracted data from studies that reported on retention in care and viral suppression, and assessed risk of bias using the Cochrane tool in randomized controlled trials (RCT) and the Newcastle-Ottawa Scale in cohort studies. For each outcome, we conducted pairwise meta-analyses comparing the reduced frequency strategy to standard of care (1-2 monthly clinic visits), using random-effect models and cluster adjusted estimates for cluster RCTs.

RESULTS: Eligible studies included 18 comparative trials (4 RCTs and 14 observational studies), and 6 single arm studies. Among the comparative trials that reported retention in care, reduced frequency of clinic appointments (>2 months vs 1-2 months) was associated with increased retention on ART and in care compared to the standard of care with a relative risk (RR) of 1.18 (95% CI 1.06-1.31). Appointments from >2 months as compared to 1-2 months increased viral suppression (RR 1.23, 95% CI: 0.97-1.54).



[Figure. Retention in care at longest time point: reduced visit frequency vs. standard of care, by appointment frequency]

CONCLUSIONS: Despite heterogeneity in effect size, reducing appointment frequency for stable patients on ART improved the attendance at the health care facility and likely improves viral suppression. Additional research on optimal interval should be conducted, but programs that have not offered quarterly (or longer) appointment intervals for stable patients should do so.

STRATEGIES TO INCREASE UPTAKE OF RETENTION IN HIV SERVICES

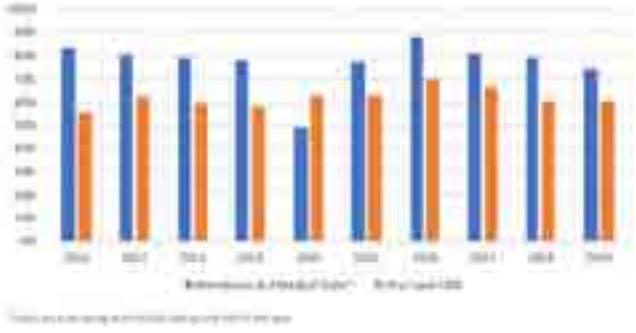
CHANGE IS THE ONLY CONSTANT: A NOVEL TEAM-BASED RETENTION AND RE-ENGAGEMENT STRATEGY (PHAST) FOR A LARGE URBAN HIV CLINIC

J. Bloome[1], E. Lynch[1], M. Ibarra[1], S. Torres[1], C. Ospina-Norvell[2], J. Oskarsson[1], S. Coffey[1], V. Jain[1], D. Havlir[1], M. Gandhi[1]
[1]University of California, Division of HIV, Infectious Diseases & Global Medicine, Department of Medicine, San Francisco, United States, [2]Center for Learning & Innovation, SFDPH, San Francisco, United States

BACKGROUND: Retention in care is critical for the health of people living with HIV (PLWH) and prevention of HIV transmission. The San Francisco General Hospital Ward 86 HIV Clinic developed a program to support patients out-of-care with re-engagement and retention in HIV care.

DESCRIPTION: The Positive Health Access to Treatment and Services (PHAST) team enrolls PLWH who have not engaged in medical care >6 months. The multidisciplinary team (clinician, nurse, social worker) provides a single point of contact to patients, clinicians, and community programs for referrals from both inpatient and community settings. Enrolled patients receive supportive services including navigation, appointment reminders, incentives, housing and food support. The PHAST team has served 1898 unique patients since 2010; median age 39 years; 87.5% male-identified, 9.4% female, 2.7% transgender. Among enrollees, 63% live below the U.S Federal Poverty Line and 37% are unstably housed or unhoused.

LESSONS LEARNED: Patients who enter the PHAST program are, by definition, not attending medical visits, but after enrollment for an average duration of 326 days, a median of 80% attended 2 medical visits within the most recent year and qualified to transition to a less-intensive care model. Moreover, once enrolled, 67% of the PHAST patients started ART and achieved virologic suppression. Key program elements include 1) Ongoing relationships and communication between PHAST and medical and community programs for PLWH, 2) Stigma-free and culturally responsive environment, 3) Low barrier drop-in services, 4) Focus on empowering patients to address their healthcare needs.



[Figure. PHAST patient engagement in care and viral load suppression]

CONCLUSIONS/NEXT STEPS: The PHAST team at Ward 86 provides a model for successfully supporting retention in care for PLWH previously disengaged from care. This model results in high retention and virologic suppression rates, and nimbly evolves in response to new needs and opportunities for vulnerable patients, including incorporating rapid ART initiation, long-acting ART when available, and HIV prevention services via a status-neutral approach.

PEE1642

A MIXED METHODS, IMPLEMENTATION SCIENCE EVALUATION OF A MHEALTH COMMUNITY HEALTH WORKER INTERVENTION FOR PROMOTION OF HIV SERVICES IN A HYPERENDEMIC SETTING IN UGANDA

L. Chang[1], I. Mbabali[2], R. Pollard[1], K.R. Amico[3], A. Anok[2], X. Kong[1], C. Kennedy[4], J. Mulamba[2], J. Ssekasanvu[4], M. Wawer[4], H. Hutton[1], G. Nakigozi[2]

[1]Johns Hopkins School of Medicine, Baltimore, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]University of Michigan, Ann Arbor, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

BACKGROUND: Effective implementation strategies are needed to increase engagement in HIV services in HIV hyperendemic settings. We conducted a mixed methods implementation science evaluation of a community health worker (CHW) intervention called "Health Scouts", which used motivational interviewing-informed strategies, and mobile health (mHealth) support tools to promote engagement in HIV services in a hyperendemic (HIV prevalence ~40%) fishing community in Uganda.

METHODS: Using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) implementation science framework, we collected and analyzed process data from physical log books, process data from mobile-phone based entries, self-reported resident data from a community-wide survey (n=1891), and qualitative data from 72 in-depth interviews (51 clients, 8 Health Scouts, 6 staff, 7 community leaders).

RESULTS: From 2015-2018, 13 Health Scouts logged a total of 11,221 counseling sessions; 2,532 unique clients were counseled; median sessions per client was 4 (IQR 2-7); 614 clients received only one counseling session. By late 2018, 95.7% (1789/1891) of community residents reported awareness of the Health Scouts and 2.2% reported being approached but refusing to be seen. Females (vs males) and HIV-seropositive persons (vs seronegative) were more likely to report having been ever counseled by Health Scouts (p<0.001). Themes arising from qualitative data analysis included: *Reach*-Residents were willing participants out of self-interest and perception of the Health Scouts as a trustworthy and helpful service; *Effectiveness*-Health Scout counseling directly impacted client behaviors, particularly ART uptake and adherence; *Adoption*-Health Scouts were broadly accepted, but negative rumors (such as questions about Health Scouts' motivations) slowed universal adoption; *Implementation*-High resident mobility was an implementation challenge; mHealth tools were initially useful to guide counseling with clients, but became less useful over time; *Maintenance*-Some Health Scouts and clients felt counseling messages became repetitive over time.

CONCLUSIONS: A novel mHealth CHW intervention was implemented with moderate success in a challenging HIV hyperendemic setting. An implementation science framework helped identify successful intervention components and areas for improvement to inform future programmatic iterations.

PEE1643

SUSTAINED IMPROVEMENTS IN LINKAGE TO TREATMENT AMONG KEY POPULATIONS IN CAMEROON

A.L. Bowring[1,2], G. Fouda[3], C.S. Minka Minka[3], F. Ngueguim Gnintedem[4], I. Mfochive Nkindam[1,5], G. Fako[5], D.A. Kob Ye Sam[6], Z. Zeh Akiy[6], U. Tamoufe[5,7], S. Baral[1], S. Georges[3], D. Levitt[8], S.C. Billong[9,10], A.-C. Zoung-Kanyi Bissek[10,11]

[1]Johns Hopkins School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Burnet Institute, Melbourne, Australia, [3]CARE Cameroon, Yaounde, Cameroon, [4]CHAMP Cameroon, Yaounde, Cameroon, [5]Metabiota, Yaounde, Cameroon, [6]USAID, Yaounde, Cameroon, [7]Johns Hopkins Cameroon, Yaounde, Cameroon, [8]CARE USA, Atlanta, United States, [9]Groupe Technique Central, National AIDS Control Committee (CNLS), Yaounde, Cameroon, [10]University of Yaounde I, Faculty of Medicine and Biomedical Sciences, Yaounde, Cameroon, [11]Ministry of Health, Department of Operational Research, Yaounde, Cameroon

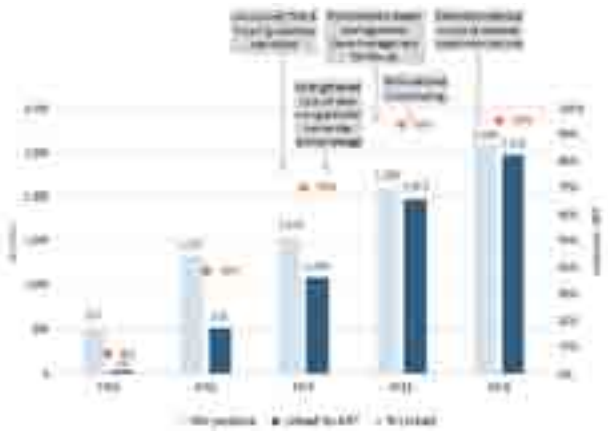
BACKGROUND: In Cameroon female sex workers (FSW) and men who have sex with men (MSM) have high burden of HIV. Barriers to accessing HIV services include stigma, discrimination, violence, long waiting times, user fees, and population mobility.

DESCRIPTION: Under the program "CHAMP", community-based organisations(CBOs) in three cities have provided peer-driven HIV services since 2014. Initiation on antiretroviral therapy(ART) is predominantly provided to new clients through HIV treatment health facilities.

HIV testing and linkage to ART data were electronically collected. Aggregate data on diagnoses and linkage to ART were analysed by fiscal year(FY) and key population(KP) from October 2014–September 2019.

LESSONS LEARNED: Prior to national 'Test & Treat' guidelines, introduced early-2017, linkage to ART was 31% (297/948) among FSW and 57% (216/379) among MSM in FY16. Linkage to ART increased to 72% (740/1,033) among FSW and 68% (345/511) among MSM in FY17 but remained below targets. Innovations to support linkage to ART were scaled in FY18, and linkage increased to 93% (1,264/1,359) and 95% (709/747), respectively. High linkage was maintained in FY19 among FSW (95%;1,688/1,777) and MSM (96%;790/819).

Key initiatives heading this success were: active referral for same-day initiation or arranged appointments by strengthening the role of peer navigators; sensitizing focal points at treatment centres on KPs' needs; involving peer navigators and clinicians during outreach testing; piloting on-site initiation; performance-based management; and weekly follow-up by case management teams. Additionally, during FY18 psychosocial counsellors and peer navigators were trained to use motivational interviewing, and during FY19 extended opening hours were arranged at selected treatment centres.



[Figure 1. Linkage to ART among FSW and MSM at CHAMP sites FY15 to FY19]

CONCLUSIONS/NEXT STEPS: Combined strategies involving active referral, coordinated and patient-centred support by peer workers, psychosocial counsellors and clinicians, and collaboration between community-based and national health facilities led to sustained improvements in linkage to ART. These approaches are likely to also support retention on ART and should be considered for widespread implementation.

PEE1644

PATIENT NAVIGATION DELIVERY AND IMPLEMENTATION MECHANISMS THAT FACILITATED CARE ENGAGEMENT AND RETENTION AMONG MSM AND TRANSGENDER WOMEN IN A HEALTH SYSTEMS INTERVENTION IN LIMA, PERU - PROYECTO ORGULLO+

A. Maiorana[1], E. Lugo[2], W. Hamasaki Reyes[2], K. Konda[2], G. Calvo Moreno[2], S. Kegeles[1], C. Cáceres[2]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, Sida y Sociedad, Lima, Peru

BACKGROUND: In Peru, HIV care engagement remains low among MSM and transgender women (TW), populations disproportionally affected by HIV. Navigating a fragmented, unfriendly and overcrowded health system, compounded with HIV stigma, hinder their linkage and retention in care. Patient navigation (PN) has proven successful at improving HIV care engagement, but its application in Latin America has been limited.

We trained four peer counselors on Anti-Retroviral Treatment and Access to Services (ARTAS), expanding their role to provide previously non-existent PN to MSM and TW at two health care facilities in Lima South.

We examined how this PN intervention helped facilitate care engagement among MSM and TW.

METHODS: We conducted in-depth interviews (N=24) with the four navigators (two gay men and two heterosexual women) living with HIV who delivered PN, and 20 (16 MSM, 4 TW) of their clients (7 newly diagnosed, 13 previously out of care). Guided by Framework Analysis, we identified salient PN mechanisms that facilitated care engagement.

RESULTS: Over two years, navigators conducted an average of three ARTAS sessions and ongoing follow-up with 192 clients, of whom 174 initiated/reengaged in treatment. Overall, their clients were lower income, marginalized, with limited HIV information, social support, and HIV disclosure due to compounded forms of stigma.

Clients appreciated the PN services and expressed their "confianza" (trust) in the navigators. Most developed strong emotional bonds with the navigators, referring to them as friends, family, or as "someone sent from heaven." PN delivery and implementation mechanisms that facilitated care engagement included:

1) Non-judgmental, client-centered services: emotional support and advocacy to navigate the health system (insurance issues, ART access); self-advocacy skills; health literacy/normalizing living with HIV; and addressing HIV stigma.

2) Empowering relationships developed by committed peer navigators who became role models, helped clients identify their strengths to address barriers to care, provided on-going attention, dedicated time (appointment reminders/accompaniment/follow up), and were available outside the health facilities.

CONCLUSIONS: PN and the support of the navigators fostered clients' resilience to address care engagement barriers. While systemic barriers remain, PN may contribute to improve the HIV care continuum among MSM and TW in Peru and potentially in other Latin American countries.

PEE1645

IMPACT OF COMMUNITY RESOURCE PERSONS AND MOBILE PHONE TECHNOLOGY ON RETURN TO HIV CARE AMONG LOSS TO FOLLOW UP HIV CLIENTS IN 104 HIV FACILITIES IN UGANDA

A. Mugisa[1], S. Ezajobo[1], B. Nakibuuka[1], J. Baluku[1], J. Nakaweesi[1], C. Ssenyimba[1], L. Mills[2], S. Nakubulwa[3]
[1]Mildmay Uganda, Health Systems Strengthening, Kampala, Uganda, [2]Center for Disease Control, Entebbe, Uganda, [3]Mildmay Uganda, Research and Strategic Information, Kampala, Uganda

BACKGROUND: Retention in HIV health care is critical for anti-retroviral therapy (ART) adherence and viral suppression. Clinical visits for patients on ART are essential to initiate ART, continuous access to medication, monitor medication side effects and diagnose treatment failure. With PEPFAR support, Mildmay Uganda Mubende Project implemented the Back to Care' campaign with the primary objective of improving 12-month retention from 66% as of December 2018 to 90% by end of September 2019 in 104 public health facilities across 8 districts in rural Uganda. Here we present the impact of previsit e-message reminders, phone calls and Community Resource Persons (CORPs) on HIV treatment retention in the project implementation area.

DESCRIPTION: Mildmay Uganda, since April 2017 is implementing a 5-year project aiming at "Accelerating Epidemic control in Mubende Region under PEPFAR". The geographical scope for this project is 8 districts in the central region of Uganda (Luwero, Nakaseke, Nakasongola, Mityana, Mubende, Kiboga, Kassanda & Kyankwanzi). Interventions included using e-messages for pre-appointment remainders, line listing of clients who miss appointments for same day follow up through phone calls. Community Resource Persons (CORPs) conducted physical community follow ups for clients without phones alongside community drug deliveries for located recipients of care.

LESSONS LEARNED: 75%(13,102/17,496) and 84.8% (24,837/29,302) of clients who were followed up using CORPs and phones were respectively returned to care. Retention improved from 66% registered in the quarter of October - December 2018 to 88% in July-September 2019 quarter.

CONCLUSIONS/NEXT STEPS:

- Community and phone follow up of clients immediately following missing of appointments is important in retaining clients in care in light of the 90% target.

PEE1646

EFFECT OF SAME-DAY ART INITIATION ON EARLY RETENTION IN RAKAI, UGANDA

J. Basiima[1], V. Ssempijja[1,2], A. Ndyanabo[1], A. Kisakye[1], G.M. Bua[1], D. Bbaale[1], L. Chang[1,3], N. Sewankambo[1,4], D. Serwadda[1,4], L. Mills[5], J. Kagaayi[1], P. Komakech[5], G. Nakigozi[1], M. R Adler[5], S.J. Reynolds[1,3,6]
[1]Rakai Health Sciences Program, Research, Kampala, Uganda, [2]Clinical Monitoring Research Program Directorate/Clinical Research Directorate (CMRPD), Frederick National Laboratory for Cancer Research Sponsored by the National Cancer Institute, Kampala, Uganda, [3]Johns Hopkins, School of Medicine, Baltimore, United States, [4]Makerere University, College of Health Sciences, Kampala, Uganda, [5]Centers for Disease Control and Prevention, Clinical Research, Kampala, Uganda, [6]Division of Intramural Research, NIAID/NIH, Bethesda, United States

BACKGROUND: Retention in care is key to achieving good clinical outcomes. With support from the President's Emergency Plan for AIDS Relief (PEPFAR) and CDC-Uganda, the Rakai Health Sciences Program supports the provision of antiretroviral therapy (ART) to about 120,000 People Living with HIV in 12 Districts in south-central Uganda. We assessed differences in retention at the first ART initiation follow-up within one-month of ART initiation and subsequent retention after the first ART follow-up. HIV infected patients who start ART on the day of HIV diagnosis, and those who delayed initiation by 1-7 or 8+ days after HIV diagnosis.

METHODS: We conducted a retrospective longitudinal analysis among HIV infected adults 18 years and older who initiated ART during the test and start program between April 2016 –September 2019 in 20 HIV clinics of Rakai district. The primary exposure was time from testing HIV positive to initiation of ART classified as same day initiation, 1-7-day or ≥8 days post-HIV test. HIV testing was conducted using rapid HIV tests. We used Poisson multi variable regression to estimate adjusted relative risk (aRR) and 95% CI of non-return within one month of ART initiation.

RESULTS: Of 1873 HIV infected patients with known dates of HIV test and ART initiation, 1147(61%) initiated ART on the same day of testing, 397 (21%) initiated within 1-7 days and 329 (18%) initiated ART after 8 days of the positive HIV test. Failure to return at the first ART follow-up occurred in 17.9%, 8.3 % and 6.1% among same day, 1-7 days, and 8+ days ART initiators respectively. After adjusting for gender, age, rural/urban setting, year of HIV testing and type of health care service center, compared to 8+ days initiation, same day initiators were twice unlikely to return at second visit (aRR= 1.84, 95%CI= 1.2-2.9). Time lapse from HIV test to ART initiation was not a significant predictor of long-term retention among those who returned for the second visit.

CONCLUSIONS: Given that clients initiating ART on the same day have poorer retention post ART initiation, retention strengthening strategies should be implemented in tandem with same-day ART initiation efforts.

PEE1647

STRATEGIES TO MAINTAIN PATIENTS ON ART IN THE CONTEXT OF MAJOR AND PROLONGED SOCIO-POLITICAL TURMOIL IN HAITI

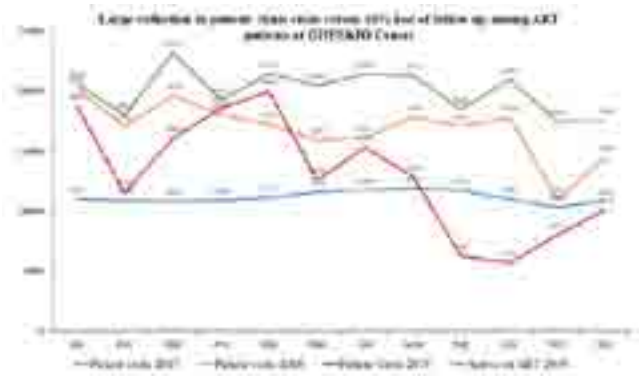
P. Joseph[1], J.E. Mathon[1], C. Torillus[1], K. Severe[1], R. Secours[1], R.I. Verdier[1], C. Guiteau Moise[1], B. Liautaud[1], A. Marcelin[1], M.M. Deschamps[1], J.W. Pape[1,2], M.A. Jean Juste[1]
[1]GHESKIO Centers, Port au Prince, Haiti, [2]Weill Cornell Medical Center, Global Health, New York, United States

BACKGROUND: With its two large health centers located in Port au Prince, Haiti, GHESKIO is the largest HIV care provider in the Caribbean. Haiti experienced in 2018 and 2019 a marked increase in socio-political turmoil. In the last three months of 2019 the country was locked-down with the set-up of large barricades in most streets often guarded by armed protesters preventing both staff and patients to reach our health care centers. Our objective is to describe our experience in maintaining care of patients on ART during this difficult period.

DESCRIPTION: To address different challenges associated with recurrent political turmoil in the last 40 years, GHESKIO had to develop a contingency plan that we improved after each crisis. We implemented a package of strategies aiming at reducing patients' waiting time, implementing test and treat, improving welcoming, overall services, staff-patients relationship and increasing the number of points of services. We also provided transportation fees, nutritional, psychosocial support, expanded clinic visits, ensured phone calls reminders, tracked patients using android tablets, used a daily "dash board" to document staff presence and availability of support for patients (transportation funds, phone call cards,) scaled up rapidly Dolutegravir to over 11,000 patients, and ART provision to over 2,000 patients through community drug distribution.

LESSONS LEARNED: There was a 35% reduction in the number of all patients coming to our center regardless of their HIV status (40, 357 patient-visits in 2017 vs. 155,965 in 2019. There was a 22% decreased among ART patients-visits (93,965 patients-visits in 2017 vs. 73,412 in 2019 while the actual loss to follow-up was 10% reduced through community drug delivery at ART distribution points.

CONCLUSIONS/NEXT STEPS:



[Figure. Large reduction in patient clinic visits versus 10% lost of follow up among ART patients at GHESKIO Center]

Despite major and prolong socio-political instability, GHESKIO was able to maintain care for patients on ART through multiple interventions aiming at improving retention, through improvement of services, active tracking and community drug distribution.

PEE1648

IMPROVING RETENTION IN HIV CARE THROUGH ROUTINE MONITORING AND BACK-TO-CARE CAMPAIGNS: LESSONS FROM EASTERN UGANDA

Y. Namanya[1], C.J. Luzze[1], C. Karutu[1], I. Mirembe[1]
[1]*IntraHealth International, Mbale, Uganda*

BACKGROUND: Despite gains in identifying new HIV-positive clients and eventual enrollment into care, retention remains a major challenge across many public health facilities in Uganda. Regional data from the USAID-funded Regional Health Integration to Enhance Services in Eastern Uganda (RHITES-E) Activity, led by IntraHealth International, showed progressive decline in patient retention across four quarters: 79% (3526) in March 2018; 66% (1398) in June 2018; 36% (1270) in September 2018; and 62% (-1022) in December 2018. RHITES-E adopted the Ministry of Health's Back-to-Care Framework and participated in the National Quality Improvement Initiative to understand barriers to retention.

DESCRIPTION: RHITES-E mentored 68 high-volume health facilities to develop standard operating procedures to mitigate patient attrition; recruited 52 HIV counselors to intensify psychosocial support and counselling at facility and community levels including routine psychosocial preparedness for newly-initiated ART patients; and procured 40 phones to facilitate appointment reminders and ongoing counseling. The counsellors conducted home visits to educate on ART and strengthen family support of patients. RHITES-E procured and distributed missed appointment registers; mentored health workers to improve early identification and line listing of patients missing appointments for immediate tracking; and conducted daily clinic audits of appointments for follow-up. Monitoring data were analyzed using composite index (TX_NET_NEW).

LESSONS LEARNED: Of 2258 HIV patients from 68 high-volume facilities followed-up between October 2018-June 2019, 60% were confirmed to be in care of whom 73% (997) had returned to their original sites and 27% had transferred out to preferred facilities. 8% (174) were unable to be traced, 13% (299) relocated, 6% (120) died, 2% (35) refused ART drugs, and 6% (132) had less than four tracing attempts; only 6% had no attempt traced. Overall, treatment net new index improved from -62% (-1,022) in December 2018 to 24% (426) in March 2019, 78% (1555) in June 2019, and 75% (1313) in September 2019.

CONCLUSIONS/NEXT STEPS: Back-to-care campaigns, routine appointment audits, intensified psychosocial support, and continuous ongoing mentorship improved retention of patients in care and health facility accountability for their own patients. Tracking TX_NET_NEW is key in monitoring early patient retention and should be used in public health facilities.

PEE1649

IMPROVING RETENTION OF HIV CLIENTS AT 12 MONTHS: SUCCESSES OF COMMUNITY-BASED DIFFERENTIATED SERVICE DELIVERY MODELS IN BUKWO DISTRICT, UGANDA

S. Cherop[1], M. Abwola[1], C. Karutu[1], I. Mirembe[1]
[1]*IntraHealth International, Mbale, Uganda*

BACKGROUND: Retention during the first 12 months of enrollment into HIV care is critical in the continuum of care because clients are adjusting to drug effects and often struggling with disclosure and acceptance of being HIV-positive. Overcoming barriers to retention is challenging in rural, resource-limited settings where clients have to travel long distances to reach health facilities. Studies have found that treatment strategies that address socio-economic obstacles to care are associated with improved retention and adherence to ARVs especially for clients who have just been diagnosed and enrolled. However, there is little documentation of community aspects of differentiated service delivery models (DSDM) to address multiple barriers to retention in rural Eastern Uganda.

DESCRIPTION: The USAID-funded Regional Health Integration to Enhance Services in Eastern Uganda (RHITES-E) Activity, led by IntraHealth International, collaborated with the Ministry of Health to strengthen HIV care models at community and facility levels. We rolled out DSDM in Bukwo District in June 2018. A total of 30 health workers, 10 expert clients, 2 counselors, and 8 lay workers were trained on DSDM with emphasis on community drug distribution points, community-based support groups, and facility-based fast-track refills for stable clients to decongest health facilities. During drug refills and support group sessions, service integration is done to test for viral load monitoring for those clients that are due, screen for opportunistic infections, and provide nutritional and peer psychosocial support and counselling. We used quality improvement approaches to track contributions of DSDM to retention. We conducted a review of programmatic data to compare retention outcomes between July 2018 and June 2019.

LESSONS LEARNED: Retention of enrolled clients improved over 12 months: 40% in July-September 2018, 60% in October-December 2018, 73% in January-March 2019, and 97% in April-June 2019, surpassing the UNAIDS and PEPFAR targets of 90% and 95%, respectively, for that quarter.

CONCLUSIONS/NEXT STEPS: Use of community-based DSDM to enhance the continuum of care is promising in improving retention when added to facility-based programs. Clients easily accessed ARVs, received peer support, and saved on transportation costs to and from facilities.

PEE1650

STRUCTURED SUPPORT THROUGH A RETURN TO CARE PACKAGE TO REDUCE LOST TO FOLLOW-UP AMONG PATIENTS ON ANTIRETROVIRAL THERAPY IN RURAL WESTERN KENYA

V. Makokha[1], H.O. Ramadhani[2], E. Amadi[1], C. Ng'eno[1], A. Ndaga[1], D. Wandina[1], E. Katiku[3], E. Oino[4], R. Onkware[5]
[1]*Ciheb, University of Maryland, Nairobi, Kenya,* [2]*Ciheb, University of Maryland, Baltimore, United States,* [3]*Division of Global HIV and TB, Centers for Disease Control, Kisumu, Kenya,* [4]*Migori County, Department of Health, Migori, Kenya,* [5]*Kisii County, Department of Health, Kisii, Kenya*

BACKGROUND: Loss to follow up (LTFU) from HIV care impedes achievement of HIV epidemic control. Studies in sub-Saharan Africa have demonstrated continued risk for attrition among patients who return to care (RTC) after disengaging. Few studies focused on subsequent outcomes of RTC.We evaluated the effectiveness of RTC in reducing LTFU in 63 ART facilities which contributed to 80% of the program losses in Kisii and Migori counties,western Kenya

METHODS: The University of Maryland, Balitimore's PACT Timiza program implemented a RTC package consisting of structured barrier analysis by an adherence counselor, development of corresponding action plan, peer case management, and a home visit. We conducted a retrospective cohort analysis to determine retention among patients on ART and LTFU between October 2018 and June 2019

and later RTC. The outcome variable was LTFU defined by the program as patients who had not had a clinical encounter 30 days after their last expected clinic visit. Data was collected from clinical encounter forms, electronic medical records and missed-appointment registers. LTFU incidence rate and 95% confidence interval (CI) were estimated using Poisson regression. Multivariate Cox proportional Hazard models were used to assess effects of RTC package on LTFU.

RESULTS: Of 665 participants who returned to care, 509 (77%) had a documented last visit date and were included in the analysis; 493/509(97%) were adults. A total of 276/509 (54%) were offered the RTC package. The median age was 32 (interquartile range: 26 – 41) years. Overall 82 individuals were lost after 2119.9 Person-Months(PM) (incidence 3.9; 95% CI: 3.1–4.8) per 100 PM. The probability of remaining in care at 3, 6 and 9 months was 84.6%, 78.9 % and 75.9% respectively among those who did not receive RTC package and 88.4%, 85.4% and 82.1% respectively among those who received RTC and were similar, log rank test p>0.05. Adjusted analysis showed that the RTC package significantly reduced LTFU (adjusted hazard ratio 0.46 95% CI [0.24-0.90]).

CONCLUSIONS: Implementing a RTC package reduces subsequent LTFU. Scaling up implementation of this strategy can increase retention of ART clients and minimize future LTFU and may contribute to achieving HIV epidemic control.

PEE1651

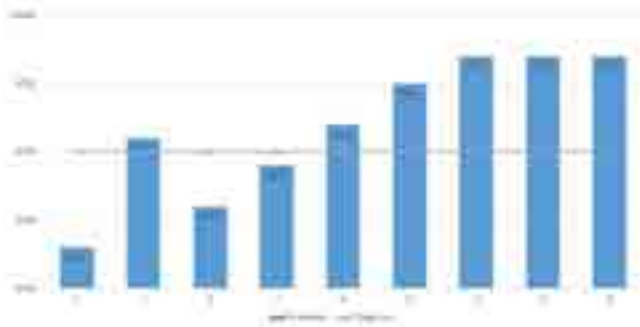
THE EFFECT OF PEER SUPPORT AND INTEGRATED SERVICE DELIVERY IN RETENTION IN CARE OF PMTCT CLIENT

K. Schmitz[1], N. Kwendeni[1], J. Igumbor[1], C. Hofmeyr[1], F. Burtt[1], E. Scheepers[1], A.M.N. Mbule[1]
[1]mothers2mothers, Cape Town, South Africa

BACKGROUND: The need to strengthen bidirectional linkages between the facility and community strategically supports PMTCT clients through retention-in-care over time. Through a peer-based model that robustly acts a support system for ART initiation among treatment-naïve clients and retention in care among all HIV PMTCT clients through an integrated service platform (ISP), where Mentor Mothers are deployed both at facilities and in communities, early identification of clients is achieved, and strengthening retention in care, treatment adherence and responsiveness to client needs thereby reaching the last mile.

METHODS: Over 2,690 women, 48% of whom were treatment-naïve were enrolled across Eswatini, Kenya, Lesotho, Malawi, South Africa and Uganda. The retention-in-care on treatment (RIC) was assessed by reviewing each woman's ART pick-up history from facility records for 24 months. The probability of retention on ART at 24 months post-initiation by the number of contact sessions a client has with a Mentor Mother was assessed. Retention-in-care at various time points was compared between clients who attend the ISP versus those at facility-only sites.

RESULTS: Retention rate 24 months post-ART initiation was 94% among m2m's treatment naive clients which increased with the number of Mentor Mother contacts a client had; however, a minimum of eight sessions is needed to reach the global target retention rate of 90% retention at 24 months (fig. 1). Retention peaks at 97% at 12 or more visits, suggesting that 12 visits may be the optimal number when balancing the goal of retaining clients in care and minimizing costs.



[Figure. Probability of retention on ART at 24 months post-initiation versus the number of contact sessions a client has with a Mentor Mother]

CONCLUSIONS: The results demonstrate the effectiveness of m2m's ISP in achieving retention-in-care among clients. The variation in retention rates by ART exposure and Mentor Mother contact indicates the need for differentiated services to optimize client outcomes; m2m will continue strengthening our risk profiling and client triaging approaches.

PEE1652

PREDICTORS OF EARLY DEFAULT UNDER UNIVERSAL ANTIRETROVIRAL THERAPY IN MALAWI: A PROSPECTIVE COHORT STUDY

K. Dovel[1,2], A. Amberbir[1,2], C. Moucheraud[3], M. Mphande[1], K. Balakasi[1], K. Phiri[1], M. Nyirenda[1], M. Chivwara[1], J. van Oosterhout[1,2], S. Gupta[1,2], R. Hoffman[2]
[1]Partners in Hope, Lilongwe, Malawi, [2]University of California, Division of Infectious Diseases, David Geffen School of Medicine, Los Angeles, United States, [3]University of California, Department of Health Policy and Management, Fielding School of Public Health, Los Angeles, United States

BACKGROUND: Default within the first 3-months of ART (early default) is a major concern for HIV treatment programs. Understanding the timing and predictors for early default is important to design interventions for improved clinical and public health outcomes.

METHODS: ART initiates aged ≥18 years who newly initiated ART at five Malawian HIV clinics were enrolled prospectively between March 2017 and January 2018. At ART initiation consenting clients completed a survey that included sociodemographic and ART readiness questions (12-items¥). The primary outcome was early default (defined as ≥60 days late for any of the required monthly appointments during the first 3-months of ART).

Analyses excluded clients who transferred out, died, or received non-standard of care multi-month prescriptions in the first 3-months. Logistic regression models were used to assess predictors of early default.

RESULTS: 626 patients were enrolled in the study: 2% died, 2% transferred out, and 20% received multi-month prescriptions, resulting in 479 patients included in the analysis. Of these, 53% were male and median age was 35 years (IQR: 28-42). 146/479 (30.5%; 95%CI: 26.5-34.8%) were early defaulters and 69/146 (47%) of these individuals never returned to care after the initial ART initiation visit.

Younger individuals, aged≤30 years (aOR 2.76; 95%CI: 1.43-5.33) and patients reporting inability to travel to clinics monthly (aOR: 5.97; 95%CI: 1.14-31.20) were at higher risk of early default. TB diagnosis at ART initiation (aOR: 0.07; 95%CI: 0.02-0.24) was protective from early default. No other ART readiness variables predicted early default (Table 1).

	Early Default n (%)	Adjusted OR (95% CI)**	P-value
±Male gender vs female	77 (30.4)	0.85 (0.54, 1.31)	0.46
Age in years			
≤30	72 (41.9)	2.76 (1.43, 5.33)	<0.01
31-45	56 (24.6)	1.04 (0.55, 1.98)	0.90
>45	18 (22.8)	1	
Primary and above education attended vs. none	138 (31.0)	1.85 (0.71, 4.78)	0.21
TB diagnosis at ART initiation	3 (4.1%)	0.07 (0.02, 0.24)	<0.01
Inability to travel to the clinic every month for ART refills	6 (75%)	5.97 (1.14, 31.20)	0.03

*Defined as ≥60 days late for any of the required monthly appointments during the first 3 months of ART).
**Final adjusted model included: age, gender, higher education attended, Tb diagnosis at ART initiation, and reported ability to travel to the clinic.
±Gender is kept in the model as a priori confounders irrespective of significance in the univariate analysis.
¥ART readiness questions include 12 items: status disclosure to a trusted partner; disclosure to a casual partner; having support from someone to continue taking ART; afraid about the status if you come to the facility to collect ARVs; willingness to take ARVs for the rest of your life; ability to travel to the clinic every month for ARV refills; away from work/home when you come for ART appointments; able to continue taking your pills even if you don't feel well; overall readiness to start ART; travel away from your village for one month or more at a time; do you think it is good for your health start ART immediately and fears about side effects from ARVs.

[Table 1: Multivariable analysis: factors independently associated with early default]*

CONCLUSIONS: We observed a high proportion of early ART defaulters, half of whom never returned after their first visit. Young adults and clients reporting inability to travel to clinics were particularly prone to early default. These groups require targeted interventions that commence at ART initiation.

PEE1653

PEER-BASED SUPPORT AND FOLLOW-UP ENHANCE RETENTION IN PMTCT CARE CASCADE IN 22 STATES OF INDIA

S. Rao[1], L. Ramakrishnan[1], A.K. Puri[2], S. Medisetti[1], K. Chudasama[3], P. Gautami[4], S. R[1], J. Jose[1], M.A. Ansari[2], S.P. Bhavsar[2], S. Kumar[1], L. Ramakrishnan[1], S.S. Raghavan[1], P. Mohanty[5]
[1]Solidarity and Action Against The HIV Infection in India (SAATHII), New Delhi, India, [2]National AIDS Control Organization (NACO), New Delhi, India, [3]GSNP+, Ahmedabad, India, [4]SVYM, Bangalore, India, [5]Solidarity and Action Against The HIV Infection in India (SAATHII), Program, New Delhi, India

BACKGROUND: As of April 2018, 77% of estimated pregnant women (30 million) were tested for HIV and 61% of the estimated HIV+ pregnant women (22,677) were identified and linked to treatment in India. Svetana consortium (SAATHII, NCPI+, GSNP+, Prayas and SVYM), with GFATM funding partnered with the National AIDS Control Programme (NACP) in 2018, to help accelerate progress towards EMTCT in 22 states, accounting for 65% of PMTCT need. This abstract describes outcomes of interventions focused on improving retention of mother-baby pairs until 18 months.
DESCRIPTION: Svetana consortium support to NACP included scaling and strengthening of HIV testing and detection, referrals, tracking, and retention. Interventions for improving retention included counseling and follow-up of HIV+ pregnant women through the home and commonplace visits, and via phone, and accompanied referrals to health facilities. Counseling focused on the importance of disclosure, antenatal and HIV care, positive-living, institutional delivery, adherence to ART, IYCF and infant diagnosis. Field coordinators (FC) mostly drawn from the community delivered the services and were supported through evidence-based planning, prioritization, joint reviews, ongoing capacity building, and case-management approach.
LESSONS LEARNED: Between January 2018 and September 2019, the program reached 76% of eligible (14,546) mother-infant pairs for 2, 6- or 18-month follow-up. Median age was 24 years, 21% non-literate, 33% had primary education, 52% were primigravida, 97% were on ART and 37% had discordant spouses. Over an 18-month period, retention increased from 51% to 82% at 2 months, 80 to 91% at 6 months and 67% to 80% at 18 months. Retention was significantly higher among those who received any service by FC compared with those with not received at 2 months (75% vs 66%) and at 18 months (82% vs 62%). Multivariate regression showed that mother-infant pairs who received FC services were two times more likely to be retained in care at 2, 6 and 18 months (sig: 0.000), after adjusting age, education and other characteristics of mothers and health system.
CONCLUSIONS/NEXT STEPS: Intensive and targeted peer-based follow up of mother-infant pairs help overcome individual and health system barriers, improve retention and completion of PMTCT cascade.

PEE1654

RATES AND PREDICTORS OF RETENTION ON ART AMONG ORPHANS AND VULNERABLE CHILDREN LIVING WITH HIV IN TANZANIA

J. Charles[1], A. Exavery[1], E. Jere[1], A. Ally[1], R. Mseya[1], A. Barankena[1]
[1]Pact Tanzania, Dar es Salaam, Tanzania, United Republic of

BACKGROUND: Uninterrupted ART and continual monitoring are critical for sustained viral suppression and optimal treatment outcomes. Community-based interventions designed to improve linkage to and retention on ART are essential for addressing subpopulation-related factors that hinder sustained retention on ART.
METHODS: A PEPFAR-support orphans and vulnerable children (OVC) project in Tanzania collected pediatric ART data from October 2017 to October 2019 in 81 councils. Lay community social welfare volunteers supported linkage and retention on ART for HIV+ OVC. The study analyzed on-ART status in a cohort of HIV+ OVC aged <20 were enrolled and monitored for 24 months. OVCLHIV who remained on ART to the end were termed as "retained" and those with interrupted or discontinued ART use as "not retained". Multivariate analysis of retention on ART was performed using logistic regression, while accounting for their baseline characteristics.
RESULTS: Of the 5,304 HIV+ OVC 3,390 were HIV+ (77% on-ART) at enrollment; 1,914 were newly-diagnosed HIV+ after risk screening and testing referral by the lay volunteers. Mean age was 13.1 years, 51.5% were female and 72.2% were in female-headed households. Retention on ART was 83.9% at 24 months. Multivariate analysis showed that; higher frequency of home visit by CCWs increased retention on ART by 1% (OR = 1.01, 95% CI 1.002-1.016, p = 0.008). Linkage of HIV+ children to HIV support groups improved retention on ART by 74% (OR = 1.74, 95% CI 1.53-1.99, p<0.001). Children in large family size were less likely to sustain ART by 9% (OR = 0.91, 95% CI 0.89-0.95, p<0.001).

In-school OVCLHIV were 17% more likely to remain on ART than out of school (OR = 1.17, 95% CI 1.03-1.32, p = 0.014). The likelihood of remaining on ART was 14% higher for OVC in economically better-off households than their peers in destitute families (OR = 1.14, 95% CI 1.003-1.31, p = 0.045). These effects were adjusted for OVC age, sex of OVC and of caregiver, and type of residence.

CONCLUSIONS: Community-based OVC support resulted in an 84% pediatric on-ART retention rate over 24 months, notably higher than most health facility-based 24-month retention rate estimates of 75%.

PEE1655

PATIENT-IDENTIFIED REASONS FOR POOR EARLY RETENTION IN HIV TREATMENT AMIDST A "SURGE STRATEGY" TO INCREASE LINKAGE TO CARE: INSIGHTS FROM EASTERN UGANDA

N. Matsiko[1], Y. Namanya[1], M. Abwola[1], C. Karutu[1], I. Mirembe[1]
[1]*IntraHealth International, Mbale, Uganda*

BACKGROUND: In 2017, Uganda's Ministry of Health (MOH) rolled out the Test-and-Treat policy, further accelerated in 2018 by a multi-pronged "surge strategy" to improve HIV testing efficiency and accelerate linkage to treatment. With increased recruitment of HIV patients in care, achieving optimal retention became a challenge. Data from 14 districts in Eastern Uganda showed that 30% of newly-enrolled ART patients were deemed as lost-to-follow-up in the three months following ART initiation. The USAID-funded Regional Health Integration to Enhance Services in Eastern Uganda (RHITES-E) Activity, led by IntraHealth International, conducted a root cause analysis (RCA) to better understand the primary reasons for failure to return to care among new patients. Solutions to address the root causes were instituted at each facility based on the results.

DESCRIPTION: RHITES-E identified and trained facility-based counselors to collect data from ART patients as part of a routine quality improvement program. Counselors used a standardized RCA questionnaire provided by the MOH. The first RCA was conducted in November 2018 with quarterly implementation thereafter. Forty-six high-volume facilities with high rates of patient attrition were identified to participate in the RCA. Based on MOH guidance, 30% of patients, per facility, who had missed their appointment at least once in six months following ART initiation were selected and interviewed. RCA data from November 2018 to October 2019 were entered and analyzed in Excel.

LESSONS LEARNED: A total of 466 respondents were interviewed. Lack of transport (19.3%), being on travel (15.5%), forgetting the appointment (11.2%), fear of non-disclosure/stigma (9.2%), being bedridden (5%), taking care of sick people (3%), and change of residence (3%) were significant factors for patients missing appointments. The analysis identified opportunities for improvement, including establishing community ART distribution points, providing longer refill periods, and implementation of appointment registers and patient reminders through text messages and phone calls.

CONCLUSIONS/NEXT STEPS: Conducting RCAs in public health facilities helps to understand facility-specific barriers to early retention and provides a quick platform for initiation of quality improvement activities to mitigate the challenges.

PEE1656

PATIENT-REPORTED REASONS FOR MISSED APPOINTMENTS AMONG ANTIRETROVIRAL THERAPY (ART) PATIENTS IN SOUTH AFRICA

C. Biedron[1], M. Insua[2], C. Scott[1], A. Koneru[2], M. Patton[2], J. Grund[2], S. Pals[3], C. Hall[2], A.J. Olivier[2], R. Taback-Esra[2], P. Chiliade[2], G. Kindra[2], M. Mogashoa[2], J. Paterson[4], J. Otchere-Darko[5], D. Rech[6], S. Prusente[7], R. Overmeyer[8], Y. Pillay[8], E. Raizes[1], A. Herman-Roloff[2], M. Briggs-Hagen[2]
[1]*U.S. Centers for Disease Control & Prevention (CDC), HIV Care & Treatment Branch, Division of Global HIV & TB, Atlanta, United States,* [2]*Centers for Disease Control & Prevention (CDC), Pretoria, South Africa,* [3]*U.S. Centers for Disease Control & Prevention (CDC), Division of Global HIV & TB, Atlanta, United States,* [4]*Health Systems Trust, Durban, South Africa,* [5]*University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [6]*The Aurum Institute, Johannesburg, South Africa,* [7]*TB HIV Care, Cape Town, South Africa,* [8]*National Department of Health, Pretoria, South Africa*

BACKGROUND: Numerous barriers to adherence to antiretroviral therapy (ART) and retention exist in resource-limited settings; however, our current understanding of such barriers remains incomplete. We conducted a rapid survey to identify the most common reasons for missed appointments among ART patients in South Africa.

METHODS: From April 1 – June 7, 2019, a rapid survey was conducted in 154 healthcare facilities across four provinces in South Africa. ART patients were contacted by phone and asked to self-report the reason that they missed their appointment. A missed appointment was defined as failure to present to the facility on the day of a scheduled appointment. Self-reported reasons were tabulated and grouped into patient-based, structural, clinic-based, and medical barriers. Data capture barriers were listed for patients who were active on ART but appeared as having missed an appointment. Data analyses were conducted using SAS 9.4.

RESULTS: A total of 34,113 entries were submitted with a documented reason for the missed appointment. A subset of 29,102 (85.3%) entries were able to be categorized during data cleaning and were included in subsequent analyses. Among the entries analyzed, 67.5% of patients were female, median patient age was 34 years, and median ART duration was 27 months. Patient-based barriers were the most common reasons for missed appointments (58.7%), followed by clinic-based (21.2%), structural (13.3%), and medical barriers (6.8%). Among patient-based barriers, the most common reasons were 'patient forgot' (54.4%), 'traveled' (38.7%), and 'moved' (3.7%). The most common clinic-based barriers were 'inconvenient hours' (42.7%), 'long wait times' (25.2%), and 'appointment system challenges' (21.6%). The same rank order of domains persisted for both sexes and across ART duration subgroups when results were disaggregated. Furthermore, 32.2% of patients were misclassified as having missed their appointments due to data capture barriers, including 'patient receiving ART through differentiated service delivery (DSD)' (55.4%), 'transferred' (33.7%), and 'visit not captured' (10.9%).

CONCLUSIONS: Rapid survey results are being used to inform the scale-up of interventions to address patient-based barriers to adherence, such as appointment reminders and case management strategies, and to strengthen data management systems in order to more effectively capture silent transfers and DSD patients.

COMBINATION PROGRAMMING ON SOCIAL DRIVERS OF HIV (INCLUDING EDUCATION, VIOLENCE AND WORKPLACES)

PEE1657

GOVERNMENT IMPLEMENTED CASH PLUS MODEL REDUCES VIOLENCE EXPERIENCES AND PERPETRATION AMONG ADOLESCENTS IN TANZANIA

T. Palermo[1], L. Prencipe[2], U. Gilbert[3], L. Kajula[4], Tanzania Adolescent Cash Plus Evaluation Team
[1]University at Buffalo, Epidemiology and Environmental Health, Buffalo, United States, [2]Erasmus University Medical Center, Social Epidemiology, Rotterdam, Netherlands, [3]UNICEF Tanzania, Children and AIDS, Dar es Salaam, Tanzania, United Republic of, [4]UNICEF Office of Research - Innocenti, Social and Economic Policy, Florence, Italy

BACKGROUND: One billion children and adolescents experience violence every year, and violence is a driver of HIV transmission behavior. Adolescents are important for prevention of onward HIV transmission and are key to prevention of emotional, physical and sexual violence through interventions addressing gender attitudes, as gender socialization intensifies during adolescence. We examine impacts of a government-run, multi-sectoral cash plus intervention which addresses poverty, a structural driver of HIV and violence, on adolescents' experiences and perpetration of violence in Tanzania.

METHODS: This study takes place in southern Tanzania and uses a longitudinal, mixed-method cluster randomized control trial design (n=130 communities) with a panel sample of 2,191 adolescents aged 14 to 19 years at baseline to evaluate the impacts of a government-run cash plus intervention on violence outcomes. The intervention was targeted to adolescents living in households receiving a government cash transfer program (the Productive Social Safety Net) and comprised adolescent-focused livelihoods and life skills training, mentoring and a productive grant, and linkages to government facilities providing adolescent-friendly, HIV and sexual and reproductive health services. We ran analysis of covariance (ANCOVA) and single difference regressions to examine intent-to-treat impacts of the program and complemented our quantitative analyses with qualitative analyses to unpack mechanisms of impact.

RESULTS: The intervention increased gender equitable attitudes along the violence domain and subsequently reduced adolescent's perpetration of physical violence by 3.3 percentage points (representing a 47.8 percent reduction in violence perpetration, driven by males). Moreover, it reduced experiences of sexual violence among the sample by 3.7 percentage points (61.7 % reduction, driven by females). There were no intervention impacts on experiences of emotional or physical violence experiences, nor on help-seeking among those experiencing violence.

CONCLUSIONS: Multi-sectoral approaches are advocated to address structural drivers of violence and HIV. Results indicated that a government-run, multi-sectoral cash plus intervention for adolescents has the potential to reduce violence experiences and perpetration among adolescents and young adults. Given government implementation within existing structures of a social protection program, there is high potential for scale-up and sustainability, and the program reaches some of the most vulnerable and marginalized youth in a high HIV prevalence setting.

PEE1658

SYSTEMICALLY ADDRESSING HIGH HIV PREVALENCE IN THE TRANSGENDER COMMUNITY THROUGH GENERATING ALTERNATIVE LIVELIHOOD OPPORTUNITIES

S. Shwetambera[1], V. Anand[1], M. Sivasubramanian[1], N. Maske[1], S. Reddy[1], P. Daruwalla[1], H. Patil[1], A. Siroya[1], C. Kaura[2]
[1]The Humsafar Trust, Mumbai, India, [2]Publicis Sapient, Delhi, India

BACKGROUND: Transgender/hijra women have the highest prevalence of HIV in India amongst all high-risk groups. This can be primarily attributed to extreme vulnerability resulting from lack of livelihood options beyond begging and sex-work. This vulnerability manifests in poor condom-negotiation capability, unaddressed mental health issues and high alcohol consumption and substance use, contributing to high-risk sexual behaviours within transgender/hijra community. The NALSA judgment in 2014 by Indian Supreme Court paved way for increased legal recognition and creating opportunities for socio-economic and political inclusion of transgender persons in India. In 2017, TRANScend, an initiative by The Humsafar Trust (India's oldest registered LGBTQ organisation) and supported by Publicis Sapient, was started to streamline these efforts.

DESCRIPTION: Primary objective of TRANScend is generating alternative livelihood opportunities through workplace inclusion initiatives, targeted skill development programmes and enabling access to identity and social entitlement documents. In 3 years, TRANScend has engaged with 144 multinational corporates, small and medium India-based businesses and start-ups and reached out to 2550 employees through workplace sensitisations on transgender issues, policy reviews, roundtables discussions, community relevant plays and recruitment drives. TRANScend facilitated 5 capacity-building workshops and 19 skill-building programs for transgender-led organisations and transgender individuals respectively, attended by 407 transgender persons. 639 transgender persons have accessed various identity and social entitlement documents with the help of TRANScend.

LESSONS LEARNED: Major challenges include lack of economically feasible alternatives to begging and sex work considering lack of employable skills and professional qualifications within the community. Skill building opportunities offered to transgender/hijra community have historically been stereotypical and myopic, resulting in few participants completing them or taking up jobs pertaining to those skills. Challenges at the end of employers include persistent gaps in understanding of transgender issues which can only be addressed through transgender representation in policy formulation and regular workplace sensitisations.

CONCLUSIONS/NEXT STEPS: As next steps, TRANScend aims to develop a community-designed and community-led accreditation process for employers to enable meaningful workplace inclusion and facilitate demand-based skilling on 21st century skills for interested transgender persons so that livelihood opportunities for transgender persons are not limited to risky sex-work and high HIV prevalence in the community can be addressed systemically.

PEE1659

MAWA GIRLS: CREATING HEALTHY FUTURES THROUGH EMPOWERMENT, EDUCATION, HIV RISK REDUCTION AND PSYCHOSOCIAL SUPPORT

K. Nash[1], E. Geoffroy[1], A. Sekani[2], L. Nyirenda[2], N. Moletsane[3]
[1]GAIA, San Rafael, United States, [2]GAIA, Mulanje, Malawi, [3]Sentebale, Maseru, Lesotho

BACKGROUND: Girls who dropout of secondary school in sub-Saharan Africa are twice as likely to be HIV-positive (UNAIDS 2019). GAIA has supported girls in Mulanje District, Malawi with bursary assistance, yet rates of dropout remained at 18% in the 2017-2018 school year. Aiming to improve educational and health outcomes among adolescent girls and young women (AGYW) in a high-HIV prevalence region, GAIA partnered with Sentebale in 2018 to implement Mawa Girls, a layered program of clubs, curriculum and parent/guardian involvement.

DESCRIPTION: In year one (2018-2019), 360 girls (including 59 on bursary) in 9 secondary schools self-selected to participate in school-based clubs once/month for 9 months. Trained female teachers/volunteers presented the curriculum, providing life skills and education on SRH, and role models and activities to help girls aspire to and plan for a healthy, productive future. Girls' guardians signed a letter of commitment to attend meetings to learn support strategies.

LESSONS LEARNED: In year one, 78% (281/360) of girls attended all club sessions and 94% (338/360) attended all but one. Pre- to post-test scores measuring knowledge/attitudes improved by 16% overall, with a 34% increase on HIV-specific questions, a 22% increase on sexual and reproductive health questions, and an 8% increase on questions measuring empowerment. Program participation appears to correlate with lower rates of school dropout, especially among those on bursary: 2% (7/360) dropout rate among all Mawa Girls' participants; and 0% (0/59) dropout among bursary recipients participating in the program, versus 18% (22/125) dropout among bursary girls in previous year without the program. Potentially more significant to decreasing rates of HIV among girls is grade attainment, and among Form 3 students participating in Mawa Girls during year 1 and completing the school year, 98% returned for Form 4 in the 2019-2020 school year.

CONCLUSIONS/NEXT STEPS: Layered programming, including bursary, safe spaces for girls to learn about SRH/goal-setting, mentors/role models to provide inspiration, and guardians creating an enabling environment, represents a promising approach to supporting secondary school completion and improving health outcomes among AGYW.

PEE1660

INTEGRATING HEALTH PROMOTION/HIV INTERVENTIONS AND ROAD SAFETY TO ENHANCE UPTAKE OF HIV SERVICES FOR TRUCKERS ALONG THE NORTHERN TRANSPORT CORRIDOR IN KENYA

H. Magutu[1], D. Mwaura[2], L. Muruthi[3], H. Amakobe[4]
[1]International Labour Organization, GEDILOAIDS, CO-DAR, Nairobi, Kenya, [2]Swedish Workplace HIV/AIDS Programme, Nairobi, Kenya, [3]Kenya HIV/AIDS Private Sector Business Council, Nairobi, Kenya, [4]Pioneer Road Safety Consultant Limited, Nairobi, Kenya

BACKGROUND: Road traffic accidents are a leading cause of death with 3,572 deaths reported in 2019 as per the Kenya National Transport Authority with male fatalities being at 85.5%. Even though the HIV incidence has been on a decline it is still high at 52,800 new infections per year. Non -communicable diseases (NCDs) cause 27% of deaths in Kenya. Road traffic accidents are caused to a varying degree by lack of knowledge and skills, non-adherence to safety regulations and drivers' health status making a health and wellness programme a vital component of road safety programmes.

DESCRIPTION: The International Labour Organization collaborated with the Swedish Workplace HIV/AIDS Programme and the Kenya HIV/AIDS Private Sector Business Council to target trucking companies for an integrated road safety, health promotion and HIV services initiative along the northern transport corridor.

The programme engaged with Pioneer Road Safety Consultant Limited, a pioneer company in road safety using journey management solutions with established Checkmate sites along the northern transport corridor.

Managers were sensitized on the importance of establishing health/HIV workplace programmes and policies as part of Occupational Safety and Health and its importance to road safety. At the checkpoints, truckers were screened for hypertension, diabetes and alcohol. Truckers were offered rest for a minimum of 15 minutes for fatigue management as vehicles underwent quick checks. Nutritional counselling was done to 52% of truckers who were obese/overweight. Those with hypertension, deranged glucose levels were referred for treatment while two male drivers were immediately admitted due to hypertension.

HIV prevention and testing services were also provided at Checkmate sites and at sex work hotspots during the International Road Safety Day and the World AIDS Day.

The three month initiative resulted in 4,104 males and 2,473 females knowing their HIV status with 24 males and 20 females who tested positive being linked to care.

LESSONS LEARNED: Combining HIV/NCDs interventions with road safety worked well for truckers as well as companies. It improved road safety, health seeking behavior amongst truckers, reduced stigma attached to HIV testing, boosted their morale, lowered turnover and increased productivity.

CONCLUSIONS/NEXT STEPS: Expand this integrated model to other companies with public service vehicles.

PEE1661

INTEGRATION OF SEXUAL AND REPRODUCTIVE HEALTH, GENDER BASED VIOLENCE, NUTRITION AND WELL-BEING EDUCATION IN THE COMMUNITY YOUTH EMPOWERMENT PROGRAM IN MAKUENI COUNTY, KENYA

J. Mwema[1], G. Giordana[1], R. Kaloki[2], M. Mumma[1], A. Mbevi[3]
[1]UN World Food Programme, Nutrition, Nairobi, Kenya, [2]Makueni County, Nutrition, Nairobi, Kenya, [3]UN World Food Programme, Food Systems and Resilience, Youth Programme, Nairobi, Kenya

BACKGROUND: Kenya is a UNAIDS Fast-Track country with the third-largest epidemic in the world. Sensitizing young people on HIV and sexual and reproductive health remains controversial. Fears of encouraging early sexual debut, among others, led 40% of adults to be against educating young people about condoms. AIDS is the leading cause of death among young people (aged 10-24) in Africa, and the second leading cause globally. In Kenya, young people (15-24 years) contributed 40% of adult new HIV infections in 2017.

DESCRIPTION: Health directly impacts youth's wellbeing. In 2019, Makueni County Government in collaboration with World Food Programme initiated the Makueni Youth Agribusiness Empowerment

Programme, targeting 1,248 youths (45% males and 55% females). Training of 17 sub-County technical officers from Youth, Gender, Agriculture-Home Economics and health departments was conducted. An integrated facilitators module was developed to guide the implementation of the model that focused on: growth and development; gender-based violence; drug and substance abuse; HIV/AIDS/STIs; reproductive health and basic human nutrition.

Modelled on a mentorship approach to strengthen youth-mentors' bond and trust, the training's were delivered through interpersonal sessions, social platforms, workshops and bench -marking learning visits. At the community level, the sensitization sessions adopted a range of social behaviour communication strategies.

LESSONS LEARNED: As stigma, discrimination, discomfort with health service providers and lack of awareness, hinder youth's health seeking behaviours, the integrated agribusiness training programme served as a pull factor for the youth to attend health and nutrition sessions. This provided access to information with regards to youth friendly centres, awareness on HIV/STIs, and available health options and services. The initiative reached 81% (1012) of the targeted youth. Among them, 69% indicated the training was very relevant, 80% strongly agreed on usefulness of the information and 78.2% indicated improved knowledge on health and nutrition issues.

CONCLUSIONS/NEXT STEPS: Sensitizing young people on HIV and sexual health remains key. Improving health care providers' capacity to offer youth-friendly services while fostering multisectoral approaches, enhancing youth sexual and reproductive knowledge is crucial. The integrated agribusiness training promoted health and nutrition knowledge while sustaining youth's economic empowerment to enhance their well-being and that of their communities.

DELIVERING GENDER-TRANSFORMATIVE PROGRAMMES AND TACKLING VIOLENCE AGAINST WOMEN AND GIRLS: PROGRAMMATIC LESSONS

PEE1662

GENDER-BASED VIOLENCE INTERVENTIONS ENHANCED UPTAKE OF HIV SERVICES AMONG FEMALE SEX WORKERS IN MONTSERRADO COUNTY, LIBERIA

F.W. Bestman[1], P.N. Flomo[1], L.M. Mannah[1], H.M. Kesselly[1], E. Logan[1], M.F. Giddings[1], B.N. Natt[1], C. Kerbay[2], T. Hallie[2], G. Kamanga[2], N.F. Clement[2], H.R. Sherman[3]
[1]White Rose Alliance, Monrovia, Liberia, [2]FHI 360, Global Health Population and Nutrition, Monrovia, Liberia, [3]FHI 360, Global Health Population and Nutrition, Washington DC, United States

BACKGROUND: Liberia has a high prevalence of HIV among female sex workers (FSWs). Approximately 10% of the estimated 163,000 FSWs are infected. High levels of sexual violence against FSWs increase the risk of HIV infection. White Rose Alliance (WRA), under the USAID/PEPFAR-funded and FHI 360-led LINKAGES/EpiC project, established a successful model of responding to gender-based violence (GBV) among FSWs in Montserrado County, Liberia.

DESCRIPTION: In August 2019, peer outreach teams were sensitized in the identification and reporting of violence cases. GBV response teams were formed to provide social, psychological, and referral services. The teams include peer educators, peer navigators, hot spot owners, and female and male "five stars" (high-ranking and respected champions at hot spots). The teams intervened with perpetrators and brought them to community mediation for resolution or referred them to police.

LESSONS LEARNED: Prior to LINKAGES/EpiC, there had been a paucity of GBV case reporting. After training peer educators on GBV awareness, reporting, and creation of crisis-response teams, 94 GBV cases were recorded in hot spots served by WRA between August and November 2019. Discussions with 40 FSWs showed a strong preference for crisis response teams to resolve GBV cases instead of relying on police, because some officers are perceived to connive with perpetrators of violence. Seventy-seven cases (82%) were physical violence such as beating or other physical manhandling, eight (9%) were cases of emotional abuse, and seven (7%) were refusal by clients to settle the agreed payment. Forced sex and eviction of FSWs from hot spots accounted for 2% (1% each). Sixty-three percent (59/94) of perpetrators were regular sexual clients. All cases were successfully managed by the crisis-response team, except 15 GBV cases whose perpetrators refused to comply with their resolutions.

CONCLUSIONS/NEXT STEPS: GBV sensitization and operational crisis response teams have provided protection for FSW victims of violence. Since some perpetrators do not cooperate with violence response teams, collaboration and coordination with the police is necessary to increase the protection of victims. The crisis-response interventions will help the entire project mitigate the effects of gender-based violence.

PEE1663

PERSISTENT AND RESILIENT HARM REDUCTION FOR FEMALES WHO USE DRUGS ENDING THE CONCENTRATED HIV EPIDEMIC

Y.N. Win[1], A.Y. Naing[2], K.W.Y. Kyaw[2], N.S. Yee[1]
[1]Asian Harm Reduction Network (AHRN-Myanmar), Program, Yangon, Myanmar, [2]Asian Harm Reduction Network (AHRN-Myanmar), Health Department, Yangon, Myanmar

BACKGROUND: In Myanmar, the prevalence of HIV and STI among key populations (KP) such as female drug users and sex workers is high due to unsafe sex and unsafe injection practices. KP faces harsh stigma and discrimination, as a consequent, they avoid or have limited access to care provided at general health care settings. In response, the Asian Harm Reduction Network, in coordination with Ministry of Health and Sports have been implementing a female-friendly Harm Reduction cascade, integrating sexual and reproductive health in Kachin State.

DESCRIPTION: Female friendly services and income generation were setups at AHRN's drop-in-centers in jade mining areas, Kachin State. Female outreach workers, health staff and peers were recruited and trained to extend the coverage of condom distribution, needle syringe programs, routine HIV testing service, sexual and reproductive health, methadone referral, hepatitis B vaccination, ART, PMTCT, early infant and children HIV referral. Staff, including community-based peers, are well trained, systematically reach hidden female drug users and sex workers and provide support and services.

LESSONS LEARNED: More frequent and consistent visits by female peers have raised awareness of harm reduction services, trust-building and encouraging clients to become peer outreach workers.

Between January 2016 and December 2019, a total of 1,559 female drug users and sex workers were reached by harm reduction services through female-friendly drop-in-centers. Of them, 1,475 (95%) received HIV test and 128 (9%) were HIV positive and enrolled in HIV

treatment and the rest were stick on prevention services. 233, 386, 508 and 691 STI screenings were done and 203, 239, 220, 221 STI treatments were provided annually and 1,613,704 condoms were distributed since 2016.

CONCLUSIONS/NEXT STEPS: Innovations in services resulted in a steep increase in reaching hidden female key populations and contributed significantly in minimizing the transmission of HIV and STIs and warrant scientific exploration. Recreational activities led by female peer educators, women and children friendly space, income-generating activities and medical interventions to meet their needs are important for the HIV care continuum and encouraging return visits. Further expansion and community-led service provision are expected to further increase reach, yield, and efficiency in service delivery.

PEE1664

WHERE THE NEED IS GREATEST: CREATING A CONTEXT-SPECIFIC THERAPEUTIC PROGRAMME FOR CHILDREN AND THEIR FAMILIES AFFECTED BY SEXUAL ABUSE INCLUSIVE OF HIV TESTING

C. Nyoni[1], M. Briedé[2]
[1]South African Government, Department of Social Development, Pretoria, South Africa, [2]Pact South Africa, Government Capapcity Building and Support Programme, Pretoria, South Africa

BACKGROUND: Abuse, neglect, exploitation and violence against children result in serious health challenges and are widespread in South Africa. One in three children are exposed to sexual violence in their childhood and sexual abuse contributes to the high number of HIV infections amongst children and adolescents. In most communities' access to mental health professionals are limited resulting in children who have experienced abuse going without support. The experience of sexual violence can have a profound impact on the health and core aspects of the emotional, behavioural, physical, and social development of children and adolescents, throughout their lives. Therapeutic interventions are critical to mitigating these long-term repercussions.

DESCRIPTION: However, the 2016-2017 South Africa Child Protection Systems Review revealed that social workers lacked the capacity to engage with clients at a therapeutic level. Social workers instead referred clients to external counsellors or psychologists. As a result of the costs of such external/private practice, few families were seeking therapeutic support. The Department of Social Development, in collaboration with the GCBS and other non-governmental organisations, developed a context-specific programme to address the need for evidence-based therapeutic interventions by social workers for children affected by sexual abuse in the particularly challenging operating environment of South Africa.

LESSONS LEARNED: Qualitative interviews revealed that the social workers felt empowered to manage children's disclosures of abuse, that the programme was practical and implementable within the social work environment provided they had access to confidential counselling rooms. Limitations were high caseloads, limited supervision for complex cases and inconsistent attendance for the 10 sessions to reach program impact.

CONCLUSIONS/NEXT STEPS: The programme created better outcomes for child victims who have previously not had therapeutic support. The program was effective at capacitating social workers with skills to therapeutically engage their clients and families. Vulnerable children were referred for HIV testing. The limitations of inconsistent attendance would suggest the intervention is well suited to residential environments, camps or holiday programmes. Further support in developing the capacity for supervisors is needed to embed this program in social work practice within the DSD

PEE1665

COACHING BOYS INTO MEN INTERVENTION CHANGES BOYS' KNOWLEDGE AND ATTITUDES ABOUT VIOLENCE: EVIDENCE FROM A PILOT IN UGANDA

J. DeSoto[1], A. Belsan[1], M. Stephens[1], L. Akite[2], D. Wamboko[2], B. O'Connor[3], G. Ekpo[1], S. Hillis[4], L. Milani[3], S. Krikscіun[3], L. Van Enk[1], S. Benson[1]
[1]World Vision, Inc., Washington, United States, [2]World Vision Uganda, Kampala, Uganda, [3]Futures Without Violence, San Francisco, United States, [4]Centers for Disease Control and Prevention, Atlanta, United States

BACKGROUND: According to the Uganda Violence Against Children Survey (2018), 20% of adolescent girls (AG) experienced forced sex before age 18, of whom 28% become pregnant. 75% acquired sexually transmitted infections including HIV, and 25% missed school due to physical violence - increasing the risk of HIV (UNAIDS, 2018). Uganda has one of the highest global HIV prevalence rates (6%), and HIV prevalence of AG ages 15-19 is approximately 2.5% - almost four times higher than boys the same age (UPHIA 2016-2017). Coaching Boys Into Men (CBIM) is an evidence-based intervention identified in the INSPIRE global framework for ending violence against children. Contributing to the UNAIDS 95-95-95 Global Strategy, the CBIM pilot in Uganda targeted boys to reduce violence through social norms change, thus reducing the risk of HIV infection for AG. CBIM was delivered to boys (ages 14-18) by trained athletic coaches in Mityana District, Uganda.

METHODS: A longitudinal pre-post study design was conducted 2018-2019. Respondents were adolescents and coaches from 20 primary schools, 5 secondary schools, and 10 community teams. 502 boys and 456 AG in and out of school and 60 coaches were interviewed. Data was collected using electronic questionnaires over the ODK platform. Data collected measured attitudes and knowledge about disrespectful and abusive behaviors. Data was exported to SPSS and was analyzed using basic descriptive statistics in the form of frequencies, means, and percentages of the variables. All data was disaggregated by out of school and in school adolescents, as well as pre-and-post intervention.

RESULTS: Findings show an increase in boys who do not accept any forms of violence from 41.9% (pre) to 85% (post) and an increase in boys who report intent to intervene when witnesses of violence from 18.9% (pre) to 88% (post). Girls and boys who rated school as a safe place that protects from violence against children increased from 54.5% (pre) to 93.5% (post) and girls and boys who feel safe at school increased from 32.4% (pre) to 71.5% (post).

CONCLUSIONS: CBIM is a scalable, low cost, and fun way to engage boys to increase their knowledge and skills for violence prevention and HIV risk reduction.

PEE1666

EXPLORING IMPLEMENTATION OF A COMPLEX MULTILEVEL COMBINATION HIV PREVENTION INTERVENTION: THE DETERMINED, RESILIENT, EMPOWERED, AIDS-FREE, MENTORED, AND SAFE (DREAMS) PARTNERSHIP IN RURAL NORTHERN KWAZULU-NATAL, SOUTH AFRICA

T. Zuma[1], N. Chimbindi[1], S. Hlongwane[1], J. Seeley[2], S. Floyd[2], I. Birdthistle[2], M. Shahmanesh[3]
[1]Africa Health Research Institute, Durban, South Africa, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University College London, London, United Kingdom

BACKGROUND: The DREAMS partnership aims to reduce HIV infections among adolescent girls and young women (AGYW) in 15 countries. We explore how the DREAMS core-intervention package, a combination approach to address related risks of HIV acquisition, poverty, gender inequality, sexual violence, and education-level.
METHODS: We conducted participatory ethnographic assessments of four communities (1 semi-urban, 1 rural, 2 deep rural) over two years, including: repeat in-depth interviews with AGYW and adolescent boys and young men (ABYM) (n=58, round 1, n=50, round 2); group discussions (n=19) with young people and community members; in-depth interviews with implementing partners (n=33) and stakeholders at district and local levels (n=9); and participatory observations of community-based condom distribution and demonstration, and of a curriculum-based intervention with AGYW.
RESULTS: The DREAMS initiative was implemented between April 2016- September 2018. Interviews and group discussions with adolescents and community members revealed that the combination of structural, behavioural and biological approaches implemented by multiple implementing partners resulted in an increase in visibility and access to services, e.g., community-based HIV testing for young women and men, access to male condoms, and voluntary medical male circumcision. Stakeholders reported that, DREAMS strengthened the Department of Health's strategy of expanding beyond a single-intervention approach and strengthened existing infrastructure to address AGYW's health-related issues, particularly those in school. However, implementing partners said that DREAMS rollout was slow, particularly for interventions (e.g., Pre-Exposure Prophylaxis) and among implementing partners who were new in the community, due to low community buy-in. Furthermore, some implementing partners and stakeholders shared that there were limited synergies between overlapping services offered by DREAMS partners and government departments, particularly in schools and social services. We also found that there were challenges in layering and coordination of services (particularly in the first year of DREAMS) between different social, health and education sectors, especially when implemented by different partners.
CONCLUSIONS: DREAMS showed it is possible to improve access to services through multiple sectors and adapt a complex intervention in rural high-prevalence settings. Appropriate and ongoing stakeholder and community engagements are necessary to ensure timely rollout, early buy-in and ownership of programmes.

SOCIAL PROTECTION: NEW EVIDENCE AND PROGRAMMATIC LESSONS

PEE1667

IMPLEMENTATION EXPERIENCE FROM IMPROVING ORPHANS AND VULNERABLE CHILDREN (OVC) HEALTH OUTCOMES IN COMMUNITIES SERVED BY MILITARY HEALTH FACILITIES IN UGANDA

J. NAMUSOBYA[1], J.B. Apire[2], L. Gahurra[2], J. Moro[3], S. Carol[3], A. Nuamanya[4], D.E. Lugada[5], D.N. Kak[6], D.H. AlMossawi[6], D.J. Akao[7], T. Rwegyema[5], D. Bwayo[5], D.G. Seruwagi[4,8]
[1]University Research Co., LLC-DHAPP Uganda | Center for Human Services, Programs, Kampala, Uganda, [2]University Research Co., LLC - Department of Defense HIV/AIDS Prevention Program (DHAPP), Monitoring and Evaluation, Kampala, Uganda, [3]Directorate of HIV/AIDS, Uganda Peoples Defense Forces (UPDF), Kampala, Uganda, [4]Centre for Health and Socioeconomic Improvement (CHASE-i), Kampala, Uganda, [5]University Research Co., LLC - Department of Defense HIV/AIDS Prevention Program (DHAPP), Kampala, Uganda, [6]University Research Co., LLC, Washington DC, United States, [7]U.S. Department of Defense (DoD), Kampala, Uganda, [8]Makerere University, Kampala, Uganda

BACKGROUND: There are approximately 1.8million orphaned children below 18 years in Uganda. Of these 45.6% are due to HIV/AIDS; with 105,000 HIV positive children. OVC vulnerability in military settings is heightened by community exclusion, high risk exposure and high mobility. URC-Department of Defense HIV/AIDS Prevention Program supports a multi-pronged OVC program in 12 military bases.
DESCRIPTION: We conducted children vulnerability assessment resident in 12 military bases. Identified vulnerable children and households were supported with a package of OVC interventions, including HIV testing, enrollment into care for identified OVC positives and child protection interventions. 492 caregivers and 672 adolescents were trained. We used program data to assess the resulting health outcomes.
LESSONS LEARNED: There were 2,827(71%) OVCs served (1,140, Male; 1,571 Female) within 1 year of the intervention. There was a significant increase in key health indicators including HIV testing to 94%, all identified HIV positive OVC were linked to ART. However, viral suppression rates remained low at 68%. No cases of GBV were reported. The standard vulnerability assessment tool is not well suited for the military setting.
CONCLUSIONS/NEXT STEPS: OVC interventions are effective in improving some health outcomes of vulnerable children in military bases. However, vulnerability assessment requires a military tailored tool. Additional interventions are required to address the low viral suppression among HIV positive OVC.

PEE1668

INCREASING ACCESS TO HIV TESTING FOR MIGRANT WORKERS, FEMALE SPOUSES AND THEIR CHILDREN IN A MIGRATION AFFECTED COMMUNITY IN BANGLADESH USING WHOLE OF SOCIETY APPROACH

S. ISLAM[1]
[1]National University, Social Science and Research, Dhaka, Bangladesh

BACKGROUND: Though HIV testing is mandatory for migrant workers to get job abroad, there is rarely interventions for them to ensure prevention, treatment and care. Data shows that migrant workers and their families constitute around 30% of newly identified cases in Bangladesh annually. Bangladesh National HIV/AIDS Strategic Plan

covers migrant workers, but no national programme is undertaken yet. This project aimed to pilot a model intervention to integrate migration, health and HIV/AIDS.

DESCRIPTION: The two-year project was implemented in a sub-district in rural Bangladesh which has high rates of migration abroad, extremely conservative society, and low service coverage. The project applied three strategies – (i) enhance knowledge and empower migrants, families and communities; (ii) increase skills of health workers and facilities in public health centres; (iii) engage local representatives and key stakeholders. Migrant workers – potential and returnees, their spouses, pregnant mothers, and families were reached through door-to-door orientation, community-based training, outreach infotainment events, helpline, day observation, etc. for building knowledge and awareness. They were periodically followed up by trained peer educators. The project provided HTC – HIV Testing and Counselling - training to health workers, supplied rapid testing kits to the health centres, and organized consultations and meetings with key stakeholders. 8,300 targeted beneficiaries received HTC at local health centres. Six were identified HIV positive - one returnee migrant worker, two non-pregnant spouses of migrant workers, one 2-year old child of a migrant, and one non-migrant couple – all were ensured treatment through referral to government hospitals.

LESSONS LEARNED: The project successfully demonstrated that the inclusive approach of migration, health and HIV/AIDS together can be an effective intervention to reduce stigma. The whole-of-society approach through effective engagement of local stakeholders, communities and beneficiaries was found useful to break prevailing taboos, attitude and behavior towards HIV testing; and the door-step HTC together with referral for free treatment to public hospitals ensured access to treatment.

CONCLUSIONS/NEXT STEPS: The community approach creates demand among the people and thus, is considered as a successful element to replicate and scale up to promote safe migration, promote migrants health, and reach target 90-90-90, and should be incorporated into National Strategic Plan.

PEE1669

POSITIVE IMPACT OF SOCIAL PROTECTION SCHEME IN RETENTION OF PLHIV IN THE CONTINUUM OF CARE

N. Pathak[1], S. Agarwal[1], D.S. Pandey[1], M.K. Hauzel[1], P. Pareek[2]
[1]Hindustan Latex Family Planning Promotion Trust, HIV/AIDS Division, Gautam Buddh Nagar, India, [2]Hindustan Latex Family Planning Promotion Trust, HIV/AIDS DIVISION - Vihaan, Jaipur, India

BACKGROUND: To improve the survival and quality of life of PLHIV , HLFPPT is managing Vihaan programme in Rajasthan State by establishing 17 Care & Support Centres (CSCs). CSCs are the comprehensive facility for providing, counselling, referral, outreach services and linkages to Social entitlements/ welfare schemes to registered PLHIV. Retention of PLHIV in treatment has always been a Challenge in Rajasthan State. As per 12 month retention data <74% clients were retained in treatment (Ref: Programme data Rajasthan: 2018-19).

DESCRIPTION: The linkages with social welfare scheme are playing an important role in increasing uptake of care and support services including retention of PLHIV in the treatment but due to identity disclosure, limited PLHIV specific scheme, lack of sensitivity towards PLHIV across various line departments, complex documentation and time taking process, majority of clients are reluctant to link with the schemes. To overcome the challenges HLFPPT ensured quality counselling to address disclosure related issues, conduct state and district level advocacy meetings with various line department for easy processing to uptake the services and synchronised the coordinate effort of ART and CSC.

Further, "Linkages Camps" were organised and to ensure the success of linkages camps detailed guideline and monitoring schedule was developed. Prior to the Linkage Camp the client mobilisation was ensured and during linkages camp 2,553 clients were mobilised about various social welfare schemes and 2,405 PLHIV applied for various welfare schemes. Out of 2,405 PLHIV, 1,121 forms were completed and remaining 1,284 PLHIV whose forms were incomplete further followed for completing the forms.

LESSONS LEARNED: All 2,405 PLHIV were linked with various social welfare schemes. Further, retention of these linked clients were analysed and it was evident that overall retention of all 2,405 linked PLHIV is >90% in comparison to state 12 month retention (<74%) for FY-2018-19. The result clearly reveals that linkages with Social welfare scheme have an impact on the retention of clients in treatment.

CONCLUSIONS/NEXT STEPS: Linkage to Social welfare schemes uptake and retention of ART is closely interrelated. Through Social Welfare Schemes the PLHIV are able to integrate into mainstream society since they are financially independent and enhancing their qualify of life.

INNOVATIONS IN BEHAVIOURAL DATA COLLECTION AND USE

PEE1670

DISCREPANCIES BETWEEN SELF-REPORTED ADHERENCE AND A BIOMARKER OF ADHERENCE IN REAL-WORLD SETTINGS

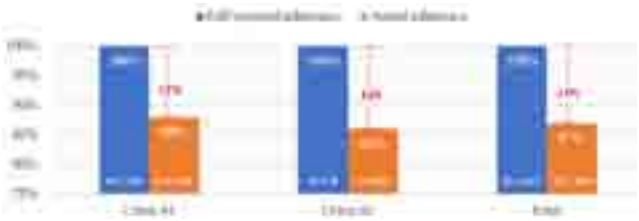
S. Hebel[1], E. Kahn-Woods[1], G. Daughtridge[1]
[1]UrSure, Inc., Boston, United States

BACKGROUND: Pre-exposure prophylaxis (PrEP) is only effective in preventing new HIV infections when taken consistently. Asking a patient about their adherence (self-report) is the predominant method of assessing adherence to PrEP. Though inexpensive and noninvasive, self-report is subject to social desirability and recall biases and several clinical trials demonstrate a discrepancy between self-reported adherence and actual adherence. Less is known about the accuracy of self-report in real-world clinical settings.

METHODS: A Liquid Chromatography-Mass Spectrometry (LC-MS/MS) urine test for Tenofovir was developed and used clinically to detect recent non-adherence (no dose in at least 48 hours) versus recent adherence (a dose in the last 6 days) for each individual. Two clinics' standard operating procedures recommend utilization of the urine-based adherence test for patients who self-report that they are not struggling with adherence, as those who self-report struggling with adherence receive enhanced adherence support without the need for additional testing. Adherence data from these two clinics were analyzed to assess the concordance of self-reported adherence to biomarker-based adherence.

RESULTS: Across the two clinics, 2,847 tests were conducted from patients self-reporting as "adherent", and 357 (13% (95% CI: 11%-14%)) demonstrated recent non-adherence with the LC-MS/MS test. At

Clinic #1 in Florida, 2,269 tests were conducted, and 275 (12% (95% CI: 11%-14%) demonstrated recent non-adherence. At Clinic #2 in Texas, 578 tests were conducted, and 82 (14% (95% CI: 11%-17%) demonstrated recent non-adherence.



[Figure. Self-reported and actual PrEP adherence]

CONCLUSIONS: Utilization of biomarker-based adherence monitoring at these two clinics resulted in 357 additional patients receiving enhanced adherence support who otherwise would not have been identified as unprotected from HIV infection. These findings suggest that objective adherence monitoring methods should be used clinically to enable providers to identify non-adherent patients and allocate support services accordingly.

PEE1671

COMBINING CROSS-SECTIONAL SURVEY DATA WITH GEOGRAPHIC ACTIVITY SPACE TO EXAMINE THE RELATIONSHIP BETWEEN PLACE AND YOUTH HIV RISK BEHAVIOR IN KENYA

C.N. Schmidt[1], E.S. Puffer[2], S.A. Broverman[2], E.P. Green[2]
[1]University of California, School of Medicine, San Francisco, United States, [2]Duke Global Health Institute, Durham, United States

BACKGROUND: The places where adolescents live, study, and play are thought to influence behavior and health, but we have limited tools for measuring environmental risk on a hyperlocal level. We combine participatory mapping activities with remote sensing and geographic information system data to identify adolescent activity spaces and create a novel measure of environmental risk for HIV transmission.

METHODS: 48 parents, teachers, and community leaders in Muhuru Bay, Kenya participated in focus groups to generate digital maps identifying risky-locations in their community. 325 adolescents (10-18 years) enrolled in a larger study of HIV risk behavior were randomly selected and invited to participate in interviews about their daily routines. Adolescents located their home on high-resolution satellite imagery and mapped how and where they spent time. We used these activity logs to generate Euclidian standard deviation ellipses—activity spaces—which we overlaid onto the digital risk maps. We quantified the ecological risk for each individual's activity space as the density of adult-reported risky locations falling inside the activity space. We used linear regression to estimate the association between self-reported HIV risk behavior and this metric of ecological risk.

RESULTS: On average, adolescents spent most of their time within an area of 2.7 km2. We do not find support for conventional narratives about the shrinking of girls' social environment as they enter puberty. Girls in this sample described activity spaces that were comparable to boys' spaces (boys 2.24 km2, girls 3.14 km2). 9 out of 10 adolescent activity spaces overlapped with a risky location, and the average activity space contained 19.8 adult-reported risky points. Activity space size increases with age, and age is correlated with environmental risk density. Ecological risk is associated with spending more time out of the home at night and reporting being sexually active (NS).

CONCLUSIONS: This study demonstrates the feasibility of quantifying adolescent risk environments through community informed, participatory techniques and spatial mapping technology. By relating activity space to psychosocial correlates of HIV risk behavior, we also demonstrate the utility of activity space analysis in generating new insights into the relationship between adolescents' movements throughout their communities and their exposure to risky environments.

PEE1672

IDENTIFYING HIV RISK PROFILES AND ASSOCIATED SERVICE UPTAKE AMONG MEN IN ESWATINI

A. Gottert[1], J. Pulerwitz[1], C. Heck[2], L. Apicella[3], Z. Reynolds[4], B. Lukhele[5], P. Shabangu[5], N. Dlamini[6], M. Dlamini[7], M. Nkhambule[6], S. Mathur[1]
[1]Population Council Washington DC, HIV and AIDS Program, Washington, United States, [2]Population Council New York, New York, United States, [3]Population Council Tanzania, Dar es Salaam, Tanzania, United Republic of, [4]MEASURE Evaluation, Chapel Hill, United States, [5]Institute for Health Management (IHM), Mbabane, Eswatini, [6]National Emergency Response Council on HIV and AIDS (NERCHA), Mbabane, Eswatini, [7]Swaziland National AIDS Program (SNAP), Mbabane, Eswatini

BACKGROUND: To help inform prevention programming, we developed HIV risk profiles among young men in Eswatini using two waves of cross-sectional data (late-2016/early-2017; mid-2018), then assessed whether higher-risk profiles are increasingly being reached by HIV services.

METHODS: Men ages 20-34 years completed surveys at informant-identified hot-spot venues in 19 Tinkhundla across Eswatini. We identified profiles via Latent Class Analysis, then assessed HIV service use by survey round for each profile.

RESULTS: We identified five profiles, distinguished by their socio-demographic and HIV risk characteristics. Younger high-risk (13% of sample; mean age=23) tended to be unemployed (62%) and urban-resident (58%), with a high number of partners, hazardous drinking (HD, 84%), IPV (33%) and inequitable gender norms, and lowest condom use (8%). Older high-risk (9%; mean age=32), largely unmarried/non-cohabiting, also had high numbers of partners, who were 10 years younger on average, plus other relatively high levels of risk. Mid-age moderate-risk (31%; mean age=27) had moderate levels across risk indicators. Younger low-risk (29%; mean age=22) were most likely to be in school (34%), unemployed (73%), and rural-resident (63%), with relatively low risk levels. Older low-risk (18%; mean age=32) were largely married/cohabiting (63%, vs. <30% for other profiles), also with low levels of risk, except for IPV (21%). HIV testing in last year increased most over time (+20-25%) among higher-risk profiles (all p<0.001). Ever-circumcised increased for most profiles (not always significantly). Less than 10% of respondents on-average had recently attended HIV-prevention-related meetings.

CONCLUSIONS: Of five HIV-risk profiles, one younger (urban and unemployed) and one older (yet unmarried/non-cohabiting) were exceedingly high-risk; these men can be reached at hot-spot venues. Profiles resembled other profiles we identified in Durban, South Africa, suggesting similarities across contexts. Current differentiated HIV testing strategies appear successful in reaching the highest-risk men, however other primary prevention needs likely require comprehensive prevention programming.

INDICATORS				LATENT CLASS					FULL SAMPLE
	Younger low-risk (29.2% of sample)		Younger high-risk (12.7% of sample)		Mid-age moderate-risk (31.5% of sample)		Older low risk (17.7% of sample)	Older high-risk (9.0% of sample)	(n=1,391)

INNOVATIVE APPROACHES TO TRACK INDIVIDUALS

PEE1673

ASSESSMENT OF THE CONTRIBUTION OF MOBILE HEALTH (MHEALTH) IN RE-SHAPING HIV/AIDS SERVICES IN TANZANIA; REVIEW FROM NJOMBE REGION

F. Nachenga[1]
[1]*Deloitte Consulting Ltd (Tanzania), S&I, Njombe, Tanzania, United Republic of*

BACKGROUND: The application of mobile technologies, 'Mobile Health' (mHealth), in the health care industry is increasingly seen as a way to provide high quality and easily accessible care at lower costs. mHealth is the practice of medical and public health supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless device. SMS Reminder system is one among a number of digital health initiatives that the program supports the government to address missed appointment and lost to follow up among CTC clients and also aiming to improve HIV client adherence to treatment and retention in care.
DESCRIPTION: The USAID Boresha Afya is a five year, PEPFAR supported program through USAID. The program is implemented by Deloitte Consulting Ltd in 42 councils in Iringa, Njombe, Morogoro, Lindi, Mtwara and Ruvuma with its technical partners Family Health International (FHI360), Engender Health and Management and Development for Health (MDH).USAID Boresha Afya is set to create a dynamic, integrated platform for delivery of health services that emphasizes intensified coordination and collaboration between the government, health facilities and communities, towards achieving

HIV epidemic control while integrating FP, TB, MNCH, Malaria care and Nutrition through innovative integration approaches at all levels and opportunities.

LESSONS LEARNED: Through this nine month period, a total of 153,875 clients were expected to attend their visits and 126,220 clients attended their visits as scheduled at the respective faciliti and 27,655 (18% of the total appointments) missed their appointment as scheduled. When compared the same data in the past nine months back (before the introduction of SMS remainder systems), the expected clients were 27,398 and only 17,327 attended and a total of 10,071 (36% of the total appointments) missed their appointments.

CONCLUSIONS/NEXT STEPS: Using the mHealth and the SMS Reminder System actively in this perspective, it's probably the best approach to reducing the LTF clients as most of the PLHIV have mobile phones, and a good way to motivate people with HIV/AIDS to go to health facilities for their scheduled visits and other services, and this might make it easier for the program and country to reach to reach 95-95-95 goals.

GENDER-BASED VIOLENCE TRACKER: REAL-TIME TRACKING OF PEP KIT CONSUMPTION TO COORDINATE THE RESPONSE TO SEXUAL VIOLENCE IN THE EASTERN CONGO

K.M. Givano[1], J. Bress[1], J. Armas[1], A.J. Ammann[1], D. Mukwege[2], C. Amisi[2]
[1]Global Strategies, Health Humanitarian Work, Albany, United States, [2]Panzi Hospital, Medical, Bukavu, Congo, Democratic Republic of the

BACKGROUND: Healthcare facilities in conflict settings face numerous barriers to the timely provision of HIV post-exposure prophylaxis, antibiotics for sexually transmitted infections and emergency contraception for survivors of sexual violence. Individual survivors often lack knowledge about the availability and utility of medical therapy, limiting care-seeking behavior after violence. Gaps in medical training and chronic inventory issues further reduce the likelihood that sexual violence survivors receive time-sensitive medical care after rape.

DESCRIPTION: Global Strategies and Panzi Foundation partnered to create the GBV Tracker, a web-based dashboard (www.kivu-dashboard.appspot.com) that presents near real-time data about the consumption of PEP kits across 45 sites in the South Kivu Province of the eastern Congo. The GBV Tracker is password protected and does not contain any individual identifiers. Its data visualizations enable stakeholders to identify trends in care-seeking after sexual violence, extrapolated from medication inventory data, at the clinic and health zone levels. The GBV Tracker also alerts stakeholders to inventory concerns, the anomalous absence of sexual violence survivors and potential mass-violence events.

LESSONS LEARNED: The GBV Tracker allows for real-time information sharing about trends in care-seeking after sexual violence across five health zones in the eastern Congo. In addition, the GBV Tracker alerts have helped prevent PEP kit stockouts and assisted in coordinating quality improvement initiatives. Since its launch in 2019, the GBV Tracker has generated nine alerts for instances where an individual rural site received >5 rape survivors in a single day. Program implementers have used the GBV Tracker to identify nine sites that have not prescribed post-rape medical kits over six month intervals. These alerts have led to investigations identifying clinic-specific access barriers, such as staff turnover. There has not been a single stockout of essential medications.

CONCLUSIONS/NEXT STEPS: Survivors of sexual violence are at high-risk for contracting HIV and other sexually transmitted infections. Tracking the consumption of post-rape medical kits provides valuable data about care-seeking after sexual violence. In addition, it enables program evaluators to prevent inventory stockouts and identify non-prescribing sites. The GBV Tracker, with its real-time data visualizations and alerts, assists stakeholders in coordinating a response to gender-based violence in a conflict setting.

"BRING BACK MOTHER-BABY PAIR" CAMPAIGN INITIATIVE TO IMPROVE RETENTION IN CARE: EXPERIENCE FROM THE UGANDA PROGRAM FOR PREVENTION OF MOTHER TO CHILD TRANSMISSION OF HIV

J. Ssendiwala[1], P. Mudiope[2], S. Muhumuza[1], E. Akello[1], C. Kyomugisha[1], D. Idipo[2], D. Ondo[2], J. Cheptoris[2], W. Bazeyo[1], L. Nabitaka Kisaakye[2]
[1]Makerere University School of Public Health, Monitoring and Evaluation Technical Support Program, Kampala, Uganda, [2]Ministry of Health, AIDS Control Program, Kampala, Uganda

BACKGROUND: Although maternal antiretroviral therapy (ART) uptake in Uganda is high, retention in care is suboptimal: More than 25% of mothers initiated on ART are lost-to-follow up at 6 months. Low retention of HIV-positive pregnant and breastfeeding mothers increases the risk of HIV transmission to their babies and ART treatment failure. In 2018, the Ministry of Health with support from PEPFAR and other partners launched a national campaign to identify and "Bring Back Mother-Baby Pairs" (BBMB) who had missed their clinic appointments within the last two years.

DESCRIPTION: A total of 1,085 facilities with high rates of loss to follow up across the country participated in the campaign. Facilities implemented a series of standardized interventions that included mobilization of district PMTCT focal persons, health facility staffs, Village Health Teams and peer mothers at community level to trace lost mothers and their babies. At each facility, retention improvement teams were established to conduct program data reviews to identify retention gaps and line-list all clients who missed appointments. Onsite mentorship for health workers and peer mothers were conducted to provide guidance on patient tracking and documentation, use of phone calls and home visits. Integrated immunization and early infant diagnosis outreaches were conducted in lower health facilities to identify mothers who might have relocated to those facilities. An SMS-based platform was established to facilitate real-time reporting.

LESSONS LEARNED: Overall, 64.5% (34,301) mothers and 41.1% (23,413) HIV-exposed infants (HEI) lost were brought back into HIV care within 9 months. The proportion of mothers and HEIs brought back varied considerably by health facility level, with the highest registered at National referral and general hospitals (68.2%). The lowest proportion of mother brought back was at Health Centre IIs (58.6%). Regional referral hospitals brought back the highest proportion of babies (75.1%). The lowest proportion of HEIs brought back into care was at Health Centre IIIs (30%). Thus, interventions for BBMB may need to be different at lower level facilities.

CONCLUSIONS/NEXT STEPS: Nationally driven interventions coupled with district and facility-based innovations are effective in improving retention of mothers and babies in care. There is need to scale-up these interventions to all HIV service outlets.

PEE1676

PREDICTORS OF RETURN TO CARE AMONG PEOPLE LIVING WITH HIV WHO MISSED A CLINIC APPOINTMENT IN UGANDA

P. Komakech[1], J. Kabanda[1], R. Nakityo Bosa[1], B. Elur[1], W. Bikokye Kafeero[1], J. Kalamya Namonyo[1], A. Namale[1], S. Malinzi[1], N. Namuwenge[2], F. Nalubega[3], J. Balaba[3], C. Katureebe[4], J. Calnan[5], M. Adler[1]
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Center for Global Health, Kampala, Uganda, [2]USAID Strategic Information Technical Support Project, Kampala, Uganda, [3]Monitoring and Evaluation Technical Support Program, Makerere University School of Public Health, Kampala, Uganda, [4]Ministry of Health, AIDS Control Program, Kampala, Uganda, [5]United States Agency for International Development, Kampala, Uganda

BACKGROUND: Retention in HIV care is a key gap along the clinical cascade in Uganda. In 2018, up to 24% of people living with HIV (PLHIV) who initiated antiretroviral therapy (ART) in Uganda were lost to follow-up within the first year. To address poor retention, Uganda launched a national campaign in January 2019 to return to care PLHIV who missed clinic appointments. We identified predictors of return to care among PLHIV who missed a clinic appointment in Uganda.

METHODS: A system for same-day follow-up by healthcare and community workers through phone calls and or home visits was established at ART sites to track PLHIV who missed a clinic appointment. Healthcare workers made four follow-up attempts to return the clients to care within 4 weeks. We developed a tool to document follow-up outcomes and individual PLHIV data. We used bivariate and multivariate analysis to determine the predictors of return to care among PLHIV who missed a clinic appointment (April–June 2019). Statistical significance was defined by P<0.05.

RESULTS: Of the 41,278 PLHIV who missed an appointment, 64% (26,252) had the required four follow-up attempts and a documented final follow-up outcome. Among those with a follow-up outcome, 83% (21,902) returned to care. Significant predictors of return to care after a missed clinic appointment were care in rural facilities (OR, 1.14 [95% CI: 1.06–1.22]), initiation of ART in a healthcare facility (odds ratio [OR], 1.35 [95% CI: 1.19–1.52]). Predictors of not returning to care were male sex (OR, 0.75 [95% confidence interval (CI): 0.70–0.81]), age 15–24 years (OR, 0.67 [95% CI: 0.61–0.72]), care in a Private Not For Profit facility (OR, 0.69 [95% CI: 0.64–0.75]), and duration of ART ≤1 year (OR, 0.41 [95% CI: 0.38–0.44]). No significant difference was observed among PLHIV in community models vs those in facility-based fast-track drug refill models (OR, 0.92 [95% CI: 0.73–1.16]).

CONCLUSIONS: Same day follow up system of PLHIV who miss a clinic appointment was successful in returning most to care, however more strategies are required to return men, 15-24 year old's and those on ART≤1year to care.

PEE1677

PROGRAMMATIC MAPPING AND SIZE ESTIMATION TO HOTSPOT LEVEL HELPED INFORM EFFECTIVE HIV PROGRAMMING FOR KEY POPULATIONS WITHIN MONTSERRADO COUNTY

T. Hallie[1], G. Kamanga[1], C. Kerbay[1], N.F. Clement[1], M. Odo[2], L. Harris[1], P.K. Thakur[3], D.D. de Mora[3], C. Akolo[3]
[1]FHI 360, Global Health Population and Nutrition, Monrovia, Liberia, [2]National AIDS and STI Control Program, Ministry of Health, Monrovia, Liberia, [3]FHI 360, Global Health Population and Nutrition, Washington DC, United States

BACKGROUND: While Liberia has a generalized HIV epidemic with an estimated prevalence of 2.1% among the general population (men 1.7% and women 2.4%), key populations (KPs) are the most vulnerable with an estimated prevalence of 19.8% among men who have sex with men (MSM) and 9.8% among female sex workers (FSWs). The PEPFAR/USAID-funded LINKAGES project implemented by FHI 360 conducted programmatic mapping and size estimation at hotspot level to strengthen reach and linkage of KPs to effective HIV programming.

DESCRIPTION: In May 2019, some lead KP representatives and key informants (bar men, hotspot owners and regular hotspot patrons) were interviewed to understand KP dynamics according to geographic locations in 124 hotspots (places where KPs are most likely to engage in risky behaviors). This was repeated in July 2019 as a validation exercise and information was collected from 305 hotspots in 7 health districts in Montserrado County. KP Peak days and times and any pointers to some risk such as approximate ages of KPs were noted. Population size estimates were calculated for each hotspot and adjusted for duplication and then aggregated to inform project estimates.

LESSONS LEARNED: Forty five percent of 428 MSM (193) operate through physical spots including entertainment centers, streets and homes of some member while fifty five percent (235) and the majority of 197 transgender people, socialize through the internet, owing to the large stigma and discrimination in Liberia. Seventy percent (300/428) of the MSM are found in 4 major health districts. A significant number of MSM (53% or 227/428) are reported to have engaged in sex with other men for money. Of the 5,327 FSWs, 90% (4,794/5,327) also operate through physical spots, while 10% (533/5,327) use cell phones for both calls and other social media networks to connect with clients. This information allowed the LINKAGES project to target outreach to where and when KPs are most accessible.

CONCLUSIONS/NEXT STEPS: Hotspot level programmatic mapping and size estimation help to understand locales, influence proper allocation of program activities according to district of areas of need and facilitate services to KPs. The mapping and size estimation will be updated annually.

PEE1678

USING OPEN DATA KIT MOBILE DATA COLLECTION AND A BARCODE-BASED UNIQUE IDENTIFICATION SYSTEM TO FACILITATE SCALE-UP OF ASSISTED PARTNER SERVICES IN A RESOURCE-LIMITED SETTING

P. Macharia[1], G. Otieno[2], M. Sharma[1], B. Wamuti[1], H. Lagat[2], S. Masyuko[1,3], C. Obong'o[2], C. Levin[1], R. Bosire[4], M. Mugambi[3], E. Kariithi[2], B. Weiner[1], C. Farquhar[1]
[1]University of Washington, Seattle, United States, [2]PATH, Nairobi, Kenya, [3]Ministry of Health, Nairobi, Kenya, [4]Kenya Medical Research Institute, Nairobi, Kenya

BACKGROUND: Integrating assisted partner services (aPS) into existing health systems in low resource settings faces constraints. Data collection is generally paper-based, posing logistical challenges in monitoring aPS and longitudinal follow-up of newly diagnosed HIV-positives (indexes) and their sexual partners. Unique patient identification is also not standardized.

DESCRIPTION: We evaluated electronic data collection using Open Data Kit (ODK) and barcode-based unique identifiers as part of an implementation science scale-up study of aPS in Homa Bay and Kisumu counties in Kenya. ODK is an android-based electronic data collection suite that enables users to collect and encrypt data offline then later upload to a remote server. Validated case report forms (CRFs) were customized into ODK and administered by HIV testing services (HTS) counsellors. An algorithm inbuilt into ODK and integrated to the workflow used barcodes to generate anonymous unique identification codes (UICs). The UICs were then used by healthcare providers (HCPs) to link female HIV-positive index clients to their male partners (MPs) and female partners to the male partners (FPMPs) in the aPS continuum of care. The barcode was recorded on securely stored index contact tracing form - the only paper-based CRF.

LESSONS LEARNED: At 82 weeks of recruitment, over 29,000 females tested for HIV with 1,400 (5%) testing positive and assigned UICs linking them to 1,610 MPs and 256 FPMPs. Electronic data collection integrating the barcode-based unique identification system made it possible to uniquely identify all clients in the aPS continuum. HCPs were able to longitudinally follow-up each case during tracing, testing and linkage to care. It was possible to monitor aPS in real-time, and the research team was able to identify errors in the data and aPS implementation challenges, and immediately offer constructive feedback. Currently, the system is established in over 30 facilities and has been running smoothly for more than 12 months.

CONCLUSIONS/NEXT STEPS: ODK offers a feasible and acceptable point-of-care m-health platform in the scale-up and integration of aPS as standard-of-care in public facilities in resource-limited settings. A similar non-invasive barcode-based unique identification system could readily be integrated into the workflow to improve HIV testing and linkage to care outcomes.

PEE1679

CAREMAT APPLICATION: MORE THAN A USER-FRIENDLY APPLICATION, IT IS AN HIV FULL CASCADE APPLICATION FROM COMMUNITY-BASED ORGANIZATION WORKING ON HIV/AIDS IN THAILAND

A. Chawilai[1], S. Sittikarn[2], P. Paree[3]
[1]Chiang Mai University, Faculty of Science, Chiang Mai, Thailand, [2]Lopburi Technical College, Faculty of Education, Chiang Mai, Thailand, [3]Chiang Mai Rajabhat University, Faculty of Business Administration, Chiang Mai, Thailand

BACKGROUND: Ongoing care and support for PLHIV is critical to ensuring ART initiation and retention and achieving viral suppression. In Thailand, where members of key populations make up a significant proportion of PLHIV, responsibility for treatment support is increasingly shifting to communities under a differentiated service delivery model. Caremat, a key population-led HIV service provider in northern Thailand, developed a software application to help track a growing cadre of HIV-positive clients and ensure timely linkage to treatment and adherence support.

DESCRIPTION: The Caremat application was designed as a retention tool to help community-based care and support staff follow up with their positive clients and link them to treatment as well as to follow up with high-risk negative clients for retesting and to access to prevention package such as PrEP, condoms and lubricants. It has been expanded to include reach and testing modules that can be used in any service point from traditional to online outreach, facility-based or mobile counselling and testing. The system sends reminders directly to clients, and even manages the progress of clients as they proceed through service at a community clinic facility. The application uses a unique identification code to track a longitudinal cohort of clients in real time, alerting staff if – for example – a client is due for a check-up or ART refill. Care and support staff can review and update client medical and personal record real time. This app is able to send notification directly to care and support staff via Line app, which is the most popular chat app in Thailand. Programmatic dashboards allow staff to monitor outreach performance, track and map case-finding rates.

LESSONS LEARNED: The Caremat application is currently tracking about 5,000 negative clients and 500 positive clients with only 10 staff.This application is also cost effective, it successfully sent direct messages to 1,242 negative clients in one time to get retesting and 88 clients get tested, it costs only about 1 USD per one retested client (retention).

CONCLUSIONS/NEXT STEPS: Caremat Application provides a high standard of real-time HIV cascade monitoring useful from the level of community-based organizations to funders and policymakers.

PEE1680

A PROSPECTIVE STUDY OF THE EFFECT OF REAL-TIME MONITORING OF NEWLY DIAGNOSED HIV+ CASES AND ENROLLMENT LEAD-TIME USING MOBILE TECHNOLOGY AMONG KEY POPULATIONS IN BENUE STATE, NIGERIA

E. Ashano[1], B. Amoo[1], S. Adamu[1], B. Banigbe[2]
[1]APIN Public Health Initiatives, Abuja, Nigeria, [2]Boston University School of Public Health, Boston, United States

BACKGROUND: The highly mobile nature of key populations in Nigeria prompts a demand for dynamic instruments to closely monitor newly diagnosed HIV+ cases, and linkage to care processes to tailor interventions that improve health outcomes. Adaptable electronic data capture mobile and server applications provide novel opportunities to inexpensively capture and transmit information that can be instantly visualized by implementing partners to identify cascade areas requiring improvement interventions. The aim of this study was to assess the impact of a real-time dashboard designed to monitor new cases and enrolment lead-time, on HIV testing positivity yield and linkage percentages among key populations in Benue State, Nigeria.

METHODS: Demographic, geographic and linkage data was collected from Female Sex Workers (FSW), Men who have Sex with Men (MSM), People Who Inject Drugs (PWID) and Transgenders newly diagnosed as HIV+ at testing and linkage points by community health workers on android mobile devices using ODK Collect (a free data collection app) in 5 Local Governments in Benue State between October and December 2019. Data was transmitted at the time of collection to an online server which instantly fed an online dashboard that was programmed to visualize concentrated areas of new cases and lead-time statistics. Insights from the dashboard were used to feedback evidence-based strategies to improve the HIV initiation-to-care cascade. Yield and linkage percentages were compared to baseline data for each KP group for statistical significance using a paired t-test.

RESULTS: A total of 754 FSW, 532 MSM, 185 PWID, and 11 Transgenders were provided HTS. From baseline, an increase in average percent yield was 1.45%, 1.63%, and -1.25% while the decrease in average lead-time in days was 8.1, 6.2, and 6.5 for FSW, MSM, and PWID categories respectively. No Transgender positive for HIV was identified.

CONCLUSIONS: A significant reduction of lead-time was demonstrated in analyzed KP groups. However, more time would be required to accumulate sufficient prevalence data to evaluate the dashboard's effect on yield. Initial implementation challenges notably inconsistent reporting were encountered during the first month of deploying this intervention. The approach may also be an inexpensive way to monitor KP HIV programs in resource-limited settings.

PEE1681

ENHANCED DATA-DRIVEN DECISION MAKING:A CASE OF APPLICATION OF DHIS 2 IN A COMMUNITY-BASED KEY POPULATION PROGRAM FOR TRACKING ACCESS TO SERVICES AT DIFFERENT SERVICE DELIVERY POINTS

S. Kalyati[1], P. Ngosi[2], C. Kamba[3], G. Kumwenda[4], S. Sikwese[4]
[1]University of Greenwich, Lilongwe, Malawi, [2]Catholic University, Blantyre, Malawi, [3]University of Malawi - College of Medicine, Blantyre, Malawi, [4]University of Malawi, Zomba, Malawi

BACKGROUND: Pakachere IHDC through Local Endeavors for HIV/AIDS prevention and treatment (LEAP) is implementing a 5-year USAID-funded program to improve access to and uptake of HIV prevention and treatment services among female sex workers (FSWs) and their social and sexual networks in Blantyre, Mangochi, Lilongwe and Mzuzu districts of Malawi. An estimated 8,262 FSW are being targeted with services across the HIV cascade of prevention-test-treat-retain. This abstract shares early efforts to establish a client level electronic monitoring and tracking system for key population services to enhance service delivery and program performance.
